		1	A bit error occurred. The SPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERRFLG is set. If BITERRENA is set an interrupt is asserted. Possible reasons for a bit error can be an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
3	DESYNCFLG		Desynchronization of slave device. Desynchronization monitor is active in master mode only. This flag can be cleared by one of the following methods: • Write a 1 to this bit • Clear the SPIEN bit to 0
		0	No slave desynchronization is detected.
		1	A slave device is desynchronized. The master monitors the ENAble signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
2	PARERRFLG		Calculated parity differs from received parity bit. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRENA is set. This flag can be cleared by one of the following methods: • Write a 1 to this bit • Clear the SPIEN bit to 0
		0	No parity error is detected.
		1	A parity error occurred.
1	TIMEOUTFLG		Time-out caused by nonactivation of ENA signal. This flag can be cleared by one of the following methods: • Write a 1 to this bit • Clear the SPIEN bit to 0
		0	No ENA-signal time-out occurred.
		1	An ENA signal time-out occurred. The SPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMEOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, that is, the SPI does not re-start a data transfer from this buffer.
0	DLENERRFLG		Data-length error flag. This flag can be cleared by one of the following methods: • Write a 1 to this bit • Clear the SPIEN bit to 0 **Note: Whenever any transmission errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected and the error flags are cleared by writing to the error bit in the SPIFLG register, the corresponding error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all of the old status bits in SPIBUF are cleared before starting the next transfer.**
		0	No data length error has occurred.
		1	A data length error has occurred.

13.9.6 SPI Pin Control Register 0 (SPIPC0)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 13-13. SPI Pin Control (SPIPC0) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIFUN		Slave out, master in function. Determines whether each SPISOMI[x] pin is to be used as a general-purpose I/O pin or as a SPI functional pin. **Note: Duplicate Control Bits for SPISOMI[0]. Bit 24 is not physically implemented. It is a mirror of Bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPISOMI[0] pin. The read value of bit 24 always reflects the value of bit 11.**
		0	The SPISOMI[x] pin is a GIO pin.
		1	The SPISOMI[x] pin is a SPI functional pin.
23-16	SIMOFUN		Slave in, master out function. Determines whether each SPISIMO[x] pin is to be used as a general-purpose I/O pin or as a SPI functional pin. **Note: Duplicate Control Bits for SPISIMO[0]. Bit 16 is not physically implemented. It is a mirror of Bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPISIMO[0] pin. The read value of bit 16 always reflects the value of bit 10.**
		0	The SPISIMO[x] pin is a GIO pin.
		1	The SPISIMO[x] pin is a SPI functional pin.
15-12	Reserved	0	Reads return 0. Writes have no effect.

Table 13-13. SPI Pin Control (SPIPC0) Field Descriptions (continued)

Bit	Field	Value	Description
11	SOMIFUN0		Slave out, master in function. This bit determines whether the SPISOMI[0] pin is to be used as a general-purpose I/O pin or as a SPI functional pin.
		0	The SPISOMI[0] pin is a GIO pin.
		1	The SPISOMI[0] pin is a SPI functional pin.
			Note: Regardless of the number of parallel pins used, the SPISOMI[0] pin will always have to be programmed as functional pins for any SPI transfers.
10	SIMOFUN0		Slave in, master out function. This bits determine whether each SPISIMO[0] pin is to be used as a general-purpose I/O pin or as a SPI functional pin.
		0	The SPISIMO[0] pin is a GIO pin.
		1	The SPISIMO[0] pin is a SPI functional pin.
			Note: Regardless of the number of parallel pins used, the SPISIMO[0] pin will always have to be programmed as functional pins for any SPI transfers.
9	CLKFUN		SPI clock function. This bit determines whether the SPICLK pin is to be used as a general-purpose I/O pin, or as a SPI functional pin.
		0	The SPICLK pin is a GIO pin.
		1	The SPICLK pin is a SPI functional pin.
8	ENAFUN		$\overline{\text{SPIENA}}$ function. This bit determines whether the $\overline{\text{SPIENA}}$ pin is to be used as a general-purpose I/O pin or as a SPI functional pin.
		0	The $\overline{\text{SPIENA}}$ pin is a GIO pin.
		1	The $\overline{\text{SPIENA}}$ pin is a SPI functional pin.
7-0	SCSFUN		$\overline{\text{SPICS}}$ function. Determines whether each $\overline{\text{SPICS}}$ pin is to be used as a general-purpose I/O pin or as a SPI functional pin. If the slave $\overline{\text{SPICS}}$ pins are in functional mode and receive an inactive high signal, the slave SPI will place its output in a high-impedance state and disable shifting.
		0	The $\overline{\text{SPICS}}$ pin is a GIO pin.
		1	The $\overline{\text{SPICS}}$ pin is a SPI functional pin.

13.9.7 SPI Pin Control Register 1 (SPIPC1)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 13-14. SPI Pin Control Register (SPIPC1) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIDIR		SPISOMI[x] direction. Controls the direction of each SPISOMI[x] pin when used for general-purpose I/O. If SPISOMI[x] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register. **Note: Duplicate Control Bits for SPISOMI[0]. Bit 24 is not physically implemented. It is a mirror of Bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPISOMI[0] pin. The read value of bit 24 always reflects the value of bit 11.**
		0	The SPISOMI[x] pin is an input.
		1	The SPISOMI[x] pin is an output.
23-16	SIMODIR		SPISIMO[x] direction. Controls the direction of each SPISIMO[x] pin when used for general-purpose I/O. If SPISIMO[x] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register. **Note: Duplicate Control Bits for SPISIMO[0]. Bit 16 is not physically implemented. It is a mirror of Bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPISIMO[0] pin. The read value of bit 16 always reflects the value of bit 10.**
		0	The SPISIMO[x] pin is an input.
		1	The SPISIMO[x] pin is an output.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIDIR0		SPISOMI[0] direction. This bit controls the direction of the SPISOMI[0] pin when it is used as a general-purpose I/O pin. If the SPISOMI[0] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
		0	The SPISOMI[0] pin is an input.
		1	The SPISOMI[0] pin is an output.
10	SIMODIR0		SPISIMO[0] direction. This bit controls the direction of the SPISIMO[0] pin when it is used as a general-purpose I/O pin. If the SPISIMO[0] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.
		0	The SPISIMO[0] pin is an input.
		1	The SPISIMO[0] pin is an output.
9	CLKDIR		SPICLK direction. This bit controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit.
		0	The SPICLK pin is an input.
		1	The SPICLK pin is an output.
8	ENADIR		$\overline{\text{SPIENA}}$ direction. This bit controls the direction of the $\overline{\text{SPIENA}}$ pin when it is used as a general-purpose I/O. If the $\overline{\text{SPIENA}}$ pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).
		0	The $\overline{\text{SPIENA}}$ pin is an input.
		1	The $\overline{\text{SPIENA}}$ pin is an output.
7-0	SCSDIR		$\overline{\text{SPICS}}$ direction. These bits control the direction of each $\overline{\text{SPICS}}$ pin when it is used as a general-purpose I/O pin. Each pin could be configured independently from the others if the $\overline{\text{SPICS}}$ is used as a SPI functional pin. The I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).
		0	The $\overline{\text{SPICS}}$ pin is an input.
		1	The $\overline{\text{SPICS}}$ pin is an output.

13.9.8 SPI Pin Control Register 2 (SPIPC2)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 13-18. SPI Pin Control Register 5 (SPIPC5) Field Descriptions (continued)

Bit	Field	Value	Description
11	SOMICLR0		SPISOMI[0] data out clear. This pin is only active when the SPISOMI[0] pin is configured as a general-purpose output pin.
		0	Read: The current value on SPISOMI[0] is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPISOMI[0] is 1. Write: Logic 0 is placed on SPISOMI[0] pin, if it is in general-purpose output mode.
10	SIMOCLR0		SPISIMO[0] data out clear. This pin is only active when the SPISIMO[0] pin is configured as a general-purpose output pin.
		0	Read: The current value on SPISIMO[0] is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPISIMO[0] is 1. Write: Logic 0 is placed on SPISIMO[0] pin, if it is in general-purpose output mode.
9	CLKCLR		SPICLK data out clear. This bit is only active when the SPICLK pin is configured as a general-purpose output pin.
		0	Read: The current value on SPICLK is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SPICLK is 1. Write: Logic 0 is placed on SPICLK pin, if it is in general-purpose output mode.
8	ENACLR		$\overline{\text{SPIENA}}$ data out clear. This bit is only active when the $\overline{\text{SPIENA}}$ pin is configured as a general-purpose output pin. A value of 1 written to this bit clears the corresponding ENABLEDOUT bit to 0.
		0	Read: The current value on $\overline{\text{SPIENA}}$ is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on $\overline{\text{SPIENA}}$ is 1. Write: Logic 0 is placed on $\overline{\text{SPIENA}}$ pin, if it is in general-purpose output mode.
7-0	SCSCLR		$\overline{\text{SPICS}}$ data out clear. This bit is only active when the $\overline{\text{SPICS}}$ pin is configured as a general-purpose output pin.
		0	Read: The current value on SCSDOUT is 0. Write: Writing a 0 to this bit has no effect.
		1	Read: The current value on SCSDOUT is 1. Write: Logic 0 is placed on $\overline{\text{SPICS}}$ pin, if it is in general-purpose output mode.

13.9.12 SPI Pin Control Register 6 (SPIPC6)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Table 13-19. SPI Pin Control Register 6 (SPIPC6) Field Descriptions

Bit	Field	Value	Description
31-24	SOMIPDR		SPISOMI[x] open drain enable. This bit enables open drain capability for each SPISOMI[x] pin, if the following conditions are met: • SOMIDIRx = 1 (SPISOMI[x] pin is configured in GIO mode as an output pin) • SOMIDOUTx = 1 **Bit 11 or bit 24 can both be used to enable open-drain for SPISOMI[0]. If a 32-bit write is performed, bit 11 will have priority over bit 24.**
		0	Output value on the SPISOMI[x] pin is logic 1.
		1	Output pin SPISOMI[x] is in a high-impedance state.
23-16	SIMOPDR		SPISIMO[x] open drain enable. This bit enables open drain capability for each SPISIMO[x] pin, if the following conditions are met: • SIMODIRx = 1 (SPISIMO[x] pin is configured in GIO mode as an output pin) • SIMODOUTx = 1 **Bit 10 or bit 16 can both be used to enable open-drain for SPISIMO[0]. If a 32-bit write is performed, bit 10 will have priority over bit 16.**
		0	Output value on the SPISIMO[x] pin is logic 1.
		1	Output pin SPISIMO[x] is in a high-impedance state.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMIPDR0		SPISOMI[0] open-drain enable. This bit enables open-drain capability for the SPISOMI[0] pin, if the following conditions are met: • SPISOMI[0] pin is configured in GIO mode as output pin • Output value on SPISOMI[0] pin is logic 1
		0	Output value on the SPISOMI[0] pin is logic 1.
		1	Output pin SPISOMI[0] is in a high-impedance state.
10	SIMOPDR0		SPISIMO[0] open-drain enable. This bit enables open drain capability for the SPISIMO[0] pin, if the following conditions are met: • SPISIMO[0] pin is configured in GIO mode as output pin • Output value on SPISIMO[0] pin is logic 1
		0	Output value on the SPISIMO[0] pin is logic 1.
		1	Output pin SPISIMO[0] is in a high-impedance state.

Table 13-19. SPI Pin Control Register 6 (SPIPC6) Field Descriptions (continued)

Bit	Field	Value	Description
9	CLKPDR		SPICLK open drain enable. This bit enables open drain capability for the SPICLK pin, if the following conditions are met: • SPICLK pin is configured in GIO mode as an output pin • SPICLKDOUT = 1
		0	Output value on the SPICLK pin is logic 1.
		1	Output pin SPICLK is in a high-impedance state.
8	ENAPDR		$\overline{\text{SPIENA}}$ open drain enable. This bit enables open drain capability for the $\overline{\text{SPIENA}}$ pin, if the following conditions are met: • $\overline{\text{SPIENA}}$ pin is configured in GIO mode as an output pin • SPIENADOUT = 1
		0	Output value on the $\overline{\text{SPIENA}}$ pin is logic 1.
		1	Output pin $\overline{\text{SPIENA}}$ is in a high-impedance state.
7-0	SCSPDR		$\overline{\text{SPICS}}$ open drain enable. This bit enables open drain capability for each $\overline{\text{SPICS}}$ pin, if the following conditions are met: • $\overline{\text{SPICS}}$ pin is configured in GIO mode as an output pin • SCSDOUT = 1
		0	Output value on the $\overline{\text{SPICS}}$ pin is logic 1.
		1	Output pin $\overline{\text{SPICS}}$ is in a high-impedance state.

13.9.13 SPI Pin Control Register 7 (SPIPC7)

Note

Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

Note

Default Register Value

The default values of these register bits vary by device. See your device datasheet for information about default pin states, which correspond to the register reset values (see the pin-list table).

TXDATA	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-22. SPI Transmit Data Register 0 (SPIDAT0) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0. Writes have no effect.
15-0	TXDATA	0-FFFFh	SPI transmit data. When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, TXBUF holds the written data. SPIEN (SPICGR1[24]) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 to 0x00. **Note: When this register is read, the contents TXBUF, which holds the latest written data, will be returned.** **Note: Regardless of character length, the transmit word should be right-justified before writing to the SPIDAT1 register.** **Note: The default data format control register for SPIDAT0 is SPIFMT0. However, it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 before using SPIDAT0, to select a different SPIFMTx register.** **Note: It is highly recommended to use SPIDAT1 register, SPIDAT0 is supported for compatibility reasons.**

13.9.16 SPI Transmit Data Register 1 (SPIDAT1)

Note

Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

Figure 13-41. SPI Transmit Data Register 1 (SPIDAT1) [offset = 3Ch]

15 0
TXDATA
R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-23. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28	CSHOLD		Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of SPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer.
		0	The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.
		1	The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.
27	Reserved	0	Reads return 0. Writes have no effect.
26	WDEL		Enable the delay counter at the end of the current transaction.
			Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored.
		0	No delay will be inserted. However, the $\overline{\text{SPICS}}$ pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.
			Note: The duration for which the $\overline{\text{SPICS}}$ pin remains deactivated depends upon the time taken to supply a new word after completing the shift operation. If TXBUF is already full, then the $\overline{\text{SPICS}}$ pin will be deasserted for at least two VCLK cycles (if WDEL = 0).
		1	After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The $\overline{\text{SPICS}}$ pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.
25-24	DFSEL		Data word format select.
		0	Data word format 0 is selected.
		1h	Data word format 1 is selected.
		2h	Data word format 2 is selected.
		3h	Data word format 3 is selected.

Table 13-23. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions (continued)

Bit	Field	Value	Description
23-16	CSNR	0-FFh	Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See Table 13-24. **Note: If your MibSPI has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSPI3 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.**
15-0	TXDATA	0-FFFFh	Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF. SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of SPIDAT1 to 0x0000. A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the $\overline{\text{SPICS}}$ pins, if the pins are configured as functional pins (automatic chip select, see Section 13.2). When this register is read, the contents of TXBUF, which holds the latest data written, will be returned. **Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.**

Table 13-24. Chip Select Number Active

R-0							
15							0
RXDATA							
R-0							

LEGEND: R = Read only; *-n* = value after reset

Table 13-25. SPI Receive Buffer Register (SPIBUF) Field Descriptions

Bit	Field	Value	Description
31	RXEMPTY		Receive data buffer empty. When the host reads the RXDATA field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA and the RXEMPTY flag is cleared.
		0	New data has been received and copied into RXDATA.
		1	No data has been received since the last read of RXDATA.
			This flag gets set to 1 under the following conditions: • Reading the RXDATA field of the SPIBUF register • Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG) Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of SPIBUF (or the entire register).
30	RXOVR		Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor). If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVECTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read). **Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.** **Note: A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR, and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.**
		0	No receive data overrun condition occurred since last read of the data field.
		1	A receive data overrun condition occurred since last read of the data field.

Table 13-25. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)

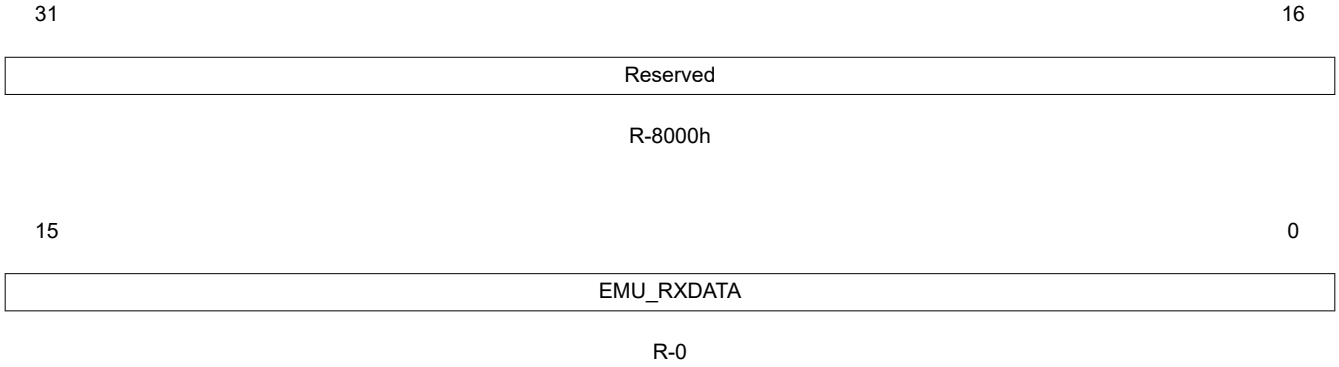
Bit	Field	Value	Description
29	TXFULL		Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.
		0	The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.
28	BITERR		Bit error. There was a mismatch of internal transmit data and transmitted data.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC		Desynchronization of slave device. This bit is valid in master mode only.
			The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
			Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always assured to be for the current buffer.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No slave desynchronization is detected.
		1	A slave device is desynchronized.
26	PARITYERR		Parity error. The calculated parity differs from the received parity bit.
			If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No parity error is detected.
		1	A parity error occurred.
25	TIMEOUT		Time-out because of non-activation of $\overline{\text{SPIENA}}$ pin.
			The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.
			Note: This bit is valid only in master mode.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No $\overline{\text{SPIENA}}$ pin time-out occurred.
		1	An $\overline{\text{SPIENA}}$ signal time-out occurred.
24	DLENERR		Data length error flag.
			Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.
		0	No data-length error occurred.
		1	A data length error occurred.
23-16	LCSNR	0-FFh	Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.

Table 13-25. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	RXDATA	0-FFFFh	SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

13.9.18 SPI Emulation Register (SPIEMU)

Figure 13-43. SPI Emulation Register (SPIEMU) [offset = 44h]



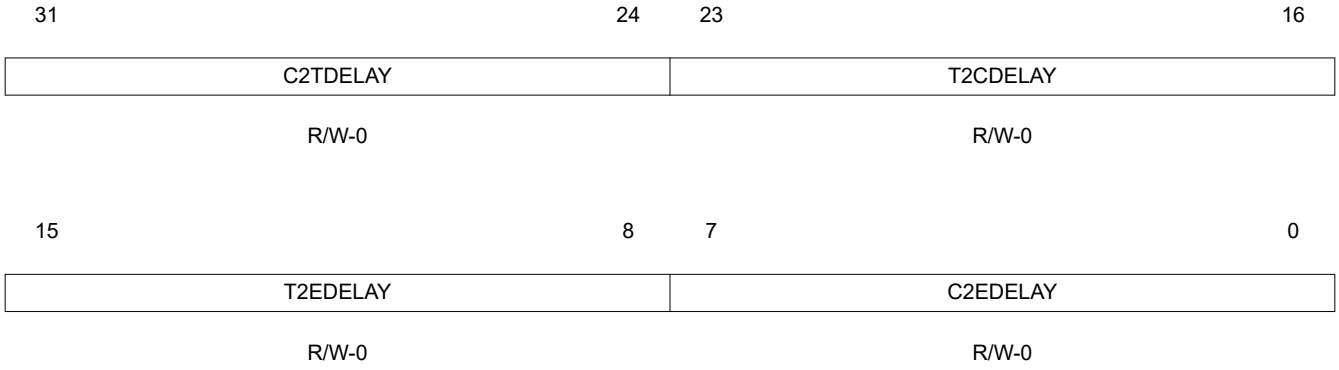
LEGEND: R = Read only; -*n* = value after reset

Table 13-26. SPI Emulation Register (SPIEMU) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	8000h	Reads return 0. Writes have no effect.
15-0	EMU_RXDATA	0-FFFFh	SPI receive data. The SPI emulation register is a mirror of the SPIBUF register. The only difference between SPIEMU and SPIBUF is that a read from SPIEMU does not clear any of the status flags.

13.9.19 SPI Delay Register (SPIDELAY)

Figure 13-44. SPI Delay Register (SPIDELAY) [offset = 48h]



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 13-27. SPI Delay Register (SPIDELAY) Field Descriptions

Bit	Field	Value	Description
31-24	C2TDELAY	0-FFh	Chip-select-active to transmit-start delay. See Figure 13-45 for an example. C2TDELAY is used only in master mode. It defines a setup time (for the slave device) that delays the data transmission from the chip select active edge by a multiple of VCLK cycles. The setup time value is calculated as follows. $t_{C2TDELAY}$ = (C2TDELAY + 2) × VCLK Period Example: VCLK = 25 MHz -> VCLK Period = 40ns; C2TDELAY = 07h; > $t_{C2TDELAY}$ = 360 ns When the chip select signal becomes active, the slave has to prepare data transfer within 360 ns. **Note: If phase = 1, the delay between SPICS falling edge to the first edge of SPICLK will have an additional 0.5 SPICLK period delay. This delay is as per the SPI protocol.**

Table 13-27. SPI Delay Register (SPIDELAY) Field Descriptions (continued)

Bit	Field	Value	Description
23-16	T2CDELAY	0-FFh	Transmit-end-to-chip-select-inactive-delay. See Figure 13-46 for an example. T2CDELAY is used only in master mode. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VCLK cycles after the last bit is transferred. The hold time value is calculated as follows: $t_{T2CDELAY}$ = (T2CDELAY +1) × VCLK Period Example: VCLK = 25 MHz -> VCLK Period = 40ns; T2CDELAY = 03h; > $t_{T2CDELAY}$ = 160 ns After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns. **Note: If phase = 0, then between the last edge of SPICLK and rise-edge of SPICS there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol.** Both C2TDELAY and T2CDELAY counters do not have any dependency on the $\overline{\text{SPIENA}}$ pin value. Even if the $\overline{\text{SPIENA}}$ pin is asserted by the slave, the master will continue to delay the start of SPICLK until the C2TDELAY counter overflows. Similarly, even if the $\overline{\text{SPIENA}}$ pin is deasserted by the slave, the master will continue to hold the $\overline{\text{SPICS}}$ pins active until the T2CDELAY counter overflows. In this way, it is assured that the setup and hold times of the $\overline{\text{SPICS}}$ pins are determined by the delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.
15-8	T2EDELAY	0-FFh	Transmit-data-finished to ENA-pin-inactive time-out. T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before $\overline{\text{SPIENA}}$ signal has to become inactive and after $\overline{\text{SPICS}}$ becomes inactive. SPICLK depends on which data format is selected. If the slave device is missing one or more clock edges, it becomes de-synchronized. In this case, although the master has finished the data transfer, the slave is still waiting for the missed clock pulses and the ENA signal is not disabled. The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the $\overline{\text{SPIENA}}$ signal is not deactivated in time. The DESYNC flag is set to indicate that the slave device did not de-assert its $\overline{\text{SPIENA}}$ pin in time to acknowledge that it received all bits of the sent word. See Figure 13-47 for an example of this condition. **Note: DESYNC is also set if the SPI detects a de-assertion of $\overline{\text{SPIENA}}$ before the end of the transmission.** The time-out value is calculated as follows: $t_{T2EDELAY}$ = T2EDELAY/SPIclock Example: SPIclock = 8 Mbit/s; T2EDELAY = 10h; > $t_{T2EDELAY}$ = 2 µs The slave device has to disable the ENA signal within 2 µs, otherwise DESYNC is set and an interrupt is asserted (if enabled).
7-0	C2EDELAY	0-FFh	Chip-select-active to ENA-signal-active time-out. C2EDELAY is used only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between when the SPI activates the chip-select signal and the addressed slave has to respond by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. See Figure 13-48 for an example of this condition. **Note: If the slave device does not respond with the ENA signal before the time-out value is reached, the TIMEOUT flag in the SPIFLG register is set and a interrupt is asserted (if enabled).** If a time-out occurs, the SPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer, and continues with the transfer of the next buffer in the sequence that is enabled. The timeout value is calculated as follows: $t_{C2EDELAY}$ = C2EDELAY/SPIclock Example: SPIclock = 8 Mbit/s; C2EDELAY = 30h; > $t_{C2EDELAY}$ = 6 ms The slave device has to activate the ENA signal within 6 ms after the SPI has activated the chip select signal ($\overline{\text{SPICS}}$), otherwise the TIMEOUT flag is set and an interrupt is asserted (if enabled).

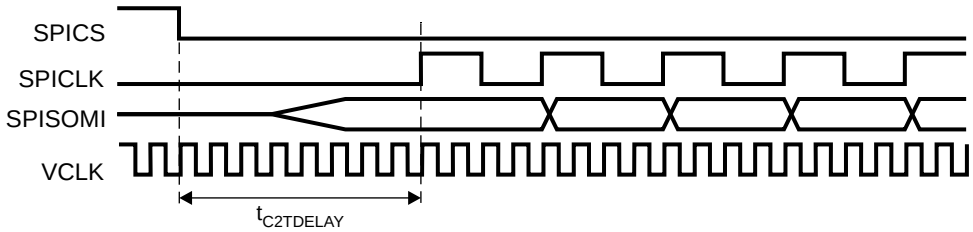


Figure 13-45. Example: $t_{C2TDELAY}$= 8 VCLK Cycles

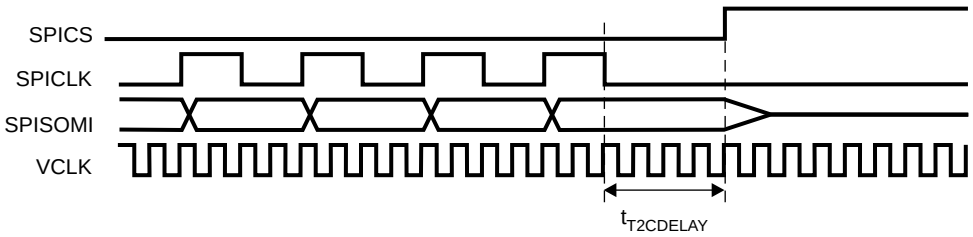

Figure 13-46. Example: $t_{T2CDELAY}$= 4 VCLK Cycles

13.9.20 SPI Default Chip Select Register (SPIDEF)

Figure 13-49. SPI Default Chip Select Register (SPIDEF) [offset = 4Ch]

31	16
Reserved	
R-0	

15	8	7	0
Reserved		CSDEF	
R-0		R/W-FFh	

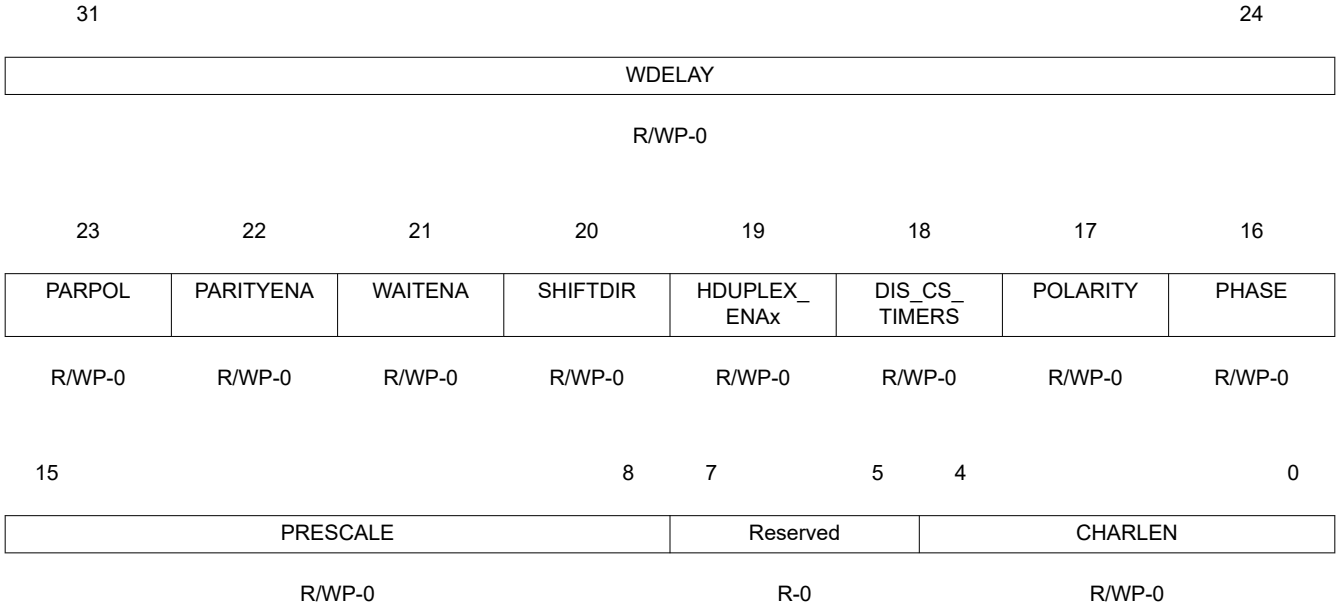
LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-28. SPI Default Chip Select Register (SPIDEF) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	CDEF	0-FFh	Chip select default pattern. Master-mode only. The CSDEF bits are output to the $\overline{\text{SPICS}}$ pins when no transmission is being performed. It allows the user to set a programmable chip-select pattern that deselects all of the SPI slaves.
		0	$\overline{\text{SPICS}}$ is cleared to 0 when no transfer is active.
		1	$\overline{\text{SPICS}}$ is set to 1 when no transfer is active.

13.9.21 SPI Data Format Registers (SPIFMT)

Figure 13-50. SPI Data Format Registers (SPIFMT[3:0]) [offset = 5Ch-50h]



LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 13-29. SPI Data Format Registers (SPIFMT) Field Descriptions

Bit	Field	Value	Description
31-24	WDELAY	0-FFh	Delay in between transmissions for data format x (x= 0,1,2,3).Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY × P_{VCLK} + 2 × P_{VCLK} P_{VCLK} -> Period of VCLK.
23	PARPOL		Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3).
		0	An even parity flag is added at the end of the transmit data stream.
		1	An odd parity flag is added at the end of the transmit data stream.
22	PARITYENA		Parity enable for data format x.
			No parity generation/ verification is performed for this data format.
		0	A parity bit is transmitted at the end of each transmitted word. At the end of a transfer the parity generator compares the received parity bit with the locally-calculated parity flag. If the parity bits do not match, the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit.
		1	**Note: If an uncorrectable error flag is set in a slave-mode SPI, then the wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SPISOMI pins will be forced to transmit all 0s, and the parity bit will be transmitted as 1 if even parity is selected and as 0 if odd parity is selected (using the PARPOLx bit of this register). This behavior occurs regardless of an uncorrectable parity error on either TXRAM or RXRAM.**
21	WAITENA		The master waits for the ENA signal from slave for data format x. WAITENA is valid in master mode only. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines, for each transferred word, whether the addressed slave generates the ENA signal or not.
		0	The SPI does not wait for the ENA signal from the slave and directly starts the transfer.
		1	Before the SPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the master aborts the transfer and sets the TIMEOUT error flag.

Table 13-29. SPI Data Format Registers (SPIFMT) Field Descriptions (continued)

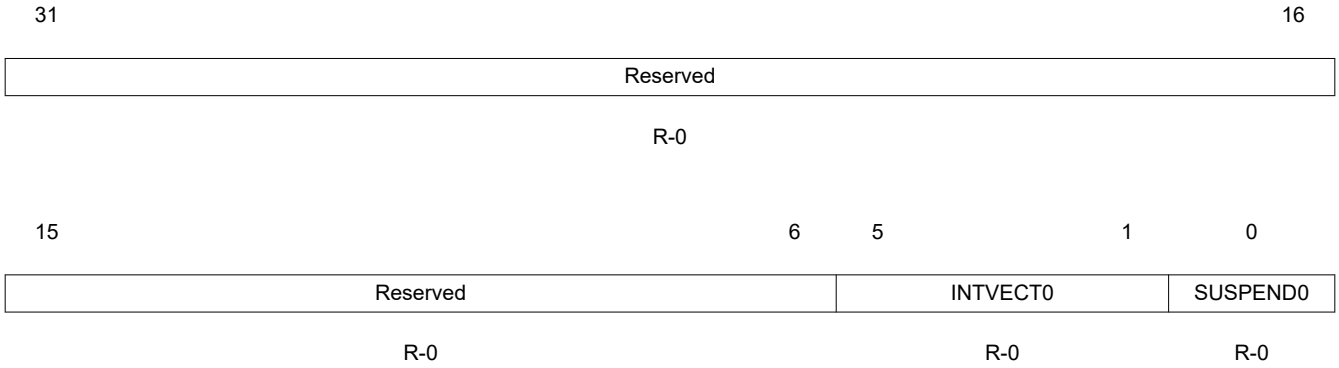
Bit	Field	Value	Description
20	SHIFTDIR		Shift direction for data format x. With bit SHIFTDIRx, the shift direction for data format x (x=0,1,2,3) can be selected.
		0	MSB is shifted out first.
		1	LSB is shifted out first.
19	HDUPLEX_ENAx		Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin.
		0	Normal Full Duplex transfer.
		1	If MASTER = 1, SPISIMO pin will act as an RX pin (No TX possible) If MASTER = 0, SPISIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain 0. It is intended for the usage when the SPISIMO pin is used for both TX and RX operations at different times.
18	DIS CS TIMERS		Disable chip-select timers for this format. The C2TDELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format, if they are not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip-select delay timers for any slaves.
		0	Both C2TDELAY and T2CDELAY counts are inserted for the chip selects.
		1	No C2TDELAY or T2CDELAY is inserted in the chip select timings.
17	POLARITY		SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. The following restrictions apply when switching clock phase and/or polarity: • In 3-pin/4-pin with $\overline{\text{SPIENA}}$ pin configuration of a slave SPI, the clock phase and polarity cannot be changed on-the-fly between two transfers. The slave should be reset and reconfigured if clock phase/polarity needs to be switched. In summary, SPI format switching is not fully supported in slave mode. • Even while using chip select pins, the polarity of SPICLK can be switched only while the slave is not selected by a valid chip select. The master SPI should ensure that while switching SPICLK polarity, it has deselected all of its slaves. Otherwise, the switching of SPICLK polarity may be incorrectly treated as a clock edge by some slaves.
		0	If POLARITYx is cleared to 0, the SPI clock signal is low-inactive, that is, before and after data transfer the clock signal is low.
		1	If POLARITYx is set to 1, the SPI clock signal is high-inactive, that is, before and after data transfer the clock signal is high.
16	PHASE		SPI data format x clock delay. PHASEx defines the clock delay of data format x.
		0	If PHASEx is cleared to 0, the SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge.
		1	If PHASEx is set to 1, the SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.
15-8	PRESCALE		SPI data format x prescaler. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is use to derive SPICLK from VCLK. If the SPI is configured as slave, PRESCALEx **does not need** to be configured. The clock rate for data format x can be calculated as: $BR_{Formatx}$ = VCLK / (PRESCALEx + 1) **Note: When PRESCALEx is cleared to 0, the SPI clock rate defaults to VCLK/2.**
7-5	Reserved	0	Reads return 0. Writes have no effect.
4-0	CHARLEN	0-1Fh	SPI data format x data-word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 10h (data word length = 16). Illegal values, such as 00 or 1Fh are not allowed; their effect is indeterminate.

13.9.22 Interrupt Vector 0 (INTVECT0)

Note

The TG interrupt is not available in MibSPI in compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

Figure 13-51. Interrupt Vector 0 (NTVECT0) [offset = 60h]



LEGEND: R = Read only; -*n* = value after reset

Table 13-30. Transfer Group Interrupt Vector 0 (INTVECT0)

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5-1	INTVECT0		INTVECT0. Interrupt vector for interrupt line INT0. Returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupt is pending, INTVECT0 always references the highest prior interrupt source first. **Note: This field reflects the status of the SPIFLG register in vector format. Any updates to the SPIFLG register will automatically cause updates to this field.**
		0	There is no pending interrupt.
		1h + x	Transfer group x (x = 0 to 15) has a pending interrupt. SUSPEND0 reflects the type of interrupt (*suspend* or *finished*).
		11h	Error Interrupt pending. The lower half of SPIFLG contains more details about the type of error.
		13h	The pending interrupt is a Receive Buffer Overrun interrupt.
		12h	**SPI mode:** The pending interrupt is a Receive Buffer Full interrupt. **Mib mode:** Reserved. This bit combination should not occur.
		14h	**SPI mode:** The pending interrupt is a Transmit Buffer Empty interrupt. **Mib mode:** Reserved. This bit combination should not occur.
		All Other Combinations	**SPI mode:** Reserved. These bit combinations should not occur.
0	SUSPEND0		Transfer suspended / Transfer finished interrupt flag. Every time INTVECT0 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT0 is updated with the vector coming next in the priority chain.
		0	The interrupt type is a transfer finished interrupt. In other words, the buffer array referenced by INTVECT0 has asserted an interrupt because all of data from the transfer group has been transferred.
		1	The interrupt type is a transfer suspended interrupt. In other words, the transfer group referenced by INTVECT0 has asserted an interrupt because the buffer to be transferred next is in suspend-to-wait mode.

Note

Reading from the INTVECT0 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

Note

In multi-buffer mode, INTVECT0 contains the interrupt for the highest priority transfer group. A read from INTVECT0 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT0 and its corresponding SUSPEND flag to get loaded into SUSPEND0. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT0 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR).

13.9.23

13.9.24 Interrupt Vector 1 (INTVECT1)

Note

The TG interrupt is not available in SPI in compatibility mode compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

Figure 13-52. Interrupt Vector 1 (INTVECT1) [offset = 64h]

31	16

LEGEND: R = Read only; *-n* = value after reset

Table 13-31. Transfer Group Interrupt Vector 1 (INTVECT1)

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.

Table 13-31. Transfer Group Interrupt Vector 1 (INTVECT1) (continued)

Bit	Field	Value	Description
5-1	INTVECT1		INTVECT1. Interrupt vector for interrupt line INT1. Returns the vector of the pending interrupt at interrupt line INT1. If more than one interrupt is pending, INTVECT1 always references the highest prior interrupt source first. **Note: This field reflects the status of the SPIFLG register in vector format. Any updates to the SPIFLG register will automatically cause updates to this field.**
		0	There is no pending interrupt. **SPI mode only.**
		11h	Error Interrupt pending. The lower half of SPIINT1 contains more details about the type of error. **SPI mode only.**
		13h	The pending interrupt is a Receive Buffer Overrun interrupt. **SPI mode only.**
		12h	The pending interrupt is a Receive Buffer Full interrupt. **SPI mode only.**
		14h	The pending interrupt is a Transmit Buffer Empty interrupt. **SPI mode only.**
		All Other Combinations	Reserved. These bit combinations should not occur. **SPI mode only.**
0	SUSPEND1		Transfer suspended / Transfer finished interrupt flag. Every time INTVECT1 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT1 is updated with the vector coming next in the priority chain.
		0	The interrupt type is a transfer finished interrupt. In other words, the buffer array referenced by INTVECT1 has asserted an interrupt because all of data from the transfer group has been transferred.
		1	The interrupt type is a transfer suspended interrupt. In other words, the transfer group referenced by INTVECT1 has asserted an interrupt because the buffer to be transferred next is in suspend-to-wait mode.

Note

Reading from the INTVECT1 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

Note

In multi-buffer mode, INTVECT1 contains the interrupt for the highest priority transfer group. A read from INTVECT1 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT1 and its corresponding SUSPEND flag to get loaded into SUSPEND1. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT1 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXOVERN_BUF_ADDR register.

13.9.25 SPI Pin Control Register 9 (SPIPC9)

SPIPC9 only applies to SPI2.

Figure 13-53. SPI Pin Control Register 9 (SPIPC9) [offset = 68h]

31	25	24	23	17	16

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-32. SPI Pin Control Register 9 (SPIPC9) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return the value that was last written. Writes have no effect.
24	SOMISRS0		SPI2 SOMI[0] slew control. This bit controls between the fast or slow slew mode.
			Note: Duplicate Control Bits for SPI2 SOMI[0]. Bit 24 is not physically implemented. It is a mirror of bit 11. Any write to bit 24 will be reflected on bit 11. When bit 24 and bit 11 are simultaneously written, the value of bit 11 will control the SPI2 SOMI[0] pin. The read value of bit 24 always reflects the value of bit 11.
		0	Fast mode is enabled; the normal output buffer is used for this pin.
		1	Slow mode is enabled; slew rate control is used for this pin.
23-17	Reserved	0	Reads return the value that was last written. Writes have no effect.
16	SIMOSRS0		SPI2 SIMO[0] slew control. This bit controls between the fast or slow slew mode.
			Note: Duplicate Control Bits for SPI2 SIMO[0]. Bit 16 is not physically implemented. It is a mirror of bit 10. Any write to bit 16 will be reflected on bit 10. When bit 16 and bit 10 are simultaneously written, the value of bit 10 will control the SPI2 SIMO[0] pin. The read value of bit 16 always reflects the value of bit 10.
		0	Fast mode is enabled; the normal output buffer is used for this pin.
		1	Slow mode is enabled; slew rate control is used for this pin.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11	SOMISRS0		SPI2 SOMI[0] slew control. This bit controls between the fast or slow slew mode.
		0	Fast mode is enabled; the normal output buffer is used for this pin.
		1	Slow mode is enabled; slew rate control is used for this pin.
10	SIMOSRS0		SPI2 SIMO[0] slew control. This bit controls between the fast or slow slew mode.
		0	Fast mode is enabled; the normal output buffer is used for this pin.
		1	Slow mode is enabled; slew rate control is used for this pin.
9	CLKSRS		SPI2 CLK slew control. This bit controls between the fast or slow slew mode.
		0	Fast mode is enabled; the normal output buffer is used for this pin.
		1	Slow mode is enabled; slew rate control is used for this pin.
8-0	Reserved	0	Reads return the value that was last written. Writes have no effect.

13.9.26 Parallel/Modulo Mode Control Register (SPIPMCTRL)

Note

Do not configure MODCLKPOLx and MMODEx bits since this device does not support modulo mode.

Note

The bits of this register are used in conjunction with the SPIFMTx registers. Each byte of this register corresponds to one of the SPIFMTx registers.

1. Byte0 (Bits 7:0) are used when SPIFMT0 register is selected by DFSEL[1:0] = 00 in the control field of a buffer.

2. Byte1 (Bits 15:8) are used when SPIFMT1 register is selected by DFSEL[1:0] = 01 in the control field of a buffer.

3. Byte2 (Bits 23:16) are used when SPIFMT2 register is selected by DFSEL[1:0] = 10 in the control field of a buffer.

4. Byte3 (Bits 31:24) are used when SPIFMT3 register is selected by DFSEL[1:0] = 11 in the control field of a buffer.

Table 13-33. SPI Parallel/Modulo Mode Control Register (SPIPMCTRL) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reads return 0. Writes have no effect.

Table 13-33. SPI Parallel/Modulo Mode Control Register (SPIPMCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
29	MODCLKPOL3		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE3 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.
28-26	MMODE3		These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if modulo option is supported by the module).
		0	Normal single data line mode - default (PMODE3 should be set to 00)
		1h	2-data line mode (PMODE3 should be set to 00)
		2h	3-data line mode (PMODE3 should be set to 00)
		3h	4-data line mode (PMODE3 should be set to 00)
		4h	5-data line mode (PMODE3 should be set to 00)
		5h	6-data line mode (PMODE3 should be set to 01)
		6h-7h	Reserved
25-24	PMODE3		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE3 should be set to 000)
		1h	2-data line mode (MMODE3 should be set to 000)
		2h	4-data line mode (MMODE3 should be set to 000)
		3h	8-data line mode (MMODE3 should be set to 000)
23-22	Reserved	0	Reads return 0. Writes have no effect.
21	MODCLKPOL2		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE2 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.
20-18	MMODE2		These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if modulo option is supported by the module).
		0	1-data line Mode - default (PMODE2 should be set to 00)
		1h	2-data line Mode (PMODE2 should be set to 00)
		2h	3-data line mode (PMODE2 should be set to 00)
		3h	4-data line mode (PMODE2 should be set to 00)
		4h	5-data line mode (PMODE2 should be set to 00)
		5h	6-data line mode (PMODE2 should be set to 01)
		6h-7h	Reserved
17-16	PMODE2		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE2 should be set to 000)
		1h	2-data line mode (MMODE2 should be set to 000)
		2h	4-data line mode (MMODE2 should be set to 000)
		3h	8-data line mode (MMODE2 should be set to 000)
15-14	Reserved	0	Reads return 0. Writes have no effect.
13	MODCLKPOL1		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE1 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.

Table 13-33. SPI Parallel/Modulo Mode Control Register (SPIPMCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
12-10	MMODE1		These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if modulo option is supported by the module).
		0	1-data line mode - default (PMODE1 should be set to 00)
		1h	2-data line mode (PMODE1 should be set to 00)
		2h	3-data line mode (PMODE1 should be set to 00)
		3h	4-data line mode (PMODE1 should be set to 00)
		4h	5-data line mode (PMODE1 should be set to 00)
		5h	6-data line mode (PMODE1 should be set to 01)
		6h-7h	Reserved
9-8	PMODE1		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE1 should be set to 000)
		1h	2-data line mode (MMODE1 should be set to 000)
		2h	4-data line mode (MMODE1 should be set to 000)
		3h	8-data line mode (MMODE1 should be set to 000)
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	MODCLKPOL0		Modulo mode SPICLK polarity. This bit determines the polarity of the SPICLK in modulo mode only. If the MMODE0 bits are 000, this bit will be ignored.
		0	Normal SPICLK in all the modes.
		1	Polarity of the SPICLK will be inverted if Modulo mode is selected.
4-2	MMODE0		These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if modulo option is supported by the module).
		0	1-data line mode - default (PMODE0 should be set to 00)
		1h	2-data line mode (PMODE0 should be set to 00)
		2h	3-data line mode (PMODE0 should be set to 00)
		3h	4-data line mode (PMODE0 should be set to 00)
		4h	5-data line mode (PMODE0 should be set to 00)
		5h	6-data line mode (PMODE0 should be set to 01)
		6h-7h	Reserved
1-0	PMODE0		Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2, 4, or 8 data lines.
		0	Normal operation/1-data line (MMODE0 should be set to 000)
		1h	2-data line mode (MMODE0 should be set to 000)
		2h	4-data line mode (MMODE0 should be set to 000)
		3h	8-data line mode (MMODE0 should be set to 000)

13.9.27 Multi-buffer Mode Enable Register (MIBSPIE)

Note

Accessibility of Multi-Buffer RAM

The multi-buffer RAM is not accessible unless the MSPIENA bit set to 1. The only exception to this is in test mode, where, by setting RXRAMACCESS to 1, the multi-buffer RAM can be fully accessed for both read and write.

Figure 13-55. Multi-buffer Mode Enable Register (MIBSPIE) [offset = 70h]

31	17	16
Reserved		RXRAM_ACCESS
R-0		R/WP-0

15	1	0
Reserved		MSPIENA
R-0		R/WP-0

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 13-34. Multi-buffer Mode Enable Register (MIBSPIE) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reads return 0. Writes have no effect.
16	RXRAM ACCESS		Receive-RAM access control. During normal operating mode of SPI, the receive data/status portion of multi-buffer RAM is read-only. To enable testing of receive RAM, direct read/write access is enabled by setting this bit.
		0	The RX portion of multi-buffer RAM is not writable by the CPU.
		1	The whole of multi-buffer RAM is fully accessible for read/write by the CPU.
			Note: The RX RAM ACCESS bit remains 0 after reset and it should remain cleared to 0 at all times, except when testing the RAM. SPI should be given a local reset by using the nRESET (SPIGCR0[0]) bit after RAM testing is performed so that the multi-buffer RAM gets re-initialized.
15-1	Reserved	0	Reads return 0. Writes have no effect.
0	MSPIENA		Multi-buffer mode enable. After power-up or reset, MSPIENA remains cleared, which means that the SPI runs in compatibility mode by default. If multi-buffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. If MSPIENA is not set to 1, the multi-buffer mode registers are not writable.
		0	The SPI runs in compatibility mode, that is, in this mode the MibSPI is fully code-compliant to the standard device SPI. No multi-buffered-mode features are supported.
		1	The SPI is configured to run in multi-buffer mode.

Note

Accessibility of Registers

Registers from this offset address onwards are not accessible in SPI compatibility mode. They are accessible only in the multi-buffer mode.

13.9.28 TG Interrupt Enable Set Register (TGITENST)

The register TGITENST contains the TG interrupt enable flags for transfer-finished and for transfer-suspended events. Each of the enable bits in the higher half-word and the lower half-word of TGITENST belongs to one TG.

The register map shown in Figure 13-56 and Table 13-35 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Table 13-35. TG Interrupt Enable Set Register (TGITENST) Field Descriptions

Bit	Field	Value	Description
31-16	SETINTENRDY[*n*]		TG interrupt set (enable) when transfer finished. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on.
		0	Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx completes. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx completes. Write: Enable the TGx-completed interrupt. The interrupt gets generated when TGx completes.
15-0	SETINTENSUS[*n*]		TG interrupt set (enabled) when transfer suspended. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.
		0	Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx is suspended. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx is suspended. Write: Enable the TGx-completed interrupt. The interrupt gets generated when TGx is suspended.

13.9.29 TG Interrupt Enable Clear Register (TGITENCR)

The register TGITENCR is used to clear the interrupt enables for the TG-completed interrupt and the TG-suspended interrupts.

The register map shown in Figure 13-57 and Table 13-36 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

		0	Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx completes. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx completes. Write: Disable the TGx-completed interrupt. The interrupt does not get generated when TGx completes.
15-0	CLRINTENSUS[*n*]		TG interrupt clear (disabled) when transfer suspended. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.
		0	Read: The TGx-completed interrupt is disabled. This interrupt does not get generated when TGx is suspended. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is enabled. The interrupt gets generated when TGx is suspended. Write: Disable the TGx-completed interrupt. The interrupt does not get generated when TGx is suspended.

13.9.30 Transfer Group Interrupt Level Set Register (TGITLVST)

The register TGITLVST sets the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 1.

The register map shown in Figure 13-58 andTable 13-37 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

		0	Read: The TGx-completed interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is set to INT1. Write: Set the TGx-completed interrupt to INT1.
15-0	SETINTLVLSUS[*n*]		Transfer-group suspended interrupt level set. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.
		0	Read: The TGx-suspended interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-suspended interrupt is set to INT1. Write: Set the TGx-suspended interrupt to INT1.

13.9.31 Transfer Group Interrupt Level Clear Register (TGITLVCR)

The register TGITLVCR clears the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 0.

The register map shown in Figure 13-59 and Table 13-38 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Bit	Field	Value	Description
31-16	CLRINTLVLRDY[*n*]		Transfer-group completed interrupt level clear. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on.
		0	Read: The TGx-completed interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-completed interrupt is set to INT1. Write: Clear the TGx-completed interrupt to INT0.
15-0	CLRINTLVLSUS[*n*]		Transfer group suspended interrupt level clear. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.
		0	Read: The TGx-suspended interrupt is set to INT0. Write: A write of 0 to this bit has no effect.
		1	Read: The TGx-suspended interrupt is set to INT1. Write: Clear the TGx-suspended interrupt to INT0.

13.9.32 Transfer Group Interrupt Flag Register (TGINTFLG)

The TGINTFLG register comprises the transfer group interrupt flags for transfer-completed interrupts (INTFLGRDYx) and for transfer-suspended interrupts (INTFLGSUSx). Each of the interrupt flags in the higher half-word and the lower half-word of TGINTFLG belongs to one TG.

The register map shown in Figure 13-60 and Table 13-39 represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

Figure 13-60. Transfer Group Interrupt Flag Register (TGINTFLG) [offset = 84h]

LEGEND: R/W = Read/Write; W1C = Write 1 to clear; -*n* = value after reset

Table 13-39. Transfer Group Interrupt Flag Register (TGINTFLG) Field Descriptions

Bit	Field	Value	Description
31-16	INTFLGRDY[*n*]		Transfer-group interrupt flag for a transfer-completed interrupt. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. **Note: Read Clear Behavior. Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the vector registers is 0.**
		0	Read: No transfer-completed interrupt occurred since last clearing of the INTFLGRDYx flag. Write: A write of 0 to this bit has no effect.
		1	Read: A transfer finished interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGRDYx is set right after the transfer from TGx is finished. Write: The corresponding bit flag is cleared.
15-0	INTFLGSUS[*n*]		Transfer-group interrupt flag for a transfer-suspend interrupt. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on. **Note: Read Clear Behavior. Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGSUSx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the corresponding vector registers is 1.**
		0	Read: No transfer-suspended interrupt occurred since the last clearing of the INTFLGSUSx flag. Write: A write of 0 to this bit has no effect.
		1	Read: A transfer-suspended interrupt from TGx occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended. Write: The corresponding bit flag is cleared.

13.9.33 Tick Count Register (TICKCNT)

One of the trigger sources for TGs is an internal periodic time trigger. This time trigger is called a tick counter and is basically a down-counter with a preload/reload value. Every time the tick counter detects an underflow it reloads the initial value and toggles the trigger signal provided to the TGs.

The trigger signal, shown in Figure 13-61 as a square wave, illustrates the different trigger event types for the TGs (for example, rising edge, falling edge, and both edges).

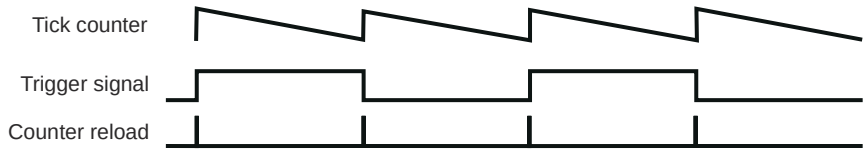

Figure 13-61. Tick Counter Operation

This register is shown in Figure 13-62 and described in Table 13-40.

Figure 13-62. Tick Count Register (TICKCNT) [offset = 90h]

31	30	29	28	27	...	16

R/W-0	R/S-0	R/W-0	R-0			

15	...	0
TICKVALUE		
R/W-0		

LEGEND: R/W = Read/Write; R = Read only; S = Set; -*n* = value after reset

Table 13-40. Tick Count Register (TICKCNT) Field Descriptions

Bit	Field	Value	Description
31	TICKENA		Tick counter enable.
		0	The internal tick counter is disabled. The counter value remains unchanged.
			Note: When the tick counter is disabled, the trigger signal is forced low.
		1	The internal tick counter is enabled and is clocked by the clock source selected by CLKCTRL. When TICKENA goes from 0 to 1, the tick counter is automatically loaded with the contents of TICKVALUE.
30	RELOAD		Pre-load the tick counter. RELOAD is a set-only bit; writing a 1 to it reloads the tick counter with the value stored in TICKVALUE. Reading RELOAD always returns a 0.
			Note: When the tick counter is reloaded by the RELOAD bit, the trigger signal is not toggled.
29-28	CLKCTRL		Tick counter clock source control. CLKCTRL defines the clock source that is used to clock the internal tick counter.
		0	SPICLK of data word format 0 is selected as the clock source of the tick counter.
		1h	SPICLK of data word format 1 is selected as the clock source of the tick counter.
		2h	SPICLK of data word format 2 is selected as the clock source of the tick counter.
		3h	SPICLK of data word format 3 is selected as the clock source of the tick counter.
27-16	Reserved	0	Reads return 0. Writes have no effect.

Table 13-40. Tick Count Register (TICKCNT) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	TICKVALUE	0-FFFFh	Initial value for the tick counter. TICKVALUE stores the initial value for the tick counter. The tick counter is loaded with the contents of TICKVALUE every time an underflow condition occurs and every time the RELOAD flag is set by the host.

13.9.34 Last TG End Pointer (LTGPEND)

Figure 13-63. Last TG End Pointer (LTGPEND) [offset = 94h]

31	29	28	24	23	16
Reserved		TG_IN_SERVICE		Reserved	
R-0		R-0		R-0	

15	14	8	7	0
Rsvd	LPEND		Reserved	
R-0	R/W-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-41. Last TG End Pointer (LTGPEND) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reads return 0. Writes have no effect.
28-24	TG_IN_SERVICE		The TG number currently being serviced by the sequencer. These bits indicate the current TG that is being serviced. This field can generally be used for code debugging.
		0	No TG is being serviced by the sequencer.
		1h	TG0 is being serviced by the sequencer.
		:	:
		10h	TG15 is being serviced by the sequencer.
			Note: The number of transfer groups varies by device.
		11h-1Fh	Invalid values.
23-15	Reserved	0	Reads return 0. Writes have no effect.
14-8	LPEND	0-7Fh	Last TG end pointer. Usually the TG end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent TG (PSTART). The TG ends one word before the next TG starts (PEND[x] = PSTART[x+1] - 1). For a full configuration of MibSPI, the last TG has no subsequent TG, that is, no end address is defined. Therefore, LPEND has to be programmed to specify explicitly the end address of the last TG. **Note: When using all 8 transfer groups, program the LPEND bits to define the end of the last transfer group. When using less than 8 transfer groups, leave the LPEND bits programmed to point to the end of the buffer and create a dummy transfer group that defines the end of your last intentional transfer group and occupies all the remaining buffer space.**
7-0	Reserved	0	Reads return 0. Writes have no effect.

13.9.35 TGx Control Registers (TGxCTRL)

Each TG can be configured via one dedicated control register. The register description shows one control register (x) that is identical for all TGs. For example, the control register for TG2 is named TG2CTRL and is located at *base address + 98h + 4 × 2*. The actual number of available control registers varies by device.

Figure 13-64. MibSPI TG Control Registers (TGxCTRL) [offsets = 98h-D4h]

31	30	29	28	27	24

23	20	19	16
TRIGEVT		TRIGSRC	
R/W-0		R/W-0	

15	14	8	7	6	0
Rsvd	PSTART		Rsvd	PCURRENT	
R-0	R/W-0		R-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-42. TG Control Registers (TGxCTRL) Field Descriptions

Bit	Field	Value	Description
31	TGENA		TGx enable. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx), a group transfer is initiated if no higher-priority TG is in active-transfer mode or if one or more higher-priority TGs are in transfer-suspend mode. Disabling a TG while a transfer is ongoing will finish the ongoing word transfer but not the whole group transfer.
		0	TGx is disabled.
		1	TGx is enabled.
30	ONESHOTx		Single transfer for TGx.
		0	TGx initiates a transfer every time a trigger event occurs and TGENA is set.
		1	A transfer from TGx will be performed only once (one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared and therefore no additional transfer can be triggered before the host enables the TG again. This one shot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data.

Table 13-42. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
29	PRSTx		TGx pointer reset mode. Configures the way to resolve trigger events during an ongoing transfer. This bit is meaningful only for level-triggered TGs. Edge-triggered TGs cannot be restarted before their completion by another edge. The PRST bit will have no effect on this behavior. **Note: When the PRST bit is set, if the buffer being transferred at the time of a new trigger event is a LOCK, CSHOLD or NOBRK buffer, then only after finishing those transfers, the TG will be restarted. This means that even if the TG is retriggered, the TG will only be restarted after finishing the transfer of the first non-LOCK or non-CSHOLD buffer. In the case of the NOBRK buffer, after completing the ICOUNT number of transfers, the TG will be restarted from its PSTART.** This means that TX control fields such as LOCK and CSHOLD, and DMA control fields such as NOBRK have higher priority over anything else. They have the capability to delay the restart of the TG even if it is retriggered when PRST is 1.
		0	If a trigger event occurs during a transfer from TGx, the event is ignored and is not stored internally. The TGx transfer has priority over additional trigger events.
		1	The TGx pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same TG is ongoing. Every trigger event resets PCURRENTx no matter whether the concerned TG is in transfer mode or not. The trigger events have priority over the ongoing transfer.
28	TGTDx		TG triggered.
		0	TGx has not been triggered or is no longer waiting for service.
		1	TGx has been triggered and is either currently being serviced or waiting for servicing.
27-24	Reserved	0	Reads return 0. Writes have no effect.

Table 13-42. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value		Description
23-20	TRIGEVTx			Type of trigger event. A level-triggered TG can be stopped by de-activating the level trigger. However, the following restrictions apply. • Deactivating the level trigger for a TG during a NOBRK transfer does not stop the transfers until all of the ICOUNT number of buffers are transferred for the NOBRK buffer. Once a NOBRK buffer is prefetched, the trigger event loses control over the TG until the NOBRK buffer transfer is completed. • Once the transfer of a buffer with CSHOLD or LOCK bit set starts, deactivating the trigger level does not stop the transfer until the sequencer completes the transfer of the next non-CSHOLD or non-LOCK buffer in the same TG. • Once the last buffer in a TG is pre-fetched, de-activating the trigger level does not stop the transfer group until the last buffer transfer is completed. This means even if the trigger level is deactivated at the beginning of the penultimate (one-before-last) buffer transfer, the sequencer continues with the same TG until it is completed.
		0	never	Never trigger TGx. This is the default value after reset.
		1h	rising edge	A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer for TGx
		2h	falling edge	A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer for TGx
		3h	both edges	Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer for TGx
		4h	Rsvd	Reserved
		5h	high-active	While the selected trigger source (TRIGSRCx) is at a logic-high level (1), the group transfer is continued and at the end of one group, transfer is restarted at the beginning. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. **Note: If ONESHOTx is set, the transfer is performed only once.**
		6h	low-active	While the selected trigger source (TRIGSRCx) is at a logic-low level (0), the group transfer is continued and at the end of one group, transfer is restarted at the beginning. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. **Note: If ONESHOTx is set, the transfer is performed only once.**
		7h	always	A repetitive group transfer will be performed. **Note: By setting the TRIGSRC to 0, the TRIGEVT to 7h (ALWAYS), and the ONESHOTx bit to 1, software can trigger this TG. Upon setting the TGENA bit, the TG is immediately triggered.** **Note: If ONESHOTx is set, the transfer is performed only once.**
		8h-Fh	Rsvd	Reserved

Table 13-42. TG Control Registers (TGxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	TRIGSRCx		Trigger source. After reset, the trigger sources of all TGs are disabled.
		0	Disabled
		1h	EXT0 External trigger source 0. The actual source varies per device (for example, HET I/O channel, event pin).
		2h	EXT1 External trigger source 1. The actual source varies per device (for example, HET I/O channel, event pin).
		3h	EXT2 External trigger source 2. The actual source varies per device (for example, HET I/O channel, event pin).
		4h	EXT3 External trigger source 3. The actual source varies per device (for example, HET I/O channel, event pin).
		5h	EXT4 External trigger source 4. The actual source varies per device (for example, HET I/O channel, event pin).
		6h	EXT5 External trigger source 5. The actual source varies per device (for example, HET I/O channel, event pin).
		7h	EXT6 External trigger source 6. The actual source varies per device (for example, HET I/O channel, event pin).
		8h	EXT7 External trigger source 7. The actual source varies per device (for example, HET I/O channel, event pin).
		9h	EXT8 External trigger source 8. The actual source varies per device (for example, HET I/O channel, event pin).
		Ah	EXT9 External trigger source 9. The actual source varies per device (for example, HET I/O channel, event pin).
		Bh	EXT10 External trigger source 10. The actual source varies per device (for example, HET I/O channel, event pin).
		Ch	EXT11 External trigger source 11. The actual source varies per device (for example, HET I/O channel, event pin).
		Dh	EXT12 External trigger source 12. The actual source varies per device (for example, HET I/O channel, event pin).
		Eh	EXT13 External trigger source 13. The actual source varies per device (for example, HET I/O channel, event pin).
		Fh	TICK Internal periodic event trigger. The tick counter can initiate periodic group transfers.
15	Reserved	0	Reads return 0. Writes have no effect.
14-8	PSTARTx	0-7Fh	TG start address. PSTARTx stores the start address of the corresponding TG. The corresponding end address is inherently defined by the subsequent TG start address minus 1 (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: • The TG is enabled • The end of the TG is reached during a transfer • A trigger event occurs while PRST is set to 1
7	Reserved	0	Reads return 0. Writes have no effect.
6-0	PCURRENTx	0-7Fh	Pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127) of the buffer that corresponds to this TG. If the TG switches from active-transfer mode to suspend-to-wait mode, PCURRENTx contains the address of the currently suspended word. After the TG resumes from suspend-to-wait mode, the next buffer will be transferred; that is, no buffer data is transferred because of suspend-to-wait mode.

Note

Register bits vary by device

TG0 has the highest priority and TG15 has the lowest priority. Under the following conditions, a lower-priority TG cannot be interrupted by a higher-priority TG:

1. When there is a CSHOLD or LOCK buffer, until the completion of the next buffer transfer that is a non-CSHOLD or non-LOCK buffer.
2. An entire sequence of words transferred for a NOBRK DMA buffer.
3. Once the last word in a TG is pre-fetched.

13.9.36 DMA Channel Control Register (DMAxCTRL)

Each DMA channel can be configured via one dedicated control register. The register description below shows one exemplary control register that is identical for all DMA channels; for example, the control register for DMA channel 0 is named DMA0CTRL. The MibSPI supports up to 8 bidirectional DMA channels.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA channel control registers may vary.

Figure 13-65. DMA Channel Control Register (DMAxCTRL) [offset = D8h-F4h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-43. DMA Channel Control Register (DMAxCTRL) Field Descriptions

Bit	Field	Value	Description
31	ONESHOT		Auto-disable of DMA channel after ICOUNT + 1 transfers. **Note: This ONESHOT applies to the DMA channel identified by x and will autodisable based on ICOUNTx.**
		0	The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.
		1	ONESHOT allows a block transfer of defined length (ICOUNTx + 1), mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx + 1 transfers, the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer.
30-24	BUFIDx	0-7Fh	Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the "suspend to wait until..." modes must be used.
23-20	RXDMA_MAPx	0-Fh	Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to 1, then RXDMA_MAPx shall differ from TXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise, unexpected interference may occur.

Table 13-43. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	TXDMA_MAPx	0-Fh	Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. TXDMA_MAPx defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to 1, then TXDMA_MAPx shall differ from RXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise, unexpected interference may occur.
15	RXDMAENAx		Receive data DMA channel enable.
		0	No DMA request upon new receive data.
		1	The physical DMA channel for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The buffer should be configured in as "skip until RXEMPTY is set" or "suspend to wait until RXEMPTY is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.
14	TXDMAENAx		Transmit data DMA channel enable.
		0	No DMA request upon new transmit data.
		1	The physical DMA channel for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The buffer should be configured in the as "skip until TXFULL is set" or "suspend to wait until TXFULL is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.
13	NOBRKx		Non-interleaved DMA block transfer. This bit is available in master mode only. **Note: Special Conditions during a NOBRK Buffer Transfer. If a NOBRK DMA buffer is currently being serviced by the sequencer, then it is not allowed to be disabled prematurely.** During a NOBRK transfer, the following operations are not allowed: • Clearing the NOBRKx bit to 0 • Clearing the RXDMAENAx to 0 (if it is already 1) • Clearing the TXDMAENAx to 0 (if it is already 1) • Clearing the BUFMODE[2:0] bits in TXRAM to 000 **Note: Any attempts to perform these actions during a NOBRK transfer will produce unpredictable results.**
		0	DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or TGs. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer.
		1	NOBRKx ensures that ICOUNTx + 1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx + 1 transfers have been processed. For example, this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD = 1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI. **Note: Triggering of higher priority TGs or enabling of higher priority DMA channels will not interrupt a NOBRK block transfer.**
12-8	ICOUNTx	0-1Fh	Initial count of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfers equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer. If ONESHOTx and NOBRKx are not set, ICOUNTx should be 0. **Note: See Section 13.9.37 (ICOUNT) and Section 13.9.38 (DMACNTLEN) about how to increase the ICOUNT to a 16-bit value. With this extended capability, MibSPI can transfer a block of up to 65535 (65K) words without interleaving (if NOBRK is used) or without deasserting the chip select between the buffers (if CSHOLD is used).**
7	Reserved	0	Reads return 0. Writes have no effect.
6	COUNT_BIT17x		The 17th bit of the COUNT field of DMAxCOUNT register.

Table 13-43. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
5-0	COUNTx	0-3Fh	Actual number of remaining DMA transfers. This field contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. **Note: If the TX and RX DMA requests are enabled, the COUNT register will be decremented when the RX has been serviced.**

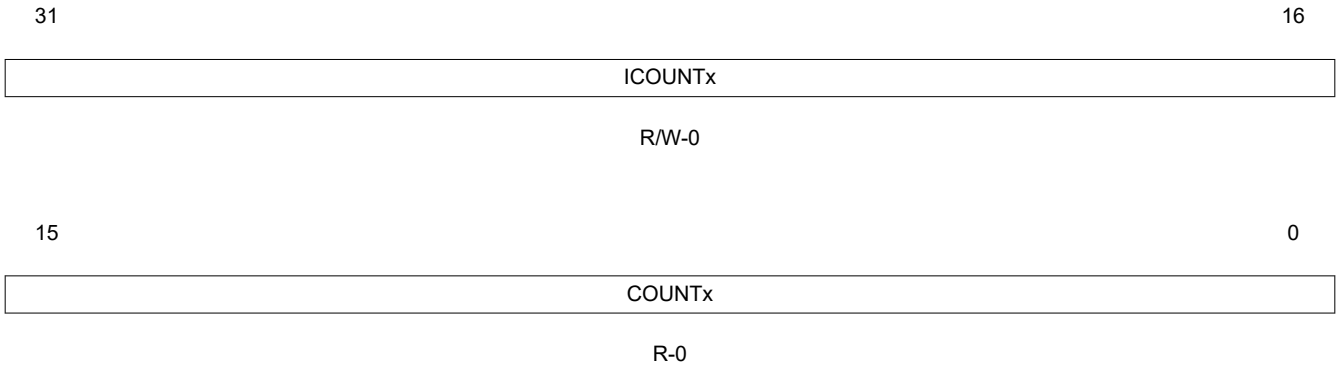
13.9.37 DMAxCOUNT Register (ICOUNT)

Note

These registers are used only if the LARGE COUNT bit in the DMACNTLEN register is set.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA registers varies by device.

Figure 13-66. DMAxCOUNT Register (ICOUNT) [offset = F8h-114h]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-44. MibSPI DMAxCOUNT Register (ICOUNT) Field Descriptions

Bit	Field	Value	Description
31-16	ICOUNTx	0-FFFFh	Initial number of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfer equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the corresponding DMA channel. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer.
15-0	COUNTx	0-FFFFh	Actual number of remaining DMA transfers. COUNTx Contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. Since the real counter value is always ICOUNTx +1, the 17th bit of COUNTx is available on DMACTRLx[6] bit. **Note: Usage Tip for Block Transfer Using a Single DMA Request. It is possible to use the multi-buffer RAM to transfer chunks of data to/from an external SPI. A DMA Controller can be used to handle the data in bursts. Suppose a chunk of 64 bytes of data needs to be transferred and a single DMA request needs to be generated at the end of transferring the 64 bytes. This can be easily achieved by configuring a TG register for the 64 buffer locations and using the DMAxCTRL/DMAxCOUNT registers to configure the last buffer (64th) of the TG as the BUFID and enable RXDMA (NOBRK = 0). At the end of the transfer of the 64th buffer, a DMA request will be generated on the selected DMA request channel. The DMA controller can do a burst read of all 64 bytes from RXRAM and/or then do a burst write to all 64 bytes to the TXRAM for the next chunk.**

13.9.38 DMA Large Count (DMACNTLEN)

Table 13-45. MibSPI DMA Large Count Register (DMACNTLEN) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	LARGE_COUNT		Select either the 16-bit DMAxCOUNT counters or the smaller counters in DMAxCTRL.
		0	Select the DMAxCTRL counters. Writes to the DMAxCTRL register will modify the ICOUNT value. Reading ICOUNT and COUNT can be done from the DMAxCTRL register. The DMAxCOUNT register should not be used since any write to this register will be overwritten by a subsequent write to the DMAxCTRL register to set the TXDMAENA or RXDMAENA bits.
		1	Select the DMAxCOUNT counters. Writes to the DMAxCTRL register will not modify the ICOUNT value. The ICOUNT value must be written to in the DMAxCOUNT register before the RXDMAENA or TXDMAENA bits are set in the DMAxCTRL register. The DMAxCOUNT register should be used for reading COUNT or ICOUNT.

13.9.39 Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL)

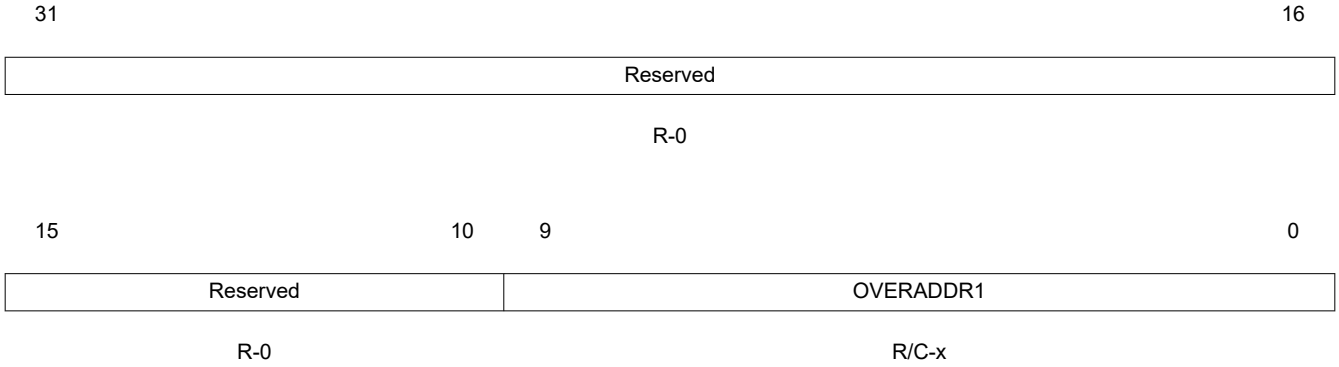
Table 13-47. Multi-buffer RAM Uncorrectable Parity Error Status Register (UERRSTAT) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	EDFLG1		Uncorrectable parity error detection flag. This flag indicates if a parity error occurred in the RXRAM. **Note: Reading the UERRADDR1 register clears the EDFLG1 bit.**
		0	Read: No error has occurred. Write: Writing a 0 to this bit has no effect.
		1	Read: An error was detected and the address is captured in the UERRADDR1 register. Write: The bit is cleared to 0.
0	EDFLG0		Uncorrectable parity error detection flag. This flag indicates if a parity error occurred in the TXRAM. **Note: Reading the UERRADDR0 register clears the EDFLG0 bit.**
		0	Read: No error has occurred. Write: Writing a 0 to this bit has no effect.
		1	Read: An error was detected and the address is captured in the UERRADDR0 register. Write: The bit is cleared to 0.

13.9.41 RXRAM Uncorrectable Parity Error Address Register (UERRADDR1)

Figure 13-70. RXRAM Uncorrectable Parity Error Address Register (UERRADDR1) [offset = 128h]



LEGEND: R = Read only; C = Clear; -*n* = value after reset

Table 13-48. RXRAM Uncorrectable Parity Error Address Register (UERRADDR1) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	OVERADDR1	200h-3FFh	Uncorrectable parity error address for RXRAM. This register holds the address where a parity error is generated while reading RXRAM. Only the CPU or DMA can read from RXRAM locations. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of RXRAM varies from 200h-3FFh. The register does not clear its contents during or after module-level reset, system-level reset or even power-on reset. A read operation to this register clears its contents to the default value 200h. After a power-on reset the contents will be unpredictable. A read operation can be performed after power-up to keep the register at its default value, if required. However, the contents of this register are meaningful only when EDFLG1 is set to 1. **Note: A read of the UERRADDR1 register will clear EDFLG1 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR1 register does not clear EDFLG1.**

Bit	Field	Value	Description
31-9	Reserved	0	Reads return 0. Writes have no effect.
8-0	UERRADDR0	0-1FFh	Uncorrectable parity error address for TXRAM. This register holds the address where a parity error is generated while reading from TXRAM. The TXRAM can be read either by CPU or by the MibSPI sequencer logic for transmission. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of TXRAM varies from 0-1FFh. The register does not clear its contents during or after module-level reset, system-level reset, or even power-on reset. A read operation to this register clears its contents to all 0s. After a power-on reset, the contents of this register will be unpredictable. A read operation can be performed after power-up to clear the this register's contents, if required. However, the contents of this register are meaningful only when EDFLG0 is set to 1. **Note: A read from the UERRADDR0 register will clear EDFLG0 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR0 register does not clear EDFLG0.**

13.9.43 RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR)

In multi-buffer mode, if a particular RXRAM location is written by the MibSPI sequencer logic after the completion of a new transfer when that location already contains valid data, the RX_OVR bit will be set to 1 while the data is being written. The RXOVRN_BUF_ADDR register captures the address of the RXRAM location for which a receiver overrun condition occurred.

Table 13-50. RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	RXOVRN_BUF_ADDR	200h-3FCh	Address in RXRAM at which an overwrite occurred. This address value will show only the offset address of the RAM location in the multi-buffer RAM address space. Refer to the device-specific data sheet for the actual absolute address of RXRAM. This word-aligned address can vary from 200h-3FCh. Contents of this register are valid only when any of the INTVECT0 or INTVECT1 and SPIFLG registers show an RXOVRN error vector while in multi-buffer mode. If there are multiple overrun errors, then this register holds the address of first overrun address until it is read. **Note: Reading this register clears the RXOVRN interrupt flag in the SPIFLG register and the TGINTVECTx.** **Note: Receiver overrun errors in multi-buffer mode can be completely avoided by using the SUSPEND until RXEMPTY feature, which can be programmed into each buffer of any TG. However, using the SUSPEND until RXEMPTY feature will make the sequencer wait until the current RXRAM location is read by the VBUS master before it can start the transfer for the same buffer location again. This may affect the overall throughput of the SPI transfer. By enabling the interrupt on RXOVRN in multi-buffer mode, the user can rely on interrupts to know if a receiver overrun has occurred. The address of the overrun in RXRAM is indicated in this RXOVRN_BUF_ADDR register.**

13.9.44 I/O-Loopback Test Control Register (IOLPBKTSTCR)

This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog. In addition, it contains control bits to induce error conditions into the module. These are to be used only for module testing.

All of the control/status bits in this register are valid only when the IOLPBKTSTENA field is set to Ah.

Table 13-51. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads return 0. Writes have no effect.
24	SCS FAIL FLG		Bit indicating a failure on $\overline{\text{SPICS}}$ pin compare during analog loopback.
		0	Read: No miscompares occurred on any of the eight chip select pins (vs. the internal chip select number CSNR during transfers). Write: Writing a 0 to this bit has no effect.
		1	Read: A comparison between the internal CSNR field and the analog looped-back value of one or more of the $\overline{\text{SPICS}}$ pins failed. A stuck-at fault is detected on one of the $\overline{\text{SPICS}}$ pins. Comparison is done only on the pins that are configured as functional and during transfer operation. Write: This flag bit is cleared.
23-21	Reserved	0	Reads return 0. Writes have no effect.
20	CTRL BITERR		Controls inducing of BITERR during I/O loopback test mode.
		0	Do not interfere with looped-back data.
		1	Induces bit errors by inverting the value of the incoming data during loopback.

Table 13-51. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions (continued)

Bit	Field	Value	Description
19	CTRL DESYNC		Controls inducing of the desync error during I/O loopback test mode.
		0	Do not cause a desync error.
		1	Induce a desync error by forcing the incoming $\overline{\text{SPIENA}}$ pin (if functional) to remain 0 even after the transfer is complete. This forcing will be retained until the kernel reaches the idle state.
18	CTRL PARERR		Controls inducing of the parity errors during I/O loopback test mode.
		0	Do not cause a parity error.
		1	Induce a parity error by inverting the polarity of the parity bit.
17	CTRL TIMEOUT		Controls inducing of the timeout error during I/O loopback test mode.
		0	Do not cause a timeout error.
		1	Induce a timeout error by forcing the incoming $\overline{\text{SPIENA}}$ pin (if functional) to remain 1 when transmission is initiated. The forcing will be retained until the kernel reaches the idle state.
16	CTRL DLENERR		Controls inducing of the data length error during I/O loopback test mode.
		0	Do not cause a data-length error.
		1	Induce a data-length error.
			Master mode: The $\overline{\text{SPIENA}}$ pin (if functional) is forced to 1 when the module starts shifting data.
			Slave mode: The incoming $\overline{\text{SPICS}}$ pin (if functional) is forced to 1 when the module starts shifting data.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IOLPBKSTENA		Module I/O loopback test enable key.
		Ah	Enable I/O loopback test mode.
		All Other Values	Disable I/O loopback test mode.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5-3	ERR SCS PIN		Inject error on chip-select pin number x. The value in this field is decoded as the number of the chip select pin on which to inject an error. During analog loopback, if CTRL SCS PIN ERR bit is set to 1, then the chip select pin selected by this field is forced to the opposite of its value in the CSNR.
		0	Select $\overline{\text{SPICS}}$[0] for injecting error.
		1h	Select $\overline{\text{SPICS}}$[1] for injecting error.
		:	:
		7h	Select $\overline{\text{SPICS}}$[7] for injecting error.
2	CTRL SCS PIN ERR		Enable/disable the injection of an error on the $\overline{\text{SPICS}}$ pins. The individual $\overline{\text{SPICS}}$ pins can be chosen using the ERR SCS PIN field.
		0	Disable the $\overline{\text{SPICS}}$ error-inducing logic.
		1	Enable the $\overline{\text{SPICS}}$ error-inducing logic.
1	LPBK TYPE		Module I/O loopback type (analog/digital). See Figure 13-22 for the different types of loopback modes.
		0	Enable Digital loopback when IOLPBKTSTENA = 1010.
		1	Enable Analog loopback when IOLPBKTSTENA = 1010.
0	RXPENA		Enable analog loopback through the receive pin.
			Note: This bit is valid only when LPBK TYPE = 1, which chooses analog loopback mode.
		0	Analog loopback is through the transmit pin.
		1	Analog loopback is through the receive pin.

13.9.45 SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1[7:0] of EXTENDED_PRESCALE1 and PRESCALE1 of SPIFMT1 register will always reflect the same contents. Similarly, EPRESCALE_FMT0[7:0] and PRESCALE0 of SPIFMT0 reflect the same contents.

Figure 13-74. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) [offset = 138h]

31	27	26	16
Reserved		EPRESCALE_FMT1	
R-0		R/WP-0	

15	11	10	0
Reserved		EPRESCALE_FMT0	
R-0		R/WP-0	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 13-52. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	EPRESCALE_FMT1	0-7FFh	EPRESCALE_FMT1. Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 determines the bit transfer rate of data format 1 if the SPI/MibSPI is the network master. EPRESCALE_FMT1 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT1 **does not need** to be configured. These EPRESCALE_FMT1[7:0] bits and PRESCALE1 bits of SPIFMT1 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as: $BR_{Format1}$ = VCLK / (EPRESCALE_FMT1 + 1) Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE1 bits of SPIFMT1 register. Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE1[26:16] or SPIFMT1[15:8] register. **Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE1 field of SPIFMT1 will automatically clear EPRESCALE_FMT1[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.**
15-11	Reserved	0	Reads return 0. Writes have no effect.

Table 13-52. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1) Field Descriptions (continued)

Bit	Field	Value	Description
10-0	EPRESCALE_FMT0	0-7FFh	EPRESCALE_FMT0. Extended Prescale value for SPIFMT0. EPRESCALE_FMT0 determines the bit transfer rate of data format 0 if the SPI/MibSPI is the network master. EPRESCALE_FMT0 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT0 **does not need** to be configured. These EPRESCALE_FMT0[7:0] bits and PRESCALE0 bits of SPIFMT0 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as: $BR_{Format0}$ = VCLK / (EPRESCALE_FMT0 + 1) Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE0 bits of SPIFMT0 register. Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE0[10:0] or SPIFMT0[15:8] register. **Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT0 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE0 field of SPIFMT0 will automatically clear EPRESCALE_FMT0[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.**

13.9.46 SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE_FMT3[7:0] of EXTENDED_PRESCALE2 and PRESCALE3 of SPIFMT3 register will always reflect the same contents. Similarly, EPRESCALE_FMT2[7:0] and PRESCALE2 of SPIFMT2 reflect the same contents.

Figure 13-75. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3) [offset = 13Ch]

Table 13-53. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26-16	EPRESCALE_FMT3	0-7FFh	EPRESCALE_FMT3. Extended Prescale value for SPIFMT3. EPRESCALE_FMT3 determines the bit transfer rate of data format 3 if the SPI/MibSPI is the network master. EPRESCALE_FMT3 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT3 **does not need** to be configured. These EPRESCALE_FMT3[7:0] bits and PRESCALE3 bits of SPIFMT3 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as: $BR_{Format3}$ = VCLK / (EPRESCALE_FMT3 + 1) Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE3 bits of SPIFMT3 register. Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE3[26:16] or SPIFMT3[15:8] register. **Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT3 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE3 field of SPIFMT3 will automatically clear EPRESCALE_FMT3[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.**
15-11	Reserved	0	Reads return 0. Writes have no effect.

Table 13-53. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2) Field Descriptions (continued)

Bit	Field	Value	Description
10-0	EPRESCALE_FMT2	0-7FFh	EPRESCALE_FMT2. Extended Prescale value for SPIFMT2. EPRESCALE_FMT2 determines the bit transfer rate of data format 2 if the SPI/MibSPI is the network master. EPRESCALE_FMT2 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT2 **does not need** to be configured. These EPRESCALE_FMT2[7:0] bits and PRESCALE2 bits of SPIFMT2 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as: $BR_{Format2}$ = VCLK / (EPRESCALE_FMT2 + 1) Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE2 bits of SPIFMT2 register. Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE2[10:0] or SPIFMT2[15:8] register. **Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT2 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE2 field of SPIFMT2 will automatically clear EPRESCALE_FMT2[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.**

13.10 Multi-Buffer RAM

The multi-buffer RAM is used for holding transmit and received data, control and status information. The multi-buffer RAM contains two banks of up to 128 32-bit words for a maximum configuration. One bank (TXRAM) contains entries for transmit data (replicating the SPIDAT1 register). The other bank (RXRAM) contains received data (replicating the SPIBUF register). The buffers can be partitioned into multiple TGs, each containing a programmable number of buffers. Each of the buffers can be subdivided into 16-bit transmit field, 16-bit receive field, 16-bit control field, and 16-bit status field, as displayed in Figure 13-76. A 4-bit parity field per word is also included in each bank of RAM.

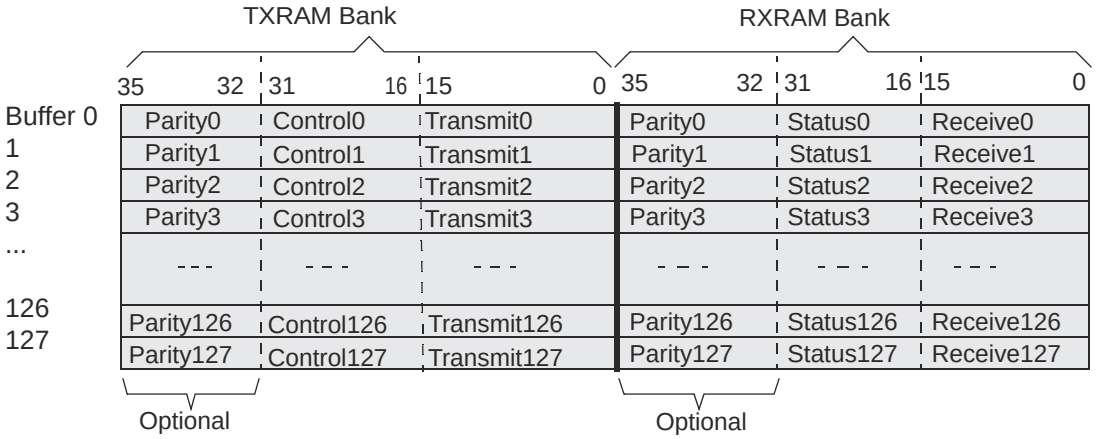

Figure 13-76. Multi-Buffer RAM Configuration

All fields can be read and written with 8-bit, 16-bit, or 32-bit accesses.

The transmit fields can be written and read in the address range 000h to 1FFh. The transmit words contain data and control fields.

The receive RAM fields are read-only and can be accessed through the address range 200h to 3FCh. The receive words contain data and status fields.

The chip select number (CSNR) bit field of the control field for a given word is mirrored into the corresponding receive-buffer status field after transmission.

The Parity is automatically calculated and copied to Parity location

Note

Please refer to the specific device datasheet for the actual number of transmit and receive buffers.

Write to unimplemented buffer is overwriting the corresponding implemented buffer. In MIBSPI, if the RAM SIZE specified is 32 buffers, write to 33rd buffer overwrites 1st buffer, write to 34th buffer overwrites 2st buffer and so on.

13.10.1 Multi-Buffer RAM Auto Initialization

When the MIBSPI is out of reset mode, auto initialization of multi-buffer RAM starts. The application code must check for BUFINITACTIVE bit to be 0 (Multi-buffer RAM initialization is complete) before configuring multi-buffer RAM.

Besides the default auto initialization after reset, the auto-initialization sequence can also be done by:

1. Enable the global hardware memory initialization key by programming a value of 1010b to the bits [3:0] of the MINITGCR register of the System module.
2. Set the control bit for the multi-buffer RAM in the MSINENA System module register. This bit is device-specific for each memory that support auto-initialization. Please refer to the device datasheet to identify the control bit for the multi-buffer RAM. This starts the initialization process. The BUFINITACTIVE bit will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUFINITACTIVE bit will get cleared.
4. Disable the global hardware memory initialization key by programming a value of 0101 to the bits [3:0] of the MINITGCR register of the System module.

Please refer to the *Architecture* chapter for more details on the memory auto-initialization process.

Note

During Auto Initialization process, all the Multi-buffer mode registers (except MIBSPIE) will be reset to their default values. So, it should be ensured that Auto Initialization is completed before configuring the Multi-buffer mode registers.

13.10.2 Multi-Buffer RAM Register Summary

This section describes the multi-buffer RAM control and transmit-data fields of each word of TXRAM, and the status and receive-data fields of each word of RXRAM. The base address for multi-buffer RAM is FF0E 0000h for MibSPI1 RAM, FF0C 000h for MibSPI3 RAM, and FF0A 0000h for MibSPI5 RAM.

Table 13-54. Multi-Buffer RAM Register Summary

Offset	Acronym	Register Description	Section
Base + 0h-1FFh	TXRAM	Multi-Buffer RAM Transmit Data Register	Section 13.10.3
Base + 200h-3FFh	RXRAM	Multi-Buffer RAM Receive Buffer Register	Section 13.10.4

13.10.3 Multi-Buffer RAM Transmit Data Register (TXRAM)

Each word of TXRAM is a transmit-buffer register.

Note

Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

Table 13-55. Multi-Buffer RAM Transmit Data Register (TXRAM) Field Descriptions

Bit	Field	Value	Description
31-29	BUFMODE		Specify conditions that are recognized by the sequencer to initiate transfers of each buffer word. When one of the "skip" modes is selected, the sequencer checks the buffer status every time it reads from this buffer. If the current buffer status (TXFULL, RXEMPTY) does not match, the buffer is skipped without a data transfer. When one of the "suspend" modes is selected, the sequencer checks the buffer status when it reads from this buffer. If TXFULL and/or RXEMPTY do not match, the sequencer waits until a match occurs. No data transfer is initiated until the status condition of this buffer changes.
		0	**disabled.** The buffer is disabled.
		1h	**skip single-transfer mode.** Skip this buffer until the corresponding TXFULL flag is set (new transmit data is available).
		2h	**skip overwrite-protect mode.** Skip this buffer until the corresponding RXEMPTY flag is set (new receive data can be stored in RXDATA without data loss).
		3h	**skip single-transfer overwrite-protect mode**. Skip this buffer until both of the corresponding TXFULL and RXEMPTY flags are set. (new transmit data available and previous data received by the host).
		4h	**continuous mode.** Initiate a transfer each time the sequencer checks this buffer. Data words are retransmitted if the buffer has not been updated. Receive data is overwritten, even if it has not been read.
		5h	**suspend single-transfer mode.** Suspend-to-wait until the corresponding TXFULL flag is set (the sequencer stops at the current buffer until new transmit data is written in the TXDATA field).
		6h	**suspend overwrite-protect mode.** Suspend-to-wait until the corresponding RXEMPTY flag is set (the sequencer stops at the current buffer until the previously-received data is read by the host.
		7h	**suspend single-transfer overwrite-protect mode.** Suspend-to-wait until the corresponding TXFULL and RXEMPTY flags are set (the sequencer stops at the current buffer until new transmit data is written into the TXDATA field and the previously-received data is read by the host).

Table 13-55. Multi-Buffer RAM Transmit Data Register (TXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
28	CSHOLD		Chip select hold mode. The CSHOLD bit is supported in master mode only, it is ignored in slave mode. CSHOLD defines the behavior of the chip select line at the end of a data transfer.
		0	The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.
		1	The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.
27	LOCK		Lock two consecutive buffer words. Do not allow interruption by TGs with higher priority.
		0	Any higher-priority TG can begin at the end of the current transaction.
		1	A higher-priority TG cannot occur until after the next unlocked buffer word is transferred.
26	WDEL		Enable the delay counter at the end of the current transaction.
			Note: The WDEL bit is supported in master mode only. In slave mode, this bit is ignored.
		0	No delay will be inserted. However, $\overline{\text{SPICS}}$ pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.
			Note: The duration for which the $\overline{\text{SPICS}}$ pin remains deactivated also depends upon the time taken to supply a new word after completing the shift operation (in compatibility mode). If TXBUF is already full, then the $\overline{\text{SPICS}}$ pin will be deasserted for at least two VCLK cycles (if WDEL = 0).
		1	After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The $\overline{\text{SPICS}}$ pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.
25-24	DFSEL		Data word format select.
		0	Data word format 0 is selected.
		1h	Data word format 1 is selected.
		2h	Data word format 2 is selected.
		3h	Data word format 3 is selected.
23-16	CSNR	0-FFh	Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See Table 13-56.
			Note: If your MibSPI has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSPI3 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.
15-0	TXDATA	0-7FFFh	Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.
			SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of TXDATA to 0.
			A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the $\overline{\text{SPICS}}$ pins, if the pins are configured as functional pins (automatic chip select, see Section 13.2).
			When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.
			Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.

Table 13-56. Chip Select Number Active

CSNR Value	Chip Select Active:							CSNR Value	Chip Select Active:					
	CS[5](1)	CS[4](1)	CS[3](1)	CS[2](1)	CS[1](1)	CS[0]			CS[5](1)	CS[4](1)	CS[3](1)	CS[2](1)	CS[1](1)	CS[0]

1Eh		x	x	x	x			3Eh	x	x	x	x	x	
1Fh		x	x	x	x	x		3Fh	x	x	x	x	x	x

(1) If your MibSPI does not have this chip select pin, this bit is 0.

13.10.4 Multi-Buffer RAM Receive Buffer Register (RXRAM)

Each word of RXRAM is a receive-buffer register.

Figure 13-78. Multi-Buffer RAM Receive Buffer Register (RXRAM) [offset = RAM Base + 200h-3FFh]

31	30	29	28	27	26	25	24

LEGEND: R/W = Read/Write; R = Read only; C = Clear; S = Set; -*n* = value after reset

Table 13-57. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions

Bit	Field	Value	Description
31	RXEMPTY		Receive data buffer empty. When the host reads the RXDATA field or the entire RXRAM register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA, and the RXEMPTY flag is cleared.
		0	New data has been received and copied into RXDATA.
		1	No data has been received since the last read of RXDATA.
			This flag gets set to 1 under the following conditions: • Reading the RXDATA field of the RXRAM register • Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG) Write-clearing the RXINTFLG bit before reading RXDATA indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of RXRAM (or the entire register).
30	RXOVR		Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to RXRAM; the contents of RXRAM are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor). If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVECTx shows the RXOVRN condition. Two read operations from the RXRAM register are required to reach the overwritten buffer word (one to read RXRAM, which then transfers RXDATA into RXRAM for the second read). **Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.** **Note: A special condition under which RXOVR flag gets set. If both RXRAM and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR, and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.**
		0	No receive data overrun condition occurred since last read of the data field.
		1	A receive data overrun condition occurred since last read of the data field.

Table 13-57. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
29	TXFULL		Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.
		0	The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.
28	BITERR		Bit error. There was a mismatch of internal transmit data and transmitted data.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No bit error occurred.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC		Desynchronization of slave device. This bit is valid in master mode only.
			The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
			Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No slave desynchronization is detected.
		1	A slave device is desynchronized.
26	PARITYERR		Parity error. The calculated parity differs from the received parity bit.
			If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No parity error is detected.
		1	A parity error occurred.
25	TIMEOUT		Time-out because of non-activation of $\overline{\text{SPIENA}}$ pin.
			The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.
			Note: This bit is valid only in master mode.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No $\overline{\text{SPIENA}}$ pin time-out occurred.
		1	An $\overline{\text{SPIENA}}$ signal time-out occurred.
24	DLENERR		Data length error flag.
			Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.
		0	No data-length error occurred.
		1	A data length error occurred.
23-16	LCSNR	0-FFh	Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.

Table 13-57. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions (continued)

Bit	Field	Value	Description
15-0	RXDATA	0-FFFFh	SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

13.11 Parity Memory

The parity portion of multi-buffer RAM is not accessible by the CPU during normal operating modes. However, each read or write operation to the control/data/status portion of the multi-buffer RAM causes reads/writes to the parity portion as well.

- Each write to the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a write operation to the parity portion of RAM simultaneously to update the equivalent parity bits.
- Each read operation from the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a read operation from the parity portion of the RAM for parity comparison purpose.
- Reads/Writes to multi-buffer RAM can either be caused by any CPU/DMA accesses or by the sequencer logic of MibSPI itself.
- Incase of Parity error ESM module is notified to generate MIBSPI Parity ESM interrupt. User can check the error status and address location captured in the UERRSTAT and UERRADDRx registers respectively.

For testing the parity portion of the multi-buffer RAM, which is a 4-bit field per word address (1 bit per byte), a separate parity memory test mode is available. Parity memory test mode can be enabled and disabled by the PTESTEN bit in the UERRCTRL register.

During the parity test mode, the parity locations are addressable at the address between RAM_BASE_ADDR + 0x400h and RAM_BASE_ADDR + 0x7FFh. Each location corresponds, sequentially, to each TXRAM word, then to each RXRAM word. See Figure 13-79 for a diagram of the memory map of parity memory during normal operating mode and during parity test mode.

During parity test mode, after writing the data/control portion of the RAM, the parity locations can be written with incorrect parity bits to intentionally cause parity errors.

See the device-specific data sheet to get the actual base address of the multi-buffer RAM.

Note

The RX_RAM_ACCESS bit can also be set to 1 during the parity test mode to be enable writes to RXRAM locations. Both parity RAM testing and RXRAM testing can be done together.

There are 4 bits of parity corresponding to each of the 32-bit multi-buffer locations. Individual bits in the parity memory are byte-addressable in parity test mode. See the example in Figure 13-80 for further details.

Note

Polarity of the parity (odd/even) varies by device. In some devices, a control register in the system module can be used to select odd or even parity.

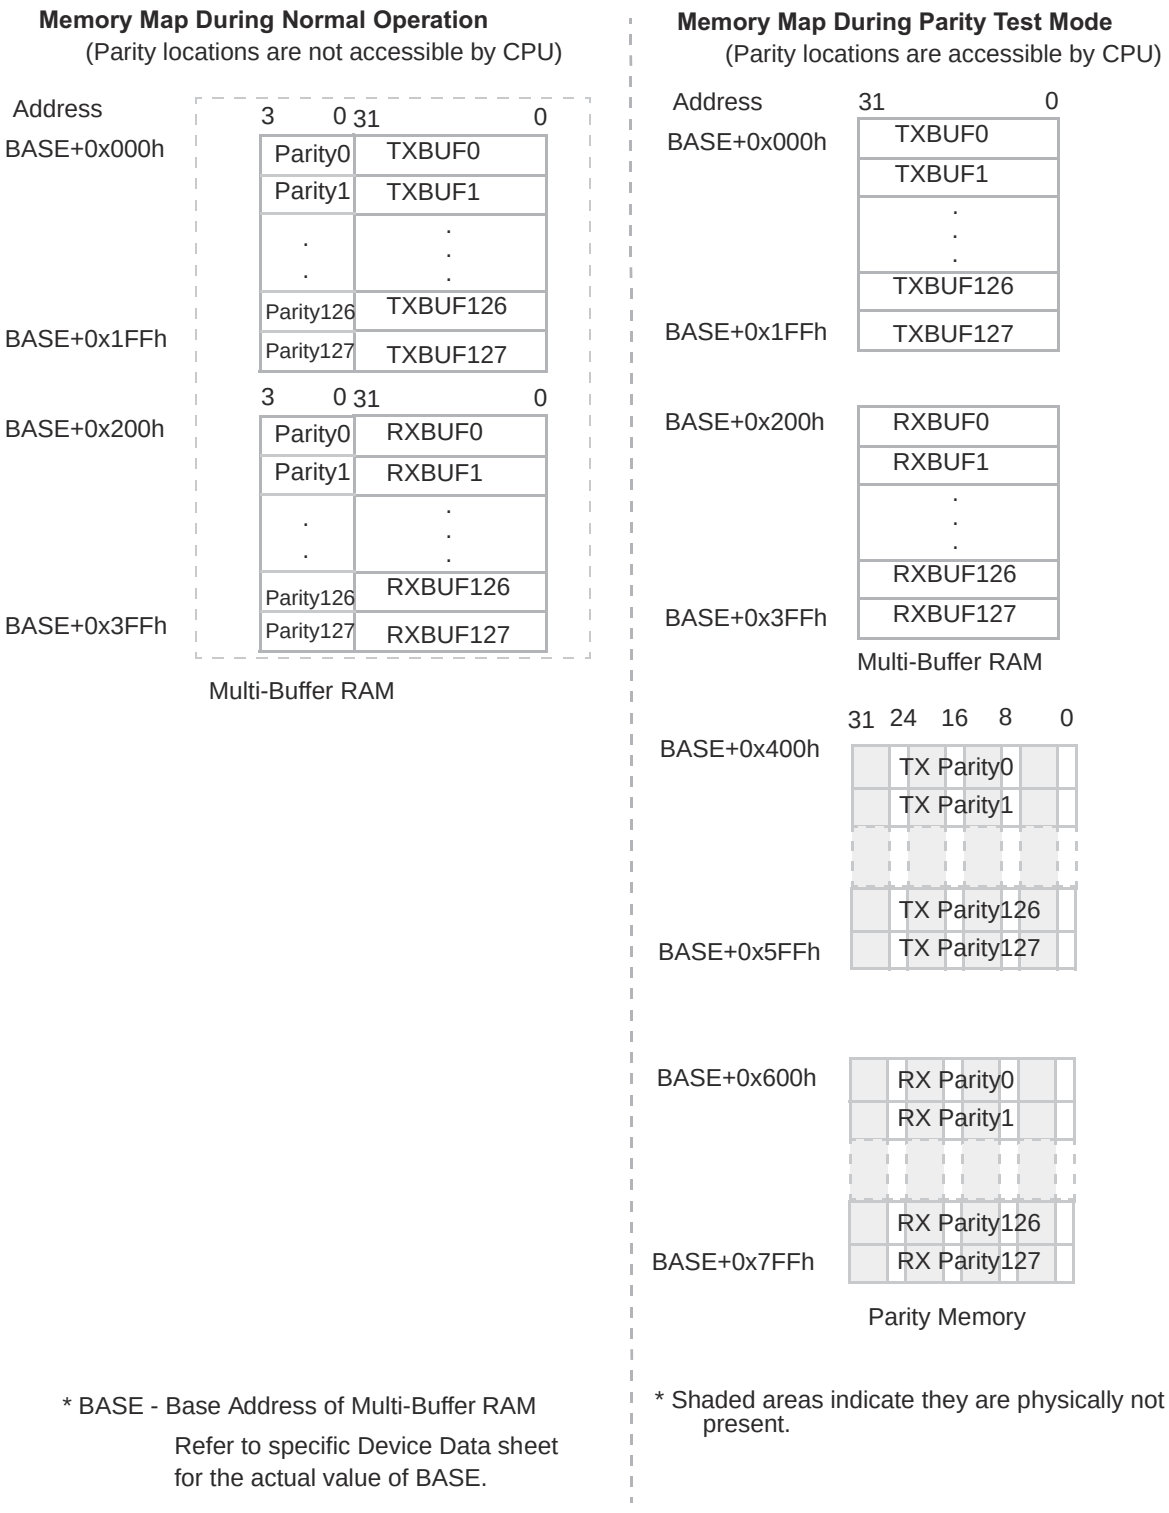

Figure 13-79. Memory Map for Parity Locations During Normal and Test Mode

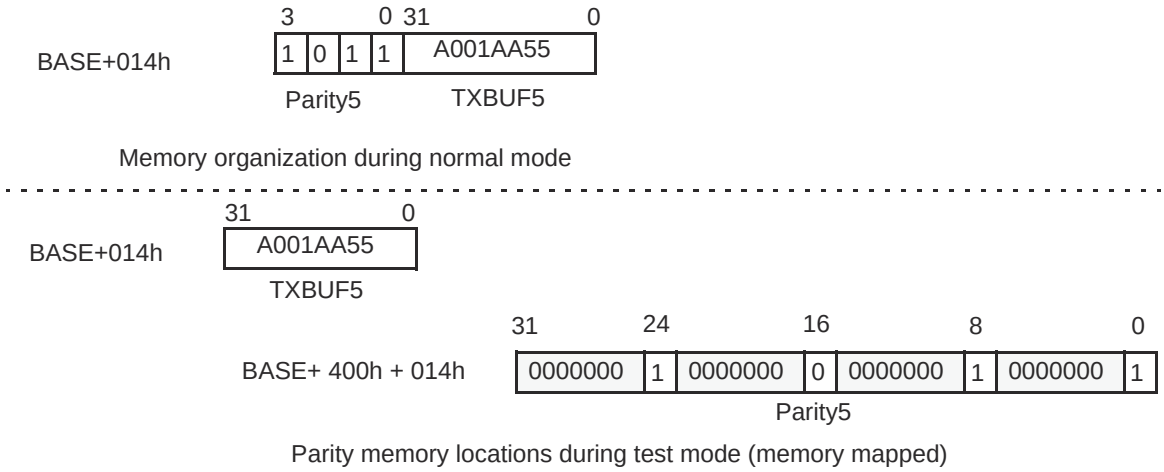
13.11.1 Example of Parity Memory Organization

Suppose TXBUF5 (6th location in TXRAM) in the multi-buffer RAM is written with a value of A001_AA55. If the polarity of the parity is set to odd, the corresponding parity location parity5 will get updated with equivalent parity of 1011 in its field.

During parity-memory test mode, these bits can be individually byte addressed. The return data will be a byte adjusted with actual parity bit in the LSB of the byte. If a word is read from the word-boundary address of parity locations, then each bit of the 4-bit parity is byte-adjusted and a 32-bit word is returned. 0s will be padded into the parity bits to get each byte. See Figure 13-80 for a diagram.



Parity memory locations during test mode (memory mapped)

1 Shaded areas indicate reads return 0, writes have no effect. These registers are not physically present.

Figure 13-80. Example of Memory-Mapped Parity Locations During Test Mode

Note

Read Access to Parity Memory Locations

Parity memory locations can be read even without entering into parity memory test mode. Their address remains as in memory test mode. It is only to enter parity-memory test mode to enable write access to the parity memory locations.

13.12 MibSPI Pin Timing Parameters

The pin timings of SPI can be classified based on its mode of operation. In each mode, different configurations like Phase and Polarity affect the pin timings.

The pin directions are based on the mode of operation.

Master mode SPI:

- SPICLK (SPI Clock) - Output
- SPISIMO (SPI Slave In Master Out) - Output
- $\overline{\text{SPICS}}$ (SPI Slave Chip Selects) - Output
- SPISOMI (SPI Slave Out Master In) - Input
- $\overline{\text{SPIENA}}$ (SPI slave ready Enable) - Input

Slave mode SPI:

- SPICLK - Input
- SPISIMO - Input
- $\overline{\text{SPICS}}$ - Input
- SPISOMI - Output
- $\overline{\text{SPIENA}}$ - Output

Note

All the timing diagrams given below are with Phase = 0 and Polarity = 0. unless explicitly stated otherwise.

13.12.3 Master Mode Timing Parameter Details

In case of Master, the module drives out SPICLK. It also drives out the Transmit data on SPISIMO with respect to its internal SPICLK. In case of Master mode, the RX data on the SPISOMI pin is registered with respect to SPICLK received through the input buffer from the I/O pad.

If the chip select pin is functional, then the Master will drive out the $\overline{\text{SPICS}}$ pins before starting the SPICLK. If the $\overline{\text{SPIENA}}$ pin is functional, then the Master will wait for an active low from the Slave on the input pin to start the SPICLK.

13.12.4 Slave Mode Timing Parameter Details

In case of Slave mode, the module will drive only the SPISOMI and $\overline{\text{SPIENA}}$ pins. All other pins are inputs to it. The RX data on the SPISIMO pin will be registered with respect to the SPICLK pin. The Slave will use the $\overline{\text{SPICS}}$ pin to drive out the $\overline{\text{SPIENA}}$ pin if both are functional. If 4-pin with $\overline{\text{SPIENA}}$ is configured, then the Slave will drive out an active-low signal on the $\overline{\text{SPIENA}}$ pin when new data is written to the TX Shift Register. Irrespective of 4-pin with $\overline{\text{SPIENA}}$ or 5-pin configuration, the Slave will deassert the $\overline{\text{SPIENA}}$ pin after the last bit is received. If ENABLE_HIGHZ (SPIINT0.24) bit is 0, the de-asserted value of the $\overline{\text{SPIENA}}$ pin will be 1. Otherwise, it will depend upon the internal pull up or pull down resistor (if implemented) depending upon the Specification of the Chip.

Chapter 14

Vectored Interrupt Manager (VIM) Module

This chapter describes the behavior of the vectored interrupt manager (VIM) module of the device family.

14.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU(s). It can be used in either split or lockstep configuration. In split, it has two independent interrupt cores, one per CPU. In lockstep, CPU1 acts as a diagnostic on CPU0; only CPU0's outputs are used but all outputs are compared to CPU1 to provide diagnostic coverage.

The VIM module supports the following features:

- 256 interrupt inputs per R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the INTPRIORITY_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the INTR_EN_SET_j register
  - Interrupt disable is done via the INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the INTVECTOR_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected
- Split or lockstep capable
  - In lockstep mode, only interrupts connected to VIM interrupt core 0 are available
- Software interrupt generation

14.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the two R5F cores can be found in Chapter , *Interrupts*.

14.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the INTMAP_j register) and is enabled (via the INTR_EN_SET_j register), then it will cause an IRQ to assert
- *CoreN_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

14.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (INTVECTOR_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 14-1 shows the VIM RAM interrupt vector map.

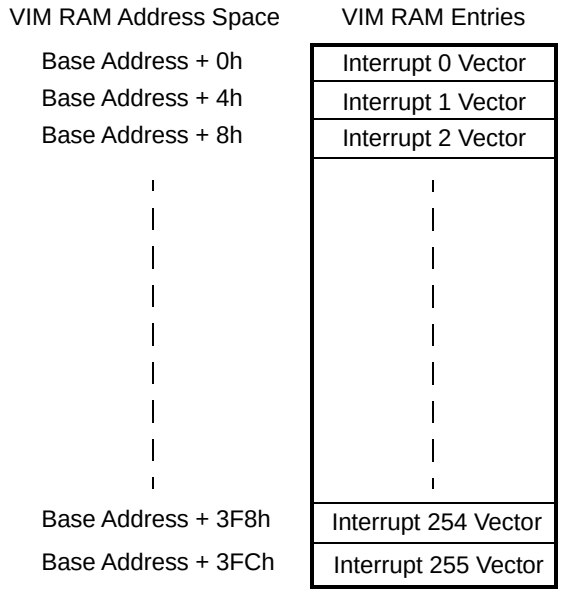

Figure 14-1. VIM RAM Interrupt Vector Map

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. Refer to the ECC aggregator map for the VIM RAM ID.

14.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the FIQVEC register; IRQ: reading the IRQVEC register, then the interrupt is loaded into the corresponding active register (ACTFIQ / ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to theFIQVEC register, or IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the FIQVEC / IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the FIQVEC / IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the ACTFIQ / ACTIRQ register, so that software may continue where it left off.

14.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the IRQVEC register, and the FIQVEC register. The DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device

4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt . This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the ECC aggregator.

14.7 VIM Lockstep Mode

In lockstep mode, CPU1 is used as a diagnostic for CPU0. In this mode, only the interrupt inputs for CPU0 are used. Besides to CPU0, these interrupt inputs are also internally routed to CPU1 (through the level-sync / edge-detect logic dedicated to CPU1, and additionally through some delay circuits). The outputs from both VIM interrupt cores are then sent to the MSS CCMR5 module through dedicated compare buses (with CPU0's outputs delayed). The CCMR5 module is responsible for comparing the two sets of output signals and for reporting any mismatches by generating an interrupt (MSS_CCMR5_ERR).

Note

In lockstep mode, only the RAM dedicated to CPU0 is used, so software *must not* do anything with the ECC interface on the RAM dedicated to CPU1.

14.8 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

14.9 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in Section 6.1.4.9.1, but the procedures in Section 6.1.4.9.2 or Section 6.1.4.9.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in Section 6.1.4.9.4, but the procedure in Section 6.1.4.9.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

14.9.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
   a. CPU asserts *coreN_IRQACK* high
   b. VIM asserts *coreN_IRQADDRV* to indicate that the *coreN_IRQADDR* bus is stable with the correct vector address
   c. CPU reads *coreN_IRQADDR*, jumps to that address, and de-asserts *coreN_IRQACK* low
   d. VIM de-asserts *coreN_IRQn* and *coreN_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority

e. VIM loads the value from the PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the ACTIRQ[9:0] NUM bit field, which causes the ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the IRQSTS_j register, or STS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the IRQSTS_j register, or STS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the ACTIRQ[31] VALID bit

14.9.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the IRQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
   b. Reading this register will cause the value from the PRIIRQ[9:0] NUM bit field to be loaded into the ACTIRQ[9:0] NUM bit field, and the ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register
      ii. Clear the interrupt at the source
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register
4. Write any value to the IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the ACTIRQ[31] VALID bit

14.9.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
   b. Optionally read the IRQGSTS register to determine which groups have IRQs pending, then read the IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse

i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register
ii. Clear the interrupt at the source.

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register

14.9.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the FIQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the PRIFIQ[9:0] NUM bit field to be loaded into the ACTFIQ[9:0] NUM bit field, and the ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the FIQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the ACTFIQ[31] VALID bit

14.9.5 Servicing FIQ (Alternative)

If a user does not want to use the FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the PRIFIQ register to determine which interrupt is the highest priority FIQ currently asserted, OR
   b. Optionally read the FIQGSTS register to determine which groups have IRQs pending, then read the FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register.

14.10 MSS_VIM Registers

Table 14-2 lists the memory-mapped registers for the MSS_VIM registers. All register offset addresses not listed in Table 14-2 should be considered as reserved locations and the register contents should not be modified.

14.10.1 PID Register (Offset = 0h) [Reset = 60900001h]

PID is shown in Figure 14-2 and described in Table 14-3.

Return to the Table 14-2.

The Revision Register contains the major and minor revisions for the module.

Figure 14-2. PID Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SCHEME		BU		FUNC											
R-1h		R-2h		R-90h											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTL					MAJOR			CUSTOM		MINOR					
R-0h					R-0h			R-0h		R-1h					

Table 14-3. PID Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	PID register scheme
29-28	BU	R	2h	Business Unit: 10 = Processors
27-16	FUNC	R	90h	Module ID
15-11	RTL	R	0h	RTL revision. Will vary depending on release.
10-8	MAJOR	R	0h	Major revision
7-6	CUSTOM	R	0h	Custom
5-0	MINOR	R	1h	Minor revision

14.10.2 INFO Register (Offset = 4h) [Reset = 100h]

INFO is shown in Figure 14-3 and described in Table 14-4.

Return to the Table 14-2.

The Info Register gives the configuration Inforrmation of this VIM.

Figure 14-3. INFO Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES1																					INTERRUPTS										
R-0h																					R-100h										

Table 14-4. INFO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RES1	R	0h	RESERVE FIELD

Table 14-4. INFO Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10-0	INTERRUPTS	R	100h	Total number of Interrupts

14.10.3 PRIIRQ Register (Offset = 8h) [Reset = 0h]

PRIIRQ is shown in Figure 14-4 and described in Table 14-5.

Return to the Table 14-2.

The Prioritized IRQ Register shows the number of the highest priority pending IRQ.

Figure 14-4. PRIIRQ Register

31	30	29	28	27	26	25	24
VALID	RES2						
R-0h	R-0h						
23	22	21	20	19	18	17	16
RES2				PRI			
R-0h				R-0h			
15	14	13	12	11	10	9	8
RES3						NUM	
R-0h						R-0h	
7	6	5	4	3	2	1	0
NUM							
R-0h							

Table 14-5. PRIIRQ Register Field Descriptions

Bit	Field	Type	Reset	Description
31	VALID	R	0h	Indicates that the num field is valid.
30-20	RES2	R	0h	RESERVE FIELD
19-16	PRI	R	0h	Priority of the highest priority pending IRQ. valid only if the valid flag is set.
15-10	RES3	R	0h	RESERVE FIELD
9-0	NUM	R	0h	Number of the highest priority pending IRQ. valid only if the valid flag is set.

14.10.4 PRIFIQ Register (Offset = Ch) [Reset = 0h]

PRIFIQ is shown in Figure 14-5 and described in Table 14-6.

Return to the Table 14-2.

The Prioritized FIQ Register shows the number of the highest priority pending FIQ.

Figure 14-5. PRIFIQ Register

31	30	29	28	27	26	25	24
VALID	RES4						
R-0h	R-0h						
23	22	21	20	19	18	17	16
RES4				PRI			
R-0h				R-0h			

Figure 14-5. PRIFIQ Register (continued)

15	14	13	12	11	10	9	8
RES5						NUM	
R-0h						R-0h	
7	6	5	4	3	2	1	0
NUM							
R-0h							

Table 14-6. PRIFIQ Register Field Descriptions

Bit	Field	Type	Reset	Description
31	VALID	R	0h	Indicates that the num field is valid.
30-20	RES4	R	0h	RESERVE FIELD
19-16	PRI	R	0h	Priority of the highest priority pending FIQ. valid only if the valid flag is set.
15-10	RES5	R	0h	RESERVE FIELD
9-0	NUM	R	0h	Number of the highest priority pending FIQ. valid only if the valid flag is set.

14.10.5 IRQGSTS Register (Offset = 10h) [Reset = 0h]

IRQGSTS is shown in Figure 14-6 and described in Table 14-7.

Return to the Table 14-2.

The IRQ Group Status Register indicates which groups have pending IRQ interrupts.

Figure 14-6. IRQGSTS Register

Table 14-334. INTVECTOR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.333 INTVECTOR_1 Register (Offset = 2004h) [Reset = 0h]

INTVECTOR_1 is shown in Figure 14-334 and described in Table 14-335.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.334 INTVECTOR_2 Register (Offset = 2008h) [Reset = 0h]

INTVECTOR_2 is shown in Figure 14-335 and described in Table 14-336.

Return to the Table 14-2.

Table 14-364. INTVECTOR_30 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.363 INTVECTOR_31 Register (Offset = 207Ch) [Reset = 0h]

INTVECTOR_31 is shown in Figure 14-364 and described in Table 14-365.

Return to the Table 14-2.

Table 14-378. INTVECTOR_44 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.377 INTVECTOR_45 Register (Offset = 20B4h) [Reset = 0h]

INTVECTOR_45 is shown in Figure 14-378 and described in Table 14-379.

Return to the Table 14-2.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 14-392. INTVECTOR_58 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Table 14-421. INTVECTOR_87 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.420 INTVECTOR_88 Register (Offset = 2160h) [Reset = 0h]

INTVECTOR_88 is shown in Figure 14-421 and described in Table 14-422.

Return to the Table 14-2.

Table 14-435. INTVECTOR_101 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.434 INTVECTOR_102 Register (Offset = 2198h) [Reset = 0h]

INTVECTOR_102 is shown in Figure 14-435 and described in Table 14-436.

Return to the Table 14-2.

Table 14-449. INTVECTOR_115 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.448 INTVECTOR_116 Register (Offset = 21D0h) [Reset = 0h]

INTVECTOR_116 is shown in Figure 14-449 and described in Table 14-450.

Return to the Table 14-2.

Table 14-463. INTVECTOR_129 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.462 INTVECTOR_130 Register (Offset = 2208h) [Reset = 0h]

INTVECTOR_130 is shown in Figure 14-463 and described in Table 14-464.

Return to the Table 14-2.

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 14-477. INTVECTOR_143 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.476 INTVECTOR_144 Register (Offset = 2240h) [Reset = 0h]

INTVECTOR_144 is shown in Figure 14-477 and described in Table 14-478.

Return to the Table 14-2.

31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.490 INTVECTOR_158 Register (Offset = 2278h) [Reset = 0h]

INTVECTOR_158 is shown in Figure 14-491 and described in Table 14-492.

Return to the Table 14-2.

It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.504 INTVECTOR_172 Register (Offset = 22B0h) [Reset = 0h]

INTVECTOR_172 is shown in Figure 14-505 and described in Table 14-506.

Return to the Table 14-2.

Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.518 INTVECTOR_186 Register (Offset = 22E8h) [Reset = 0h]

INTVECTOR_186 is shown in Figure 14-519 and described in Table 14-520.

Return to the Table 14-2.

Table 14-548. INTVECTOR_214 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.547 INTVECTOR_215 Register (Offset = 235Ch) [Reset = 0h]

INTVECTOR_215 is shown in Figure 14-548 and described in Table 14-549.

Return to the Table 14-2.

Table 14-562. INTVECTOR_228 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 14-562. INTVECTOR_228 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.561 INTVECTOR_229 Register (Offset = 2394h) [Reset = 0h]

INTVECTOR_229 is shown in Figure 14-562 and described in Table 14-563.

Return to the Table 14-2.

Table 14-576. INTVECTOR_242 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

14.10.575 INTVECTOR_243 Register (Offset = 23CCh) [Reset = 0h]

INTVECTOR_243 is shown in Figure 14-576 and described in Table 14-577.

Return to the Table 14-2.

Chapter 15

Real-Time Interrupt (RTI) and Watchdog Module

This chapter describes the functionality of the real-time interrupt (RTI) module. The RTI is designed as an operating system timer to support a real time operating system (RTOS).

Note

This chapter describes a superset implementation of the RTI module that includes features and functionality related to DMA and Timebase control. These features are dependent on the device-specific feature content. Consult your device-specific datasheet to determine the applicability of these features to your device being used.

15.1 Overview

The real-time interrupt (RTI) module provides timer functionality for operating systems and for benchmarking code. The RTI module can incorporate several counters that define the timebases needed for scheduling in the operating system.

The timers also allow you to benchmark certain areas of code by reading the values of the counters at the beginning and the end of the desired code range and calculating the difference between the values.

15.1.1 Features

The RTI module has the following features:

- Two independent 64 bit counter blocks
- Four configurable compares for generating operating system ticks or DMA requests. Each event can be driven by either counter block 0 or counter block 1.
- Fast enabling/disabling of events
- Two time stamp (capture) functions for system or peripheral interrupts, one for each counter block
- Digital windowed watchdog

15.1.2 Industry Standard Compliance Statement

This module is specifically designed to fulfill the requirements for OSEK (**O**ffene **S**ysteme und deren **S**chnittstellen für die **E**lektronik im **K**raftfahrzeug, or Open Systems and the Corresponding Interfaces for Automotive Electronics) as well as OSEK/time-compliant operating systems, but is not limited to it.

15.2 Module Operation

Figure 15-1 illustrates the high level block diagram of the RTI module.

The RTI module has two independent counter blocks for generating different timebases: counter block 0 and counter block 1. The two counter blocks provide the same basic functionality.

A compare unit compares the counters with programmable values and generates four independent interrupt or DMA requests on compare matches. Each of the compare registers can be programmed to be compared to either counter block 0 or counter block 1.

The following sections describe the individual functions in more detail.

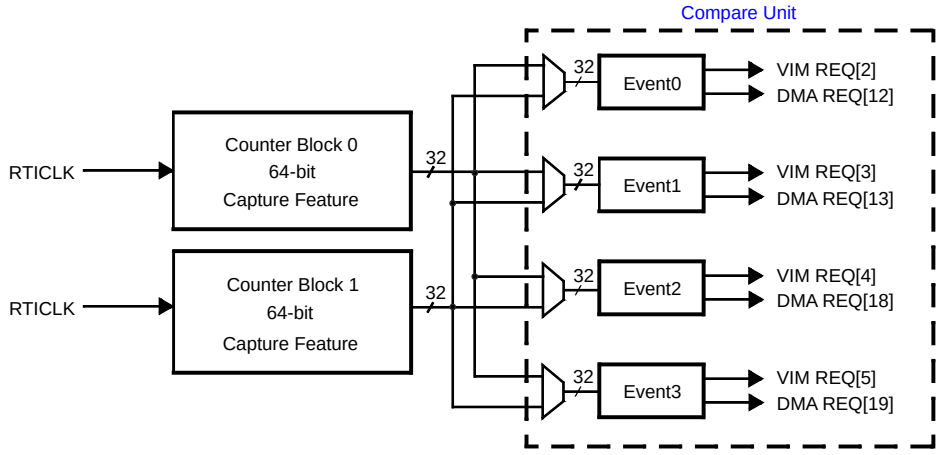

Figure 15-1. RTI Block Diagram

15.2.1 Counter Operation

Each counter block consists of the following (see Figure 15-2):

- One 32-bit prescale counter (RTIUC0 or RTIUC1)
- One 32-bit free running counter (RTIFRC0 or RTIFRC1)

The RTIUC0/1 is driven by the RTICLK and counts up until the compare value in the compare up counter register (RTICPUC0 or RTICPUC1) is reached. When the compare matches, RTIFRC0/1 is incremented and RTIUC0/1 is reset to 0. If RTIFRC0/1 overflows, an interrupt is generated to the vectored interrupt manager (VIM). The overflow interrupt is not intended to generate the timebase for the operating system. See Section 15.2.2 for the timebase generation. The up counter together with the compare up counter value prescale the RTI clock. The resulting formula for the frequency of the free running counter (RTIFRC0/1) is:

$$f_{RTIFRCx} = \begin{cases} \dfrac{f_{RTICLK}}{RTICPUCx + 1} & \text{when RTICPUCx} \neq 0 \\ \dfrac{f_{RTICLK}}{2^{32}+1} & \text{when RTICPUCx} = 0 \end{cases} \quad (1)$$

Note

Setting RTICPUCx equal to zero is not recommended. Doing so will hold the Up Counter at zero for two RTICLK cycles after it overflows from 0xFFFFFFFF to zero.

The counter values can be determined by reading the respective counter registers or by generating a hardware event which captures the counter value into the respective capture register. Both functions are described in the following sections.

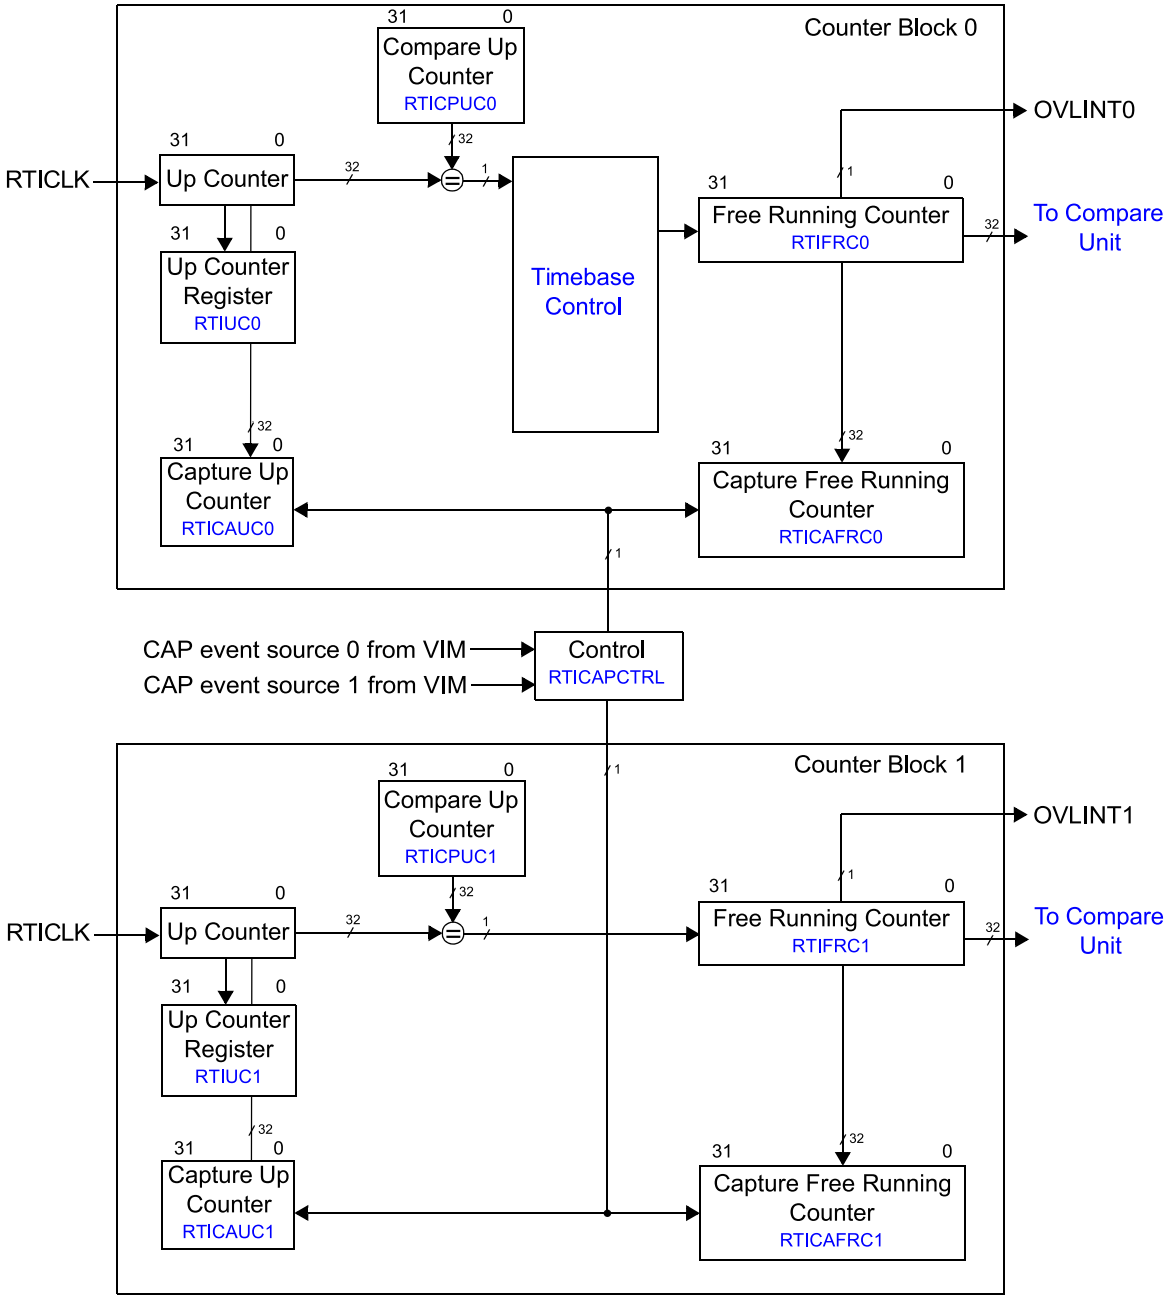

Figure 15-2. Counter Block Diagram

15.2.1.1 Counter and Capture Read Consistency

Portions of the device internal databus are 32-bits wide. If the application wants to read the 64-bit counters or the 64-bit capture values, a certain order of 32-bit read operations needs to be followed. This is to prevent one counter incrementing in between the two separate read operations to both counters.

Reading the Counters

The free running counter (RTIFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTIFRCx, the up counter value is stored in its counter register (RTIUCx). The second read has to access the up counter register (RTIUCx), which then holds the value which corresponds to the number of RTICLK cycles that have elapsed at the time reading the free running counter register (RTIFRCx).

Note

The up counters are implemented as shadow registers. Reading RTIUCx without having read RTIFRCx first will return always the same value. RTIUCx will only be updated when RTIFRCx is read.

Reading the Capture Values

The free running counter capture register (RTICAFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTICAFRCx, the up counter value is stored in its counter register (RTICAUCx). The second read has to access the up counter register (RTICAUCx), which then holds the value captured at the time when reading the capture free running counter register (RTICAFRCx).

Note

The capture up counter registers are implemented as shadow registers. Reading RTICAUCx without having read RTICAFRCx first will return always the same value. RTICAUCx will only be updated when RTICAFRCx is read.

15.2.1.2 Capture Feature

Both counter blocks also provide a capture feature on external events. Two capture sources can trigger the capture event. The source triggering the block is configurable (RTICAPCTRL). The sources originate from the Vectored Interrupt Manager (VIM) and allow the generation of capture events when a peripheral modules has generated an interrupt. Any of the peripheral interrupts can be selected as the capture event in the VIM.

When an event is detected, RTIUCx and RTIFRCx are stored in the capture up counter (RTICAUCx) and capture free running counter (RTICAFRCx) registers. The read order of the captured values must be the same as the read order of the actual counters (see Section 15.2.1.1).

15.2.2 Interrupt/DMA Requests

There are four compare registers (RTICOMPy) to generate interrupt requests to the VIM or DMA requests to the DMA controller. The interrupts can be used to generate different timebases for the operating system. Each of the compare registers can be configured to be compared to either RTIFRC0 or RTIFRC1. When the counter value matches the compare value, an interrupt is generated. To allow periodic interrupts, a certain value can be added to the compare value in RTICOMPy automatically. This value is stored in the update compare register (RTIUDCPy) and will be added after a compare is matched. The period of the generated interrupt/DMA request can be calculated with:

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times RTIUDCPy$$

if RTICPUCy ≠ 0,

$$t_{COMPx} = t_{RTICLK} \times (2^{32}+1) \times RTIUDCPy$$

if RTIUDCPy = 0,

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times 2^{32} \quad (2)$$

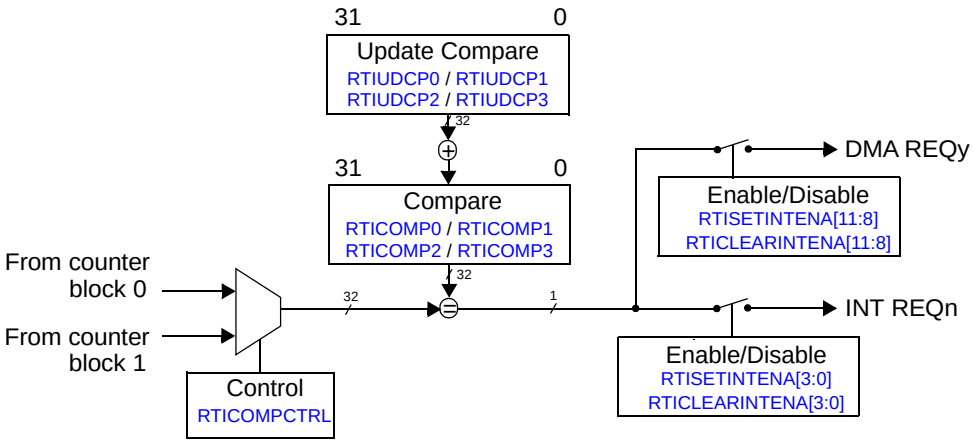

Figure 15-3. Compare Unit Block Diagram (shows only 1 of 4 blocks for simplification)

Another interrupt that can be generated is the overflow interrupt (OVLINTx) in case the RTIFRCx counter overflows.

The interrupts/DMA requests can be enabled in the RTISETINTENA register and disabled in the RTICLEARINTENA register. The RTIINTFLAG register shows the pending interrupts.

15.2.3 RTI Clocking

The counter blocks are clocked with RTICLK.

A clock supervision for the NTUx clocking scheme is implemented to avoid missing operating system ticks.

15.2.4 Digital Watchdog (DWD)

The digital watchdog (DWD) is an optional safety diagnostic which can detect a runaway CPU and generate either a reset or NMI (non-maskable interrupt) response. It generates resets or NMIs after a programmable period, or if no correct key sequence was written to the RTIWDKEY register. Figure 15-4 illustrates the DWD.

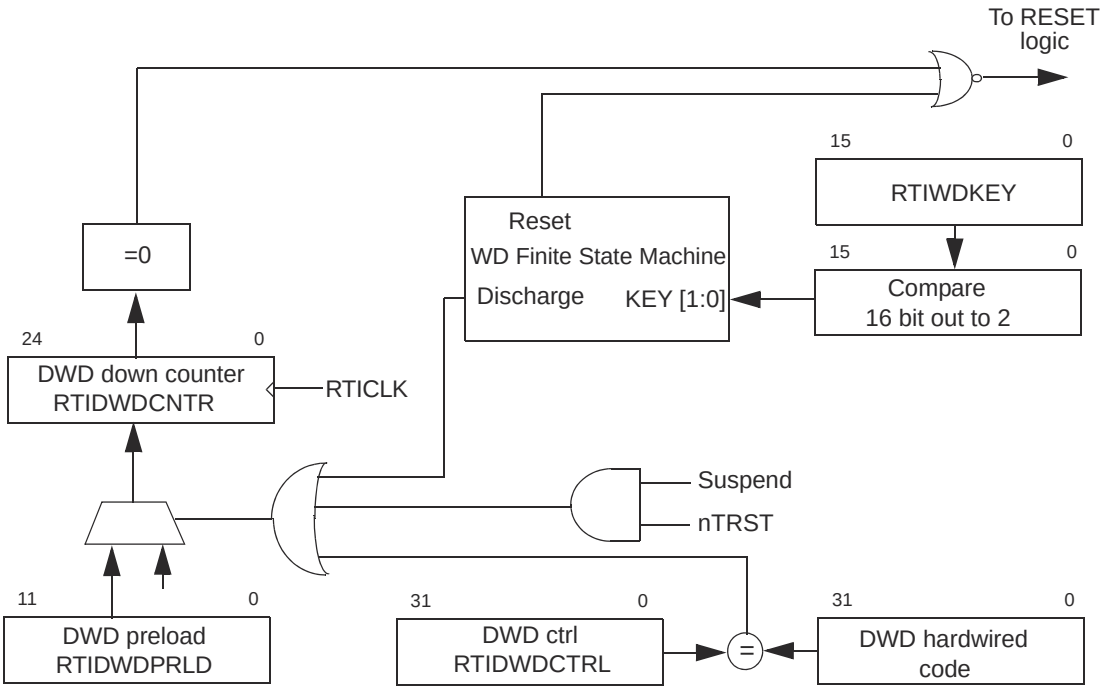

Figure 15-4. Digital Watchdog

15.2.4.1 Digital Watchdog (DWD)

The DWD is disabled by default. If it should be used, it must be enabled by writing a 32-bit value to the RTIDWDCTRL register.

Note

Once the DWD is enabled, it cannot be disabled except by system reset or power on reset.

If the correct key sequence is written to the RTIWDKEY register (0xE51A followed by 0xA35C), the 25-bit DWD down counter is reloaded with the left justified 12-bit preload value stored in RTIDWDPRLD. If an incorrect value is written, a watchdog reset or NMI will occur immediately. A reset or NMI will also be generated when the DWD down counter is decremented to 0.

While the device is in suspend mode (halting debug mode), the DWD down counter keeps the value it had when entering suspend mode.

The DWD down counter will be decremented with the RTICLK frequency.

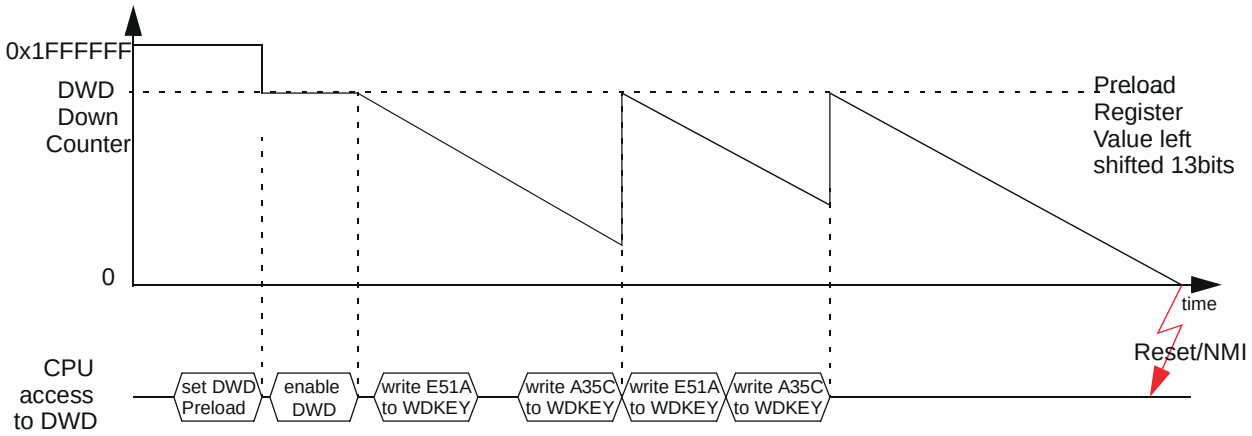

Figure 15-5. DWD Operation

The expiration time of the DWD down counter can be determined with the following equation:

$texp = (DWDPRLD + 1) \times 2^{13}/RTICLK$

where

DWDPRLD = 0...4095

Note

Care should be taken to ensure that the CPU write to the watchdog register is made allowing time for the write to propagate to the RTI.

15.2.4.2 Digital Windowed Watchdog (DWWD)

In addition to the time-out boundary configurable via the digital watchdog discussed in Section 15.2.4.1, for enhanced safety metrics it is desirable to check for a watchdog "pet" within a time window rather than using a single time threshold. This is enabled by the digital windowed watchdog (DWWD) feature.

- Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a NMI to the CPU. This is controlled by configuring the

RTIWWDRXNCTRL register. As with the DWD, the DWWD is disabled after power on reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The NMI handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the NMI handler does not service the watchdog in time, it could count down all the way to zero and wrap around. If the NMI Handler does not service the watchdog in time, the NMI gets generated continuously, each time the counter counts to '0'.

The DWWD uses the Digital Watchdog (DWD) preload register (RTIDWDPRLD) setting to define the end-time of the window. The start-time of the window is defined by a window size configuration register(RTIWWDSIZECTRL).

The default window size is set to 100%, which corresponds to the DWD functionality of a time-out-only watchdog. The window size can be selected (through register RTIWWDSIZECTRL) from among 100%, 50%, 25%, 12.5%, 6.25% and 3.125% as shown in Figure 15-6. The window with the respective size will be opened before the end of the DWD expiration. The user has to serve the watchdog in the window. Otherwise, a reset or NMI will generate. Figure 15-7 shows an DWWD operation example (25% window).

- Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD. This feature can be utilized to dynamically set windows of different sizes based on task execution time, adding a program sequence element to the diagnostic which can improve fault coverage.

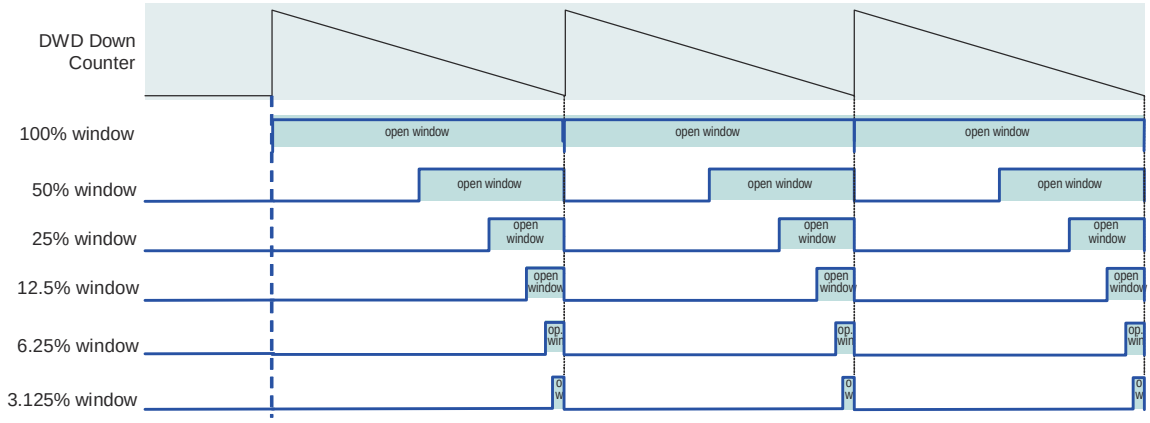

Figure 15-6. Digital Windowed Watchdog Timing Example

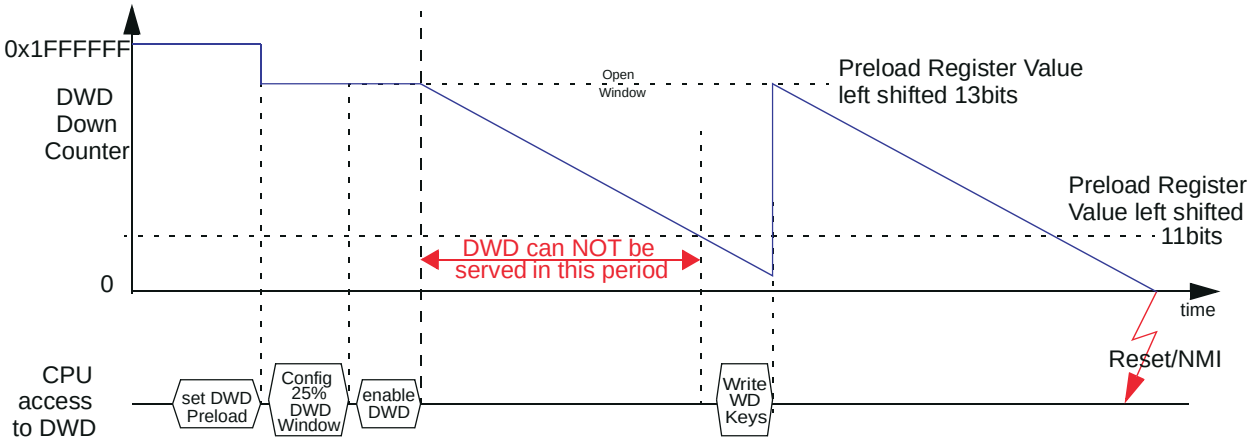

Figure 15-7. Digital Windowed Watchdog Operation Example (25% Window)

15.2.5 Low Power Modes

Low power modes allow the trade off of the current used during low power versus functionality and fast wakeup response. All low power modes have the following characteristics:

- CPU and system clocks are disabled.
- Flash banks and pump are in sleep mode.
- All peripheral modules are in low power modes and the clocks are disabled (exceptions to this may occur and would be documented in the specific device data sheet).

Flexibility in enabling and disabling clocks allows for many different low-power modes.

The operation of the RTI Module is guaranteed in Run, Doze and Snooze modes. In Sleep mode, all clocks will be switched off and the RTI will not work.

In Doze and Snooze modes, the RTI is active and is able to wake up the device with compare, timebase and overflow interrupts. The compare interrupts can be used to periodically wake up the device. The overflow interrupt can be used to notify the operating system that a counter overflow has occurred. Capturing events generated by the Vectored Interrupt Module (VIM) is also possible since, in both of these low power modes, the peripheral modules are able to generate interrupts that can trigger capture events. Capturing events while in Sleep mode is not supported as the clock to the RTI is not active.

When the device is put into low power mode, the peripheral which is generating the external clock NTU is no longer active, and the timebase control circuitry has to switch to an internal clocking scheme when it detects a missing clock on NTU. The timebase interrupt will wake up the device and the application software has to adapt the periodic interrupt generation to the internal clock source.

DMA transfers will be disabled, and DMA requests will not be generated after device wakeup since the DMA controller will be powered down.

Note

RTICLK in Doze Mode

In the special case of Doze Mode with PLL off, RTICLK might have a different period than with PLL enabled since RTICLK will be derived from the oscillator output. It has to be ensured that the VCLK to RTICLK ratio is at least 3:1.

15.2.6 Halting Debug Mode Behaviour

Once the system enters halting debug mode, the behavior of the RTI depends on the COS (continue on suspend) bit. If the bit is cleared and halting debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode. However, if the external timebase (NTU) is used and the system is in halting debug mode, the timebase control circuit will switch to internal timebase once it detects the missing NTU signal of the suspended communication controller. This will be signaled with an TBINT interrupt so that software can resynchronize after the device exits halting debug mode.

15.3 RTI Control Registers

Table 15-1 provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers.

Table 15-1. RTI Registers

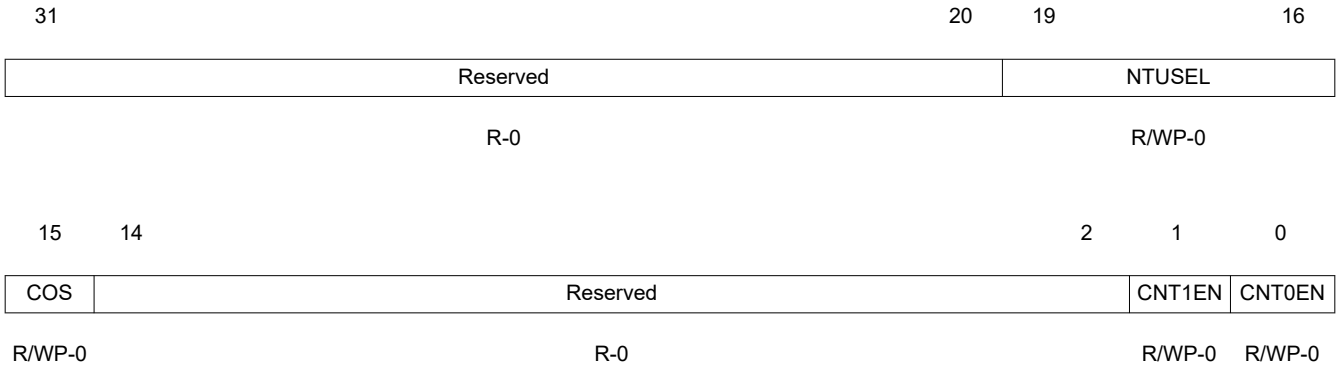
RTI Global Control Register (RTIGCTRL)

The global control register starts/stops the counters and selects the signal compared with the timebase control circuit. This register is shown in Figure 15-8 and described in Table 15-2.

Figure 15-8. RTI Global Control Register (RTIGCTRL) [offset = 00]



LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 15-2. RTI Global Control Register (RTIGCTRL) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	NTUSEL		Select NTU signal. These bits determine which NTU input signal is used as external timebase
		0h	NTU0
		5h	NTU1
		Ah	NTU2
		Fh	NTU3
		All other values	Tied to 0
15	COS		Continue on suspend. This bit determines if both counters are stopped when the device goes into halting debug mode or if they continue counting.
		0	Counters are stopped while in halting debug mode.
		1	Counters are running while in halting debug mode.
14-2	Reserved	0	Reads return 0. Writes have no effect.
1	CNT1EN		Counter 1 enable. This bit starts and stops counter block 1 (RTIUC1 and RTIFRC1).
		0	Counter block 1 is stopped.
		1	Counter block 1 is running.
0	CNT0EN		Counter 0 enable. This bit starts and stops counter block 0 (RTIUC0 and RTIFRC0).
		0	Counter block 0 is stopped.
		1	Counter block 0 is running.

Note

If the application uses the timebase circuit for synchronization between the communications controller and the operating system and the device enters halting debug mode, the synchronization may be lost depending on the COS setting in the RTI module and the halting debug mode behavior of the communications controller.

RTI Timebase Control Register (RTITBCTRL)

The timebase control register selects if the free running counter 0 is incremented by RTICLK or NTU. This register is shown in Figure 15-9 and described in Table 15-3.

Figure 15-9. RTI Timebase Control Register (RTITBCTRL) [offset = 04h]

Table 15-3. RTI Timebase Control Register (RTITBCTRL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	INC		Increment free running counter 0. This bit determines whether the free running counter 0 (RTIFRC0) is automatically incremented if a failing clock on the NTU signal is detected.
		0	RTIFRC0 will not be incremented on a failing external clock.
		1	RTIFRC0 will be incremented on a failing external clock.
0	TBEXT		Timebase external. This bit selects whether the free running counter 0 (RTIFRC0) is clocked by the internal up counter 0 (RTIUC0) or from the external signal NTU. Setting the TBEXT bit from 0 to 1 will not increment RTIFRC0, since RTIUC0 is reset. When the timebase supervisor circuit detects a missing clock edge, then the TBEXT bit is reset. Only the software can select whether the external signal should be used.
		0	RTIUC0 clocks RTIFRC0.
		1	NTU clocks RTIFRC0.

RTI Capture Control Register (RTICAPCTRL)

The capture control register controls the capture source for the counters. This register is shown in Figure 15-10 and described in Table 15-4.

Figure 15-10. RTI Capture Control Register (RTICAPCTRL) [offset = 08h]

		0	Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.

RTI Free Running Counter 0 Register (RTIFRC0)

The free running counter 0 register holds the current value of free running counter 0. This register is shown in Figure 15-12 and described in Table 15-6.

Figure 15-12. RTI Free Running Counter 0 Register (RTIFRC0) [offset = 10h]

Table 15-6. RTI Free Running Counter 0 Register (RTIFRC0) Field Descriptions

Bit	Field	Value	Description
31-0	FRC0	0-FFFF FFFFh	Free running counter 0. This registers holds the current value of the free running counter 0. A read of this counter returns the current value of the counter. The counter can be preset by writing (in privileged mode only) to this register. The counter increments then from this written value upwards. **Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0.**

RTI Up Counter 0 Register (RTIUC0)

The up counter 0 register holds the current value of prescale counter. This register is shown in Figure 15-13 and described in Table 15-7.

Figure 15-13. RTI Up Counter 0 Register (RTIUC0) [offset = 14h]

Table 15-7. RTI Up Counter 0 Register (RTIUC0) Field Descriptions

Bit	Field	Value	Description
31-0	UC0	0-FFFF FFFFh	Up counter 0. This register holds the current value of the up counter 0 and prescales the RTI clock. It will be only updated by a previous read of free running counter 0 (RTIFRC0). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on up counter 0 (RTIUC0) and free running counter 0 (RTIFRC0). A read of this counter returns the value of the counter at the time RTIFRC0 was read. A write to this counter presets it with a value. The counter then increments from this written value upwards. Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0. **Note: If the preset value is bigger than the compare value stored in register RTICPUC0, then it can take a long time until a compare matches, since RTIUC0 has to count up until it overflows.**

RTI Compare Up Counter 0 Register (RTICPUC0)

The compare up counter 0 register holds the value to be compared with prescale counter 0 (RTIUC0). This register is shown in Figure 15-14 and described in Table 15-8.

Figure 15-14. RTI Compare Up Counter 0 Register (RTICPUC0) [offset = 18h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; *-n* = value after reset

Table 15-8. RTI Compare Up Counter 0 Register (RTICPUC0) Field Descriptions

Bit	Field	Value	Description

31-0	CPUC0	0-FFFF FFFFh	Compare up counter 0. This register holds the value that is compared with the up counter 0. When the compare shows a match, the free running counter 0 (RTIFRC0) is incremented. RTIUC0 is set to 0 when the counter value matches the RTICPUC0 value. The value set in this register prescales the RTI clock.
			If CPUC0 = 0, then
			f_{FRC0} = RTICLK/(2^{32}+1) (Setting CPUC0 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)
			If CPUC0 ≠ 0, then
			f_{FRC0} = RTICLK/(RTICPUC0+1)
			A read of this register returns the current compare value.
			A write to this register:
			• If TBEXT = 0, the compare value is updated.
			• If TBEXT = 1, the compare value is unchanged.

RTI Capture Free Running Counter 0 Register (RTICAFRC0)

The capture free running counter 0 register holds the free running counter 0 on external events. This register is shown in Figure 15-15 and described in Table 15-9.

Figure 15-15. RTI Capture Free Running Counter 0 Register (RTICAFRC0) [offset = 20h]

Table 15-9. RTI Capture Free Running Counter 0 Register (RTICAFRC0) Field Descriptions

Bit	Field	Value	Description
31-0	CAFRC0	0-FFFF FFFFh	Capture free running counter 0. This register captures the current value of the free running counter 0 (RTIFRC0) when an event occurs, controlled by the external capture control block. A read of this register returns the value of RTIFRC0 on a capture event.

RTI Capture Up Counter 0 Register (RTICAUC0)

The capture up counter 0 register holds the current value of prescale counter 0 on external events. This register is shown in Figure 15-16 and described in Table 15-10.

Figure 15-16. RTI Capture Up Counter 0 Register (RTICAUC0) [offset = 24h]

LEGEND: R = Read only; -*n* = value after reset

Table 15-10. RTI Capture Up Counter 0 Register (RTICAUC0) Field Descriptions

Bit	Field	Value	Description
31-0	CAUC0	0-FFFF FFFFh	Capture up counter 0. This register captures the current value of the up counter 0 (RTIUC0) when an event occurs, controlled by the external capture control block. **Note: The read sequence must be the same as with RTIUC0 and RTIFRC0. Therefore, the RTICAFRC0 register must be read before the RTICAUC0 register is read. This sequence ensures that the value of the RTICAUC0 register is the corresponding value to the RTICAFRC0 register, even if another capture event happens in between the two reads.** A read of this register returns the value of RTIUC0 on a capture event.

RTI Free Running Counter 1 Register (RTIFRC1)

The free running counter 1 register holds the current value of the free running counter 1. This register is shown in Figure 15-17 and described in Table 15-11.

Figure 15-17. RTI Free Running Counter 1 Register (RTIFRC1) [offset = 30h]

FRC1	
R/WP-0	

15	0
FRC1	
R/WP-0	

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -*n* = value after reset

Table 15-11. RTI Free Running Counter 1 Register (RTIFRC1) Field Descriptions

Bit	Field	Value	Description
31-0	FRC1	0-FFFF FFFFh	Free running counter 1. This register holds the current value of the free running counter 1 and will be updated continuously. A read of this register returns the current value of the counter. A write to this register presets the counter. The counter increments then from this written value upwards. **Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.**

RTI Up Counter 1 Register (RTIUC1)

The up counter 1 register holds the current value of the prescale counter 1. This register is shown in Figure 15-18 and described in Table 15-12.

Figure 15-18. RTI Up Counter 1 Register (RTIUC1) [offset = 34h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -*n* = value after reset

Table 15-12. RTI Up Counter 1 Register (RTIUC1) Field Descriptions

Bit	Field	Value	Description
31-0	UC1	0-FFFF FFFFh	Up counter 1. This register holds the current value of the up counter 1 and prescales the RTI clock. It will be only updated by a previous read of free running counter 1 (RTIFRC1). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on RTIUC1 and RTIFRC1. A read of this register will return the value of the counter when the RTIFRC1 was read. A write to this register presets the counter. The counter then increments from this written value upwards. **Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.** **Note: If the preset value is bigger than the compare value stored in register RTICPUC1, then it can take a long time until a compare matches, since RTIUC1 has to count up until it overflows.**

RTI Compare Up Counter 1 Register (RTICPUC1)

The compare up counter 1 register holds the value compared with prescale counter 1. This register is shown in Figure 15-19 and described in Table 15-13.

Figure 15-19. RTI Compare Up Counter 1 Register (RTICPUC1) [offset = 38h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; *-n* = value after reset

Table 15-13. RTI Compare Up Counter 1 Register (RTICPUC1) Field Descriptions

Bit	Field	Value	Description

31-0	CPUC1	0-FFFF FFFFh	Compare up counter 1. This register holds the compare value, which is compared with the up counter 1. When the compare matches, the free running counter 1 (RTIFRC1) is incremented. The up counter is cleared to 0 when the counter value matches the CPUC1 value. The value set in this prescales the RTI clock according to the following formula:
			If CPUC1 = 0, then
			f_{FRC1} = RTICLK/(2^{32}+1) (Setting CPUC1 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)
			If CPUC1 ≠ 0, then
			f_{FRC1} = RTICLK/(RTICPUC1+1)
			A read of this register returns the current compare value.
			A write to this register updates the compare value.

RTI Capture Free Running Counter 1 Register (RTICAFRC1)

The capture free running counter 1 register holds the current value of free running counter 1 on external events. This register is shown in Figure 15-20 and described in Table 15-14.

Figure 15-20. RTI Capture Free Running Counter 1 Register (RTICAFRC1) [offset = 40h]

Bit	Field	Value	Description
31-0	COMP0	0-FFFF FFFFh	Compare 0. This registers holds a value that is compared with the counter selected in the compare control logic. If RTIFRC0 or RTIFRC1, depending on the counter selected, matches the compare value, an interrupt is flagged. With this register it is also possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register (in privileged mode only) will update the compare register with a new compare value.

RTI Update Compare 0 Register (RTIUDCP0)

The update compare 0 register holds the value to be added to the compare register 0 value on a compare match. This register is shown in Figure 15-23 and described in Table 15-17.

Bit	Field	Value	Description
31-0	UDCP0	0-FFFF FFFFh	Update compare 0. This register holds a value that is added to the value in the compare 0 (RTICOMP0) register each time a compare matches. This function allows periodic interrupts to be generated without software intervention. A read of this register will return the value to be added to the RTICOMP0 register on the next compare match. A write to this register will provide a new update value.

RTI Compare 1 Register (RTICOMP1)

The compare 1 register holds the value to be compared to the counters. This register is shown in Figure 15-24 and described in Table 15-18.

This process makes it possible to generate periodic interrupts without software intervention. A read of this register will return the value to be added to the RTICOMP3 register on the next compare match. A write to this register will provide a new update value.

RTI Timebase Low Compare Register (RTITBLCOMP)

The timebase low compare register holds the value to activate the edge detection circuit. This register is shown in Figure 15-30 and described in Table 15-24.

Figure 15-30. RTI Timebase Low Compare Register (RTITBLCOMP) [offset = 70h]

31	16
TBLCOMP	
R/WP-0	

15	0

R/WP-0	

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -*n* = value after reset

Table 15-24. RTI Timebase Low Compare Register (RTITBLCOMP) Field Descriptions

Bit	Field	Value	Description
31-0	TBLCOMP	0-FFFF FFFFh	Timebase low compare value. This value determines when the edge detection circuit starts monitoring the NTU signal. It will be compared with RTIUC0. A read of this register will return the current compare value. A write to this register has the following effects: If TBEXT = 0: The compare value is updated. If TBEXT = 1: The compare value is not changed.

RTI Timebase High Compare Register (RTITBHCOMP)

The timebase high compare register holds the value to deactivate the edge detection circuit. This register is shown in Figure 15-31 and described in Table 15-25.

Figure 15-31. RTI Timebase High Compare Register (RTITBHCOMP) [offset = 74h]

LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -*n* = value after reset

Table 15-25. RTI Timebase High Compare Register (RTITBHCOMP) Field Descriptions

Bit	Field	Value	Description
31-0	TBHCOMP	0-FFFF FFFFh	Timebase high compare value. This value determines when the edge detection circuit will stop monitoring the NTU signal. It will be compared with RTIUC0. RTITBHCOMP must be less than RTICPUC0 because RTIUC0 will be reset when RTICPUC0 is reached. Example: The NTU edge detection circuit should be active ± 10 RTICLK cycles around RTICPUC0. • RTICPUC0 = 0050h • RTITBLCOMP = 0046h • RTITBHCOMP = 0009h A read of this register will return the current compare value. A write to this register has the following effects: If TBEXT = 0: The compare value is updated. If TBEXT = 1: The compare value is not changed.

RTI Set Interrupt Enable Register (RTISETINTENA)

This register prevents the necessity of a read-modify-write operation if a particular interrupt should be enabled. This register is shown in Figure 15-32 and described in Table 15-26.

Table 15-28. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18	OVL1INT		Free running counter 1 overflow interrupt flag. This bit determines if an interrupt is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
17	OVL0INT		Free running counter 0 overflow interrupt flag. This bit determines if an interrupt is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
16	TBINT		Timebase interrupt flag. This flag is set when the TBEXT bit is cleared by detection of a missing external clock edge. It will not be set by clearing TBEXT by software. It determines if an interrupt is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
15-4	Reserved	0	Reads return 0. Writes have no effect.
3	INT3		Interrupt flag 3. These bits determine if an interrupt due to a Compare 3 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.

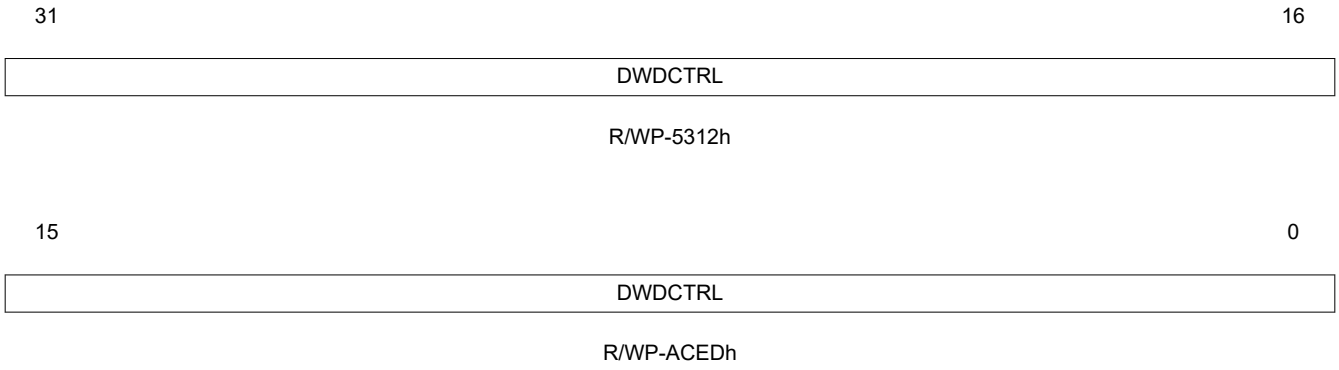
Table 15-28. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions (continued)

Bit	Field	Value	Description
2	INT2		Interrupt flag 2. These bits determine if an interrupt due to a Compare 2 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
1	INT1		Interrupt flag 1. These bits determine if an interrupt due to a Compare 1 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
0	INT0		Interrupt flag 0. These bits determine if an interrupt due to a Compare 0 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.

Digital Watchdog Control Register (RTIDWDCTRL)

The software has to write to the DWDCTRL field in order to enable the DWD, as described below. Once enabled, the watchdog can only be disabled by a system reset. The application cannot disable the watchdog. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog. This register is shown in Figure 15-34 and described in Table 15-28.

Figure 15-35. Digital Watchdog Control Register (RTIDWDCTRL) [offset = 90h]



LEGEND: R/W = Read/Write; WP = Write in privileged mode only; -*n* = value after reset

Table 15-29. Digital Watchdog Control Register (RTIDWDCTRL) Field Descriptions

Bit	Field	Value	Description
31-0	DWDCTRL	5312 ACEDh	Digital Watchdog Control. *Read:* DWD counter is disabled. *Write:* State of DWD counter is unchanged (stays enabled or disabled).
		A985 59DAh	*Read:* DWD counter is enabled. *Write:* DWD counter is enabled.
		All other values	*Read:* DWD counter state is unchanged (enabled or disabled). *Write:* State of DWD counter is unchanged (stays enabled or disabled). **Note:** Once the enable value is written, all other future writes are blocked. In other words, once DWD is enabled, it can only be disabled by system reset or power on reset. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog.

Digital Watchdog Preload Register (RTIDWDPRLD)

This register sets the expiration time of the DWD. This register is shown in Figure 15-34 and described in Table 15-28.

Figure 15-36. Digital Watchdog Preload Register (RTIDWDPRLD) [offset = 94h]

31	16
Reserved	
R-0	

15	12	11	0
Reserved		DWDPRLD	
R-0		R/WP-FFFh	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

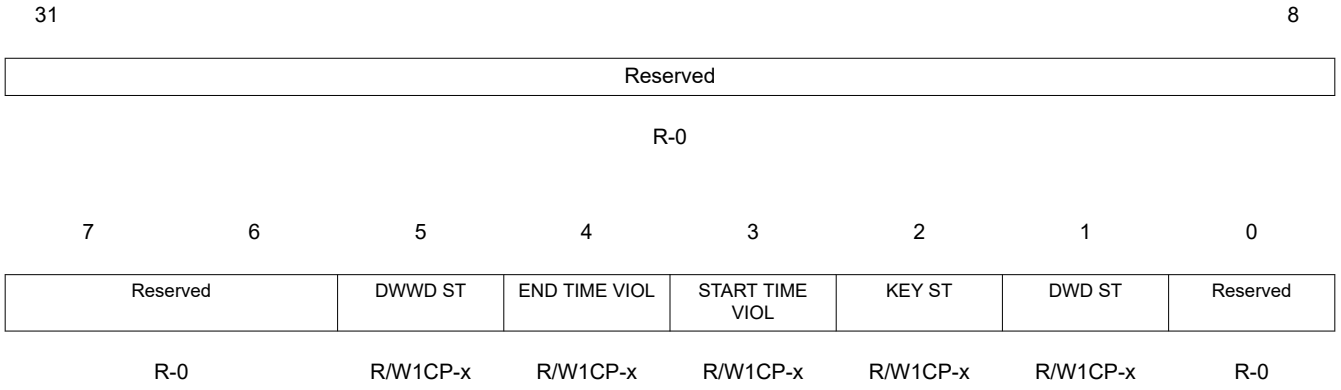
Table 15-30. Digital Watchdog Preload Register (RTIDWDPRLD) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reads return 0 and writes have no effect.
11-0	DWDPRLD	0-FFFh	Digital Watchdog Preload Value. *Read:* The current preload value *Write:* Set the preload value. The DWD preload register can be configured only when the DWD is disabled. Therefore, the application can only configure the DWD preload register before it enables the DWD down counter. The expiration time of the DWD Down Counter can be determined with following equation: texp = (DWDPRLD+1) x 2^{13} / RTICLK1 where: DWDPRLD = 0...4095

Watchdog Status Register (RTIWDSTATUS)

This register records the status of the DWD. The values of the following status bits will not be affected by a soft reset. These bits are cleared by a power-on reset, or by a write of 1. These bits can be used for debug purposes. This register is shown in Figure 15-34 and described in Table 15-28.

Figure 15-37. Watchdog Status Register (RTIWDSTATUS) [offset = 98h]



LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; *-n* = value after reset

Table 15-31. Watchdog Status Register (RTIWDSTATUS) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5	DWWD ST		Windowed Watchdog Status
		0	*Read:* No time-window violation has occurred. *Write:* Leaves the current value unchanged.
		1	*Read:* Time-window violation has occurred. The watchdog has generated either a system reset or a non-maskable interrupt to the CPU in this case. *Write:* Bit is cleared to 0. This will also clear all other status flags in the RTIWDSTATUS register. Clearing of the status flags will deassert the non-maskable interrupt generated due to violation of the DWWD.
4	END TIME VIOL		Windowed Watchdog End Time Violation Status. This bit indicates whether the Watchdog counter expired.
		0	*Read:* No end-time window violation has occurred. *Write:* Leaves the current value unchanged.
		1	*Read*: End-time defined by the windowed watchdog configuration has been violated. *Write:* Bit is cleared to 0.
3	START TIME VIOL		Windowed Watchdog Start Time Violation Status. This bit indicates whether the key is written before the watchdog window opened up.
		0	*Read:* No start-time window violation has occurred. *Write:* Leaves the current value unchanged.
		1	*Read:* Start-time defined by the windowed watchdog configuration has been violated. *Write:* Bit is cleared to 0.
2	KEY ST		Watchdog key status. This bit indicates a reset or NMI generated by a wrong key or key sequence written to the RTIWDKEY register.
		0	*Read:* No wrong key or key-sequence written. *Write:* Bit is unchanged.
		1	*Read:* Wrong key or key-sequence written to RTIWDKEY register. *Write:* Bit is cleared to 0.

Table 15-31. Watchdog Status Register (RTIWDSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
1	DWD ST		DWD status. This bit is equivalent to bit END TIME VIOL.
		0	*Read:* No reset or NMI was generated. *Write:* Bit is unchanged.
		1	*Read:* Reset or NMI was generated. *Write:* Bit is cleared to 0.
0	Reserved	0	Reads return 0. Writes have no effect.

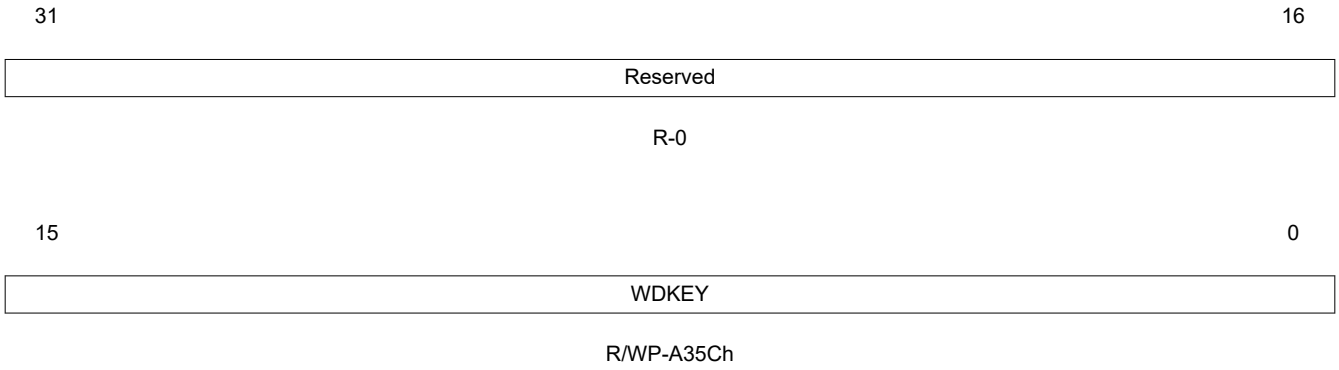
RTI Watchdog Key Register (RTIWDKEY)

This register must be written with the correct written key values to serve the watchdog. This register is shown in Figure 15-38 and described in Table 15-32.

Note

It has to be taken into account that the write to the RTIWDKEY register takes 3 VCLK cycles.

Figure 15-38. RTI Watchdog Key Register (RTIDWDKEY) [offset = 9Ch]



LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 15-32. RTI Watchdog Key Register (RTIDWDKEY) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0 and writes have no effect.
15-0	WDKEY	0-FFFFh	Watchdog key. These bits provide the key sequence location. Reads returns the current WDKEY value. A write of E51Ah followed by A35Ch in two separate write operations defines the key sequence and reloads the DWD. Writing any other value causes a reset or NMI, as shown in Table 15-33. Writing any other value will cause the WDKEY to reset to A35Ch.

Table 15-33. Example of a WDKEY Sequence

Step	Value Written to WDKEY	Result
1	A35Ch	No action
2	A35Ch	No action
3	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
4	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
5	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
6	A35Ch	Watchdog is reset.
7	A35Ch	No action
8	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
9	A35Ch	Watchdog is reset.
10	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
11	2345h	System reset or NMI; incorrect value written to WDKEY.

RTI Digital Watchdog Down Counter (RTIDWDCNTR)

This register provides the current value of the DWD down counter. This register is shown in Figure 15-39 and described in Table 15-34.

Figure 15-39. RTI Watchdog Down Counter Register (RTIDWDCNTR) [offset = A0h]

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0 and writes have no effect.

Table 15-35. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
3-0	WWDRXN		The DWWD reaction
		5h	The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
		Ah	The windowed watchdog will generate a non-maskable interrupt to the CPU if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
		All other values	The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
			Note: The DWWD reaction can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDRXN is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDRXN is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced.

Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL)

This register selects the DWWD window size. This register is shown in Figure 15-41 and described in Table 15-36.

Bit	Field	Value	Description
31-0	WWDSIZE	0	The DWWD window size
		0000 0005h	100% (The functionality is the same as the standard time-out digital watchdog.)
		0000 0050h	50%
		0000 0500h	25%
		0000 5000h	12.5%
		0005 0000h	6.25%
		All other values	3.125%
			Note: The DWWD window size can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDSIZE is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDSIZE is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced.

RTI Compare Interrupt Clear Enable Register (RTIINTCLRENABLE)

When the RTI compare event is configured to generate a DMA request or triggers (all triggered by RTI compare interrupt request flag) to other peripherals, it is often desirable to clear the RTI compare flag automatically so that the requests can be generated repeatedly without any CPU intervention. This register works with the RTI compare clear registers to enable an "auto-clear" of the compare interrupt enable bit after a compare equal event. This register is shown in Figure 15-42 and described in Table 15-37.

Figure 15-42. RTI Compare Interrupt Clear Enable Register (RTIINTCLRENABLE) [offset = ACh]

		All other values	*Read:* Auto-clear for compare 0 interrupt is enabled. *Privileged Write:* Auto-clear for compare 0 interrupt becomes enabled.

RTI Compare 0 Clear Register (RTICMP0CLR)

This registers holds an initial value which is larger than the value in the RTI Compare 0 register Section RTI Compare Control Register (RTICOMPCTRL). The user needs to choose the value such that the compare clear 0 event occurs before next compare 0 event. If the Free Running Counter matches the compare value, the compare 0 interrupt request flag is cleared and the value in the RTIUDCP0 register Section RTI Update Compare 0 Register (RTIUDCP0) is added to this register. This register is shown in Figure 15-43 and described in Table 15-38.

Chapter 16

UART/SCI

This chapter contains the description of the serial communication interface (SCI) module.

16.1 Introduction

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

16.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode with no CLK pin
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports 2^{24} different baud rates provide high accuracy baud rate selection
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Four error flags and Five status flags provide detailed information regarding SCI events
- Two external pins: SCIRX and SCITX

Note

SCI module does not support UART Hardware Flow Control. This feature can be implemented in Software using a General Purpose I/O pin.

16.1.2 Block Diagram

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

Transmitter (TX) contains two major registers to perform double buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the SCITX pin, one bit at a time.

Baud Clock Generator

- A programmable baud generator produces a baud clock scaled from VCLK.

Receiver (RX) contains two major registers to perform double buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the SCIRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 16-1 shows the detailed SCI block diagram.

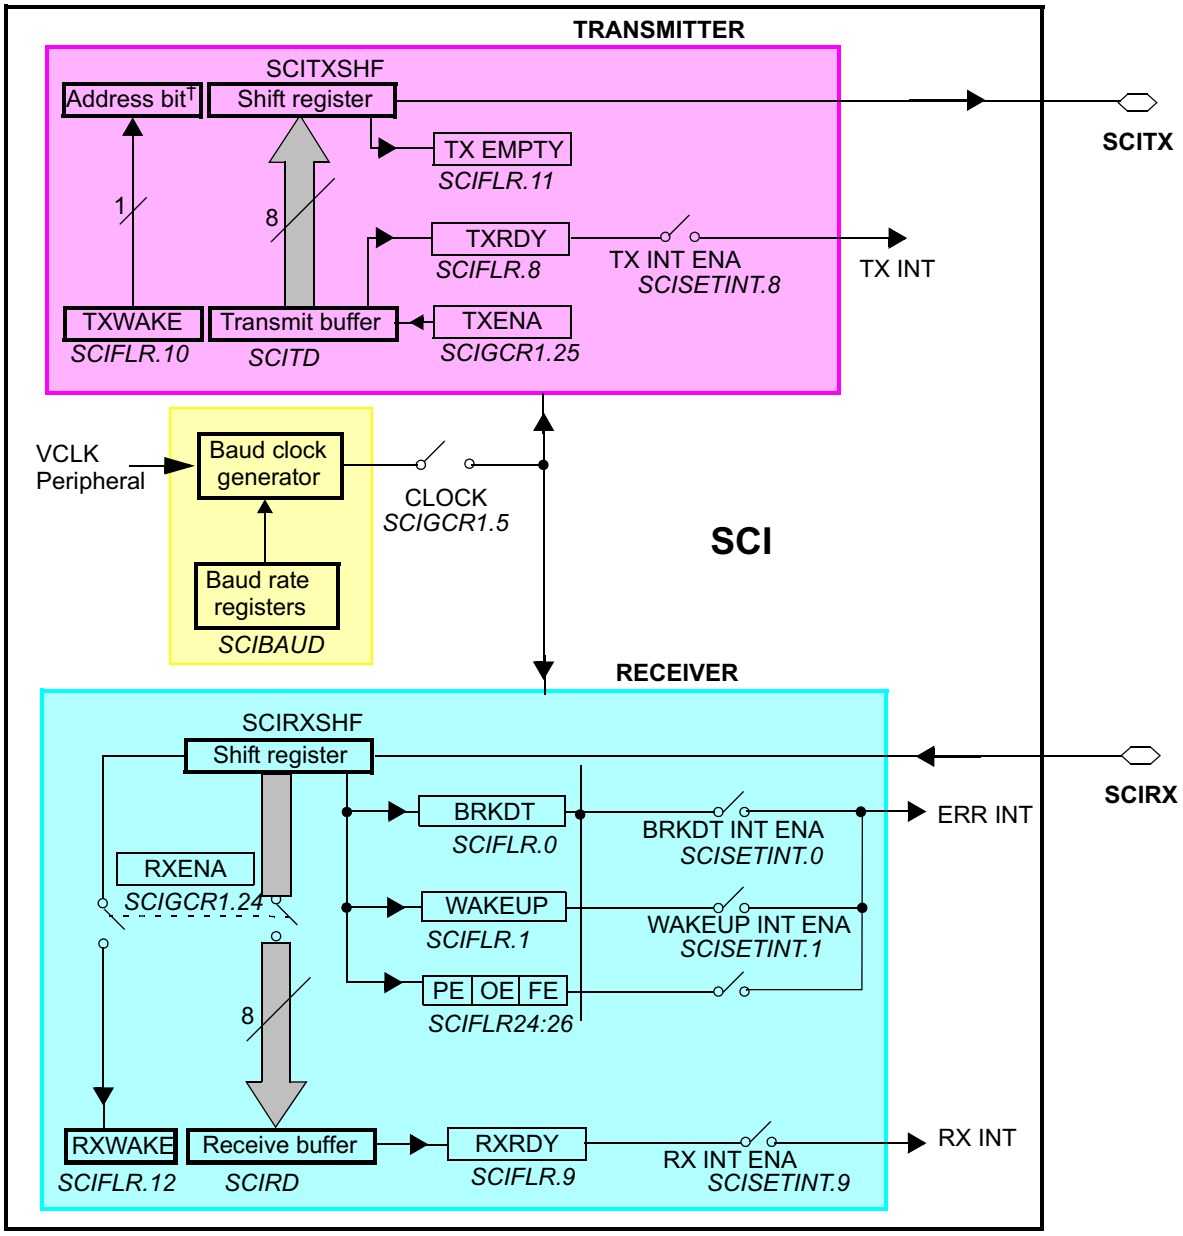

Figure 16-1. Detailed SCI Block Diagram

16.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

16.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in Figure 16-2.

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in Figure 16-2 have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in Figure 16-2 use one stop bit per frame.

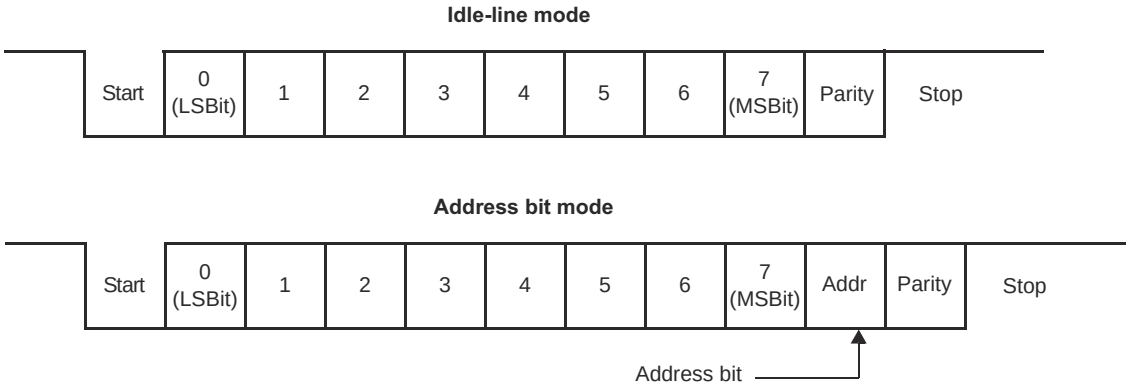

Figure 16-2. Typical SCI Data Frame Formats

16.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

16.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver- transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the SCIRX pin are of logic level 0. As soon as a falling edge is detected on SCIRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects SCIRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the SCIRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 16-3 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the SCITX pin. The transmitter then holds the current bit value on SCITX for 16 SCI baud clock periods.

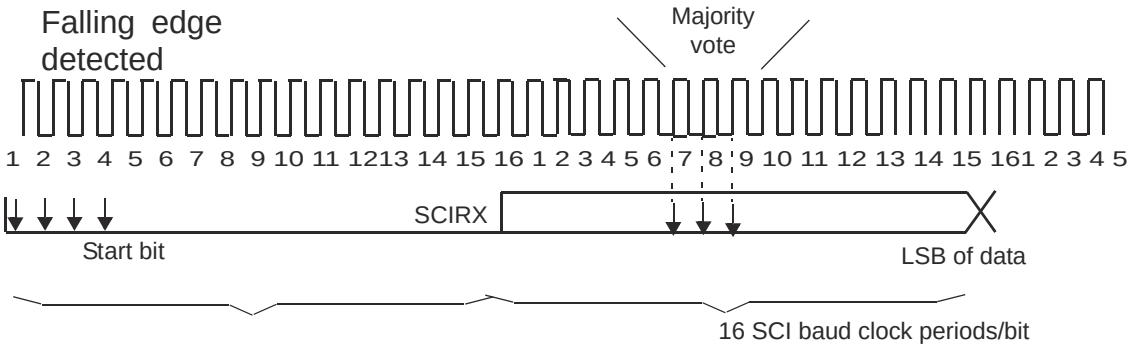

Figure 16-3. Asynchronous Communication Bit Timing

16.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not fully supported on this device because SCICLK pin is not available.**

16.2.3 SCI Baud Rate

The SCI has an internally generated serial clock determined by the peripheral VCLK and the prescalers BAUD. The SCI uses the 24-bit integer prescaler BAUD value of the BRS register to select the required baud rates.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\textit{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{16 * (\text{BAUD} + 1)}$$

For BAUD = 0,

$$\textit{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (3)$$

In isosynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\textit{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{\text{BAUD} + 1}$$

For BAUD = 0,

$$\textit{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (4)$$

16.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor Communication Modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

Note

Avoid Transmitting Simultaneously on the Same Serial Bus

The system designer must ensure that devices connected to the same serial bus line do not attempt to transmit simultaneously. If two devices are transmitting different data, the resulting bus conflict could damage the device..

16.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 16-4 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1 : Write a 1 to the TXWAKE bit.

Step 2 : Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3 : Wait for the SCI to clear the TXWAKE flag.

Step 4 : Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

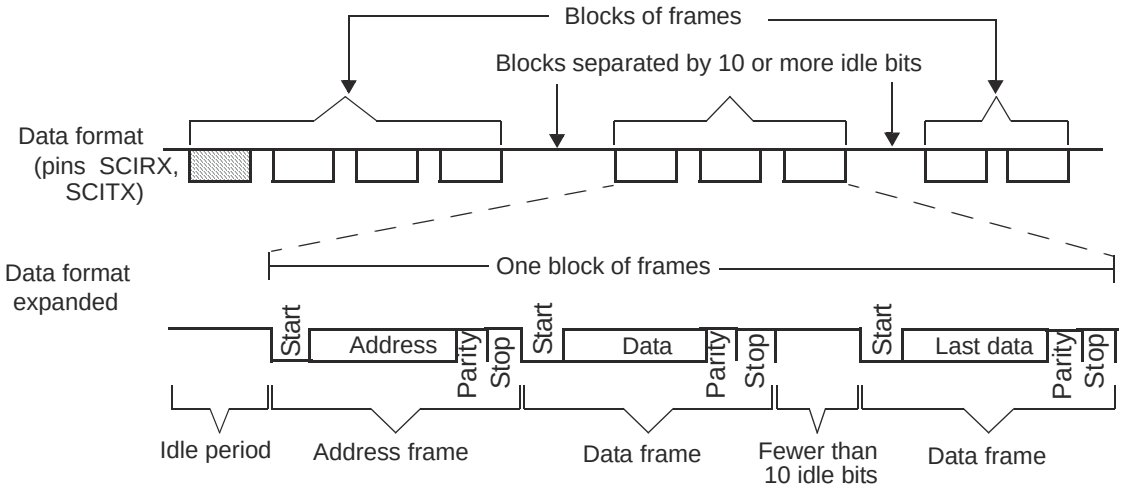

Figure 16-4. Idle-Line Multiprocessor Communication Format

16.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 16-5 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

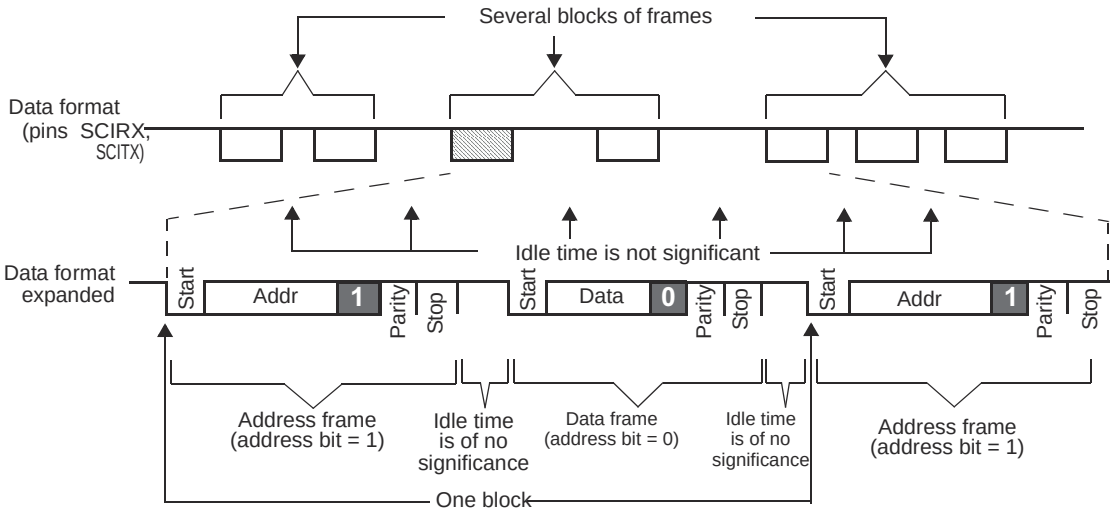

Figure 16-5. Address-Bit Multiprocessor Communication Format

16.3 SCI Interrupts

The SCI module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see Figure 16-6). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable and disable the interrupt in the SCISETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

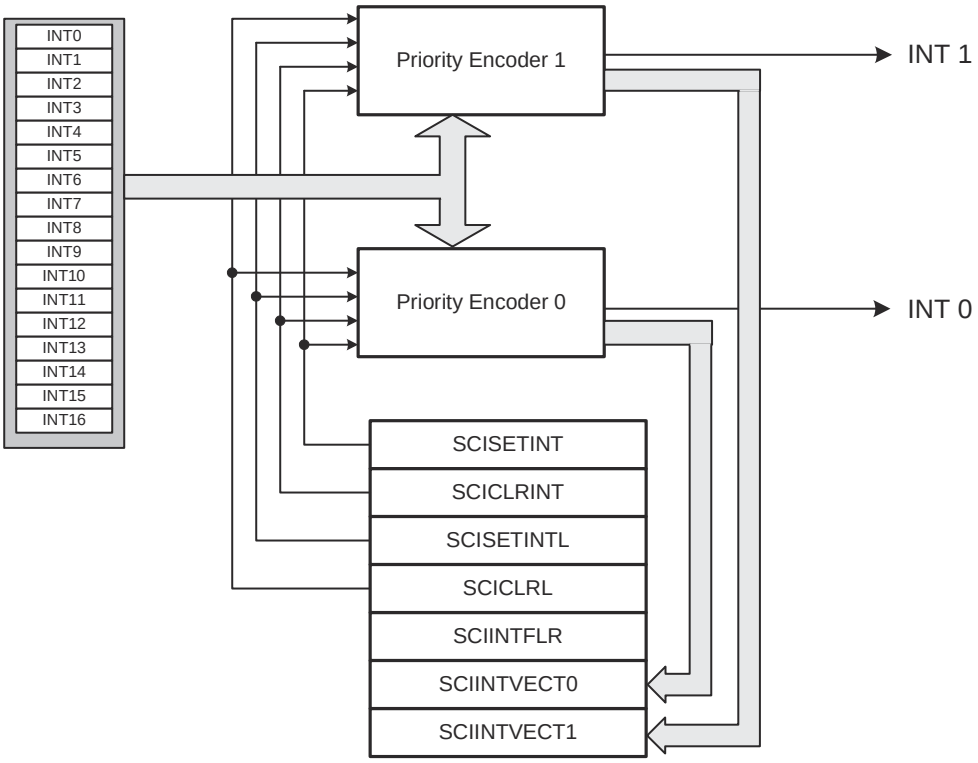

Figure 16-6. General Interrupt Scheme

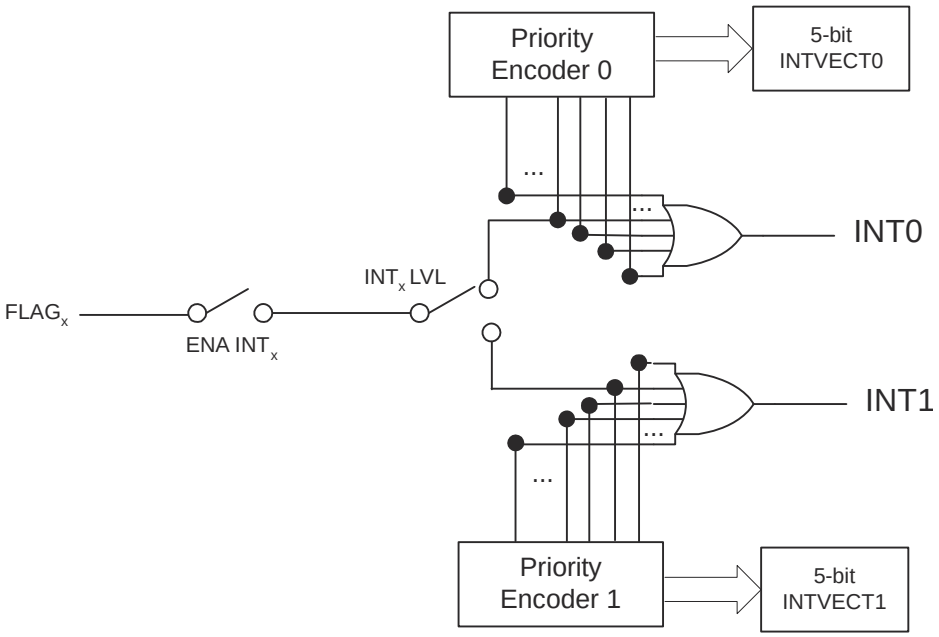

Figure 16-7. Interrupt Generation for Given Flags

16.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

16.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

16.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

16.3.4 Error Interrupts

The following error detection features are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)

If any of these errors (PE, FE, BRKDT, OE) is flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register. Further details on these flags are explained in SCIFLR register description.

The SCI module supports the following 7 interrupts as listed in Table 16-1.

Table 16-1. SCI Interrupts

Offset (1)	Interrupt
0	Reserved
1	Wakeup
2	Reserved
3	Parity error
4	Reserved
5	Reserved
6	Frame error
7	Break detect error
8	Reserved
9	Overrun error
10	Reserved
11	Receive
12	Transmit
13-15	Reserved

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

16.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI module. Refer to the DMA module chapter for DMA module configurations.

16.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

The receiver DMA request is set when a frame is received successfully and DMA functionality has been previously enabled. The RXRDY flag is set when the SCI transfers newly received data from the SCIRXSHF register to the SCIRD buffer. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive DMA requests are enabled by the SET RX INT bit.

Parity, overrun, break detect, wake-up, and framing errors generate an error interrupt request immediately upon detection, if enabled, even if the device is in the process of a DMA data transfer. The DMA transfer is postponed until the error interrupt is served. The error interrupt can delete this particular DMA request by reading the receive buffer.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames. This is controlled by an extra select bit SET RX DMA ALL.

If the SET RX DMA ALL bit is set and the SET RX DMA bit is set when the SCI sets the RXRDY flag, then a receive DMA request is generated for address and data frames.

If the SET RX DMA ALL bit is cleared and the SET RX DMA bit is set when the SCI sets the RXRDY flag upon receipt of a data frame, then a receive DMA request is generated. Receive interrupt requests are generated for address frames.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received. Table 16-2 specifies the bit values for DMA requests in multiprocessor modes.

Table 16-2. DMA and Interrupt Requests in Multiprocessor Modes

SET RX INT	SET RX DMA	SET RX DMA ALL	ADDR FRAME INT	ADDR FRAME DMA	DATA FRAME INT	DATA FRAME DMA
0	0	x	N	N	N	N
0	1	0	Y	N	N	Y
0	1	1	N	Y	N	Y
1	0	x	Y	N	Y	N
1	1	0	Y	N	Y	Y
1	1	1	Y	Y	Y	Y

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

16.4.2 Transmit DMA Requests

DMA functionality is enabled and disabled by the CPU with the SET TX DMA and CLR TX DMA bits, respectively.

The TXRDY flag is set when the SCI transfers the contents of SCITD to SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty.

Transmit DMA requests are enabled by the setting SET TX DMA and SET TX INT bits. If the SET TX DMA bit is set, then a TX DMA request is sent to the DMA when data is written to SCITD and TXRDY is set. The DMA will write the first byte to the transmit buffer.

16.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the SCIRX and SCITX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bitin SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see Section 16.5.1 and Section 16.5.2).

16.5.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the SCIRX pin functions as a general-purpose I/O pin rather than as an SCI function pin. After a valid idle period is detected, data is automatically received as it arrives on the SCIRX pin.

SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from SCIRD register once RXRDY is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

16.5.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the SCITX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

16.6 SCI Low-Power Mode

The SCI can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI. During global low-power mode, all clocks to the SCI are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the SCIRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI immediately enters low-power mode whenever it is requested and also any activity on the SCIRX pin does not cause the SCI to exit low-power mode.

Note

Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the power-down bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

16.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see Table 16-11) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

16.7 SCI Control Registers

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI is controlled and accessed through the registers listed in Table 16-3. Among the features that can be programmed are the SCI communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

Table 16-3. SCI Control Registers Summary

Offset	Acronym	Register Description	Section
00h	SCIGCR0	SCI Global Control Register 0	Section 16.7.1

16.7.1 SCI Global Control Register 0 (SCIGCR0)

The SCIGCR0 register defines the module reset. Figure 16-8 and Table 16-4 illustrate this register.

Figure 16-8. SCI Global Control Register 0 (SCIGCR0) [offset = 00]

Bit	Field	Value	Description
31-1	Reserved	0	Reads return 0. Writes have no effect.
0	RESET		This bit resets the SCI module.
		0	SCI module is in reset.
		1	SCI module is out of reset.
			Note: Read/Write in privileged mode only.

16.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 16-9 and Table 16-5 illustrate this register.

Note

The SCIGCR1 Control Register Bits should not be changed during Frame Transmission or Reception.

Figure 16-9. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]

Table 16-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reads return 0. Writes have no effect.
25	TXENA		Transmit enable. Data is transferred from SCITD to the SCITXSHF shift out register only when the TXENA bit is set.
		0	Disable transfers from SCITD to SCITXSHF.
		1	Enable SCI to transfer data from SCITD to SCITXSHF.
			Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent.

Table 16-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
24	RXENA		Receive enable. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD.
		0	The receiver will not transfer data from the shift buffer to the receive buffer.
		1	The receiver will transfer data from the shift buffer to the receive buffer.
			Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 16-11) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.
			Note: If RXENA is cleared before a frame is completely received, the data from the frame is not transferred into the receive buffer.
			Note: If RXENA is set before a frame is completely received, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not assured to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame.
23-18	Reserved	0	Reads return 0. Writes have no effect.
17	CONT		Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI operates when the program is suspended. The
		0	When debug mode is entered, the SCI state machine is frozen. Transmissions are halted and resume when debug mode is exited.
		1	When debug mode is entered, the SCI continues to operate until the current transmit and receive functions are complete.
16	LOOP BACK		Loopback bit. The self-checking option for the SCI can be selected with this bit. If the SCITX and SCIRX pins are configured with SCI functionality, then the SCITX pin is internally connected to the SCIRX pin. Externally, during loop back operation, the SCITX pin outputs a high value and the SCIRX pin is in a high-impedance state. If this bit value is changed while the SCI is transmitting or receiving data, errors may result.
		0	Loop back mode is disabled.
		1	Loop back mode is enabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	POWERDOWN		Power down. When the POWERDOWN bit is set, the SCI attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wake-up interrupt is enabled, then the SCI immediately asserts an error interrupt to prevent low-power mode from being entered. Only Privilege mode writes allowed.
		0	Normal operation.
		1	Low-power mode is enabled.
8	SLEEP		SCI sleep. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.
		0	Sleep mode is disabled.
		1	Sleep mode is enabled.
			Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags (see Table 16-11) are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.
			Note: The SLEEP bit is not automatically cleared when an address byte is detected.
			See for more information on using the SLEEP bit for multiprocessor communication.
7	SWnRST		Software reset (active low).
		0	The SCI is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI state machines and operating flags as defined in Table 16-11 and Table 16-12. All affected logic is held in the reset state until a 1 is written to this bit.
		1	The SCI is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.
			Note: The SCI should only be configured while SWnRESET = 0.

Table 16-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
6	Reserved	0	Reads return 0. Writes have no effect.
5	CLOCK		SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin.
		0	The external SCICLK is the clock source.
		1	The internal SCICLK is the clock source.
			Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.
4	STOP		SCI number of stop bits per frame.
		0	One stop bit is used.
		1	Two stop bits are used.
			Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.
3	PARITY		SCI parity odd/even selection. If the PARITY ENA bit is set, PARITY designates odd or even parity.
		0	Odd parity is used.
		1	Even parity is used.
			The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.
			For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.
			For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.
2	PARITY ENA		Parity enable. This bit enables or disables the parity function.
		0	Parity is disabled; no parity bit is generated during transmission or is expected during reception.
		1	Parity is enabled. A parity bit is generated during transmission and is expected during reception.
1	TIMING MODE		SCI timing mode bit.
		0	Synchronous timing is used.
		1	Asynchronous timing is used.
0	COMM MODE		SCI communication mode bit.
		0	Idle-line mode is used.
		1	Address-bit mode is used.

16.7.3 SCI Set Interrupt Register (SCISETINT)

Figure 16-10 and Table 16-6 illustrate this register. SCISETINT register is used to enable the required interrupts supported by the module.

Figure 16-10. SCI Set Interrupt Register (SCISETINT) [offset = 0Ch]

31	27	26	25	24
Reserved		SET FE INT	SET OE INT	SET PE INT
R-0		R/W-0	R/W-0	R/W-0

R-0		R/WC-0	R/W-0	R/W-0

15	10	9	8
Reserved		SET RX INT	SET TX INT
R-0		R/W-0	R/W-0

7	2	1	0
Reserved		SET WAKEUP INT	SET BRKDT INT
R-0		R/W-0	R/WC-0

LEGEND: R/W = Read/Write; R = Read only; WC = Write in sci-compatible mode only; -*n* = value after reset

Table 16-6. SCI Set Interrupt Register (SCISETINT) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	SET FE INT		Set framing-error interrupt. Setting this bit enables the SCI module to generate an interrupt when a framing error occurs.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.
25	SET OE INT		Set overrun-error interrupt. Setting this bit enables the SCI module to generate an interrupt when an overrun error occurs.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.
24	SET PE INT		Set parity interrupt. Setting this bit enables the SCI module to generate an interrupt when a parity error occurs.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.

Table 16-6. SCI Set Interrupt Register (SCISETINT) Field Descriptions (continued)

Bit	Field	Value	Description
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	SET RX DMA ALL		Set receive DMA all. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames.
		0	*Read:* The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames). *Write:* Writing a 0 to this bit has no effect.
		1	*Read and write:* The DMA request is enabled for address and data frames
17	SET RX DMA		Set receiver DMA. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on the SET RX INT bit (SCISETINT[9]).
		0	*Read:* The DMA request is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read and write:* The DMA request is enabled for address and data frames
16	SET TX DMA		Set transmit DMA. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on the SET TX INT bit (SCISETINT[8]).
		0	*Read:* Transmit DMA request is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read and write:* Transmit DMA request is enabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	SET RX INT		Receiver interrupt enable. Setting this bit enables the SCI to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.
8	SET TX INT		Set transmitter interrupt. Setting this bit enables the SCI to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	SET WAKEUP INT		Set wakeup interrupt. Setting this bit enables the SCI to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local lowpower mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.
0	SET BRKDT INT		Set break detect interrupt. Setting this bit enables the SCI to generate an error interrupt if a break condition is detected on the SCIRX pin.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read or write:* The interrupt is enabled.

16.7.4 SCI Clear Interrupt Register (SCICLEARINT)

Figure 16-11 and Table 16-7 illustrate this register. SCICLEARINT register is used to clear the selected enabled interrupts with out accessing SCISETINT register.

Figure 16-11. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]

Table 16-7. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reads return 0. Writes have no effect.
26	CLR FE INT		Clear framing-error interrupt. This bit disables the framing-error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
25	CLR CE INT		Clear overrun-error interrupt. This bit disables the SCI overrun error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
24	CLR PE INT		Clear parity interrupt. This bit disables the parity error interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.

Table 16-7. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)

Bit	Field	Value	Description
23-19	Reserved	0	Reads return 0. Writes have no effect.
18	CLR RX DMA ALL		Clear receive DMA all. This bit clears the receive DMA request for address frames when set. Only receive data frames generate a DMA request.
		0	*Read:* Receive DMA request for address frames is disabled; Instead, RX interrupt requests are enabled for address frames. Receive DMA requests are still enabled for data frames. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The receive DMA request for address and data frames is enabled. *Write:* The receive DMA request for address and data frames is disabled.
17	CLR RX DMA		Clear receive DMA request. This bit disables the receive DMA request when set.
		0	*Read:* The DMA request is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The receive DMA request is enabled. *Write:* The receive DMA request for is disabled.
16	CLR TX DMA		Clear transmit DMA request. This bit disables the transmit DMA request when set.
		0	*Read:* Transmit DMA request is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The transmit DMA request is enabled. *Write:* The transmit DMA request for is disabled.
15-10	Reserved	0	Reads return 0. Writes have no effect.
9	CLR RX INT		Clear receiver interrupt. This bit disables the receiver interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
8	CLR TX INT		Clear transmitter interrupt. This bit disables the transmitter interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	CLR WAKEUP INT		Clear wakeup interrupt. This bit disables the wakeup interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.
0	CLR BRKDT INT		Clear break detect interrupt. This bit disables the break-detect interrupt when set.
		0	*Read:* The interrupt is disabled. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* The interrupt is enabled. *Write:* The interrupt is disabled.

16.7.5 SCI Set Interrupt Level Register (SCISETINTLVL)

Figure 16-12 and Table 16-8 illustrate this register. This register is used to set the interrupt level for the supported interrupts.

LEGEND: R/W = Read/Write; R = Read only; WC = Write in sci-compatible mode only; -*n* = value after reset

Table 16-10. SCI Flags Register (SCIFLR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved		Reads return 0. Writes have no effect.
26	FE		Framing error flag. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt, if the SET FE INT bit (SCISETINT[26]) is set. The framing error flag is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 • Reception of a new character In multi-buffer mode, the frame is defined in the SCIFORMAT register.
		0	*Read:* No framing error has been detected since the last clear. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* A framing error has been detected since the last clear. *Write:* The bit is cleared to 0.

Table 16-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
25	OE		Overrun error flag. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD. Detection of an overrun error causes the SCI to generate an error interrupt if the SET OE INT bit (SCISETINT[25]) is set. The OE flag is reset by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No overrun error has been detected since the last clear. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* An overrun error has been detected since the last clear. *Write:* The bit is cleared to 0.
24	PE		Parity error flag. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the SCI to generate an error interrupt if the SET PE INT bit (SCISETINT[24]) is set. The PE bit is reset by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new character • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No parity error has been detected since the last clear. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* A parity error has been detected since the last clear. *Write:* The bit is cleared to 0.
23-13	Reserved	0	Reads return 0. Writes have no effect.
12	RXWAKE		Receiver wakeup detect flag. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RXWAKE is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Upon receipt of a data frame.
		0	The data in SCIRD is not an address.
		1	The data in SCIRD is an address.
11	TX EMPTY		Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty. **Note: The RESET bit, an active SW nRESET (SCIGCR1[7]) or a system reset sets this bit. This bit does not cause an interrupt request.**
		0	Transmitter buffer or shift register (or both) are loaded with data.
		1	Transmitter buffer and shift registers are both empty.

Table 16-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
10	TXWAKE		Transmitter wakeup method select. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. **Note: TXWAKE is not cleared by the SW nRESET bit.** *Address-bit mode*
		0	Frame to be transmitted will be data (address bit = 0).
		1	Frame to be transmitted will be an address (address bit = 1).
			Idle-line mode
		0	The frame to be transmitted will be data.
		1	The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).
9	RXRDY		Receiver ready flag. The receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU or DMA. The SCI generates a receive interrupt when RXRDY flag bit is set if the SET RX INT bit (SCISETINT[9]) is set; RXRDY is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the SCIRD register in compatibility mode • Reading the last data byte RDy of the response in SCI mode **Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.**
		0	*Read:* No new data is in SCIRD. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* New data is ready to be read from SCIRD. *Write:* The bit is cleared to 0.
8	TXRDY		Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer is ready to get another character from a CPU or DMA write. Writing data to SCITD automatically clears this bit. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the SET TX INT bit (SCISETINT[8]) is set. **Note: 1) TXRDY is also set to 1 by setting of the RESET bit, setting of the RESET bit, or by a system reset.** **2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.** **3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers SCITD0 and SCITD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1[25]).**
		0	SCITD is full.
		1	SCITD is ready to receive the next character.
7-4	Reserved	0	Reads return 0. Writes have no effect.

Table 16-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
3	BUSY		Bus busy flag. TThis bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI clears the BUSY bit. If the SET WAKEUP INT bit (SCISETINT[2]) is set and power down is requested while this bit is set, the SCI automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver, but this bit can also be cleared by the following: • Setting the SW nRST bit • Setting of the RESET bit • A system reset occurring
		0	The receiver is not currently receiving a frame.
		1	The receiver is currently receiving a frame.
2	IDLE		SCI receiver in idle state. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs: • A system reset • An SCI software reset • A power down • The RX pin is configured as a general I/O pin
		0	The idle period has been detected; the SCI is ready to receive.
		1	The idle period has not been detected; the SCI will not receive any data.
1	WAKEUP		Wakeup flag. This bit is set by the SCI when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISETINT[2]) is set. It is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 For compatibility mode, see the SCI document for more information on low-power mode.
		0	*Read:* The module will not wake up from power-down mode. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* Wake up from power-down mode. *Write:* The bit is cleared to 0.
0	BRKDT		SCI break-detect flag. This bit is set when the SCI detects a break condition on the SCIRX pin. A break condition occurs when the SCIRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit (SCISETINT[0]) is set. The BRKDT bit is reset by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No break condition has been detected since the last clear. *Write:* Writing a 0 to this bit has no effect.
		1	*Read:* A break condition has been detected. *Write:* The bit is cleared to 0.

Table 16-11. SCI Receiver Status Flags

SCI Flag	Register	Bit	Value After SW nRESET (1)
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with their reset value while SW nRESET = 0.

Table 16-12. SCI Transmitter Status Flags

SCI Flag	Register	Bit	Value After SW nRESET (1)
TX EMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with their reset value while SW nRESET = 0.

16.7.8 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

Figure 16-15 and Table 16-13 illustrate this register.

Figure 16-15. SCI Interrupt Vector Offset 0 (SCIINTVECT0) [offset = 20h]

31	16

R-0	

15	4	3	0
Reserved		INTVECT0	
R-0		R-0	

LEGEND: R = Read only; *-n* = value after reset

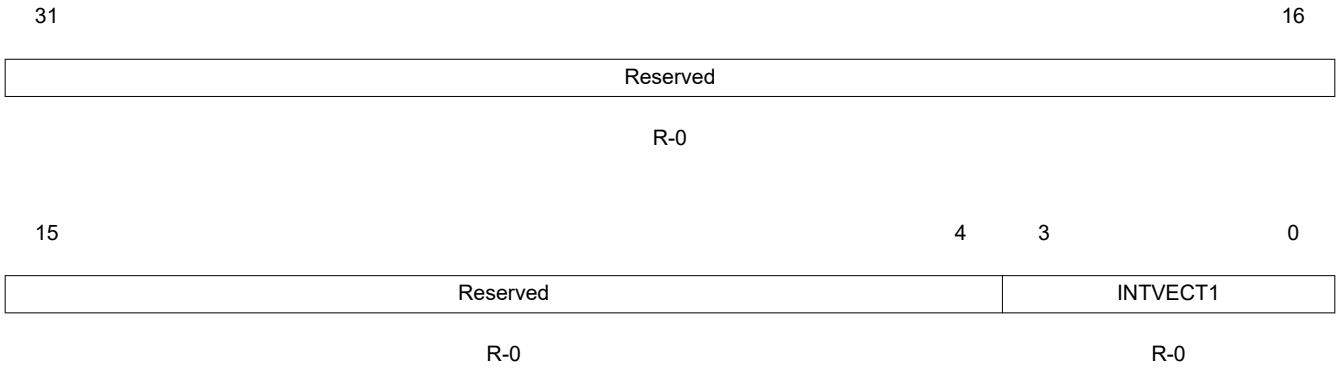
Table 16-13. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INVECT0	0-Fh	Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See for a list of the interrupts. **Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).**

16.7.9 SCI Interrupt Vector Offset 1 (SCIINTVECT1)

Figure 16-16 and Table 16-14 illustrate this register.

Figure 16-16. SCI Interrupt Vector Offset 1 (SCIINTVECT1) [offset = 24h]



LEGEND: R = Read only; -*n* = value after reset

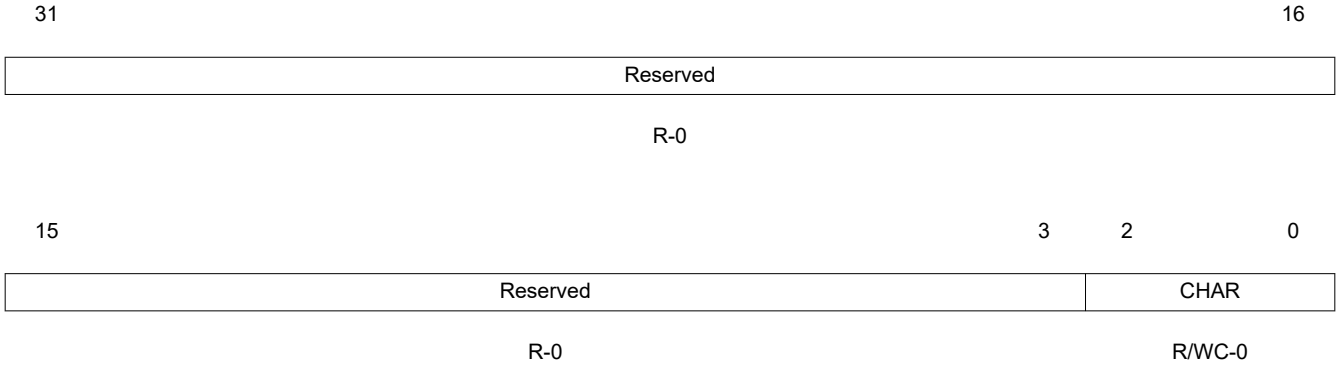
Table 16-14. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INVECT1	0-Fh	Interrupt vector offset for INT1. This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. **Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).**

16.7.10 SCI Format Control Register (SCIFORMAT)

Figure 16-17 and Table 16-15 illustrate this register.

Figure 16-17. SCI Format Control Register (SCIFORMAT) [offset = 28h]



LEGEND: R/W = Read/Write; R = Read only; WC = Write in SCI-compatible mode only; -*n* = value after reset

Table 16-15. SCI Format Control Register (SCIFORMAT) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	CHAR		Character length control bits. These bits set the SCI character length from 1 to 8 bits. **When data of fewer than eight bits in length is received, it is left-justified in SCIRD and padded with trailing zeros.** **Data read from the SCIRD should be shifted by software to make the received data right-justified.** **Data written to the SCITD should be right-justified but does not need to be padded with leading zeros.**
		0	The character is 1 bit long.
		1h	The character is 2 bits long.
		2h	The character is 3 bits long.
		3h	The character is 4 bits long.
		4h	The character is 5 bits long.
		5h	The character is 6 bits long.
		6h	The character is 7 bits long.
		7h	The character is 8 bits long.

16.7.11 Baud Rate Selection Register (BRS)

This section describes the baud rate selection register. Figure 16-18 and Table 16-16 illustrate this register.

Figure 16-18. Baud Rate Selection Register (BRS) [offset = 2Ch]

31	24	23	16
Reserved		BAUD	
R-0		R/W-0	

15	0
BAUD	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 16-16. Baud Rate Selection Register (BRS) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reads return 0. Writes have no effect.
23-0	BAUD	0-FF FFFFh	SCI 24-bit baud selection. The SCI has an internally-generated serial clock determined by the VCLK and the prescalers BAUD in this register. The SCI uses the 24-bit integer prescaler BAUD value of this register to select one of over 16,700,000. The baud rate can be calculated using the following formulas: $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{16(\text{Baud} + 1)}\right)$ (5) $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{\text{Baud} + 1}\right)$ (6) For BAUD = 0, $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{32}\right)$ (7) $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{2}\right)$ (8) Table 16-17 contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode.

Table 16-17. Comparative Baud Values (Asynchronous Mode) (1) (2)

24-Bit Register Value		Baud Selected		Percent Error
Decimal	Hex	Ideal	Actual	
26	00001A	115200	115740	0.47
53	000035	57600	57870	0.47
80	000050	38400	38580	0.47
162	0000A2	19200	19172	-0.15
299	00012B	10400	10417	0.16
325	000145	9600	9586	-0.15
399	00018F	7812.5	7812.5	0.00
650	00028A	4800	4800	0.00

Table 16-17. Comparative Baud Values (Asynchronous Mode) (1) (2) (continued)

24-Bit Register Value		Baud Selected		Percent Error
Decimal	Hex	Ideal	Actual	
15624	003BA0	200	200	0.00
624999	098967	5	5	0.00

(1) VCLK = 50 MHz
(2) Values are in decimal except for column 2.

16.7.12 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored.

16.7.12.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. Figure 16-19 and Table 16-18 illustrate this register.

Figure 16-19. Receiver Emulation Data Buffer (SCIED) [offset = 30h]

31	16
Reserved	
R-0	

15	8	7	0
Reserved		ED	
R-0		R-0	

LEGEND: R = Read only; *-n* = value after reset

Table 16-18. Receiver Emulation Data Buffer (SCIED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	ED	0-FFh	Emulator data. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag.

16.7.12.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. Figure 16-20 and Table 16-19 illustrate this register.

Note

When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left-justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

Figure 16-20. Receiver Data Buffer (SCIRD) [offset = 34h]

31	16
Reserved	

R-0

15	8	7	0
Reserved		RD	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 16-19. Receiver Data Buffer (SCIRD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	RD	0-FFh	Receiver data. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set. **Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.**

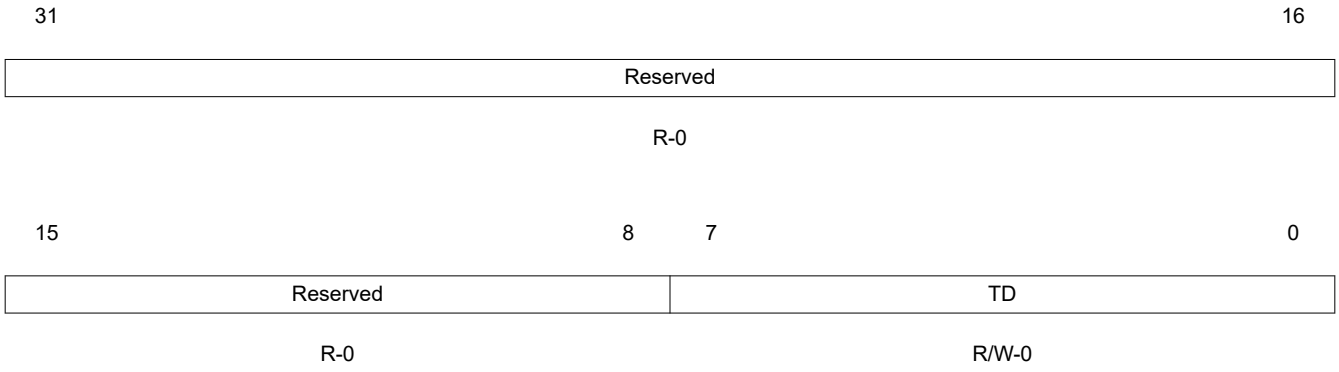
16.7.12.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. Figure 16-21 and Table 16-20 illustrate this register.

Note

Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

Figure 16-21. Transmit Data Buffer Register (SCITD) [offset = 38h]



LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

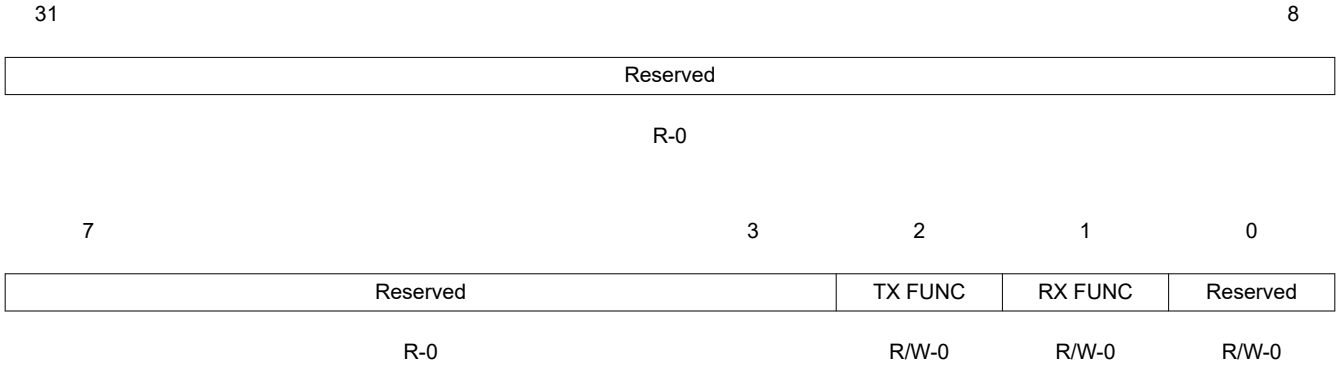
Table 16-20. Transmit Data Buffer Register (SCITD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TD	0-FFh	Transmit data. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag, which indicates that SCITD is ready to be loaded with another byte of data. **Note: If TX INT ENA is set, this data transfer also causes an interrupt.**

16.7.13 SCI Pin I/O Control Register 0 (SCIPIO0)

Figure 16-22 and Table 16-21 illustrate this register.

Figure 16-22. SCI Pin I/O Control Register 0 (SCIPIO0) [offset = 3Ch]



LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 16-21. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reads return 0. Writes have no effect.
2	TX FUNC		Transfer function. This bit defines the function of pin SCITX.
		0	SCITX is a general-purpose digital I/O pin.
		1	SCITX is the SCI transmit pin.
1	RX FUNC		Receive function. This bit defines the function of pin SCIRX.
		0	SCIRX is a general-purpose digital I/O pin.
		1	SCIRX is the SCI receive pin.
0	Reserved	0	Reads return 0. Writes have no effect.

16.7.14 SCI Pin I/O Control Register 1 (SCIPIO1)

Figure 16-23 and Table 16-22 illustrate this register.

31-27	Reserved	0	Reads return 0. Writes have no effect.
26	FEN		Frame error enable. This bit is used to create a frame error.
		0	No error is created.
		1	The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.
25	PEN		Parity error enable. This bit is used to create a parity error.
		0	No parity error occurs.
		1	The parity bit received is toggled so that a parity error occurs.
24	BRKD TENA		Break detect error enable. This bit is used to create a BRKDT error.
		0	No error is created.
		1	The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T_{BITS} so that a BRKDT error occurs.
32-21	Reserved	0	Reads return 0. Writes have no effect.

Table 16-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
20-19	PIN SAMPLE MASK		Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry.
		0	No mask is used.
		1h	Invert the TX Pin value at 7th.SCLK.
		2h	Invert the TX Pin value at 8th.SCLK.
		3h	Invert the TX Pin value at 9th.SCLK.
18-16	TX SHIFT		Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.
		0	No delay occurs.
		1h	The value is delayed by 1 SCLK.
		2h	The value is delayed by 2 SCLK.
		3h	The value is delayed by 3 SCLK.
		4h	The value is delayed by 4 SCLK.
		5h	The value is delayed by 5 SCLK.
		6h	The value is delayed by 6 SCLK.
		7h	No delay occurs.
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	IODFTENA		IODFT enable key. Write access permitted in Privilege mode only.
		Ah	IODFT is enabled.
		All Others	IODFT is disabled.
7-2	Reserved	0	Reads return 0. Writes have no effect.
1	LPBENA		Module loopback enable. Write access permitted in Privilege mode only. **Note: In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path.**
		0	Digital loopback is enabled.
		1	Analog loopback is enabled in module I/O DFT mode when IODFTENA = 1010.
0	RXPENA		Module analog loopback through receive pin enable. Write access permitted in Privilege mode only. This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode).
		0	Analog loopback through the transmit pin is enabled.
		1	Analog loopback through the receive pin is enabled.

16.8 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

16.8.1 GPIO Functionality

Figure 16-32 illustrates the GPIO functionality.

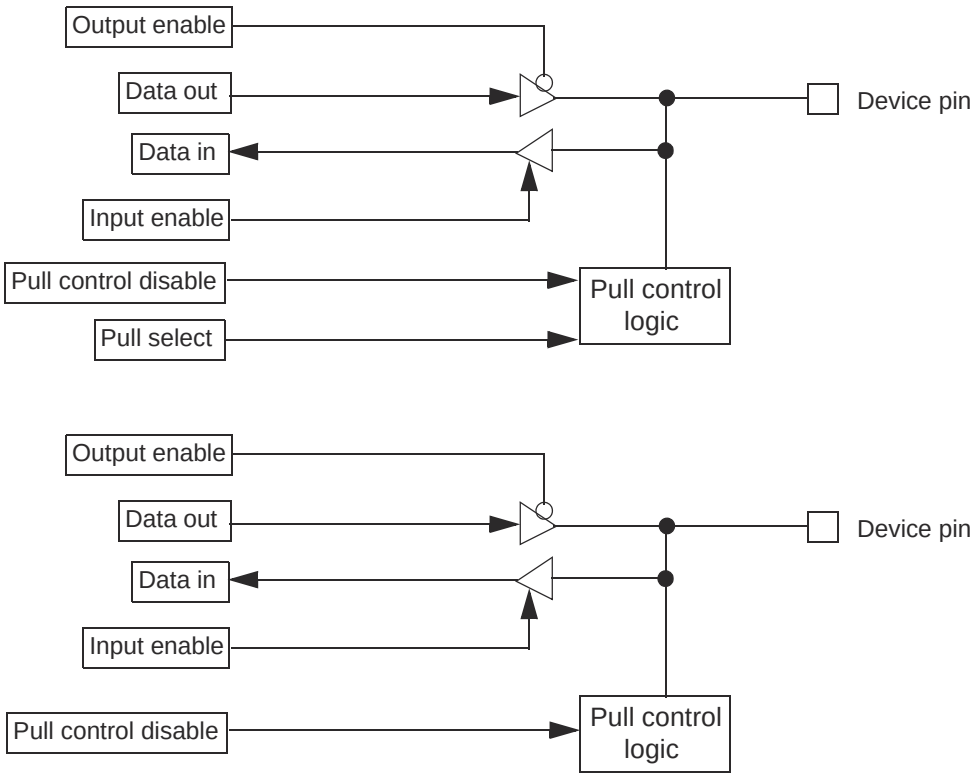

Figure 16-32. GPIO Functionality

16.8.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

16.8.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 16.7.20). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 16.7.21) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is always enabled in functional mode.

Note

The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically. If the pin is configured as input or receive, the pulls are enabled or disabled depending on bit PD in the pull disable register SCIPIO7 (Section 16.7.20).

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 16.7.14) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 16.7.19).

16.8.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled, if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low), if a high signal is being driven on to the pin.

Note

The open-drain feature is available only in I/O mode (SCIPIO0; Section 16.7.13).

16.8.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 16-33.

Table 16-33. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) (1) (2)	Pull Disable (PULDIS) (1) (3)	Pull Select (PULSEL) (1) (4)	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care
(2) DIR = 0 for input, = 1 for output
(3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control
(4) PULSEL= 0 for pull-down functionality
= 1 for pull-up functionality

Chapter 17

Inter-Integrated Circuit (I2C) Module

This chapter describes the inter-integrated circuit (I2C or I^2C) module. The I2C is a multi-slave communication module providing an interface between the Texas Instruments (TI) microcontroller and devices compliant with Philips Semiconductor I^2C-bus specification version 2.1 and connected by an I2C-bus. This module will support any master or slave I2C compatible device.

17.1 Overview

The I2C has the following features:

- Compliance to the Philips (now NXP Semiconductors) I^{2}C bus specification, v2.1 (*The I 2 C Specification,* Philips document number 9398 393 40011)
  - Bit/Byte format transfer
  - 7-bit and 10-bit device addressing modes
  - General call
  - START byte
  - Multi-controller transmitter/target receiver mode
  - Multi-controller receiver/target transmitter mode
  - Combined controller transmit/receive and receive/transmit mode
  - Transfer rates of 10 kbps up to 400 kbps (Fast mode transfer rate)
- Free data format
- Two DMA events (transmit and receive)
- DMA event enable/disable capability
- Seven interrupts that can be used by the CPU
- Operates with VBUS frequency from 6.7 MHz up
- Operates with module frequency between 6.7 MHz and 13.3 MHz
- Module enable/disable capability
- The SDA and SCL are optionally configurable as general purpose I/O
- Slew rate control of the outputs
- Open drain control of the outputs
- Programmable pullup/pulldown capability on the inputs
- Supports Ignore NACK mode

Note

This I2C module does **not** support:

- High-speed (HS) mode (only supports up to 400 kbps (Fast mode))
- C-bus compatibility mode
- The combined format in 10-bit address mode (the I2C sends the target address second byte every time it sends the target address first byte)

17.1.1 Introduction to the I2C Module

The I2C module supports any slave or master I2C-compatible device. Figure 17-1 shows an example of multiple I2C serial ports connected for a two-way transfer from one device to another device.

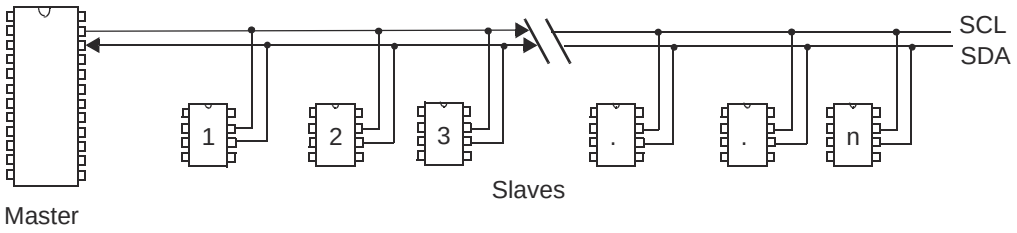

Figure 17-1. Multiple I2C Modules Connection Diagram

17.1.2 Functional Overview

The I2C module is a serial bus that supports multiple master devices. In multimaster mode, one or more devices can be connected to the same bus and are capable of controlling the bus. Each I2C device on the bus is recognized by a unique address and can operate as either a transmitter or a receiver, depending on the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered a master or a slave when performing data transfers.

Note

A master device is the device that initiates the data transfer on a bus and generates the clock signal that permits the transfer. During the transmission, any device addressed by the master is considered the slave.

Data is communicated to devices interfacing to the I2C module using the serial data pin (SDA) and the serial clock pin (SCL) as shown in Figure 17-2. These two wires carry information between the device and the other devices connected to the I2C bus. Both SDA and SCL pins on the device are bidirectional. They must be connected to a positive supply voltage through a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the wired-AND function.

The device has a special mode that can be entered to ignore a NACK generated from non-compliant I2C devices that are incapable of generating an ACK.

The I2C module consists of the following primary blocks:

- A serial Interface: one data pin (SDA) and one clock pin (SCL)
- The device register interface
  - Data registers to temporarily hold received data and transmitted data traveling between the SDA pin and the CPU or the DMA
  - Control and status registers
- A prescaler to divide down the input clock that is driven to the I2C module
- A peripheral bus interface to enable the CPU and DMA to access the I2C module registers
- An arbitrator to handle arbitration between the I2C module (when configured as a master) and another master
- Interrupt generation logic (interrupts can be sent to the CPU)
- A clock synchronizer that synchronizes the I2C input clock (from the system module) and the clock on the SCL pin, and synchronizes data transfers with masters of different clock speeds.
- A noise filter on each of the two serial pins
- DMA event generation logic that synchronizes data reception and data transmission in the I2C module for DMA transmission

In Figure 17-2, the CPU or the DMA writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

When the I2C function is not needed, the pins may be controlled as general-purpose input/output (GPIO) pins. The I/O structure of each pin includes:

- programmable slew rate control of the outputs
- open drain mode
- programmable pull enable/disable on the input
- programmable pull up/pull down function on the input

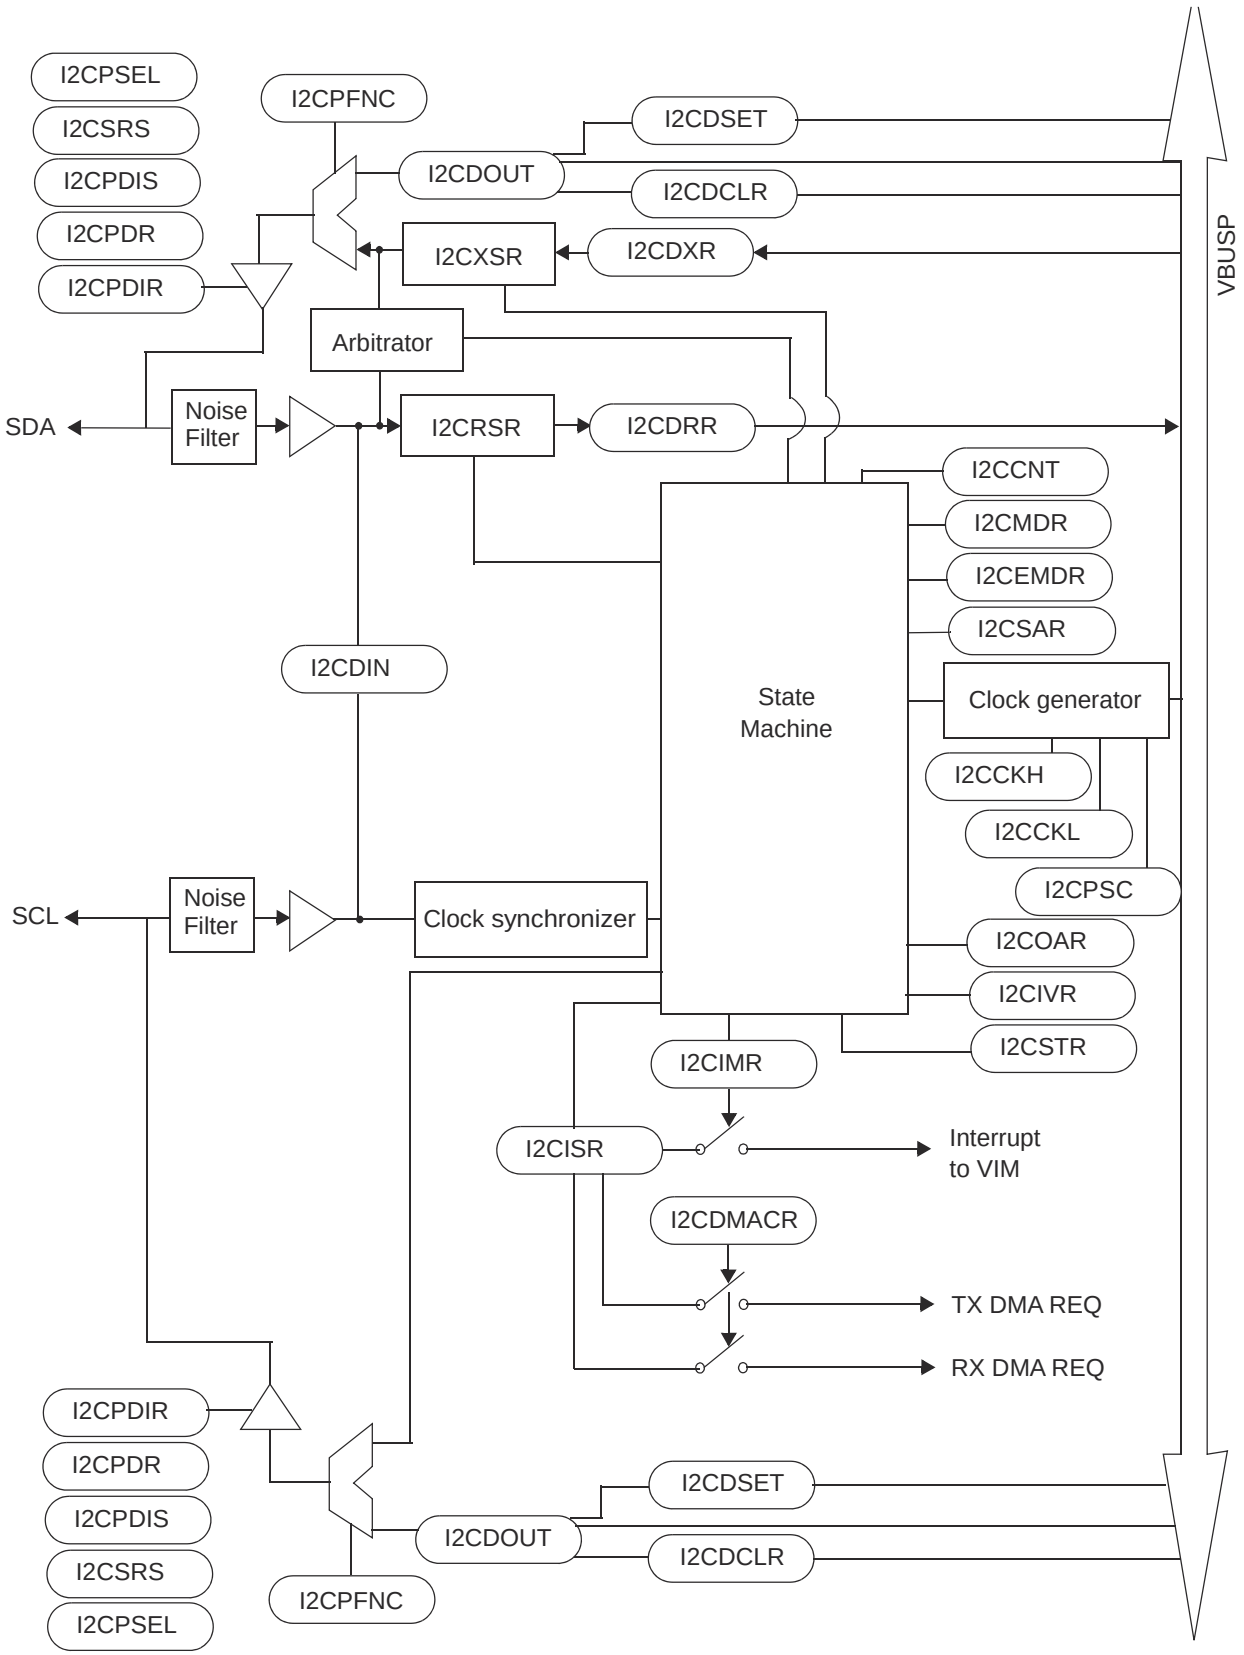

Figure 17-2. Simple I2C Block Diagram

17.1.3 Clock Generation

As shown in Figure 17-3, the I2C module uses the input clock generated from the device clock generator to generate the module clock and master clock. The I2C input clock is the device peripheral clock (VBUS_CLK). The clock is then divided twice more inside the I2C module to produce the module clock and the master clock.

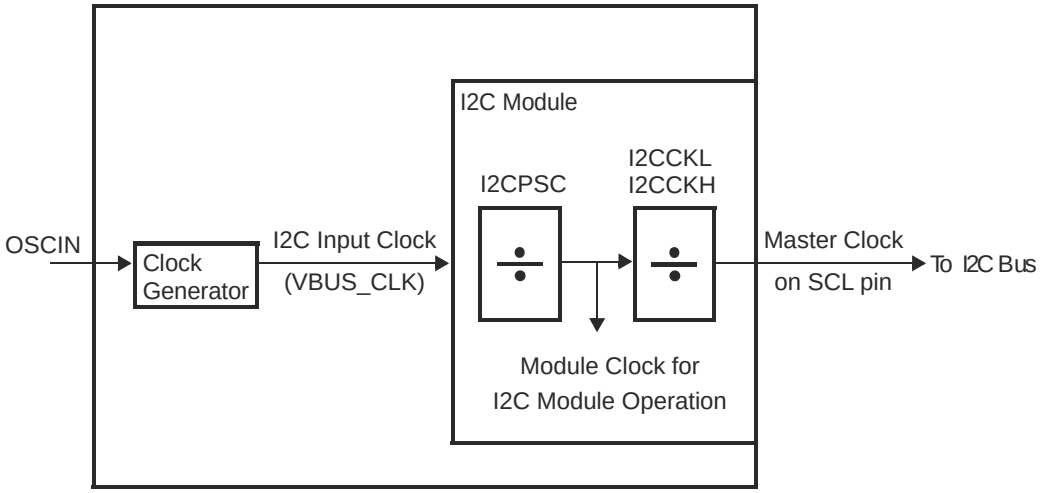

Figure 17-3. Clocking Diagram for the I2C Module

The module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the input clock to produce the module clock. To specify the divide-down value, initialize the I2CPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$ModuleClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)} \tag{9}$$

The module clock frequency must be between 6.7MHz and 13.3MHz. The prescaler can only be initialized while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the I2CPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of the communication between the I2C module and a slave. As shown in Figure 17-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the I2CCKL to divide down the low portion of the module clock signal and uses the I2CCKH to divide down the high portion of the module clock signal.

The resulting frequency is:

$$MasterClockFrequency = \frac{ModuleClockFrequency}{(I2CCKL + d) + (I2CCKH + d)} \tag{10}$$

$$MasterClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)((I2CCKL + d) + (I2CCKH + d))} \tag{11}$$

where *d* depends on the value of I2CPSC:

I2CPSC	d
0	7

I2CPSC	d
1	6
Greater than 1	5

Note

The master clock frequency defined above does not include rise/fall time and latency of the synchronizer inside the module. The actual transfer rate will be slower than the value calculated from the formula above. Also, due to the nature of SCL synchronization, the SCL clock period could change if SCL synchronization is taking place.

17.2 I2C Module Operation

The following section discusses how the I2C module operates.

17.2.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Because of a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{CCIO}. For details, see the device specific data sheet.

17.2.2 I2C Module Reset Conditions

The I2C module can be reset in the following two ways:

- Through the global peripheral reset. A device reset causes a global peripheral reset.
- By clearing the $\overline{IRS}$ bit in the I2C mode register (I2CMDR). When the global peripheral reset is removed, the $\overline{IRS}$ bit is cleared to 0, keeping the I2C module in the reset state.

17.2.3 I2C Module Data Validity

The data on the SDA must be stable during the high period of the clock. See Figure 17-4. The high and low state of the data line, the SDA, can only change when the clock signal is low.

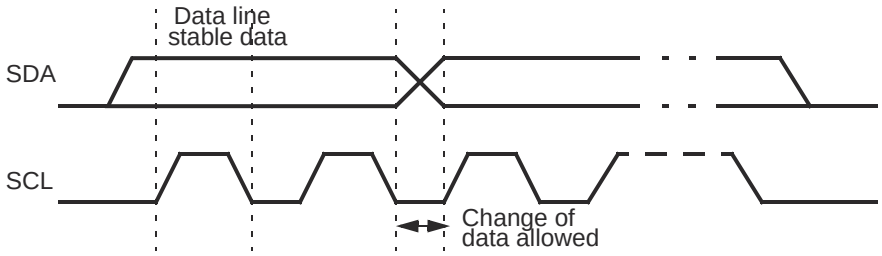

Figure 17-4. Bit Transfer on the I2C Bus

17.2.4 I2C Module Start and Stop Conditions

START and STOP conditions are generated by a master I2C module.

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of data transfer. The bus is considered to be busy after the START condition, and the bus busy bit (BB) in I2CSR is set to 1.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of data transfer. The bus is considered to be free after the STOP condition, therefore the BB bit in I2CSR is cleared to 0.

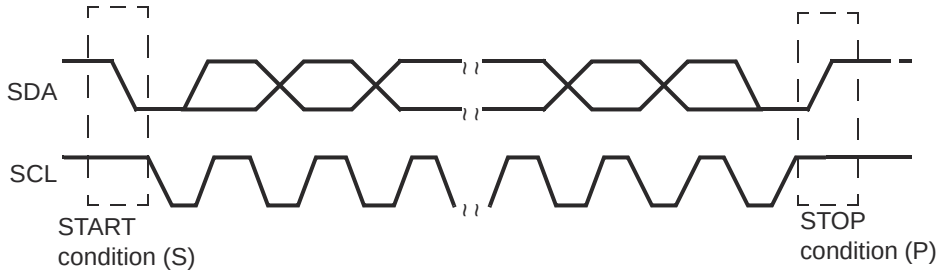

Figure 17-5. I2C Module START and STOP Conditions

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in the I2CMDR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated.

17.2.5 Serial Data Formats

The I2C module operates in byte data format. Each message put on the SDA line is 2 to 8-bits long. The number of messages that can be transmitted or received is unrestricted. The data is transferred with the most significant bit (MSB) first (Figure 17-6). Each message is followed by an acknowledge bit from the I2C if it is in receiver mode. The I2C module does not support little endian systems.

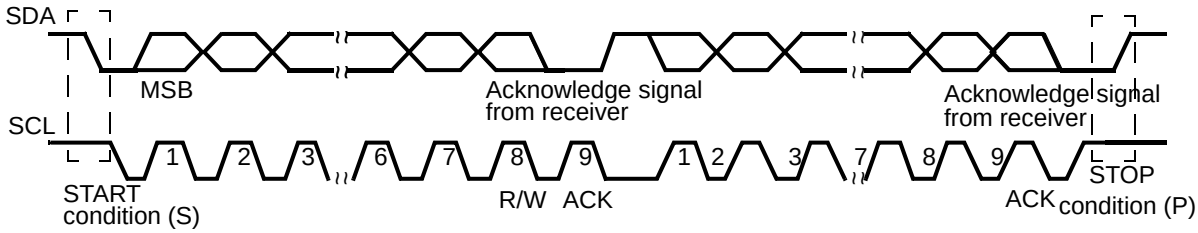

Figure 17-6. I2C Module Data Transfer

The first byte after a START condition (S) always consists of 8 bits that comprise either a 7-bit address plus the R/ $\overline{W}$ bit, or 8 data bits. The eighth bit, R/W, in the first byte determines the direction of the data. When the R/ $\overline{W}$ bit is 0, the master writes (transmits) data to a selected slave device; when the R/ $\overline{W}$ bit is 1, the master reads (receives) data from the slave device. In acknowledge mode, an extra bit dedicated for the acknowledgement (ACK) bit is inserted after each message.

The I2C module supports the following formats:

- 7-bit addressing format (Figure 17-7)
- 10-bit addressing format (Figure 17-8)
- 7-bit/10-bit addressing format with repeated START condition (Figure 17-9)
- Free-data format (Figure 17-10)

17.2.5.1 7-Bit Addressing Format

In the 7-bit addressing format (Figure 17-7), the first byte after the START condition consists of a 7-bit slave address followed by the R/ $\overline{W}$ bit (in the LSB). The R/ $\overline{W}$ bit determines the direction of the data transfer:

- R/ $\overline{W}$ = 0: The master writes (transmits) data to the addressed slave.
- R/ $\overline{W}$ = 1: The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgement (ACK) is inserted after each byte. If the ACK is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/ $\overline{W}$ bit). The device I2C allows n to be a number between 2 to 8, programmable by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

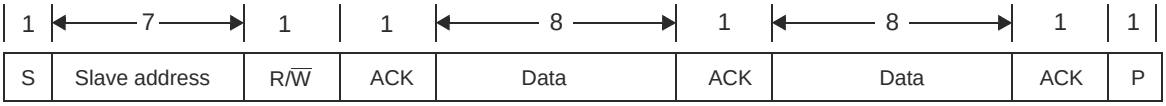

Figure 17-7. I2C Module 7-Bit Addressing Format

17.2.5.2 10-Bit Addressing Format

The 10-bit addressing format is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. In the 10-bit addressing format (Figure 17-8), the first byte is 11110b, the two MSBs of the 10-bit slave address, and the R/ $\overline{W}$ bit. The ACK bit is inserted after each byte. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send an acknowledgement after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use repeated a START condition to change the data direction.

To select the 10-bit addressing format, write 1 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

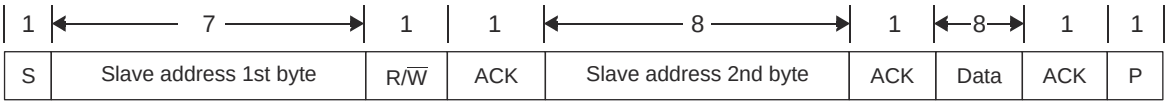

Figure 17-8. I2C Module 10-bit Addressing Format

17.2.5.3 Using the Repeated START Condition

At the end of each byte, the master can drive another START condition (Figure 17-9). Using this capability, a master can transmit/receive any number of data bytes before generating a STOP condition. The length of a data byte can be from 2 to 8 bits. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, or the free data formats.

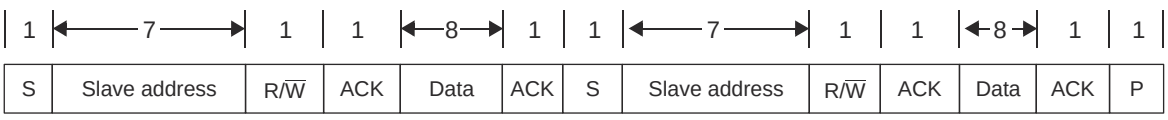

Figure 17-9. I2C Module 7-Bit Addressing Format with Repeated START

17.2.5.4 Free Data Format

In this format (Figure 17-10), the first byte after a START condition is a data byte. The ACK bit is inserted after each byte, followed by another 8 bits of data. No address or data direction bit is sent. Therefore, the transmitter and receiver must both support the free data format. The direction of data transmission (transmit or receive) remains constant throughout the transfer.

To select the free data format, write a 1 to the free data format (FDF) bit of the I2CMDR. The free data format is not supported in the digital loop back mode.

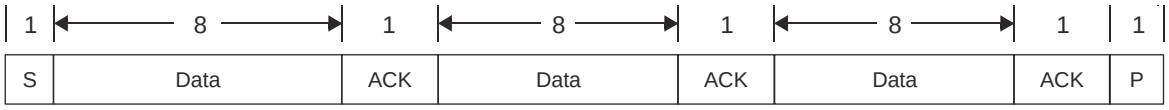

Figure 17-10. I2C Module in Free Data Format

17.2.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 17-1 summarizes the various ways a NACK can be generated.

Table 17-1. Ways to Generate a NACK Bit

I2C Module Condition	Basic NACK Bit Generation Options	Additional Option
Slave receiver mode	Disable data transfers (STT = 0) Allow an overrun condition (RSFULL = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode and repeat mode (RM = 1)	Generate a STOP condition (STP = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode with non-repeat mode (RM = 0)	If STP = 1, allow the internal data counter to count down to 0 and thus force a STOP condition. If STP = 0, make STP = 1 to generate a STOP condition. Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.

In some applications, the slave cannot generate the ACK signal. If the IGNACK bit is set in the I2CEMDR register, the resulting NACK will be ignored and the I2C block will continue the data transfer.

17.3 I2C Operation Modes

17.3.1 Master Transmitter Mode

All masters begin in this mode. The I2C module is a master and transmits control information and data to a slave. In this mode, data assembled in any of the addressing formats shown in Figure 17-7, Figure 17-8, or Figure 17-9 is shifted out onto the SDA pin and synchronized with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL pin is held low when the intervention of the device is required ($\overline{\text{XSMT}}$ = 0) after a byte has been transmitted.

Note

If the I2C is configured for two simultaneous master transmissions, wait until the MST and BB have been reset before performing the second master transmission.

Failure to wait for the MST and BB to reset will prevent the start condition on the second transfer from being issued and the bus BB will not be set. Typically the end of the first transfer is handled by polling BB. However, the MST bit is not reset at the same instant as the BB bit. As a result, when the second master transmission is initiated before the resetting of the MST, the MST bit for the second transfer is reset. This prevents the I2C from recognizing itself as the master, thus failing to occupy the bus.

17.3.2 Master Receiver Mode

In this mode, the I2C module is a master and receives data from a slave. This mode can only be entered from the master transmitter mode (the I2C module must first transmit a command to the slave). In any of the addressing formats shown in Figure 17-7, Figure 17-8, or Figure 17-9, the master receiver mode is entered after the slave address byte and the R/ $\overline{\text{W}}$ bit have been transmitted (if the R/ $\overline{\text{W}}$ bit is 1). Serial data bits received on the SDA pin are shifted in with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL is held low when the intervention of the device is required (RSFULL = 1) after a byte has been received. At the end of the transfer, the master-receiver signals the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter then releases the data line allowing the master-receiver to generate a STOP condition or a repeated START condition.

In many applications, the size of the message is in the initial bytes of the message itself. Since the size of the message is not known to the master before the transmission/reception starts, the master must use the repeat mode in order to force the stop condition when the reception is completed. The repeat mode is enabled by setting the RM bit to 1. Due to the double buffer implementation on the receive side, the master must generate the stop condition (STP =1) after reading the (message size - 1)th data.

17.3.3 Slave Transmitter Mode

In this mode, the I2C module is a slave and transmits data to a master. This mode can only be entered from the slave receiver mode (The I2C module must first receive a command from the master). In any of the addressing formats shown in Figure 17-7, Figure 17-8, or Figure 17-9, the slave transmitter mode is entered if the slave address byte is the same as its own address and the R/ $\overline{\text{W}}$ bit has been transmitted (if the R/ $\overline{\text{W}}$ bit is set to 1). The slave transmitter shifts the serial data out on the SDA pin with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low when intervention of the device is required ($\overline{\text{XSMT}}$ = 0) after a byte has been transmitted.

17.3.4 Slave Receiver Mode

In this mode, the I2C module is a slave and receives data from a master. All slaves begin in this mode. Serial data bits received on the SDA pin are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low while intervention of the device is required (RSFULL = 1) after a byte has been received.

17.3.5 Low Power Mode

The I2C module can be placed in low-power mode by a global low-power mode initiated by the system (by writing to the Peripheral Power-Down Set Register in the Peripheral Central Resource (PCR) module.

In effect, low-power mode shuts down all the clocks to the module. In global low-power mode, no registers are visible to the software; nothing can be written to or read from any register.

17.3.6 Free Run Mode

The I2C module can be placed in free run mode when the FREE bit (I2CMDR.14) is set to 1. This bit is primarily used on an emulator when encountering a breakpoint while debugging software. When the FREE bit is set to 0, the I2C responds differently depending on whether the SCL is high or low. If the SCL is low, the I2C stops immediately and keeps driving the SCL low whether the I2C is the master transmitter or receiver. If the SCL is high, the I2C waits until the SCL becomes a low and then stops. If the I2C is a slave, it stops when the transmission/reception completes.

17.3.7 Ignore NACK Mode

The I2C module can be placed in the ignore NACK mode by setting the IGNACK bit in the I2CEMDR register. This mode allows an I2C module that is configured as a master transmitter to ignore a NACK from a slave device that is not capable of generating a proper ACK signal.

17.4 I2C Module Integrity

The following section discusses how the I2C module maintains priorities and order among signals and commands.

17.4.1 Arbitration

If two or more master transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. Figure 17-11 illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on the SDA bus by the competing transmitters. The first master transmitter that generates a high is overruled by the other master that generates a low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that loses the arbitration switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt. The data transmitted by the other master module is salvaged, and the I2C continues to receive data from the master module. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If, during a serial transfer, the arbitration procedure is still in progress when a repeated START condition or STOP condition is transmitted to I2C bus, the master transmitters involved must send the repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Slaves are not involved in the arbitration procedure.

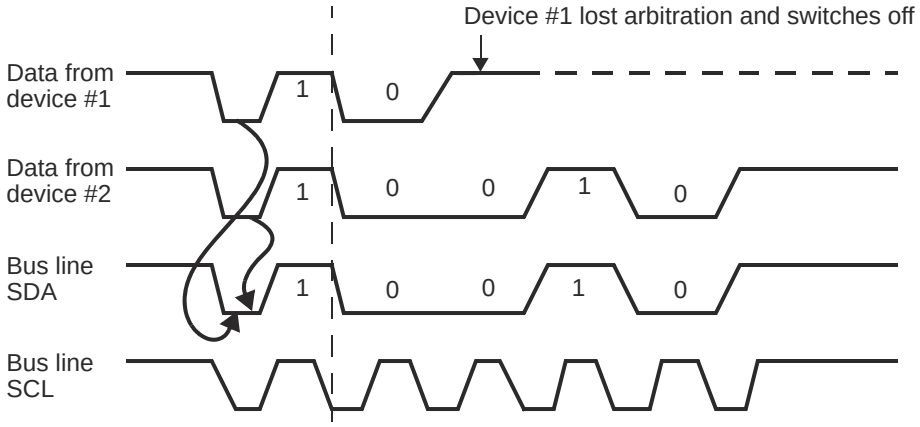

Figure 17-11. Arbitration Procedure Between Two Master Transmitters

17.4.2 I2C Clock Generation and Synchronization

Under normal conditions only one master device generates the clock signal; the SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. Figure 17-12 illustrates clock synchronization. The wired-AND property of the SCL line means that a device that first generates a low period on the SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL line is held low by the device with the longest low period. The other devices that finish their low periods must wait for the SCL line to be released before starting their high periods. A synchronized signal on the SCL is obtained where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

Note

I2C Protocol Fault

The following conditions violate the clock spec as defined in the Philips I^2C bus specification, v2.1 (*The I 2 C Specification,* Philips document number 9398 393 40011), and will result in an I2C protocol fault: I2CCLKH = 2 I2CCLKL = 2I2CPSC = 2. This will cause the SDA data transition to occur while the SCL is high.

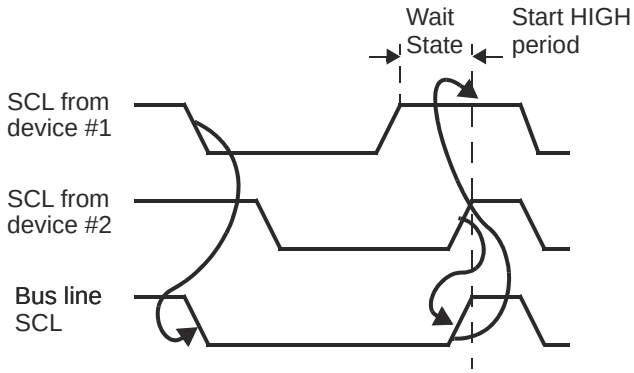

Figure 17-12. Synchronization of Two I2C Clock Generators During Arbitration

17.4.3 Prescaler

The I2C module is operated by the module clock. This clock is generated by way of the I2C prescaler block. The prescaler block consists of a 8-bit register, I2CPSC, used for dividing down the device peripheral clock (VBUS_CLK) to obtain a module clock between 6.7 MHz and 13.3 MHz.

17.4.4 Noise Filter

The noise filter is used to suppress any noises that are 50ns or less. It is designed to suppress noise with one module clock, assuming the lower and upper limits of the module clock are 6.7MHz and 13.3MHz, respectively.

17.5 Operational Information

The following section provides specific information about how the I2C module operates.

17.5.1 I2C Module Interrupts

The I2C module generates seven types of interrupts. These seven interrupts are accompanied with seven interrupt mask bits in the interrupt mask register (I2CIMR) and with seven interrupt flag bits in the status register (I2CSR).

17.5.1.1 I2C Interrupt Requests

The I2C module generates the interrupt requests described below. All requests are multiplexed through an arbiter into a single I2C interrupt request to the CPU. Each interrupt request has a flag bit and an enable bit. Interrupts must be enabled prior to the occurrence of the expected interrupt condition. When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the interrupt request is forwarded to the CPU as an I2C interrupt request. As an alternative, the CPU can poll all of the bits shown in Table 17-2.

Table 17-2. Interrupt Requests Generated by I2C Module

Flag	Name	Generated
AL	Arbitration-lost interrupt	Generated when the I2C module has lost an arbitration contest with another master-transmitter
NACK	No-acknowledge interrupt	Generated when the master I2C does not receive an acknowledge from the receiver
ARDY	Register-access-ready interrupt	Generated when the previously programmed address, data and command have been performed and the status bits have been updated. The interrupt is used to notify the device that the I2C registers are ready to be accessed.
RXRDY	Receive-data-ready interrupt	Generated when the received data in the receive-shift register (I2CSR) has been copied into the data receive register (I2CDRR). The RXRDY bit can also be polled by the device to determine when to read the received data in the I2CDRR.
TXRDY	Transmit-data-ready interrupt	Generated when the transmitted data has been copied from the data transmit register (I2CDXR) into the transmit-shift register (I2CXSR). The TXRDY bit can also be polled by the device to determine when to write the next data into I2CDXR.
SCD	Stop-condition-detect interrupt	Generated when a STOP condition has been detected.
AAS	Address-as-slave interrupt	Generated when the I2C has recognized its own slave address or an address of all zeroes.

17.5.2 DMA Controller Events

The I2C module has two events that use the DMA controller to synchronously read received data (I2CREVNT) from I2CDRR, and synchronously write data (I2CWEVNT) to the transmit buffer, I2CDXR. The read and write events have the same timing as I2CRRDY (I2CRINT) and I2CXRDY (I2CXINT), respectively.

The CPU or the DMA controller reads the received data from I2CDRR and writes the data to be transmitted to I2CDXR. The RXRDY bit is automatically cleared when the DMA controller reads the I2CDRR register, and the TXRDY bit is automatically cleared when the DMA controller writes to the I2CDXR register.

Data written to I2CDXR is copied to I2CXSR and shifted out from the SDA pin when the I2C module is configured as a transmitter. When the I2C module is configured as a receiver, received data is shifted into ICRSR and copied to I2CDRR, which can be read by the CPU or the DMA controller.

A transmit event (I2CWEVNT) is generated after a START condition in master transmitter mode. This ensures that the DMA gets an event even if no slave returns an ACK to the slave address following the START condition.

Note

Unexpected DMA transmit and receive event

An unexpected DMA transmit event (ICXEVT) and a DMA receive event (ICXRDY) are generated in 10-bit, master transmit, repeat mode. This event occurs soon after the start condition but before the first bit of the address is transmitted. In this event, no DMA activity should be initiated without the slave ACK being received.

17.5.3 I2C Enable/Disable

The I2C module can be enabled or disabled with the I2C reset enable bit (IRS) in the I2C module register (I2CMDR). This occurs in one of two ways:

- Write 0 to the I2C reset bit (IRS) in I2CMDR. All status bits are forced to the default values and the I2C mode remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high impedance state.
- Initiate a device reset by driving the $\overline{\text{PORRST}}$ pin low. The entire device is reset and is held in the reset state until the pin is released and is driven high. When $\overline{\text{PORRST}}$ is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until a 1 is written to the IRS bit.

IRS must be 0 while the I2C module is being configured. Forcing IRS to 0 can be used to save power and also clear error conditions.

17.5.4 General Purpose I/O

Both of the I2C pins can be programmed to be general-purpose I/O pins via the I2C pin control registers (I2CPFNC, I2CDIR, I2CDOUT, and I2CDIN).

When the I2C module is not used, the I2C pins may be programmed to be either general purpose input or general-purpose output pins. This function is controlled in the I2CDIR and I2CPFNC registers. Note that each pin can be programmed to be either an I2C pin or a GIO pin.

If the I2C function is to be used, the application software must ensure that each pin is configured as an I2C pin and not a GIO pin, or else unexpected behavior may result.

17.5.5 Pull Up/Pull Down Function

I2C module pins can have either an active pull up or active pull down that makes it possible to leave the pins unconnected externally. The pins can be programmed to have the active pull function enabled or disabled by writing to the corresponding bit in the I2CPDIS register. Please see the device-specific data sheet for the default internal pull (pull-up, pull-down or no pull) on the pins.

The pull on the pins is programmable to a setting other than the default internal pull as specified in the data sheet. The pins can be programmed to have either an active pull up or an active pull down function by writing to the corresponding bit in I2CPSEL register. The pull up/pull down function is active on the pin only when the pull enabled is programmed in the I2CPDIS register.

The pull up/pull down functions are deactivated when a bidirectional pin is configured as an output. At system reset, the pull up function of all the pins is enabled. Please see the device-specific data sheet for the current supplied by the pull up/pull down.

17.5.6 Open Drain Function

The I2C pins can be programmed to include an open drain function when they are configured as output pins. This is done by writing to the corresponding bit of the I2CPDR register. When the open drain function is enabled, a low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower), whereas a high value (1) written to the data output register forces the pin to a high-impedance state. The open drain function is disabled when the pin is configured as an input pin.

17.6 I2C Control Registers

Table 17-3 provides a summary of the control registers. The upper word (upper 16 bits) of the registers all read as 0s. Writes have no effect on these bits.

Table 17-3. I2C Control Registers

Offset	Acronym	Register Description	Section

17.6.1 I2C Own Address Manager (I2COAR)

The 16-bit memory-mapped I2C own address register is used to specify its own address. Figure 17-13 and Table 17-4 describe this register.

Figure 17-13. I2C Own Address Manager Register (I2COAR) [offset = 00]

15	10	9	0
Reserved		OA	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-4. I2C Own Address Manager Register (I2COAR) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	OA	0-3FFh	Own address These bits reflect the bus address of the I2C module. When the expand address (XA) bit I2CMDR.8 is set to 1, the I2C is in expand address mode (10-bit addressing mode). In either 7 or 10-bit address mode, all 10-bits are both readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. Table 17-5 provides the correct modes for these bits. Note that the user can program the I2C own address to any value as long as it does not conflict with other components in the system.

Table 17-5. Correct Mode for OA Bits

Bits Used	Mode	Value of XA
OA.6:0	7 Bit Addressing	0
OA.9:0	10 Bit Addressing	1

17.6.2 I2C Interrupt Mask Register (I2CIMR)

The 7-bit memory-mapped I2C interrupt mask register is used by the device to enable/disable the interrupts. Figure 17-14 and Table 17-6 describe this register.

Figure 17-14. I2C Interrupt Mask Register (I2CIMR) [offset = 04h]

Table 17-6. I2C Interrupt Mask Register (I2CIMR) Field Descriptions

Bit	Field	Value	Description
15-7	Reserved	0	Reads return 0. Writes have no effect.
6	AASEN		Address As Slave Interrupt Enable.
		0	AASEN interrupt is disabled.
		1	AASEN interrupt is enabled.
5	SCDEN		Stop Condition Interrupt Enable.
		0	SCDEN interrupt is disabled.
		1	SCDEN interrupt is enabled.
4	TXRDYEN		Transmit Data Ready Interrupt Enable.
		0	TXRDYEN interrupt is disabled.
		1	TXRDYEN interrupt is enabled.
3	RXRDYEN		Receive Data Ready Interrupt Enable.
		0	RXRDYEN interrupt is disabled.
		1	RXRDYEN interrupt is enabled.
2	ARDYEN		Register Access Ready Interrupt Enable.
		0	ARDYEN interrupt is disabled.
		1	ARDYEN interrupt is enabled.
1	NACKEN		No Acknowledgement Interrupt Enable.
		0	NACKEN interrupt is disabled.
		1	NACKEN interrupt is enabled.
0	ALEN		Arbitration Lost Interrupt Enable.
		0	ALEN interrupt is disabled.
		1	ALEN interrupt is enabled.

17.6.3 I2C Status Register (I2CSTR)

Figure 17-15 and Table 17-7 describe this register.

Figure 17-15. I2C Status Register (I2CSR) [offset = 08h]

15	14	13	12	11	10	9	8
Reserved	SDIR	NACKSNT	BB	RSFULL	XSMT	AAS	AD0

R-0		R/W1C-0	R/W-1	R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 17-7. I2C Status Register (I2CSTR) Field Descriptions

Bit	Field	Value	Description
15	Reserved	0	Reads return 0. Writes have no effect.
14	SDIR		Slave direction. Setting this bit to 1 indicates that the I2C slave is a transmitter. Clearing this bit to 0 indicates that the I2C is a master transmitter/receiver or a slave receiver. This bit is also cleared by the STOP or START conditions. In DLB mode (in which the configuration should be master-transmitter slave-receiver), this bit is cleared to 0. **Writing a 1 to this bit will clear it.**
		0	The I2C is a master transmitter/receiver or a slave receiver.
		1	The I2C is a slave transmitter.
13	NACKSNT		No acknowledge sent. This bit is set to 1 to indicate that a no acknowledgement (NACK) has been sent because the NACKMOD bit was set to 1. **Writing a 1 to this bit will clear it.**
		0	A NACK has not been sent.
		1	A NACK was sent because the NACKMOD was set to 1.
12	BB		Bus busy. This bit indicates the state of the serial bus. On reception of a START condition or if the I2C detects a low state on I2CSCL, the device sets BB = 1. If the nIRS is set to 1 during transaction between other I2C devices, the BB bit is set at the first falling edge of SCL or START condition. BB is cleared to 0 after the reception of a STOP condition. BB is kept to 0 regardless of the SCL state when the I2C is in reset (nIRS = 0).
		0	The bus is free.
		1	The bus is busy.

Table 17-7. I2C Status Register (I2CSTR) Field Descriptions (continued)

Bit	Field	Value	Description
11	RSFULL		Receiver shift full. This bit is set to 1 to indicate that the receiver has experienced overrun. Overrun occurs when the receive shift register is full and I2CDRR has not been read since the receive shift register to I2CDRR transfer. The contents of I2CDRR are not lost. The I2C core logic is holding for I2CDRR read access. This bit is also set when, in master-repeat-mode, the I2C receives a byte of data. There is no difference between RXRDY and RSFULL in this case. The I2C master will not continue the transfer as long as the received data is in the I2CDRR or receive shift register. **RSFULL is cleared when reading the I2CDRR, resetting the I2C (nIRS = 0), or resetting the device.**
		0	No overrun has occurred.
		1	An overrun has occurred.
10	XSMT		Transmit shift empty. This bit is cleared to 0 to indicate that the transmitter has experienced underflow. Underflow occurs when the transmit shift register is empty and I2CDXR has not been loaded since the last I2CDXR to transmit shift register transfer. The I2C core logic is waiting for I2CDXR write access. **XSMT is set to 1 as a result of writing to I2CDXR, by resetting the I2C block (nIRS = 0), or by resetting the device.** In repeat mode, if the I2C in master transmitter mode is holding transfer with $\overline{\text{XSMT}}$ = 0 (that is, waiting for further action) and the STT or STP bit is set, XSMT is set to 1 by hardware.
		0	An underflow has occurred.
		1	No underflow has occurred.
9	AAS		Address as slave. **This bit cannot be cleared by writing a 1 to the bit or by reading the I2CIVR register.**
		0	This bit is cleared by a STOP condition or detection of any address byte that does not match I2COAR.
		1	This bit is set to 1 by the device when it has recognized its own slave address or an address of all zeros (general call).
8	AD0		Address zero status.
		0	A START or STOP condition was detected. No general call was detected.
		1	An address of all zeros (general call) was detected.
7-6	Reserved	0	Reads return 0. Writes have no effect.
5	SCD		Stop condition detect interrupt flag. This bit is set to 1 when the I2C receives or sends a STOP condition. **This bit is cleared to 0 by writing a 1 to this bit or reading the value 0x0006 from I2CIVR. Writing a 1 to this bit will clear the value 0x0006 from I2CIVR.**
		0	No STOP condition has been sent or received.
		1	A STOP condition has been sent or received.
4	TXRDY		Transmit data ready interrupt flag. This bit is set to 1 to indicate when data in the transmit data register, I2CDXR, has been copied into the transmit shift register. This bit can also be polled by the device to indicate when to write the next transmitted data into the I2CDXR. **Writing a 1 to this bit will set it.** **This bit is cleared to 0 and code 0x0005 in I2CIVR is cleared when the I2CDXR is written. This bit cannot be cleared by reading the I2CIVR register.**
		0	I2CDXR contains data to transmit.
		1	I2CDXR is empty.

Table 17-7. I2C Status Register (I2CSTR) Field Descriptions (continued)

Bit	Field	Value	Description
3	RXRDY		Receive data ready interrupt flag. This bit is set to 1 to indicate when the data in the receive shift register has been copied into the data receive register (I2CDRR). This bit can also be polled by the device to indicate when to read the received data in the I2CDRR. **Writing a 1 to this bit or reading from I2CDRR will clear this bit, and will also clear code 0x0004 from I2CIVR. This bit cannot be cleared by reading the I2CIVR register.**
		0	The I2CDRR has been read.
		1	The received data has been written into the I2CDRR.
2	ARDY		Register access ready interrupt flag. This bit is set to 1 when the previously programmed address, data and command has been performed and the status bit has been updated. The flag is used by the device to indicate that the I2C registers are ready to be accessed again. **This bit is automatically cleared by hardware when writing data to I2CDXR in transmit mode, reading data from I2CDRR in receive mode, or setting STT or STP bit. Writing a 1 to this bit will clear this bit. This bit cannot be cleared by reading the I2CIVR register.** When RM = 0, ARDY is set when I2CCNT is passed 0 if STP register bit has not been set. When RM = 1, ARDY is set at each byte end. When FDF = 0, ARDY is asserted after the ACK for the slave address. When FDF = 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition.
		0	*Nonrepeat mode, (RM = 0):* I2C registers are not ready to be accessed. *Repeat mode (RM = 1):* I2C registers are not ready to be accessed.
		1	*Nonrepeat mode, (RM = 0):* ICCNT passes 0 (if STP bit has not been set). *Repeat mode (RM = 1)*: The end of each byte was transmitted from I2CDXR.
1	NACK		No acknowledgement interrupt. This bit is set to 1 when the master I2C does not receive an acknowledgement from the receiver. This bit is set only when the I2C has received a no-acknowledge in master mode. This bit is NOT set by no-acknowledgement after Start byte. In master start byte mode, the first byte (address of all zeroes) receives a NACK but does not clear the stop bit. **Writing a 1 to this bit or reading the value 0x0002 from I2CIVR will clear this bit.**
		0	An acknowledge was detected.
		1	No acknowledge was detected or the I2C is operating in the general call, even though an acknowledgement was received. This value clears the STP bit.
0	AL		Arbitration lost interrupt flag. This bit is set to 1 when arbitration has been lost. **Writing a 1 to this bit or reading the value 0x0001 from I2CIVR will clear this bit.**
		0	No loss of arbitration has been detected.
		1	The device in the master transmitter mode senses it has lost an arbitration. This occurs when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB=1. When this is set to 1 due to arbitration lost, the device becomes a slave receiver and the MST, STT and STP bits in I2CMDR are cleared to 0.

17.6.4 I2C Clock Divider Low Register (I2CCKL)

The I2C clock divider low register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock low time. Figure 17-16 and Table 17-8 describe this register.

Figure 17-16. I2C Clock Divider Low Register (I2CCKL) [offset = 0Ch]

CLKL	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 17-8. I2C Clock Divider Low Register (I2CCKL) Field Descriptions

Bit	Field	Description
15-0	CLKL	Low time clock division factor. Used to divide down the module clock to create the low-time portion of the master clock signal that will appear on the SCL pin: $LowTime = \left(\frac{I2CCLKL + d}{ModuleClockFrequency} \right)$ (12) where *d* is the value that depends on the I2CPSC This register must be configured while the I2C is still in reset (nIRS = 0).

17.6.5 I2C Clock Control High Register (I2CCKH)

The I2C clock divider high register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock high time. Figure 17-17 and Table 17-9 describe this register.

Figure 17-17. I2C Clock Control High Register (I2CCKH) [offset = 10h]

CLKH	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 17-9. I2C Clock Control High Register (I2CCKH) Field Descriptions

Bit	Field	Description
15-0	CLKH	High time clock division factor. Used to divide down the module clock to create the high-time portion of the master clock signal that will appear on the SCL pin: $HighTime = \left(\frac{I2CCLKH + d}{ModuleClockFrequency} \right)$ (13) where *d* is the value that depends on the I2CPSC This register must be configured while the I2C is still in reset (nIRS = 0).

17.6.6 I2C Data Count Register (I2CCNT)

The I2C data count register is a 16-bit memory-mapped register used to count received or transmitted data bytes. This register is also used to generate the STOP condition that terminates the transfer after the counter reaches zero. Figure 17-18 and Table 17-10 describe this register.

Figure 17-18. I2C Data Count Register (I2CCNT) [offset = 14h]

15	0
CNT	
R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 17-10. I2C Data Count Register (I2CCNT) Field Descriptions

Bit	Field	Value	Description
15-0	CNT		Data counter. This down counter is used to generate a stop condition if a stop condition is specified (STP = 1). **Note: ICCNT is a don't care when RM is set to 1.**
		0	The data counter is 65536.
		1	The data counter is 1.

17.6.7 I2C Data Receive Register (I2CDRR)

The I2C data receive register is a 16-bit memory-mapped register used by the device to read the received data. Figure 17-19 and Table 17-11 describe this register.

Figure 17-19. I2C Data Receive Register (I2CDRR) [offset = 18h]

15	8	7	0
Reserved		DATARX	
R-0		R-0	

LEGEND: R = Read only; *-n* = value after reset

Table 17-11. I2C Data Receive Register (I2CDRR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	DATARX	0-FFh	Receive data. A read from this register clears the RXRDY bit and clears code 4h from the I2CIVR register.

17.6.8 I2C Slave Address Register (I2CSAR)

The I2C slave address register is a 16-bit memory-mapped register used to specify the address of the slave device to communicate to on the I2C bus. Figure 17-20 and Table 17-12 describe this register.

Figure 17-20. I2C Slave Address Register (I2CSAR) [offset = 1Ch]

15	10	9	0
Reserved		SA	
R-0		R/W-3FFh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-12. I2C Slave Address Register (I2CSAR) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reads return 0. Writes have no effect.
9-0	SA		7- or 10-bit programmable slave address. In either mode, all 10-bits are readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. Table 17-13 illustrates the correct mode for each bit.

Table 17-13. Correct Mode for SA Bits

Bits Used	Mode	Value of XA
SA(6–0)	7-bit addressing	0
SA(9–0)	10-bit addressing	1

17.6.9 I2C Data Transmit Register (I2CDXR)

Figure 17-21 and Table 17-14 describe this register.

Figure 17-21. I2C Data Transmit Register (I2CDXR) [offset = 20h]

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 17-15. I2C Mode Register (I2CMDR) Field Descriptions

Bit	Field	Value	Description
15	NACKMOD		No-acknowledge (NACK) mode. This bit is used to send an acknowledge (ACK) or a no-acknowledge (NACK) to the transmitter. This bit is only applicable when the I2C is in receiver mode. In master receiver mode, when the internal data counter decrements to 0, the I2C sends a NACK. The master receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is 1. The NACKMOD bit should be set before the rising edge of the last data bit if a NACK must be sent, and this bit is cleared once a NACK has been sent.
		0	The I2C sends an ACK to the transmitter during the acknowledge cycle.
		1	The I2C sends a NACK to the transmitter during the acknowledge cycle.
14	FREE		Free running bit. This bit is used to determine the state of the I2C when a breakpoint is encountered in the high level language (HLL) debugger.
		0	The I2C stops immediately if SCL is low and keeps driving SCL low if the I2C master is a transmitter/receiver. If SCL is high, I2C waits until SCL becomes low and then stops. If the I2C is a slave, it will stop when the transmission/reception completes.
		1	The I2C runs free.
13	STT		Start condition. The start condition bit works with the STP bit (master only mode). The STT and STP bits are configured to generate different transfer formats (see Table 17-16). The STT and STP bits can be used to terminate the repeat mode. This bit takes one I2C module clock cycle to set.
		0	STT is reset to 0 by the hardware after the START condition has been generated.
		1	STT is set to 1 by the device to generate a START condition. In master mode, setting STT to 1 generates a START condition.
12	Reserved	0	Reads return 0. Writes have no effect.
11	STP		Stop condition (Master mode only). This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when ICCNT passes 0 when the I2C is in non-repeat mode (RM=0). In repeat mode (RM=1), the stop condition is generated if STP bit is 1. In transmitter mode, I2CTXRDY needs to be 1 (that is, you have to set STP bit unless you write data into I2CDXR).
		0	STP is reset to 0 by the hardware after the STOP condition has been generated.
		1	STP is set to 1 by the device to generate a STOP condition.

Table 17-15. I2C Mode Register (I2CMDR) Field Descriptions (continued)

Bit	Field	Value	Description
10	MST		Master/slave mode bit. This bit determines whether the module will operate in master or slave mode; see Table 17-17. This bit is cleared after generating a STOP condition. The BB bit is cleared first, and MST bit is cleared second. Before starting the next transaction in master mode, this bit must be confirmed to be cleared.
		0	The module is in the slave mode and the clock is received from the master device.
		1	The module is in the master mode and it generates the clock. This bit is cleared when the transfer has completed.
9	TRX		Transmit/receive bit. This bit determines the direction of data transmission of the I2C module. See Table 17-17.
		0	The module is in the receive mode and data on the SDA line is shifted into the data register I2CDRR.
		1	The module is in the transmit mode and the data in the I2CDXR is shifted out on the SDA line.
8	XA		Expand address enable bit. This bit controls the addressing mode. When XA is set to 1, the I2C does not support the combined format in master mode operations. However, the I2C will acknowledge and support the formats when configured as a slave. This bit needs to be configured even if the I2C is in slave mode.
		0	The mode is set to 7-bit addressing mode (normal address mode).
		1	The mode is set to 10-bit addressing mode (expanded address mode).
7	RM		Repeat mode enable bit (Master mode only). This bit is a ‘don’t care’ if the module is configured in slave mode (MST = 0); see Table 17-16. Each time a byte of data is received, the user should decide whether or not to continue receiving more data. See Figure 17-23 for a diagram of this function.
		0	The mode is not in repeat mode.
		1	In repeat mode, data is continuously transmitted out of the ICDXR or received into the ICDRR until the STP bit is set to 1 regardless of ICCNT value. See Table 17-16 for module conditions.
6	DLB		Digital loop back enable bit. This bit enables the digital loopback mode of the I2C. This bit only applies in Master transmitter mode.
		0	Digital loop back mode is disabled.
		1	Digital loop back mode is enabled. In digital loop back mode, data transmitted out of the I2CDXR will be received in the I2CDRR. The address of the I2COAR is output on SDA.
5	nIRS		I2C reset enable bit. When cleared to 0, this bit will place all status registers in this module to their default state. Resetting nIRS during a data transfer can hang the I2C bus.
		0	I2C is in reset.
		1	I2C is out of reset.
4	STB		Start byte mode enable bit (Master mode only). The Start byte mode bit is set to 1 by the CPU to configure the I2C in Start byte mode. The I2C sends 00000001 regardless of the I2CSAR value. Refer to the Philips I2C specification for more details.
		0	The module is not in START byte mode.
		1	The module is in START byte mode.
3	FDF		Free data format enable bit. This bit configures the module to operate in free data format mode (see Table 17-17) in both master and slave modes. When FDF is 0, ARDY is asserted after ACK for the slave address. When FDF is 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition. FDF mode is not supported in digital loop back mode.
		0	The module is not in free data format mode.
		1	The module is in free data format mode.

Table 17-15. I2C Mode Register (I2CMDR) Field Descriptions (continued)

Bit	Field	Value	Description
2-0	BC		Bit count. This bit defines the number of bits starting from the LSB (excluding the acknowledge bit) that are sent on the bus when data is written to the data transmit register. If the bits BC0, BC1, and BC2 are all 0, then the number of bits sent on the bus is 8. If the bit count bits are a non-zero value, then the number of bits sent on the bus is that value. The value 001 is reserved. When performing a transfer using the bit count of, for example, n (where n is nonzero), only the n least significant bits in the data receive register are valid and correct. The rest of the bits should be disregarded. See Table 17-18 for more information.

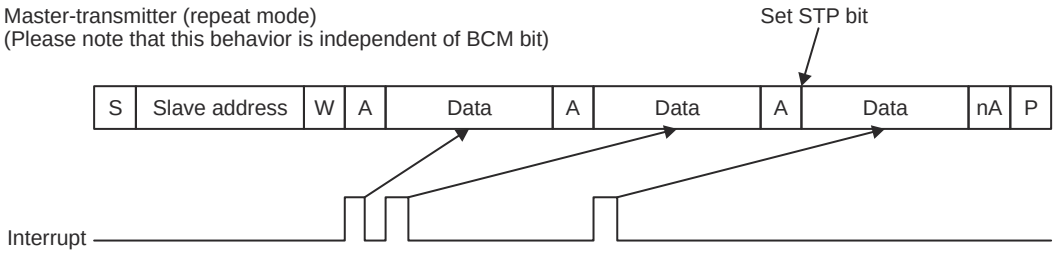

Figure 17-23. Typical Timing Diagram of Repeat Mode

Table 17-16. I2C Module Condition, Bus Activity, and Mode

RM	STT	STP	Condition	Bus Activities (1)	Mode
0	0	0	Idle	None	N/A
0	0	1	Stop	P	N/A
0	1	0	(Repeat) Start	S-A-D..(n)..D	Repeat n
0	1	1	(Repeat) Start-Stop	S-A-D..(n)..D-P	Repeat n
1	0	0	Idle	None	N/A
1	0	1	Stop	P	N/A
1	1	0	(Repeat) Start	S-A-D-D-D-....	Continuous
1	1	1	Reserved	None	N/A

(1) P = Stop condition; S = Start condition; A = Acknowledge bit; D = data

Table 17-17. I2C Module Operating Modes

FDF	MST	TRX	Operating Mode
0	0	x	Slave in non-FDF mode
0	1	0	Master receive in non-FDF mode
0	1	1	Master transmit in non-FDF mode
1	0	0	Slave receive in FDF mode
1	0	1	Slave transmit in FDF mode
1	1	0	Master receive in FDF mode
1	1	1	Master transmit in FDF mode

Table 17-18. Number of Bits Sent on Bus

BC2	BC1	BC0	Bits in FDF	Bits with ACK
0	0	0	8	9
0	0	1	NA (reserved)	NA (reserved)
0	1	0	2	3

Table 17-18. Number of Bits Sent on Bus (continued)

BC2	BC1	BC0	Bits in FDF	Bits with ACK
0	1	1	3	4
1	0	0	4	5
1	0	1	5	6
1	1	0	6	7
1	1	1	7	8

17.6.11 I2C Interrupt Vector Register (I2CIVR)

The I2C interrupt vector register is a 16-bit memory-mapped register used to indicate the occurrence of an interrupt. Figure 17-24 and Table 17-19 describe this register.

Figure 17-24. I2C Interrupt Vector Register (I2CIVR) [offset = 28h]

15 12	11 8	7 3	2 0
Reserved	TESTMD	Reserved	INTCODE
R-0	R/W-0	R-0	R/WC-0

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -*n* = value after reset

Table 17-19. I2C Interrupt Vector Register (I2CIVR) Field Descriptions

Bit	Field	Value	Description
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	TESTMD	0-3h	Reserved for internal testing.
7-3	Reserved	0	Reads return 0. Writes have no effect.
2-0	INTCODE	0-3h	Interrupt Code Bits. This binary coded interrupt vector indicates which interrupt has occurred. If there is more than one interrupt pending, reading I2CIVR provides the vector for the highest priority interrupt that is pending. Reading the I2CIVR will clear the corresponding flags in I2CSTR for AL, NACK and SCD as long as those interrupts are enabled. A new interrupt will be generated for each pending source. Reading I2CIVR will clear the INTCODE for AL, NACK, SCD, AAS, RXRDY and TXRDY. Reading I2CIVR **will not** clear the INTCODE for ARDY. The INTCODE for certains codes can also be cleared by either writing a 1 to the corresponding interrupt flag bits in I2CSTR, or by reading and writing to the receive or transmit registers. See Section 17.6.3 for more details. Users must read (clear) the I2CIVR before doing another start otherwise the I2CIVR could contain incorrect (old interrupt flag) value.

Table 17-20. Interrupt Codes for INTCODE Bits

Code	INTCODE(2-0)	Interrupt Occurred
00h	000	None
01h	001 (highest priority)	Arbitration lost (AL)
02h	010	No acknowledgement (NACK)
03h	011	Receive access ready (ARDY)
04h	100	Receive data ready (RXRDY)
05h	101	Transmit data ready (TXRDY)
06h	110	Stop condition detection (SCD)

Table 17-20. Interrupt Codes for INTCODE Bits (continued)

Code	INTCODE(2-0)	Interrupt Occurred
07h	111 (lowest priority)	Address as slave (AAS)

17.6.12 I2C Extended Mode Register (I2CEMDR)

The I2C extended mode register is a 16-bit memory-mapped register that contains additional mode select bits. Figure 17-25 and Table 17-21 describe this register.

Figure 17-25. I2C Extended Mode Register (I2CEMDR) [offset = 2Ch]

15	2	1	0
Reserved		IGNACK	BCM
R-0		R/W-0	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-21. I2C Extended Mode Register (I2CEMDR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	IGNACK		Ignore NACK mode.
		0	The master transmitter will operate normally, discontinue the data transfer, and set the ARDY and NACK status bits when a NACK signal is received from the slave.
		1	The master transmitter will ignore a NACK received from the slave.
0	BCM		Backwards compatibility mode. When set to 1, the I2C is compatible with previous versions of the I2C. This means the TXRDY interrupt is generated in slave-transmit mode when TXRDY is set and the I2C needs more data to transmit. This behavior causes an extra TXRDY interrupt to be generated because the I2C recognizes the end of transfer after generating an interrupt for the next byte of data. When BCM is 0, the TXRDY interrupt in slave-transmit mode is generated when XSMT = 1. In this case, the I2C generates an interrupt for the next byte after receiving the ACK from previous data. The setting of this bit only applies to slave transmit mode.
		0	The I2C is not in compatibility mode.
		1	The I2C is in compatibility mode.

17.6.13 I2C Prescale Register (I2CPSC)

The I2C prescaler register is a 16-bit memory-mapped register used for dividing down the VBUS_CLK to obtain a module clock frequency between 6.7 MHz and 13.3 MHz. Figure 17-26 and Table 17-22 describe this register.

Figure 17-26. I2C Prescale Register (I2CPSC) [offset = 30h]

15	8	7	0
Reserved		PSC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-22. I2C Prescale Register (I2CPSC) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	PSC	0-FFh	Prescale 8-bit prescaler to divide down the VBUS clock to obtain the I2C module clock. This register must be initialized while the I2C is still in reset (nIRS = 0). The value takes effect on the rising edge of nIRS.

17.6.14 I2C Peripheral ID Register 1 (I2CPID1)

Figure 17-27 and Table 17-23 describe this register.

Figure 17-27. I2C Peripheral ID Register 1 (I2CPID1) [offset = 34h]

15	8	7	0
CLASS		REVISION	
R-1		R-46h	

LEGEND: R = Read only; *-n* = value after reset

Table 17-23. I2C Peripheral ID Register 1 (I2CPID1) Field Descriptions

Bit	Field	Value	Description
15-8	CLASS	0-FFh	Peripheral class. These bits identify the class of peripheral.
7-0	REVISION	0-FFh	Revision level of the I2C. These bits identify the revision level of the I2C.

17.6.15 I2C Peripheral ID Register 2 (I2CPID2)

Figure 17-28 and Table 17-24 describe this register.

Figure 17-28. I2C Peripheral ID Register 2 (I2CPID2) [offset = 38h]

15	8	7	0
Reserved		TYPE	
R-0		R-5h	

LEGEND: R = Read only; *-n* = value after reset

Table 17-24. I2C Peripheral ID Register 2 (I2CPID2) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reads return 0. Writes have no effect.
7-0	TYPE	0-FFh	Peripheral type. These bits identify the type of peripheral.

17.6.16 I2C DMA Control Register (I2CDMACR)

This register contains the transmit and receive DMA enable bits. Figure 17-29 and Table 17-25 describe this register.

Figure 17-29. I2C DMA Control Register (I2CDMACR) [offset = 3Ch]

15	2	1	0
Reserved		TXDMAEN	RXDMAEN
R-0		R/W-1	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-25. I2C DMA Control Register (I2CDMACR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	TXDMAEN		Transmitter DMA enable. This bit controls the transmit DMA event pin to the system. When this bit is a 1, the DMA transmit event is enabled and the DMA can occur. When this bit is a 0, the DMA transmit event is disabled. Writing a 1 to this bit will send a TXDMA request to the DMA module, if PINFUNC is also cleared to 0.
		0	The transmit DMA is disabled.
		1	The transmit DMA is enabled.
0	RXDMAEN		Receive DMA enable. This bit controls the receive DMA event pin to the system. When this bit is 1, the DMA receive event is enabled and the DMA can occur. When this bit is a 0, the DMA receive event is disabled.
		0	The receive DMA is disabled.
		1	The receive DMA is enabled.

17.6.17 I2C Pin Function Register (I2CPFNC)

Figure 17-30 and Table 17-26 describe this register.

Figure 17-30. I2C Pin Function Register (I2CPFNC) [offset = 48h]

15	1	0
Reserved		PINFUNC
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-26. I2C Pin Function Register (I2CPFNC) Field Descriptions

Bit	Field	Value	Description
15-1	Reserved	0	Reads return 0. Writes have no effect.
0	PINFUNC		SDA and SCL pin function. This bit controls whether the SDA and SCL pins function as I2C pins or as I/O pins.
		0	SDA and SCL pins function as I2C pins.
		1	SDA and SCL pins function as I/O pins.

17.6.18 I2C Pin Direction Register (I2CPDIR)

This register is used to independently configure each I2C pin, when configured as a general-purpose I/O, as either an input or output. Figure 17-31 and Table 17-27 describe this register.

Figure 17-31. I2C Pin Direction Register (I2CPDIR) [offset = 4Ch]

15	2	1	0
Reserved		SDADIR	SCLDIR
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-27. I2C Pin Direction Register (I2CPDIR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDADIR		SDA pin direction. This bit controls the direction of the I2C SDA pin when configured as a GPIO.
		0	SDA pin functions as an input.
		1	SDA pin functions as an output.
0	SCLDIR		SCL pin direction. This bit controls the direction of the I2C SCL pin when configured as a GPIO.
		0	SCL pin functions as an input.
		1	SCL pin functions as an output.

17.6.19 I2C Data Input Register (I2CDIN)

Figure 17-32 and Table 17-28 describe this register.

Figure 17-32. I2C Data Input Register (I2CDIN) [offset = 50h]

15	2	1	0
Reserved		SDAIN	SCLIN
R-0		R-X	R-X

LEGEND: R = Read only; -X = value is indeterminate; -*n* = value after reset

Table 17-28. I2C Data Input Register (I2CDIN) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAIN		Serial data in. The value of this bit reflects the value on the SDA pin.
0	SCLIN		Serial clock data in. The value of this bit reflects the value on the SCL pin.

17.6.20 I2C Data Output Register (I2CDOUT)

This register contains the values sent to the I2C pins. Figure 17-33 and Table 17-29 describe this register.

Figure 17-33. I2C Data Output Register (I2CDOUT) [offset 0x54]

15	2	1	0
Reserved		SDAOUT	SCLOUT
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 17-29. I2C Data Output Register (I2CDOUT) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAOUT		SDA data output. This function is only active if the SDA pin is configured as an I/O pin with PINFUNC = 1. This bit contains the value sent to the SDA pin.
		0	The pin is driven low.
		1	The pin is driven high.
0	SCLOUT		SCL data output. This function is only active if the SCL pin is configured as an I/O pin with PINFUNC = 1. This bit contains the value sent to the SCL pin.
		0	The pin is driven low.
		1	The pin is driven high.

17.6.21 I2C Data Set Register (I2CDSET)

The I2CDSET register is an alias of the I2CDOUT register. Figure 17-34 and Table 17-30 describe this register.

Figure 17-34. I2C Data Set Register (I2CDSET) [offset = 58h]

15	2	1	0
Reserved		SDASET	SCLSET
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 17-30. I2C Data Set Register (I2CDSET) Field Description

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDASET		Serial data set. This bit is used to set the SDA GPIO pin.
		0	Read: Reads return value of SDAOUT. Write: No effect.
		1	Read: Reads return value of SDAOUT. Write: SDAOUT is set to logic high (1).

Table 17-30. I2C Data Set Register (I2CDSET) Field Description (continued)

Bit	Field	Value	Description
0	SCLSET		Serial clock set. This bit is used to set the SCL GPIO pin.
		0	Read: Reads return value of SCLOUT. Write: No effect.
		1	Read: Reads return value of SCLOUT. Write: SCLOUT is set to logic high (1).

17.6.22 I2C Data Clear Register (I2CDCLR)

The I2CDCLR register is an alias of the I2CDOUT register. Figure 17-35 and Table 17-31 describe this register.

Figure 17-35. I2C Data Clear Register (I2CDCLR) [offset = 5Ch]

15	2	1	0
Reserved		SDACLR	SCLCLR
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-31. I2C Data Clear Register (I2CDSET) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDACLR		Serial data clear. This bit is used to clear the SDA GPIO pin.
		0	Read: Reads return value of SDAOUT. Write: No effect.
		1	Read: Reads return value of SDAOUT. Write: SDAOUT is cleared to logic low (0).
0	SCLCLR		Serial clock clear. This bit is used to clear the SCL GPIO pin.
		0	Read: Reads return value of SCLOUT. Write: No effect.
		1	Read: Reads return value of SCLOUT. Write: SCLOUT is cleared to logic low (0).

17.6.23 I2C Pin Open Drain Register (I2CPDR)

Figure 17-36 and Table 17-32 describe this register.

Figure 17-36. I2C Pin Open Drain Register (I2CPDR) [offset = 60h]

15	2	1	0
Reserved		SDAPDR	SCLPDR
R-0		R/W-0	R/W-0

Table 17-32. I2C Pin Open Drain Register (I2CPDR) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAPDR		SDA pin open drain enable.
		0	The open drain function is enabled (the output voltage is V_{OL} or lower if SDAOUT = 0 and high-impedance if SDAOUT = 1).
		1	The open drain function is disabled (output voltage is V_{OL} or lower if SDAOUT = 0; V_{OH} or higher if SDAOUT = 1).

Table 17-32. I2C Pin Open Drain Register (I2CPDR) Field Descriptions (continued)

Bit	Field	Value	Description
0	SCLPDR		SCL pin open drain enable.
		0	The open drain function is enabled (the output voltage is V_{OL} or lower if SCLOUT = 0 and high-impedance if SCLOUT = 1).
		1	The open drain function is disabled (output voltage is V_{OL} or lower if SCLOUT = 0; V_{OH} or higher if SCLOUT = 1).

17.6.24 I2C Pull Disable Register (I2CPDIS)

Values in the I2CPDIS register enable or disable the pull control capability of the pins. Figure 17-37 and Table 17-33 describe this register.

Figure 17-37. I2C Pull Disable Register (I2CPDIS) [offset = 64h]

15	2	1	0
Reserved		SDAPDIS	SCLPDIS
R-0		R/W-1	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-33. I2C Pull Disable Register (I2CPDIS) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAPDIS		SDA pull disable.
		0	The pull function is enabled.
		1	The pull function is disabled.
0	SCLPDIS		SCL pull disable.
		0	The pull function is enabled.
		1	The pull function is disabled.

17.6.25 I2C Pull Select Register (I2CPSEL)

Values in the I2CPSEL register select the pull up or pull down functions of the corresponding pins. Figure 17-38 and Table 17-34 describe this register.

Figure 17-38. I2C Pull Select Register (I2CPSEL) [offset = 68h]

15	2	1	0
Reserved		SDAPSEL	SCLPSEL
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-34. I2C Pull Select Register (I2CPSEL) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDAPSEL		SDA pull select enable.
		0	The pull down function is enabled.
		1	The pull up function is enabled.
0	SCLPSEL		SCL pull select enable.
		0	The pull down function is enabled.
		1	The pull up function is enabled.

17.6.25.1 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 17-35.

Table 17-35. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) (1) (2)	Pull Disable (PULDIS) (1) (3)	Pull Select (PULSEL) (1) (4)	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Enabled	Disabled	Enabled
No	0	0	0	Pull down	Disabled	Enabled
No	0	0	1	Pull up	Disabled	Enabled
No	0	1	0	Disabled	Disabled	Enabled
No	0	1	1	Disabled	Disabled	Enabled
No	1	X	X	Disabled	Enabled	Enabled

(1) X = Don't care
(2) DIR = 0 for input, = 1 for output
(3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control
(4) PULSEL= 0 for pull-down functionality
= 1 for pull-up functionality

17.6.26 I2C Pins Slew Rate Select Register (I2CSRS)

This register controls the slew rate of the signal on the I2C pins. Figure 17-39 and Table 17-36 describe this register.

Figure 17-39. I2C Pins Slew Rate Select Register (I2CSRS) [offset = 6Ch]

15	2	1	0
Reserved		SDASRS	SCLSRS
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-36. I2C Pins Slew Rate Select Register (I2CSRS) Field Descriptions

Bit	Field	Value	Description
15-2	Reserved	0	Reads return 0. Writes have no effect.
1	SDASRS		SDA slew rate select.
		0	The slow buffer is selected.
		1	The normal buffer is selected.
0	SCLSRS		SCL slew rate select.
		0	The slow buffer is selected.
		1	The normal buffer is selected.

17.7 Sample Waveforms

Figure 17-40 provides waveforms to illustrate the difference between normal operation and backward compatibility mode.

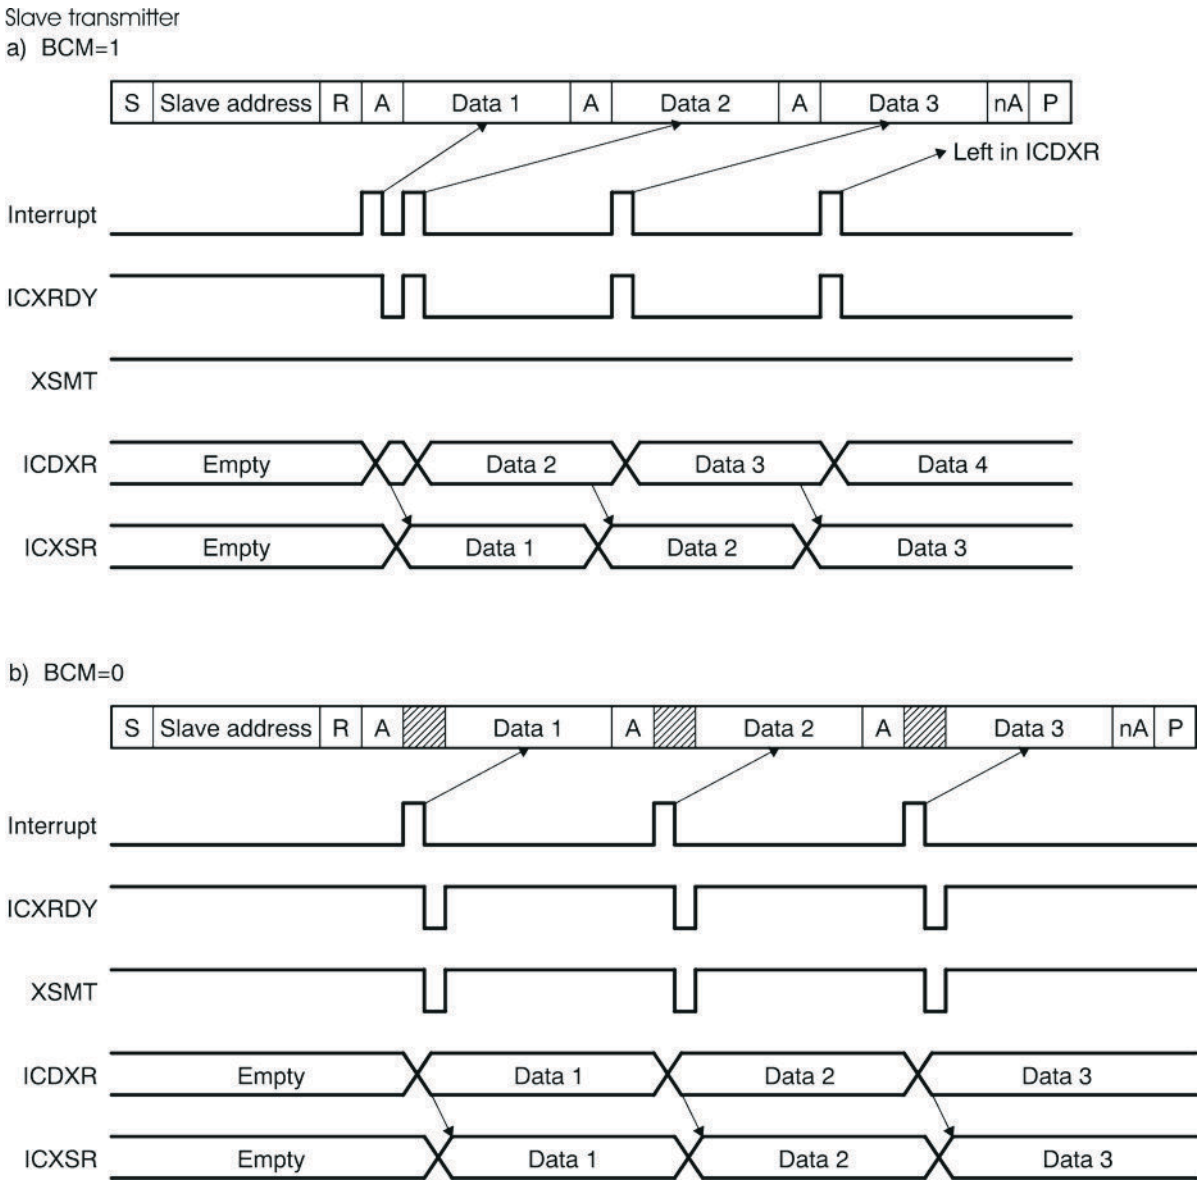

Figure 17-40. Difference between Normal Operation and Backward Compatibility Mode

Chapter 18

General-Purpose Input/Output (GIO) Module

This chapter describes the general-purpose input/output (GIO) module. The GIO module provides the family of devices with input/output (I/O) capability. The I/O pins are bidirectional and bit-programmable. The GIO module also supports external interrupt capability.

Note

The "GIO" module is also known as the "GPIO" module in other TI MCU and MPU devices. The two terms are used interchangeably and represent the general use I/O module of the device.

18.1 Overview

The GIO module offers general-purpose input and output capability. It supports up to eight 8-bit ports for a total of up to 64 GIO terminals. Each of these 64 terminals can be independently configured as input or output and configured as required by the application. The GIO module also supports generation of interrupts whenever a rising edge or falling edge or any toggle is detected on up to 32 of these GIO terminals. Refer to the device datasheet for identifying the number of GIO ports supported and the GIO terminals capable of generating an interrupt.

The main features of the GIO module are summarized as follows:

- Allows each GIO terminal to be configured for general-purpose input or output functions
- Supports programmable pull directions on each input GIO terminal
- Supports GIO output in push/pull or open-drain modes
- Allows up to 32 GIO terminals to be used for generating interrupt requests

18.2 Quick Start Guide

The GIO module comprises two separate components: an input/output (I/O) block and an interrupt generation block. Figure 18-1 and Figure 18-2 show what you should do after reset to configure the GIO module as I/O or for generating interrupts.

In GIO interrupt service routine, you shall read the GIO offset register (GIOOFF1 or GIOOFF2, depending on high-/low-level interrupt) to clear the flag and find the pending interrupt GIO channel.

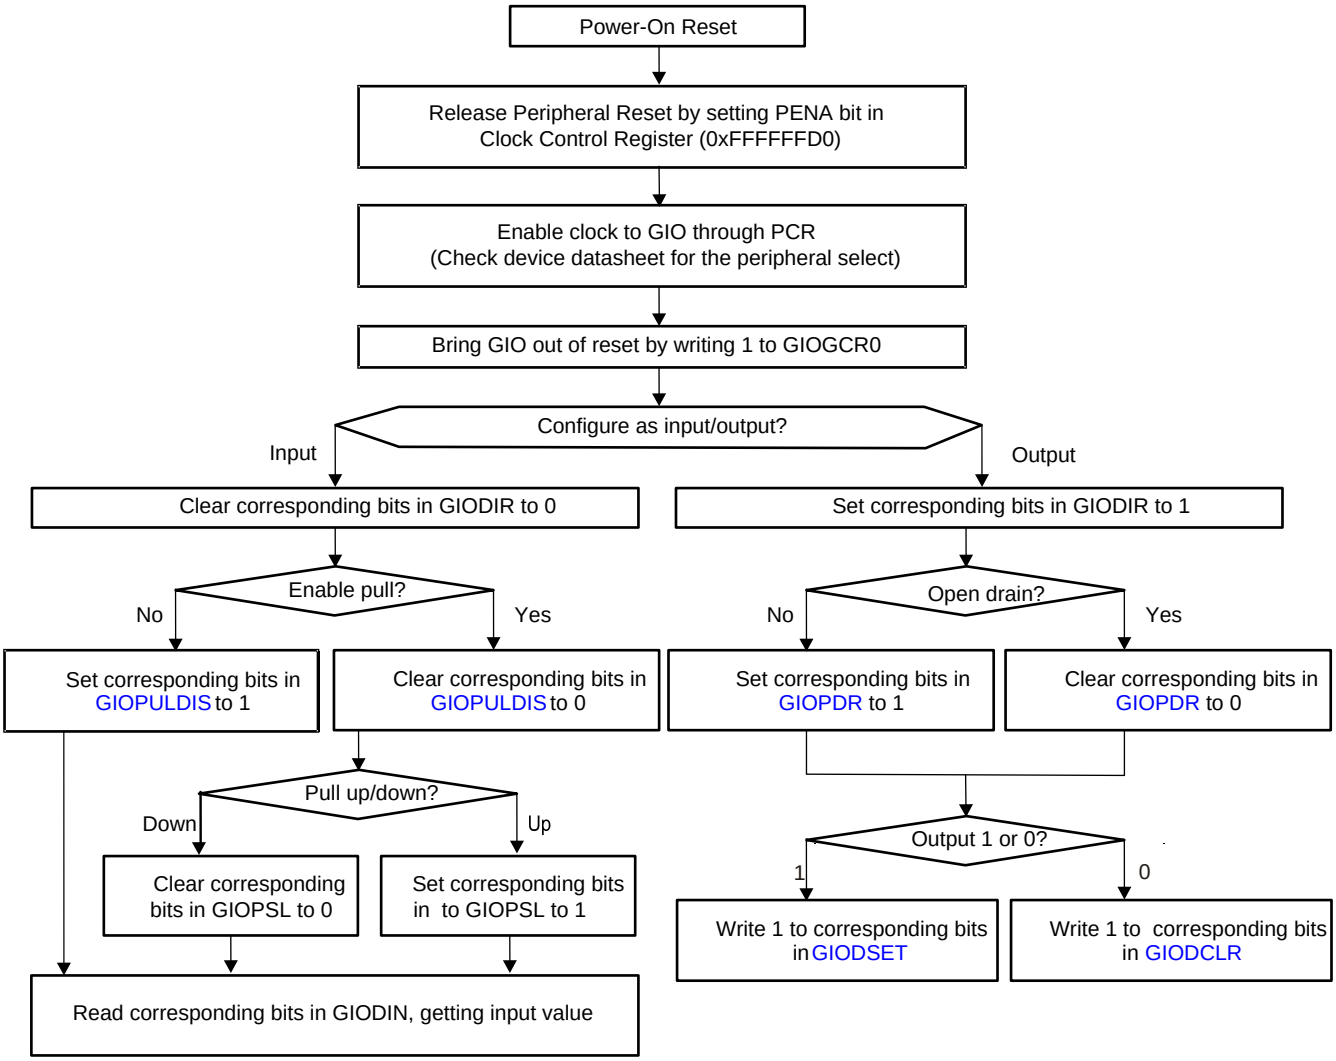

Figure 18-1. I/O Function Quick Start Flow Chart

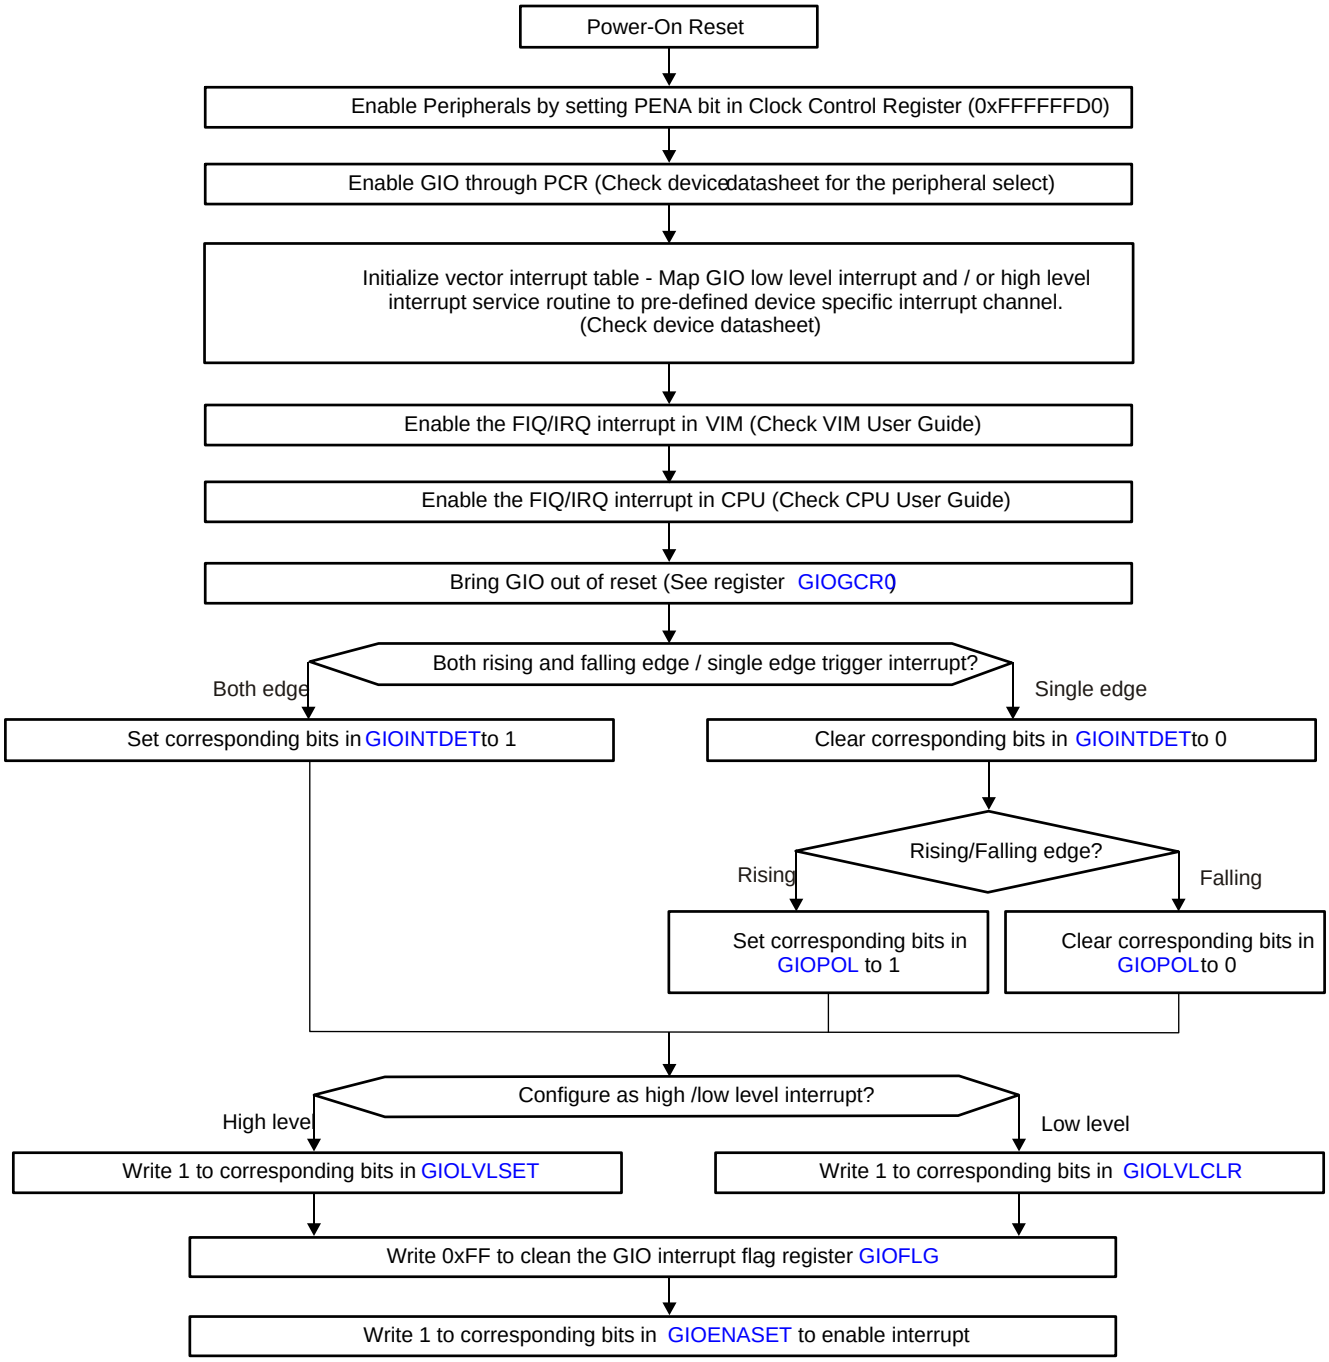

Figure 18-2. Interrupt Generation Function Quick Start Flow Chart

18.3 Functional Description of GIO Module

As shown in Figure 18-3, the GIO module comprises of two separate components: an input/output (I/O) block and an interrupt block.

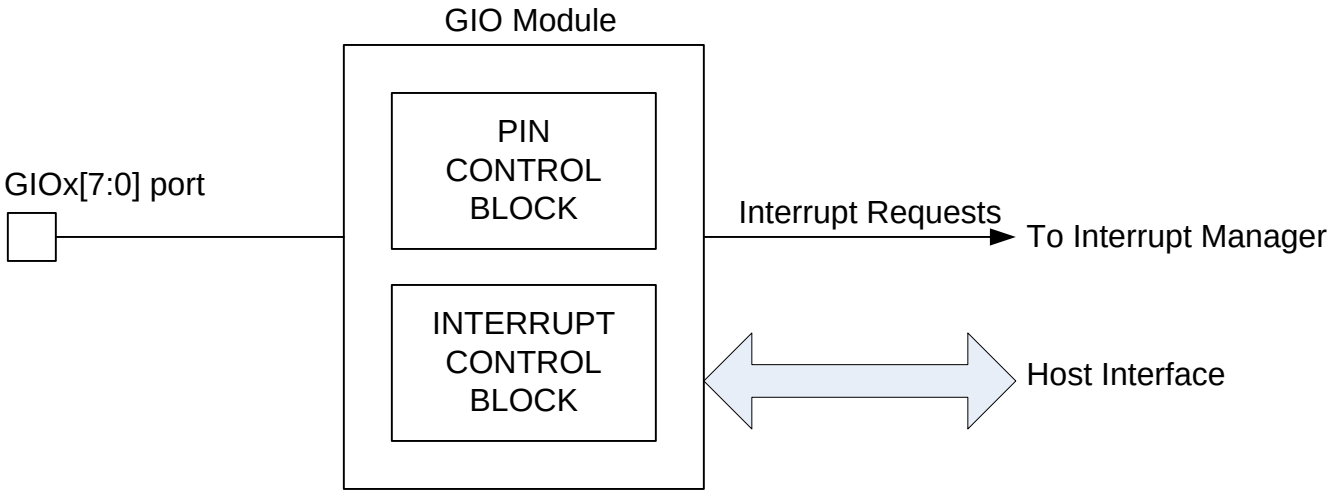

Figure 18-3. GIO Module Diagram

18.3.1 I/O Functions

The I/O block allows each GIO terminal to be configured for use as a general-purpose input or output in the application. The GIO module supports multiple registers to control the various aspects of the input and output functions. These are described as follows.

- Data direction (GIODIR)

  Configures GIO terminal(s) as input (default) or output through the GIODIRx registers.
- Data input (GIODIN)

  Reflects the logic level on GIO terminals in the GIODINx registers. A high voltage (V_{IH} or greater) applied to the pin causes a high value (1) in the data input register (GIODIN[7:0]). When a low voltage (V_{IL} or less) is applied to the pin, the data input register reads a low value (0). The V_{IH} and V_{IL} values are device specific and can be found in the device datasheet.
- Data output (GIODOUT)

  Configures the logic level to be output on GIO terminal(s) configured as outputs. A low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower). A high value (1) written to the data output register (GIODOUTx) forces the pin to a high output voltage (V_{OH} or higher) if the open drain functionality is disabled (GIOPDRx[7:0]). If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z).
- Data set (GIODSET)

  Allows logic HIGH to be output on GIO terminal(s) configured as outputs by writing 1's to the required bits in the GIODSETx registers. If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z). The GIODSETx registers eliminate the need for the application to perform a read-modify-write operation when it needs to set one or more GIO pin(s).
- Data clear (GIODCLR)

  Allows logic LOW to be output on GIO terminal(s) configured as outputs by writing 1s to the required bits in the GIODCLRx registers. The GIODCLRx registers eliminate the need for the application to perform a read-modify-write operation when it needs to clear one or more GIO pin(s).
- Open drain (GIOPDR)

Open drain functionality is enabled or disabled (default) using the open drain register GIOPDR[7:0] register. If open-drain mode output is enabled on a pin, a high value (1) written to the data output register (GIODOUTx[7:0]) forces the pin to a high impedance state (Z).

- Pull disable (GIOPULDIS)

  Disables the internal pull on GIO terminal(s) configured as inputs by writing to the GIOPULDISx registers.
- Pull select (GIOPSL)

  Selects internal pull down (default) or pull up on GIO terminal(s) configured as inputs by writing to the GIOPULSELx registers.

Refer to the specific device's datasheet to identify the number of GIO ports as well as the input and output functions supported. Some devices may not support the programmable pull controls. In that case, the pull disable and the pull select register controls will not work.

18.3.2 Interrupt Function

The GIO module supports up to 32 terminals to be configured for generating an interrupt to the host processor through the Vectored Interrupt Manager (VIM). The main functions of the interrupt block are:

- Select the GIO pin(s) that is/are used to generate interrupt(s)

  This is done via the interrupt enable set and clear registers, GIOENASET and GIOENACLR.
- Select the edge on the selected GIO pin(s) that is/are used to generate interrupt(s): rising/falling/both

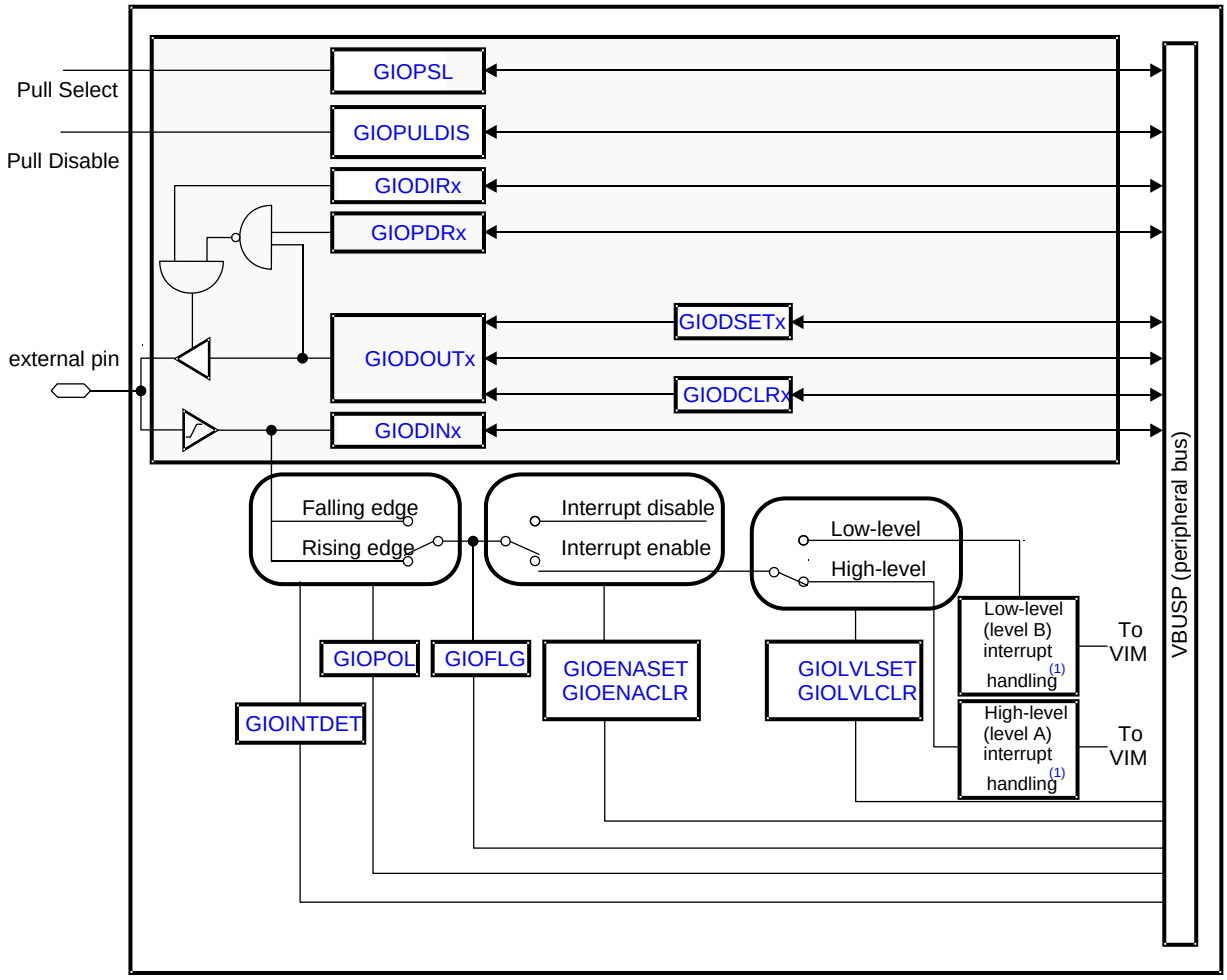
  Rising or falling edge can be selected via the GIOPOL register. If interrupt is required to be generated on both rising and falling edges, this can be configured via the GIOINTDET register.
- Select the interrupt priority

  Low- or high-level interrupt can be selected through the GIOLVLSET and GIOLVLCLR registers.
- Individual interrupt flags are set in the GIOFLG register

The terminals on GIO ports A through D are all interrupt-capable and can be used to handle either general I/O functions or interrupt requests. Each interrupt request can be connected to the VIM at one of two different levels – High (or A) and Low (or B), depending on the VIM channel number. The VIM has an inherent priority scheme so that a request on a lower number channel has a higher priority than a request on a higher number channel. Refer the device datasheet to identify the VIM channel numbers for the GIO level A and level B interrupt requests. Also note that the interrupt priority of level A and level B interrupt handling blocks can be re-programmed in the VIM.

18.3.3 GIO Block Diagram

The GIO block diagram (Figure 18-4) represents the flow of information through a pin. The shaded area corresponds to the I/O block; the unshaded area corresponds to the interrupt block.



A. A single low-level-interrupt-handling block and a single high-level-interrupt-handling block service all of the interrupt-capable external pins, but only one pin can be serviced by an interrupt block at a time.

Figure 18-4. GIO Block Diagram

18.4 Device Modes of Operation

The GIO module behaves differently in different modes of operation. There are two main modes:

- Emulation mode
- Power-down mode (low-power mode)

18.4.1 Emulation Mode

Emulation mode is used by debugger tools to stop the CPU at breakpoints to read registers.

Note

Emulation Mode and Emulation Registers

Emulation mode is a mode of operation of the device and is separate from the GIO emulation registers (GIOEMU1 and GIOEMU2). The contents of these emulation registers are identical to the contents of GIO offset registers (GIOOFF1 and GIOOFF2). Both emulation registers and GIO offset registers are NOT cleared when they are read in emulation mode. GIO offset registers are cleared when they are read in normal mode (other than emulation mode). The emulation registers are NOT cleared when they are read in normal mode. The intention for the emulation registers is that software can use them without clearing the flags.

During emulation mode:

- External interrupts are not captured because the VIM is unable to service interrupts.
- Any register can be read without affecting the state of the system.
- A write to a register still does affect the state of the system.

18.4.2 Power-Down Mode (Low-Power Mode)

In power-down mode, the clock signal to the GIO module is disabled. Thus, there is no switching and the only current draw comes from leakage current. In power-down mode, interrupt pins become level-sensitive rather than edge-sensitive. The polarity bit changes function from falling-edge-triggered to low-level-triggered and rising-edge-triggered to high-level-triggered. A corresponding level on an interrupt pin pulls the module out of low-power mode, if the interrupt is also enabled to wake up the device out of a low-power mode.

18.4.2.1 Module-Level Power Down

The GIO module can be placed into a power down state by disabling the GIO peripheral module via the appropriate bit in the peripheral power down register. Please refer to the Peripheral Central Resource Registers for details.

18.4.2.2 Device-Level Power Down

The entire device can be placed in one of the pre-defined low-power modes: doze, snooze, or sleep using the clock source and clock domain disable registers in the system module.

18.4.3 Interrupts

GIO generates aggregated interrupts for all inputs from PAD. Some of the interrupts to MSS_R5F are directly taken from GPIO-PAD.

MSS_GIO_INT0/1

MSS_GIO_PAD_INT0 from GPIO[0]

MSS_GIO_PAD_INT1 from GPIO[1]

MSS_GIO_PAD_INT2 from GPIO[2]

MSS_CTRL:: MSS_GIO_CFG_GIO:: MSS_GIO_CFG_GIO_CONFIG is used for selecting the edge that can give a trigger.

18.5 MSS_GIO Registers

Table 18-1 lists the MSS_GIO registers. All register offset addresses not listed in Table 18-1 should be considered as reserved locations and the register contents should not be modified.

18.6 I/O Control Summary

The behavior of the output buffer and the pull control is summarized in Table 18-87.

Table 18-87. Output Buffer and Pull Control Behavior for GIO Pins

Module under Reset?	Pin Direction (GIODIR)[1] [2]	Open Drain Enable (GIOPDR)[1]	Pull Disable (GIOPULDIS)[1] [3]	Pull Select (GIOPSL)[1] [4]	Pull Control	Output Buffer[5]
Yes	X	X	X	X	Enabled	Disabled
No	0	X	0	0	Pull down	Disabled
No	0	X	0	1	Pull up	Disabled
No	0	X	1	0	Disabled	Disabled
No	0	X	1	1	Disabled	Disabled
No	1	0	X	X	Disabled	Enabled
No	1	1	X	X	Disabled	Enabled

(1) X = Don't care
(2) GIODIR = 0 for input; = 1 for output
(3) GIOPULDIS = 0 for enabling pull control; = 1 for disabling pull control
(4) GIOPSL= 0 for pull-down functionality; = 1 for pull-up functionality
(5) If open drain is enabled, output buffer will be disabled if a high level (1) is being output.

Chapter 19

Enhanced Pulse Width Modulator (ePWM) Module

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. The features supported by the ePWM make it especially suitable for digital motor control.

19.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

19.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in Figure 19-1. Each ePWM instance is identical and is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 19-1. The signals are described in detail in subsequent sections.

Each ePWM module consists of eight submodules and is connected within a system via the signals shown in Figure 19-2.

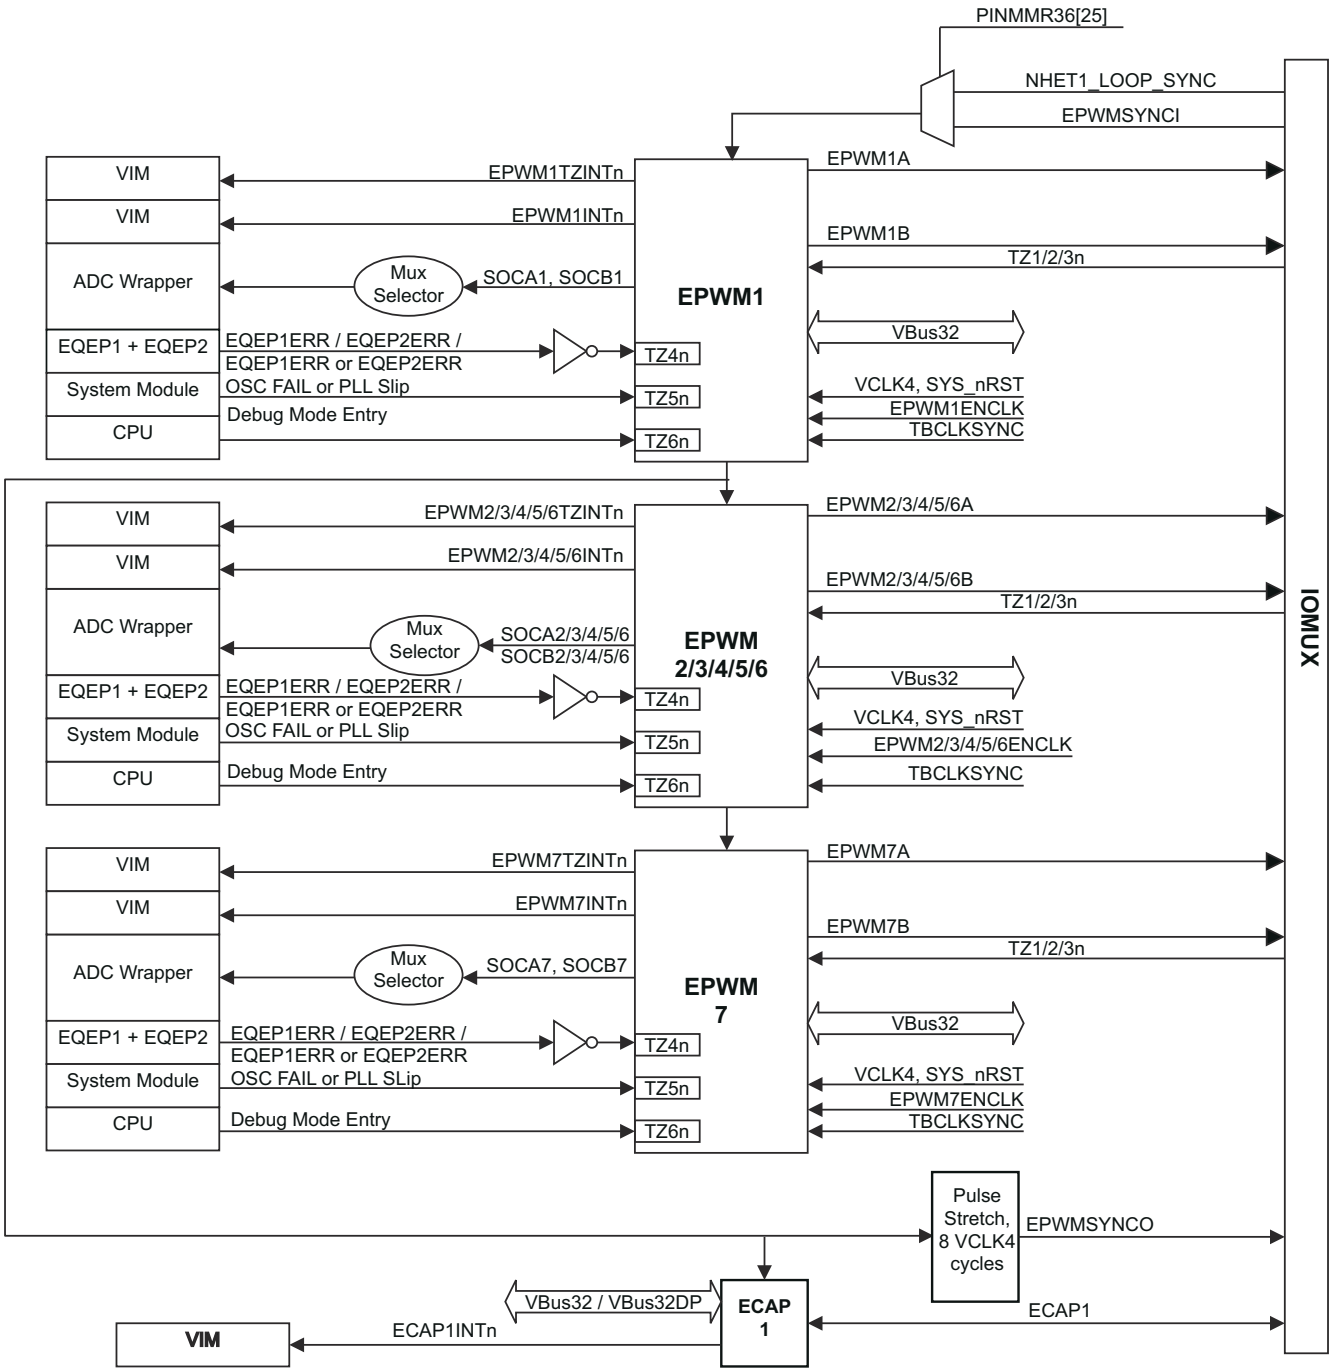

Figure 19-1. Multiple ePWM Modules

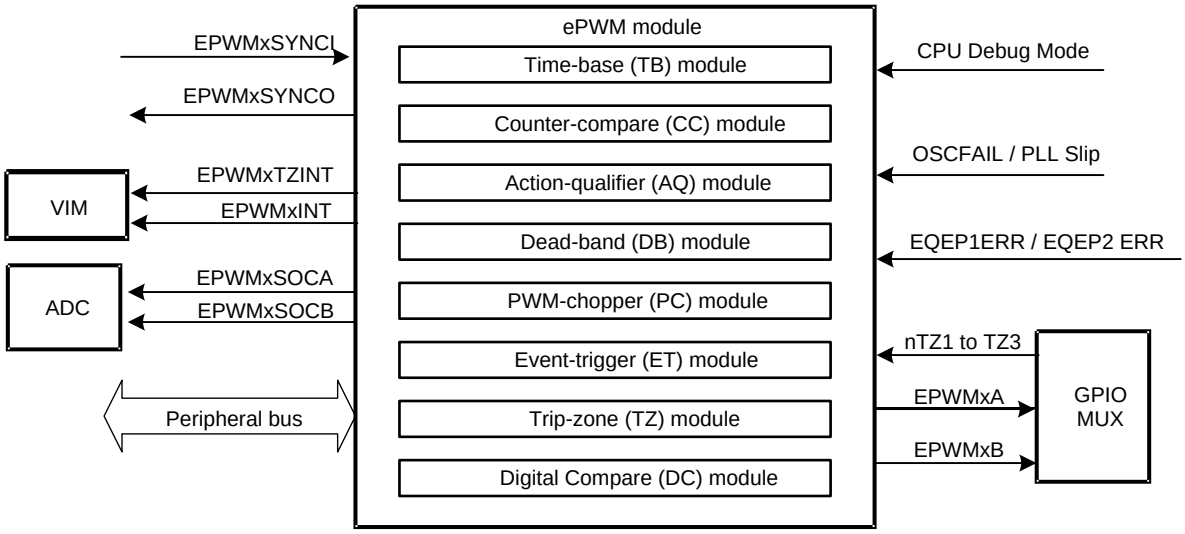

Figure 19-2. Submodules and Signal Connections for an ePWM Module

The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

  The PWM output signals are made available external to the device through the I/O Multiplexing Module (IOMM) as described in the IOMM chapter of the device's technical reference manual.
- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$).**

  These input signals alert the ePWM module of fault conditions external to the ePWM module. Each ePWM module can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs, or double-synchronized using VCLK4, or double-synchronized and filtered through a 6-VCLK4-cycle counter before connecting to the ePWM modules. This selection is done by configuring registers in the IOMM. $\overline{TZ4}$ is connected to an inverted eQEP1 error signal (EQEP1ERR), or to an inverted eQEP2 error signal (EQEP2ERR), or an OR-combination of EQEP1ERR and EQEP2ERR. This selection is also done via the IOMM registers . $\overline{TZ5}$ is connected to the system clock fail status. This is asserted whenever an oscillator failure is detected, or a PLL slip is detected. $\overline{TZ6}$ is connected to the debug mode entry indicator output from the CPU. This allows you to configure a trip action when the CPU halts.
- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals**.

  The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCI of the first enhanced capture module (eCAP1).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

  Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.
- **Peripheral Bus**

  The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

19.1.2 Register Mapping

The complete ePWM module control and status register set is grouped by submodule as shown in Table 19-1. Each register set is duplicated for each instance of the ePWM module. The start address for each ePWM register file instance on a device is specified in the specific part's datasheet.

Table 19-1. ePWM Module Control and Status Register Set Grouped by Submodule

19.2 ePWM Submodules

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

19.2.1 Overview

Table 19-2 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 19.2.3 for relevant details.

Table 19-2. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (VCLK4). • Configure the PWM time-base counter (TBCTR) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output

Table 19-2. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. • Option to enable half-cycle clocking for double resolution.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to each trip-zone signal: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Enable ePWM events that will trigger an ADC start-of-conversion event. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
Digital-compare (DC)	• Enables trip zone signals to create events and filtered events • Specify event-filtering options to capture TBCTR counter or generate blanking window

Code examples are provided in the remainder of this document that show how to implement various ePWM module configurations. These examples use the constant definitions in the device *EPwm_defines.h* file in the device-specific header file and peripheral examples software package.

19.2.2 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 19-3 illustrates the time-base module's place within the ePWM.

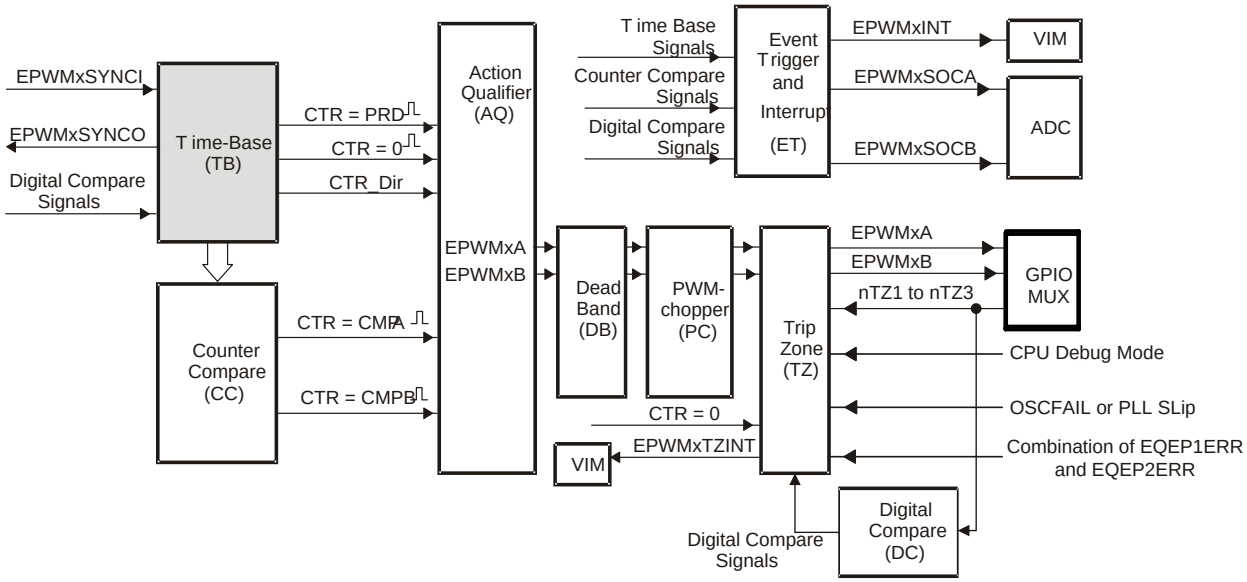

Figure 19-3. Time-Base Submodule Block Diagram

19.2.2.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD) .
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000).
- Configure the rate of the time-base clock; a prescaled version of the device peripheral clock domain (VCLK4). This allows the time-base counter to increment/decrement at a slower rate.

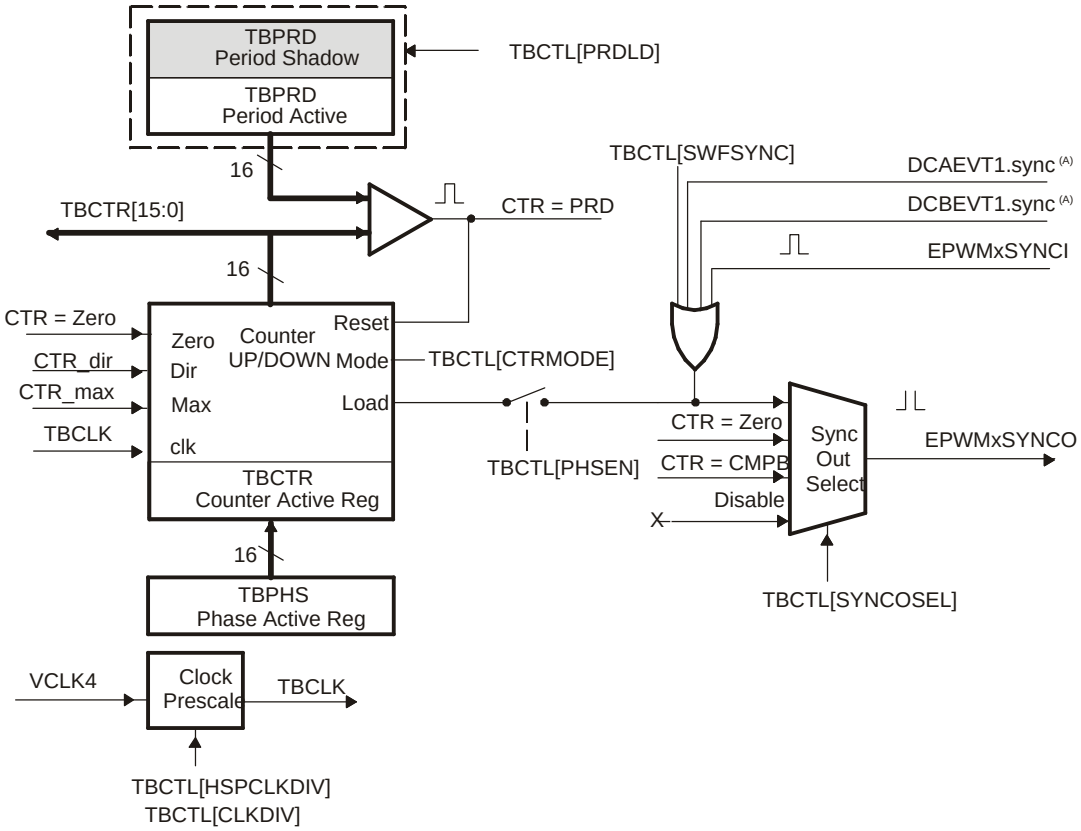
19.2.2.2 Controlling and Monitoring the Time-base Submodule

Table 19-3 shows the registers used to control and monitor the time-base submodule.

Table 19-3. Time-Base Submodule Registers

Register Name	Address Offset	Shadowed	Description
TBCTL	0x0002	No	Time-Base Control Register
TBSTS	0x0000	No	Time-Base Status Register
TBPHS	0x0004	No	Time-Base Phase Register
TBCTR	0x000A	No	Time-Base Counter Register
TBPRD	0x0008	Yes	Time-Base Period Register

The block diagram in Figure 19-4 shows the critical signals and registers of the time-base submodule. Table 19-4 provides descriptions of the key signals associated with the time-base submodule.



A. These signals are generated by the digital compare (DC) submodule.

Figure 19-4. Time-Base Submodule Signals and Registers

Table 19-4. Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1), this signal comes from a device pin or from the N2HET1 module. For subsequent ePWM modules, this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral, EPWM3SYNCI is generated by ePWM2 and so forth. See Section 19.2.2.3.3 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x0000). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x0000.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF) Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock. This is a prescaled version of the system clock (VCLK4) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

19.2.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 19-5 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VCLK4).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

  In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:**

  In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:**

  In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

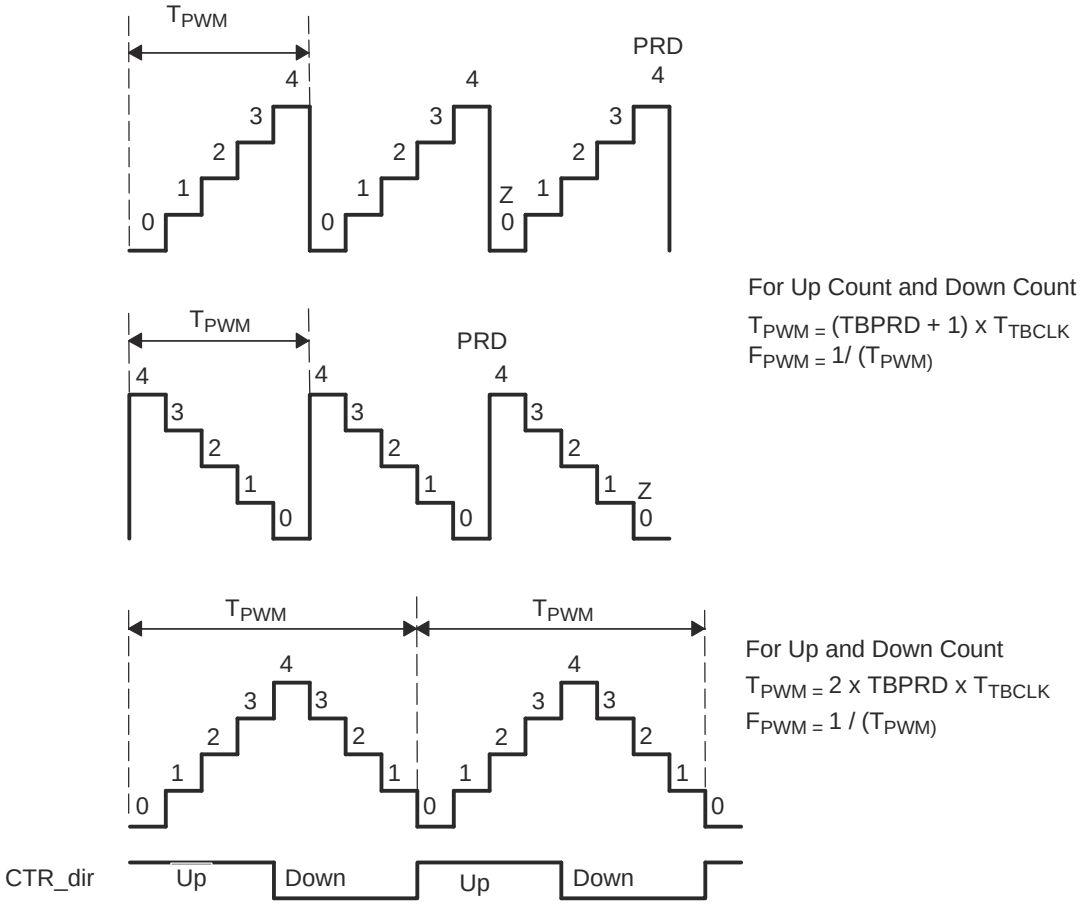


Figure 19-5. Time-Base Frequency and Period

19.2.2.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

  The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register**

  The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

  The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x0000). By default the TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:**

  If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

19.2.2.3.2 Time-Base Clock Synchronization

Bit 1 of the device-level multiplexing control module (IOMM) register PINMMR37 is defined as the TBCLKSYNC bit. The TBCLKSYNC bit allows users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

19.2.2.3.3 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The synchronization connections for the remaining ePWM modules are shown in Figure 19-6.

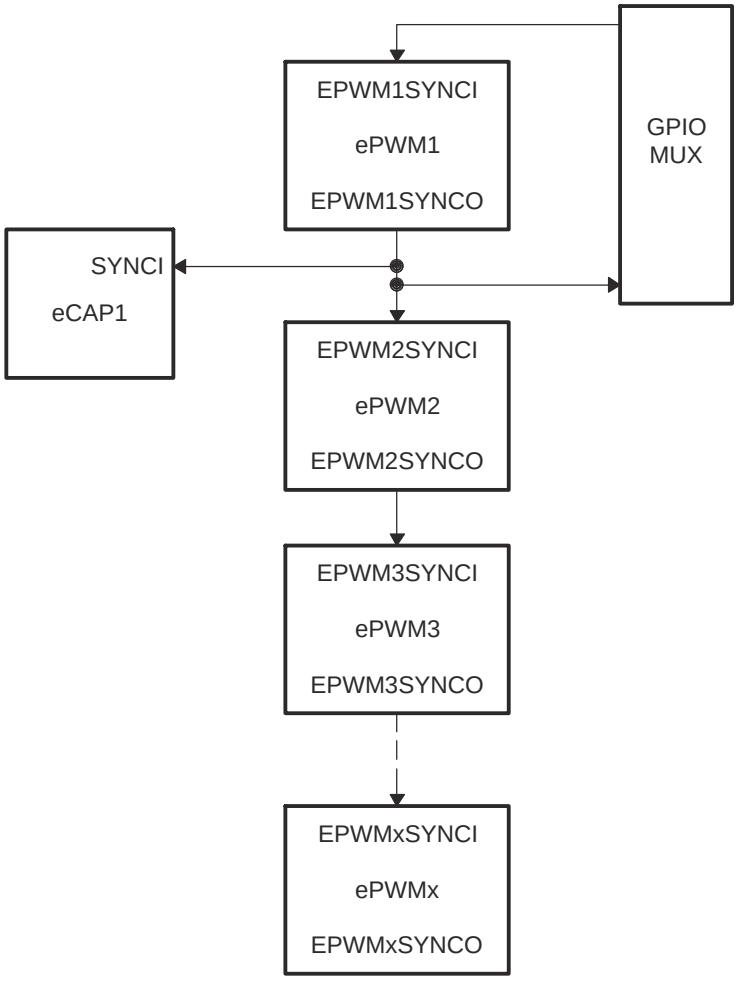

Figure 19-6. Time-Base Counter Synchronization Scheme

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:**

  The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

  The delay from internal master module to slave modules is given by:
  – if (TBCLK = VCLK4): 2 × VCLK4
  – if (TBCLK != VCLK4): 1 TBCLK
- **Software Forced Synchronization Pulse:**

  Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.
- **Digital Compare Event Synchronization Pulse:**

  DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See Figure 19-7 through Figure 19-10 for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

19.2.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

19.2.2.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

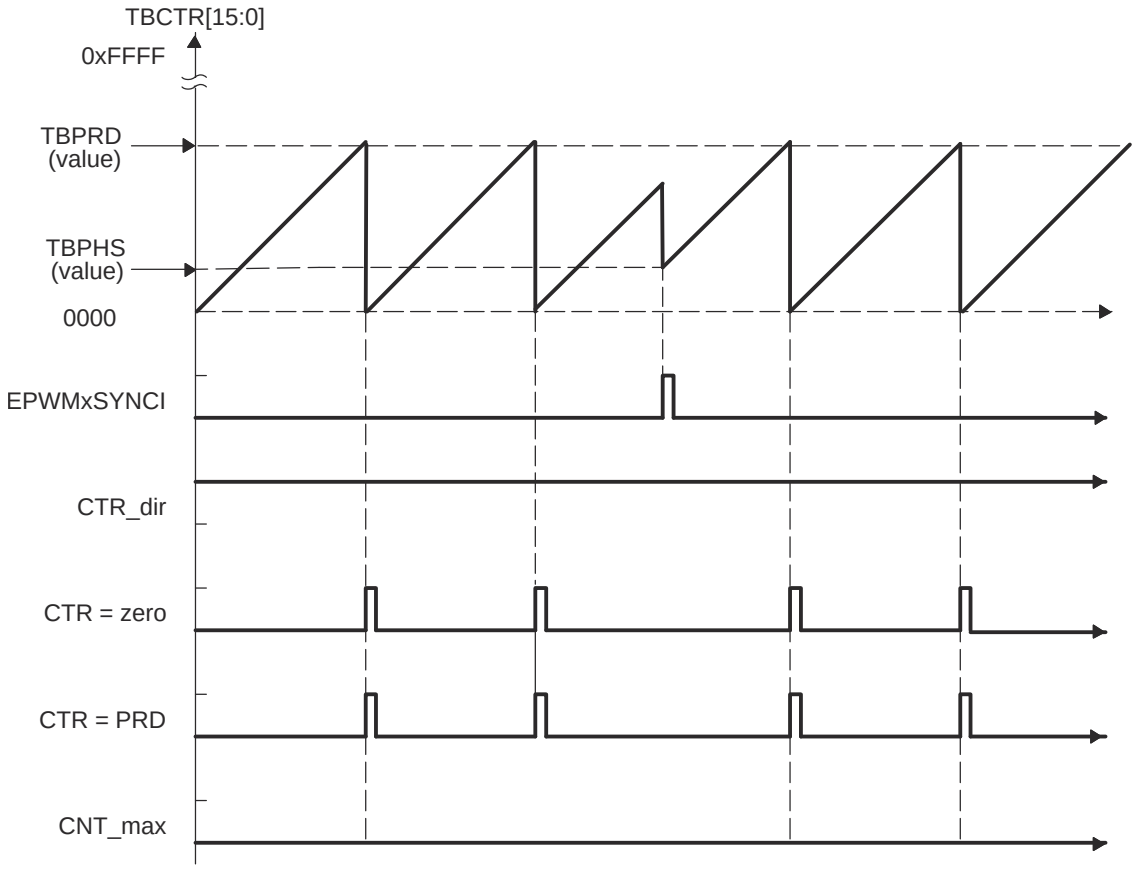

Figure 19-7. Time-Base Up-Count Mode Waveforms

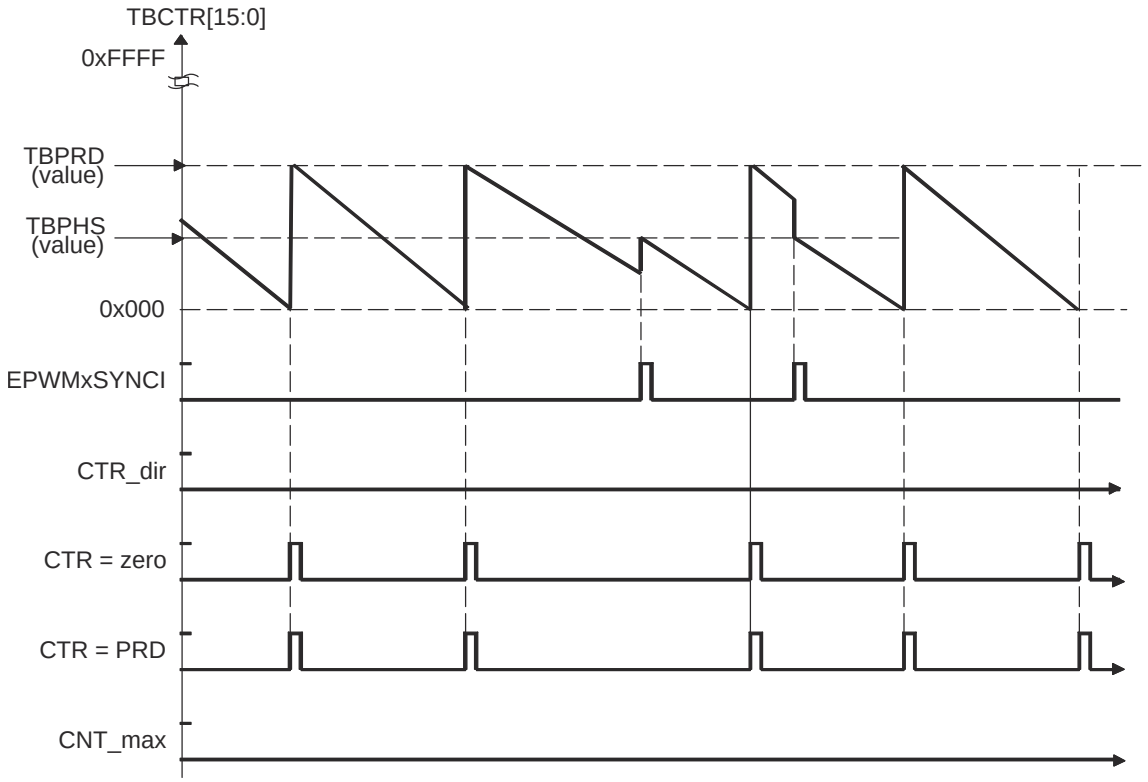

Figure 19-8. Time-Base Down-Count Mode Waveforms

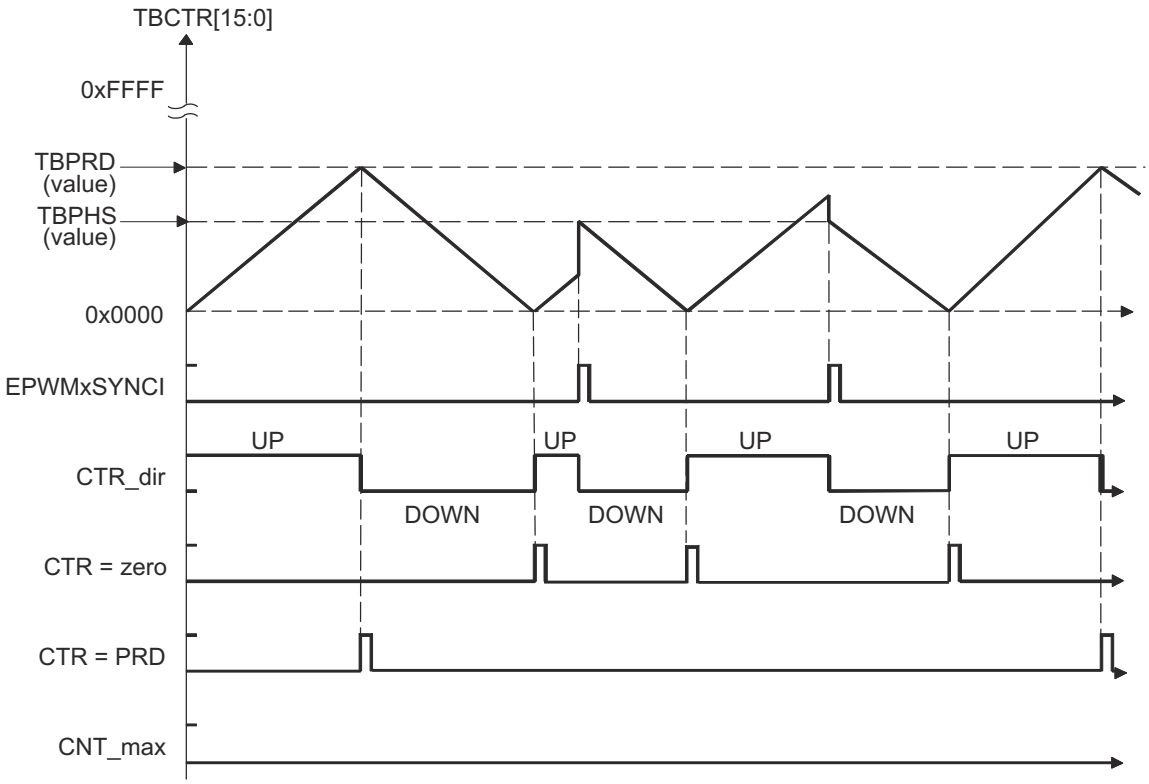

Figure 19-9. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

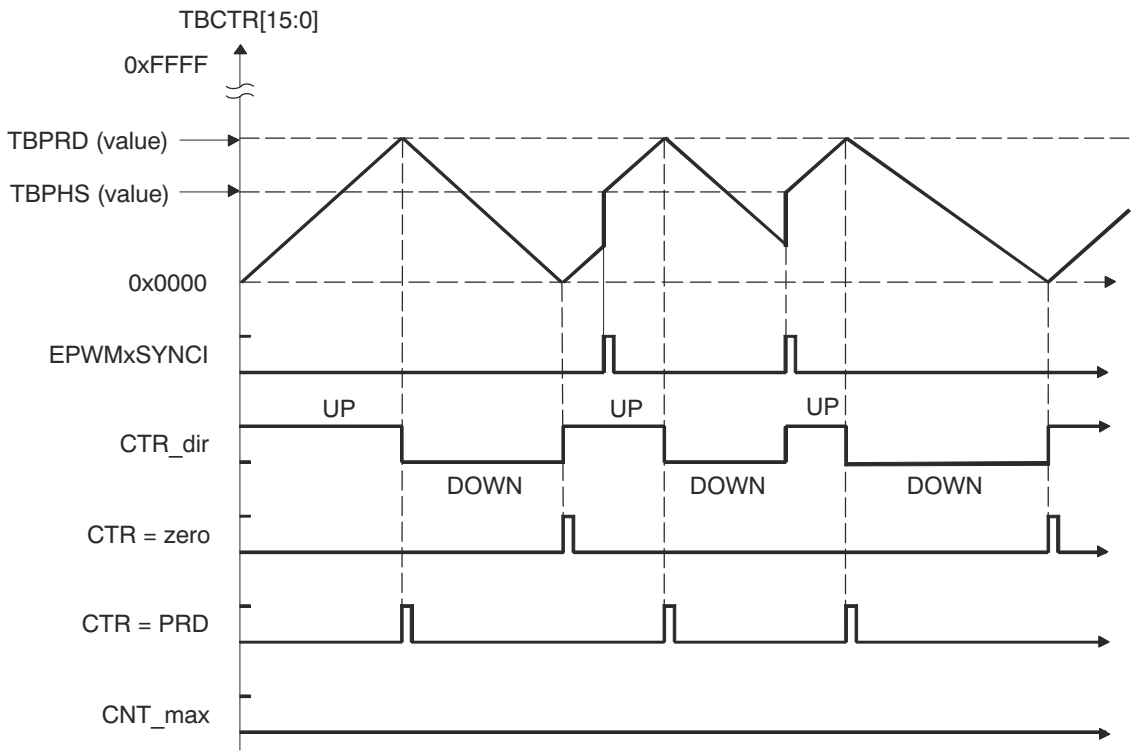

Figure 19-10. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

19.2.3 Counter-Compare (CC) Submodule

Figure 19-11 illustrates the counter-compare submodule within the ePWM.

Figure 19-12 shows the basic structure of the counter-compare submodule.

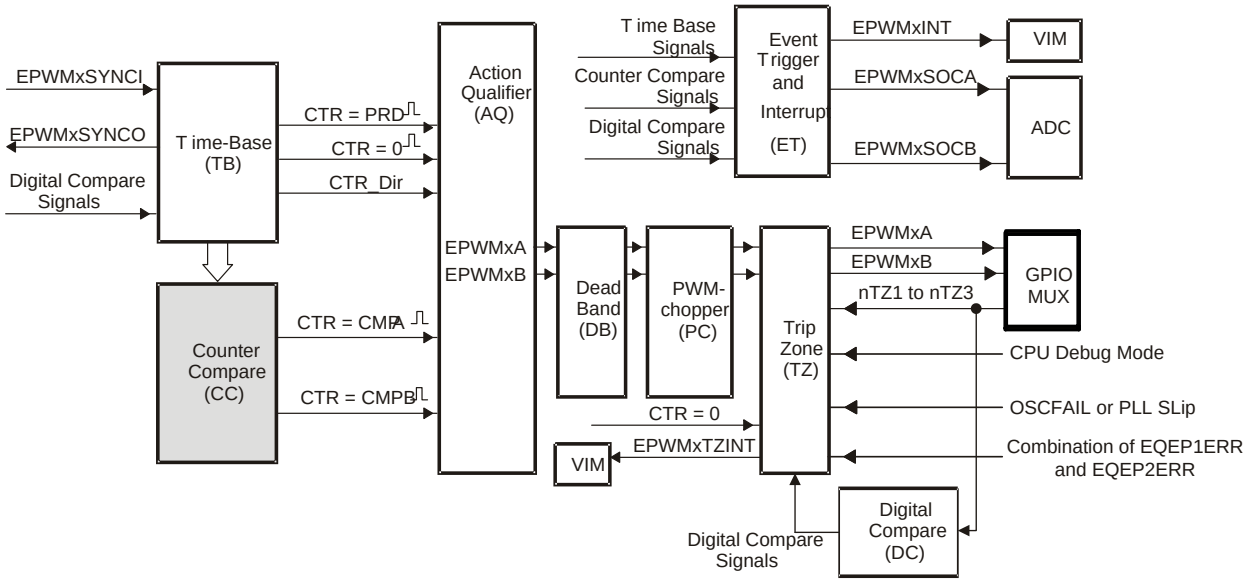

Figure 19-11. Counter-Compare Submodule

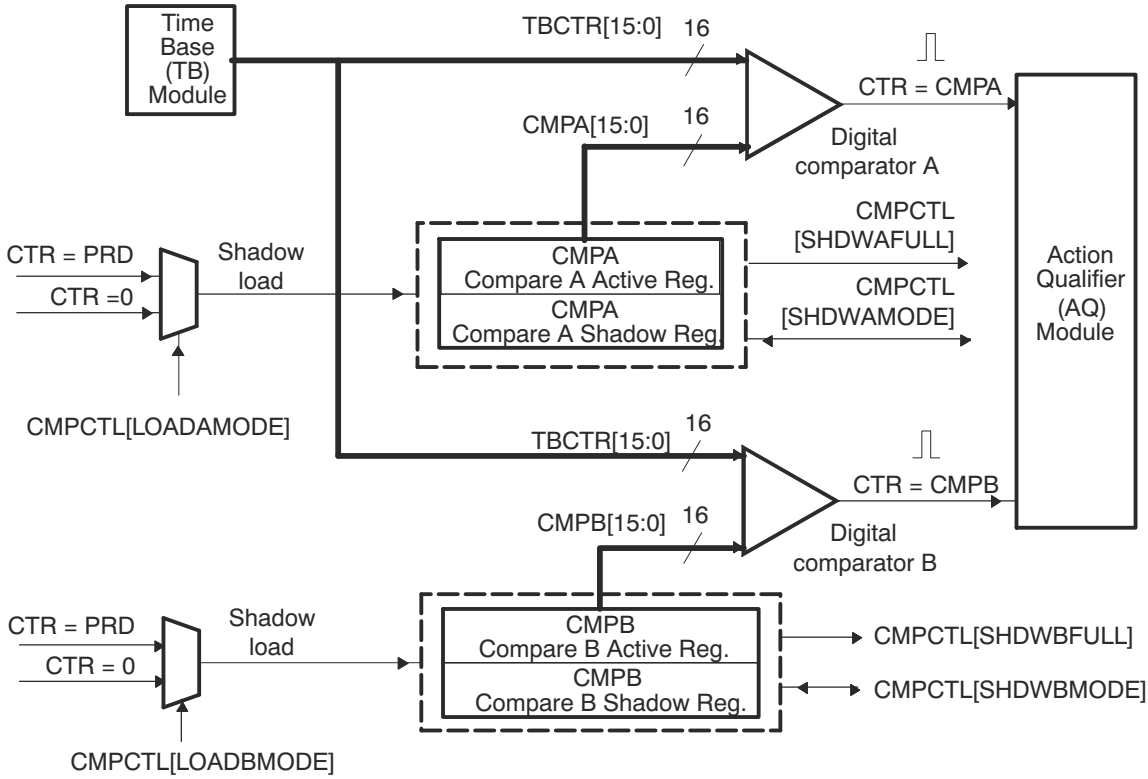

Figure 19-12. Detailed View of the Counter-Compare Submodule

19.2.3.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA).
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

19.2.3.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is controlled and monitored by the registers shown in Table 19-5:

Table 19-5. Counter-Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
CMPCTL	0x000C	No	Counter-Compare Control Register.
CMPA	0x0010	Yes	Counter-Compare A Register
CMPB	0x0016	Yes	Counter-Compare B Register

The key signals associated with the counter-compare submodule are described in Table 19-6.

Table 19-6. Counter-Compare Submodule Key Signals

Signal	Description of Event	Registers Compared
CTR = CMPA	Time-base counter equal to the active counter-compare A value	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the active counter-compare B value	TBCTR = CMPB
CTR = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCTR = TBPRD
CTR = ZERO	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCTR = 0x0000

19.2.3.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle if the compare value is between 0x0000-TBPRD and once per cycle if the compare value is equal to 0x0000 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to Section 19.2.4.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is as described:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
- Both CTR = PRD and CTR = Zero

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

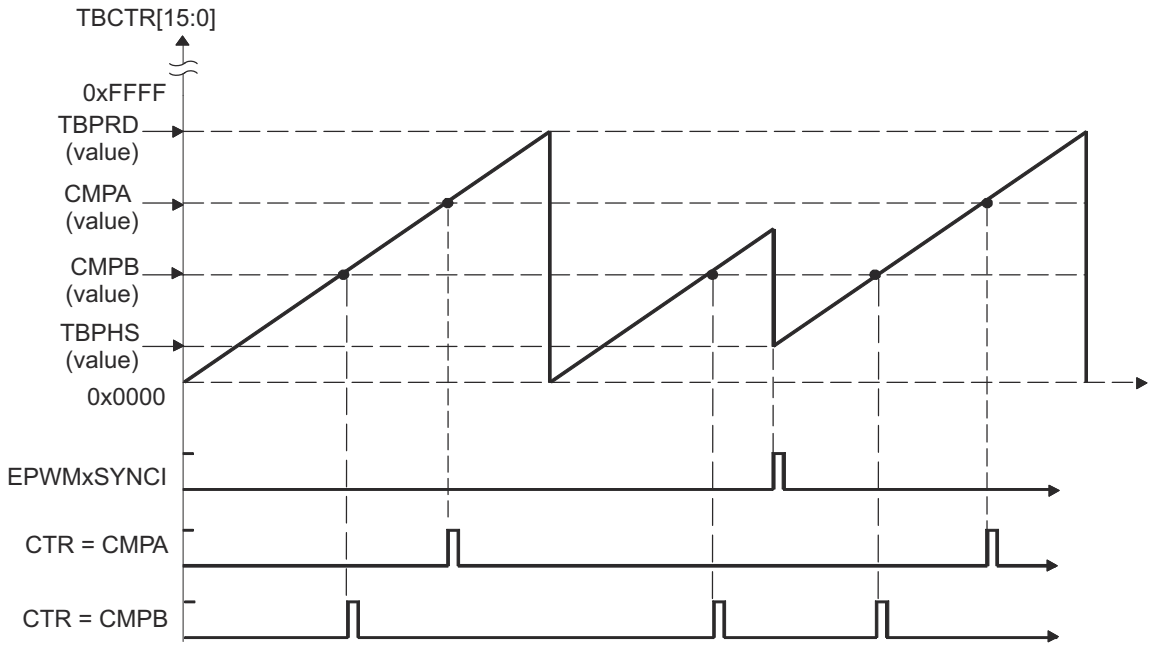
If immediate load mode is selected (that is, TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

19.2.3.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 19-13 through Figure 19-16 show when events are generated and how the EPWMxSYNCI signal interacts.



An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 19-13. Counter-Compare Event Waveforms in Up-Count Mode

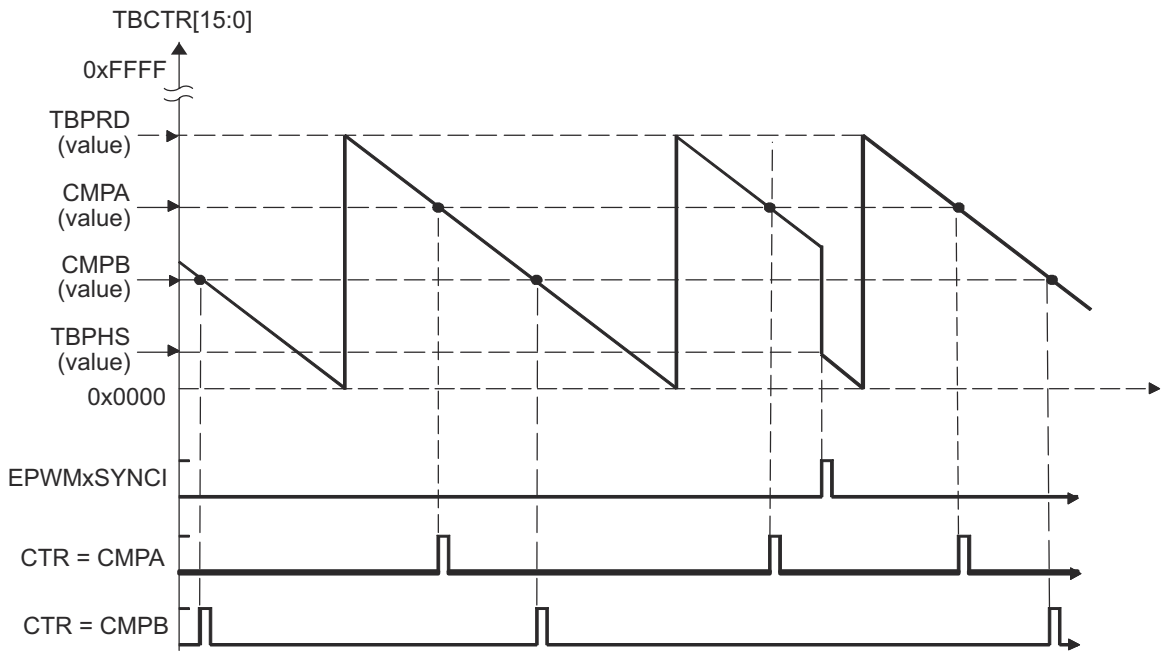


Figure 19-14. Counter-Compare Events in Down-Count Mode

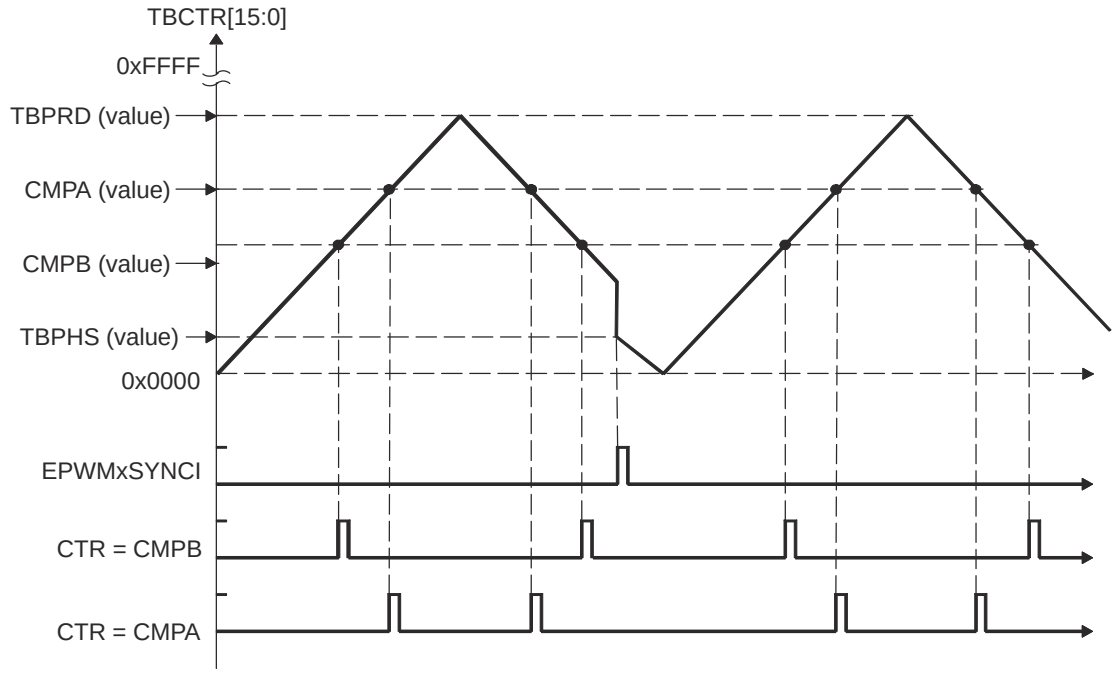

Figure 19-15. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

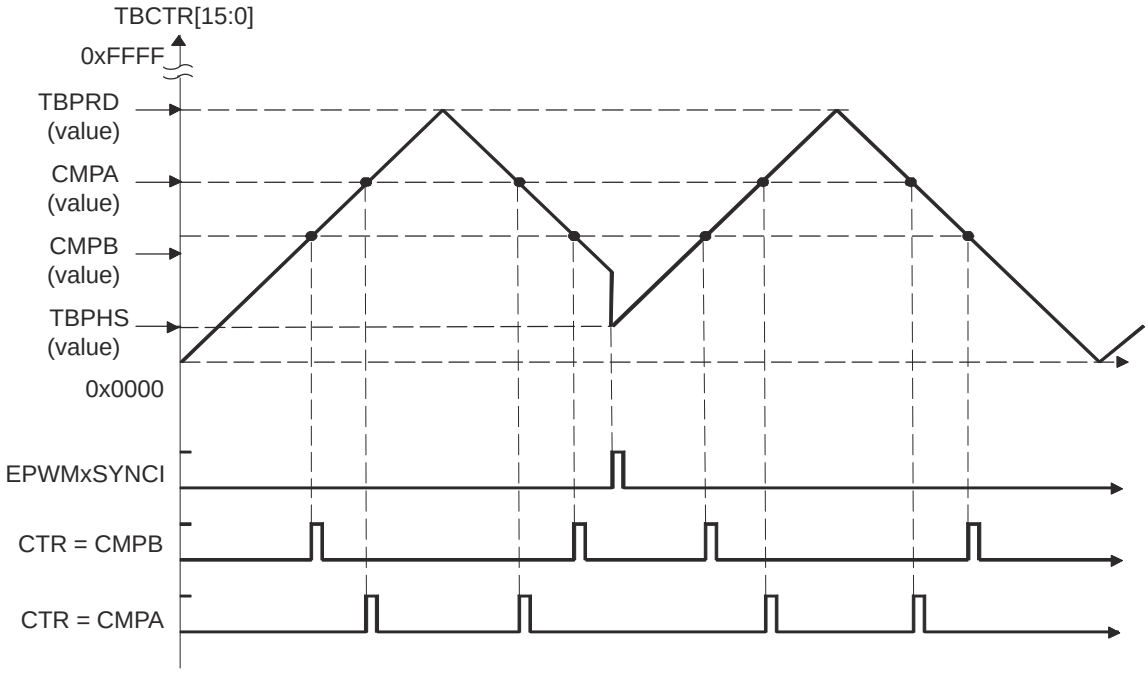

Figure 19-16. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

19.2.4 Action-Qualifier (AQ) Submodule

Figure 19-17 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system.

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

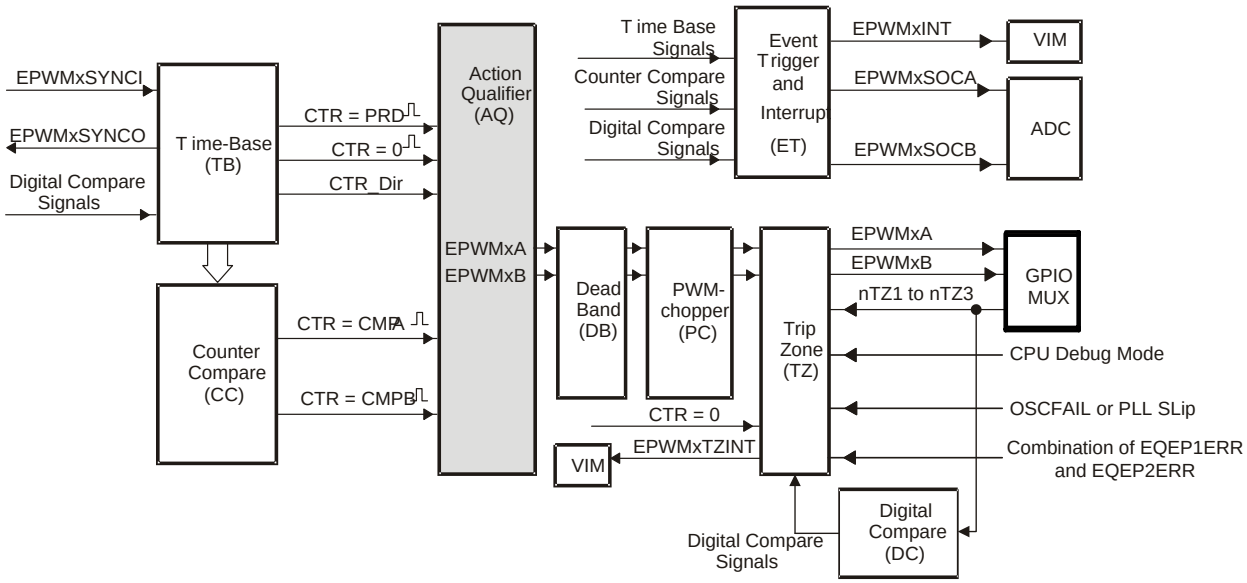

Figure 19-17. Action-Qualifier Submodule

19.2.4.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

19.2.4.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is controlled and monitored via the registers in Table 19-7.

Table 19-7. Action-Qualifier Submodule Registers

Register Name	Address Offset	Shadowed	Description
AQCTLA	0x0014	No	Action-Qualifier Control Register For Output A (EPWMxA)
AQCTLB	0x001A	No	Action-Qualifier Control Register For Output B (EPWMxB)
AQSFRC	0x0018	No	Action-Qualifier Software Force Register
AQCSFRC	0x001E	Yes	Action-Qualifier Continuous Software Force

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Table 19-7.

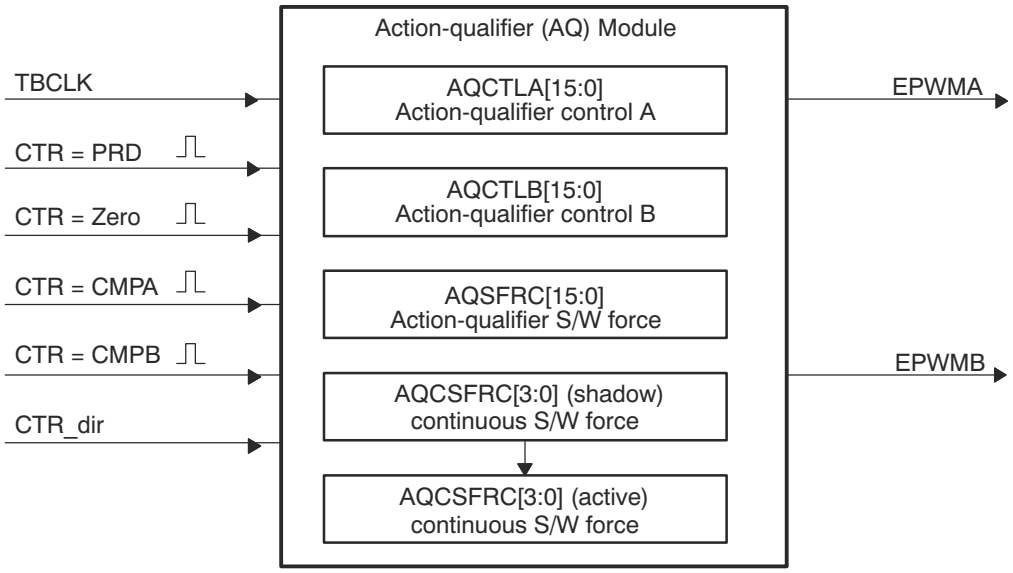

Figure 19-18. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in Table 19-8.

Table 19-8. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to zero	TBCTR = 0x0000
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers AQSFRC and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**

  Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**

  Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**

  If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:**

  Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the Event-trigger Submodule description in Section 19.2.8 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in Figure 19-19. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
SW ✕	Z ✕	CA ✕	CB ✕	P ✕	Do Nothing
SW ↓	Z ↓	CA ↓	CB ↓	P ↓	Clear Low
SW ↑	Z ↑	CA ↑	CB ↑	P ↑	Set High
SW T	Z T	CA T	CB T	P T	Toggle

Figure 19-19. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

19.2.4.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in Table 19-9. A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 19-9. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD)
5	Counter equals CMPB on down-count (CBD)	Counter equals CMPB on up-count (CBU)
6 (Lowest)	Counter equals CMPA on down-count (CAD)	Counter equals CMPA on up-count (CBU)

Table 19-10 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 19-10. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

Table 19-11 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 19-11. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in Table 19-12.

Table 19-12. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event will occur on a period match (TBCTR=TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB is ≥ TBPRD, the event will occur on a period match (TBCTR = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).

19.2.4.4 Waveforms for Common Configurations

Note

The waveforms in this document show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD - 1.

  This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD + 1 to achieve 0-100% PWM duty.

See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control* Application Report (SPRAAI1)

Figure 19-20 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD - 1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

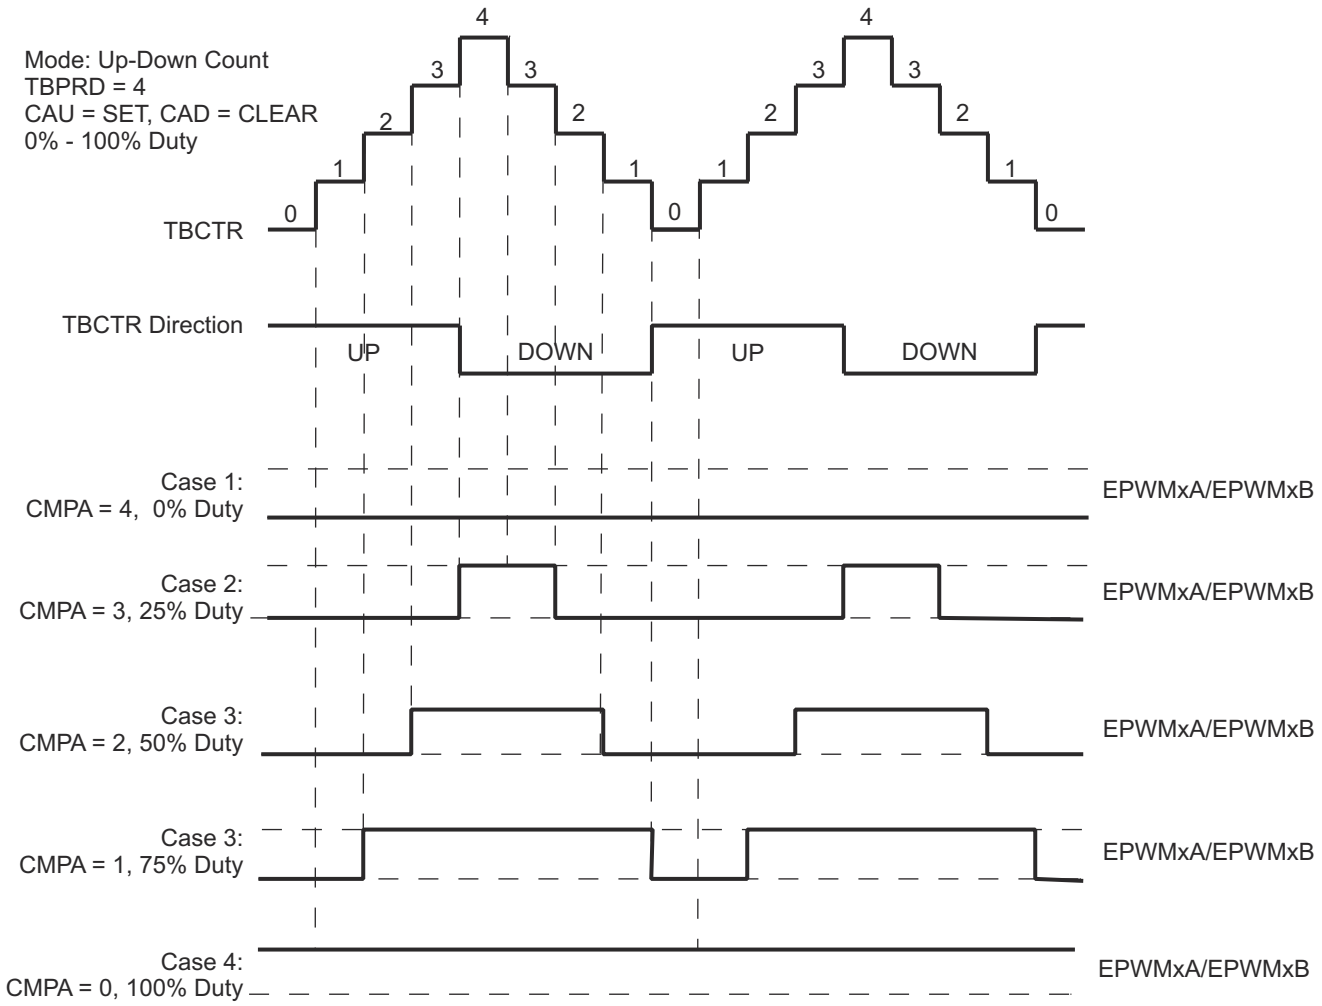

Figure 19-20. Up-Down-Count Mode Symmetrical Waveform

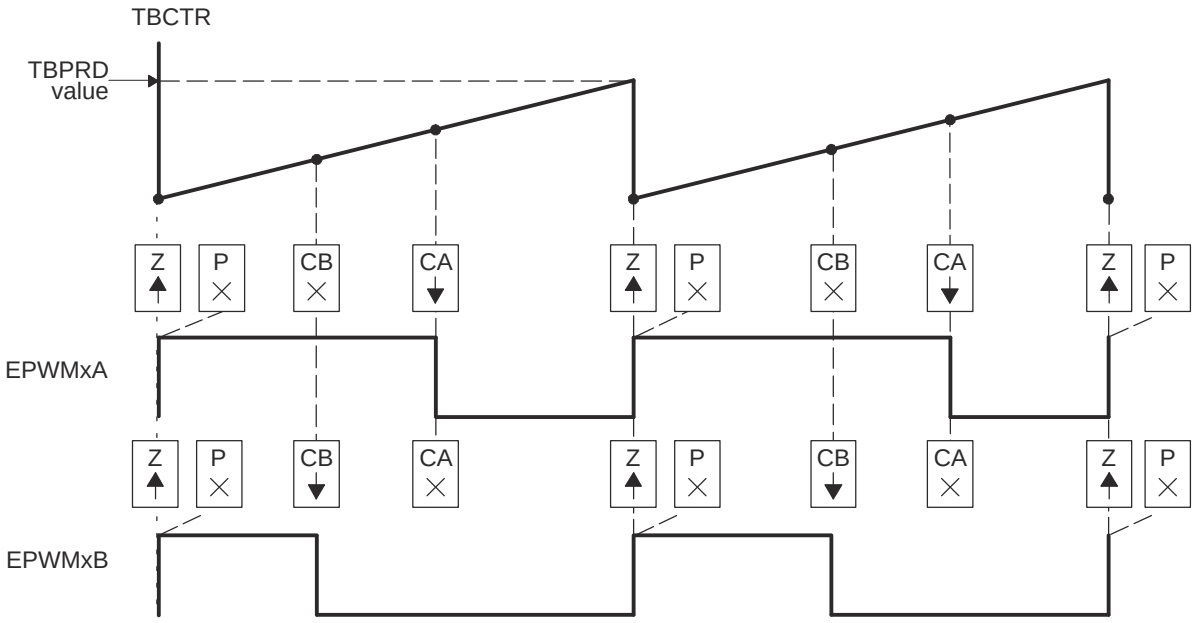
The PWM waveforms in Figure 19-21 through Figure 19-26 show some common action-qualifier configurations. The C-code samples in Example 19-1 through Example 19-6 shows how to configure an ePWM module for each case. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric



A. PWM period = (TBPRD + 1) × T_{TBCLK}
B. Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
D. The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Figure 19-21. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High

Example 19-1 contains a code sample showing initialization and run time for the waveforms in Figure 19-21.

Example 19-1. Code Sample for Figure 19-21

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.TBPRD = 600;                        // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;               // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                         // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0;                          // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                          // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;       // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDLD = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;      // TBCLK = SYSCLK
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero

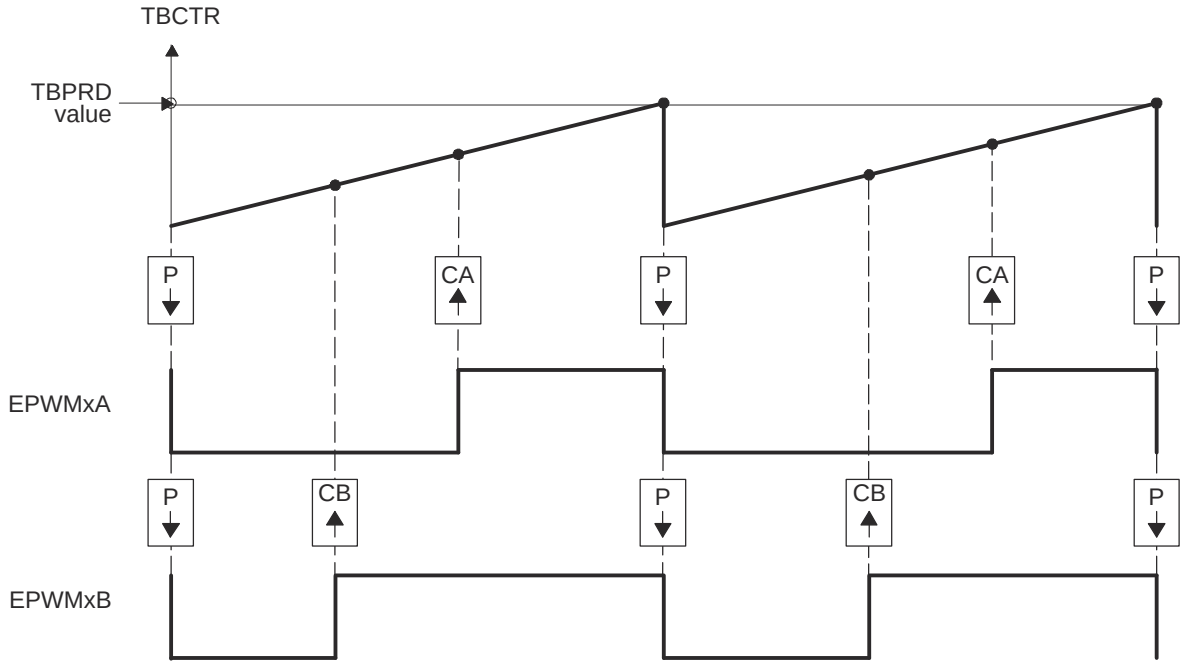
//
// Run Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.CMPA.half.CMPA = Duty1A;            // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B;                      // adjust duty for output EPWM1B
```

19.2.4.5



A. PWM period = (TBPRD + 1) × T_{TBCLK}
B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
D. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Figure 19-22. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low

Example 19-2 contains a code sample showing initialization and run time for the waveforms in Figure 19-22.

Example 19-2. Code Sample for Figure 19-22

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.TBPRD = 600;                        // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;               // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                         // Compare B = 200 TBCLK counts

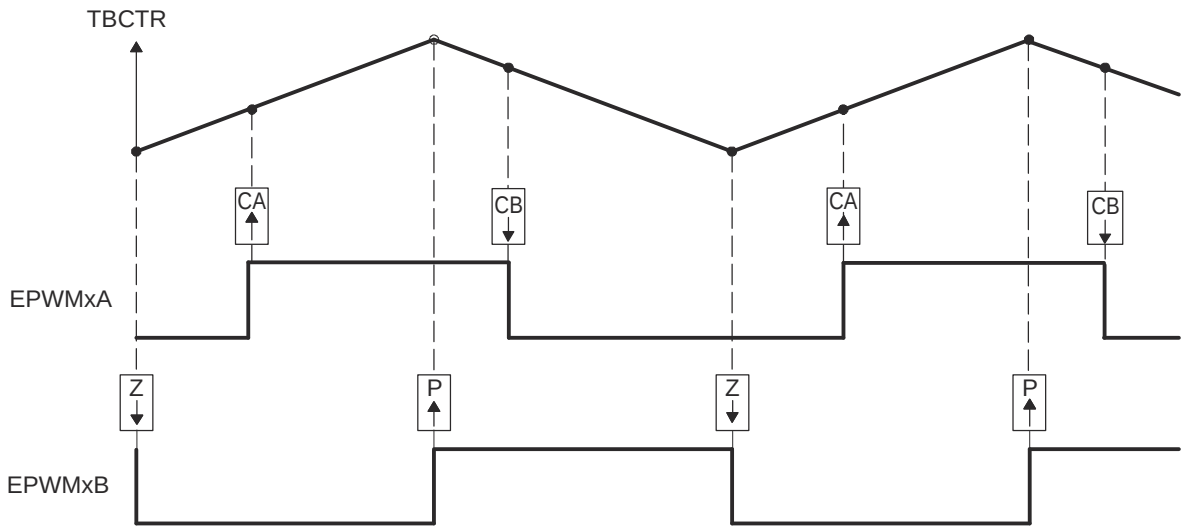
EPwm1Regs.CMPB = Duty1B;                    // adjust duty for output EPWM1B
```

19.2.4.9



A. PWM period = 2 × TBPRD × TBCLK
B. Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
C. Duty modulation for EPWMxA is set by CMPA and CMPB.
D. Low time duty for EPWMxA is proportional to (CMPA + CMPB).
E. To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Set ! Clear and Clear Set).
F. Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB)

Figure 19-26. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low

```

19.2.5 Dead-Band Generator (DB) Submodule

Figure 19-27 illustrates the dead-band submodule within the ePWM module.

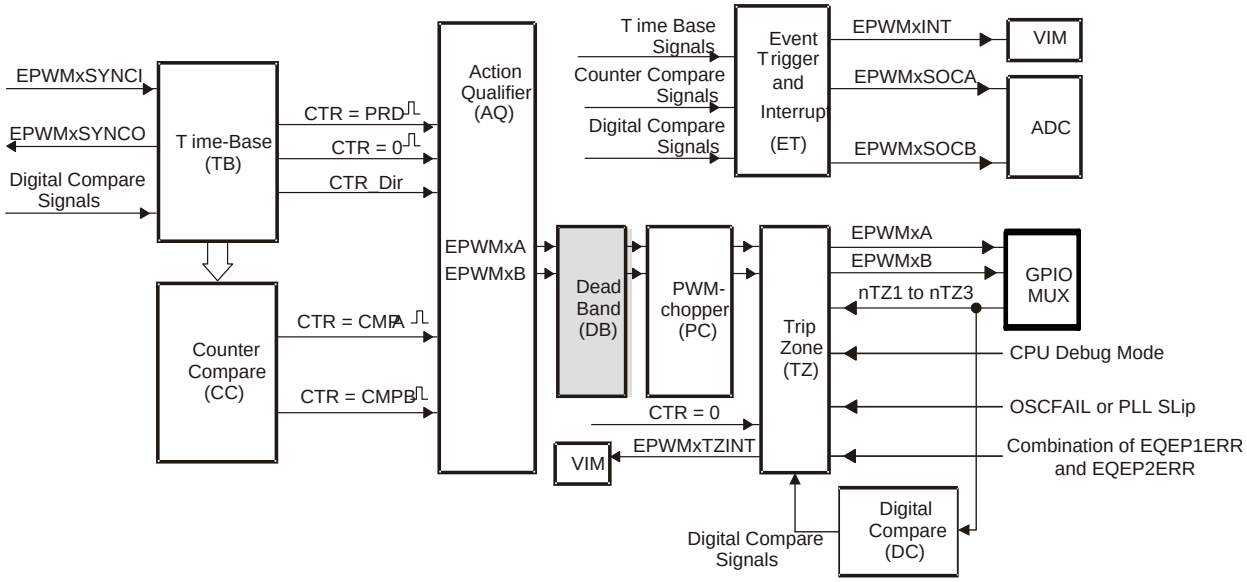

Figure 19-27. Dead_Band Submodule

19.2.5.1 Purpose of the Dead-Band Submodule

Section 19.2.4 discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

19.2.5.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band submodule operation is controlled and monitored via the following registers:

Table 19-13. Dead-Band Generator Submodule Registers

Register Name	Address Offset	Shadowed	Description
DBCTL	0x001C	No	Dead-Band Control Register
DBRED	0x0022	No	Dead-Band Rising Edge Delay Count Register
DBFED	0x0020	No	Dead-Band Falling Edge Delay Count Register

19.2.5.3 Operational Highlights for the Dead-Band Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in Figure 19-28.

- **Input Source Selection:**

  The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN_MODE] control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Half Cycle Clocking:**

  The dead-band submodule can be clocked using half cycle clocking to double the resolution (that is, counter clocked at 2× TBCLK)
- **Output Mode Control:**

  The output mode is configured by way of the DBCTL[OUT_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:**

  The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

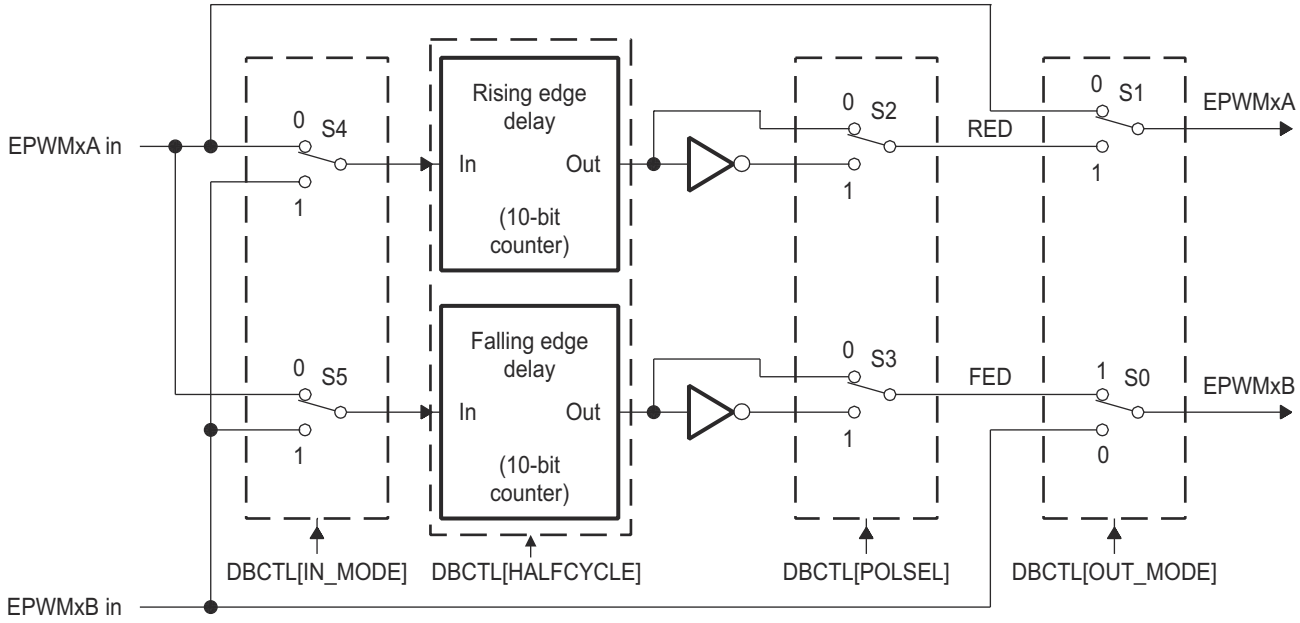

Figure 19-28. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. Table 19-14 documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 19-14 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**

  Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:**

  These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 19-29. Note that to generate equivalent waveforms to Figure 19-29, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**

  Finally the last two entries in Table 19-14 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 19-14. Classical Dead-Band Operating Modes

		DBCTL[POLSEL]		DBCTL[OUT_MODE]	
Mode	**Mode Description**	**S3**	**S2**	**S1**	**S0**
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

Figure 19-29 shows waveforms for typical cases where 0% < duty < 100%.

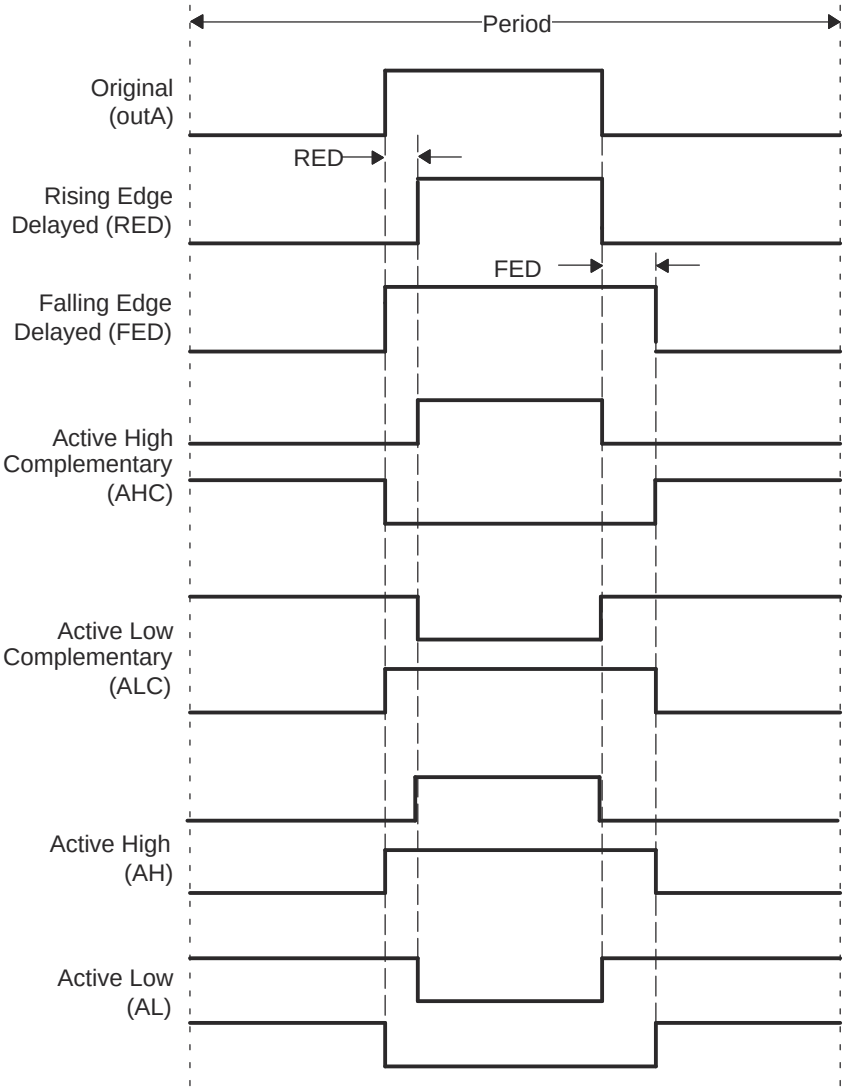

Figure 19-29. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$FED = DBFED \times T_{TBCLK}$

$RED = DBRED \times T_{TBCLK}$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of VCLK4.

For convenience, delay values for various TBCLK options are shown in Table 19-15.

Table 19-15. Dead-Band Delay Values in µS as a Function of DBFED and DBRED

Dead-Band Value	Dead-Band Delay in µS		
DBFED, DBRED	**TBCLK = VCLK4/1**	**TBCLK = VCLK4 /2**	**TBCLK = VCLK4/4**
1	0.02 µS	0.03 µS	0.07 µS
5	0.08 µS	0.17 µS	0.33 µS
10	0.17 µS	0.33 µS	0.67 µS
100	1.67 µS	3.33 µS	6.67 µS
200	3.33 µS	6.67 µS	13.33 µS
400	6.67 µS	13.33 µS	26.67 µS
500	8.33 µS	16.67 µS	33.33 µS
600	10.00 µS	20.00 µS	40.00 µS
700	11.67 µS	23.33 µS	46.67 µS
800	13.33 µS	26.67 µS	53.33 µS
900	15.00 µS	30.00 µS	60.00 µS
1000	16.67 µS	33.33µS	66.67 µS

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$FED = DBFED \times T_{TBCLK}/2$

$RED = DBRED \times T_{TBCLK}/2$

19.2.6 PWM-Chopper (PC) Submodule

Figure 19-30 illustrates the PWM-chopper (PC) submodule within the ePWM module.

The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

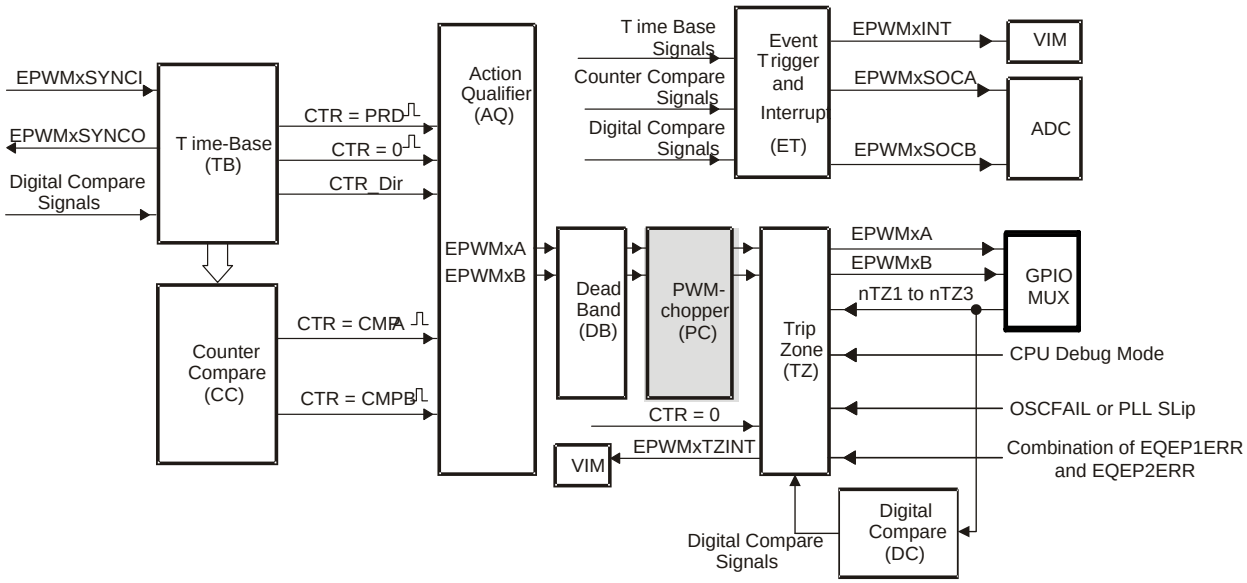

Figure 19-30. PWM-Chopper Submodule

19.2.6.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

19.2.6.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the registers in Table 19-16.

Table 19-16. PWM-Chopper Submodule Registers

Register Name	Address Offset	Shadowed	Description
PCCTL	0x003E	No	PWM-chopper Control Register

19.2.6.3 Operational Highlights for the PWM-Chopper Submodule

Figure 19-31 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from VCLK4. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

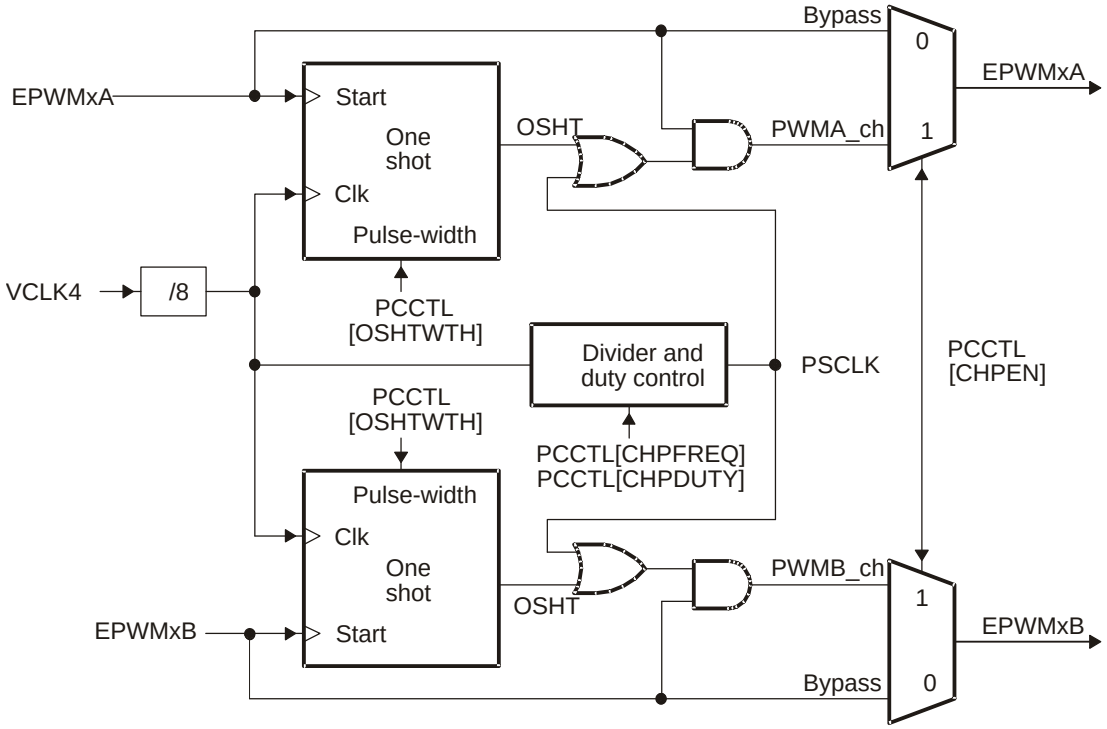

Figure 19-31. PWM-Chopper Submodule Operational Details

19.2.6.4 Waveforms

Figure 19-32 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

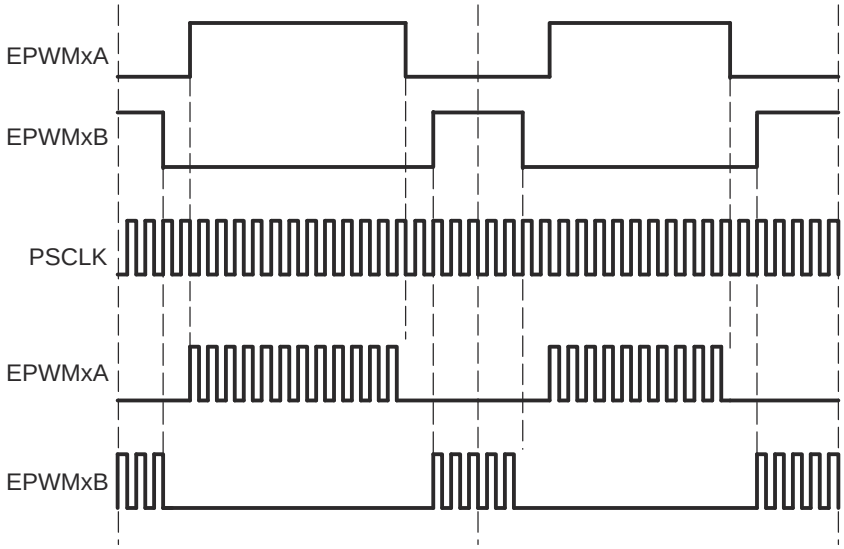

Figure 19-32. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only

19.2.6.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$T_{1stpulse} = T_{VCLK4} \times 8 \times OSHTWTH$

Where T_{VCLK4} is the period of the system clock (VCLK4) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 19-33 shows the first and subsequent sustaining pulses and Table 19-17 gives the possible pulse width values for a VCLK4 = 100 MHz.

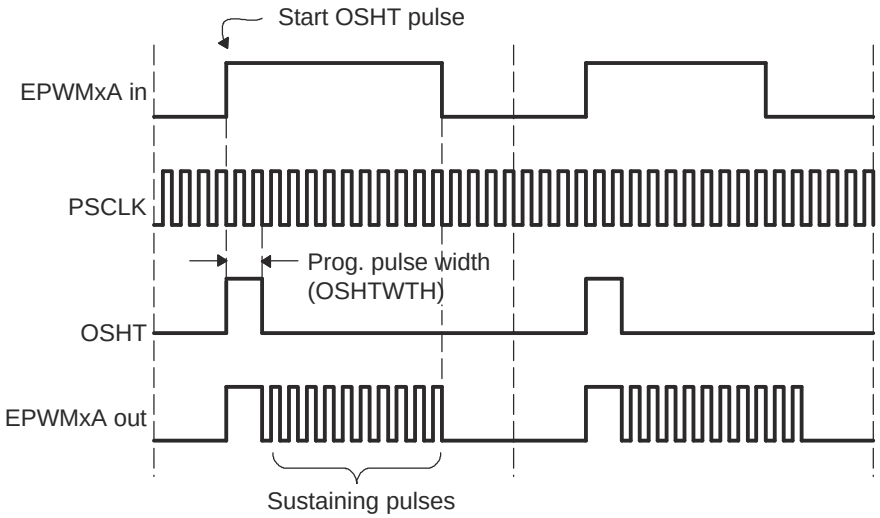

Figure 19-33. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

Table 19-17. Possible Pulse Width Values for VCLK4 = 100 MHz

OSHTWTHz (hex)	Pulse Width (nS)
0	100
1	200
2	300
3	400
4	500
5	600
6	700
7	800
8	900
9	1000
A	1100
B	1200
C	1300
D	1400
E	1500

Table 19-17. Possible Pulse Width Values for VCLK4 = 100 MHz (continued)

OSHTWTHz (hex)	Pulse Width (nS)
F	1600

19.2.6.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 19-34 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

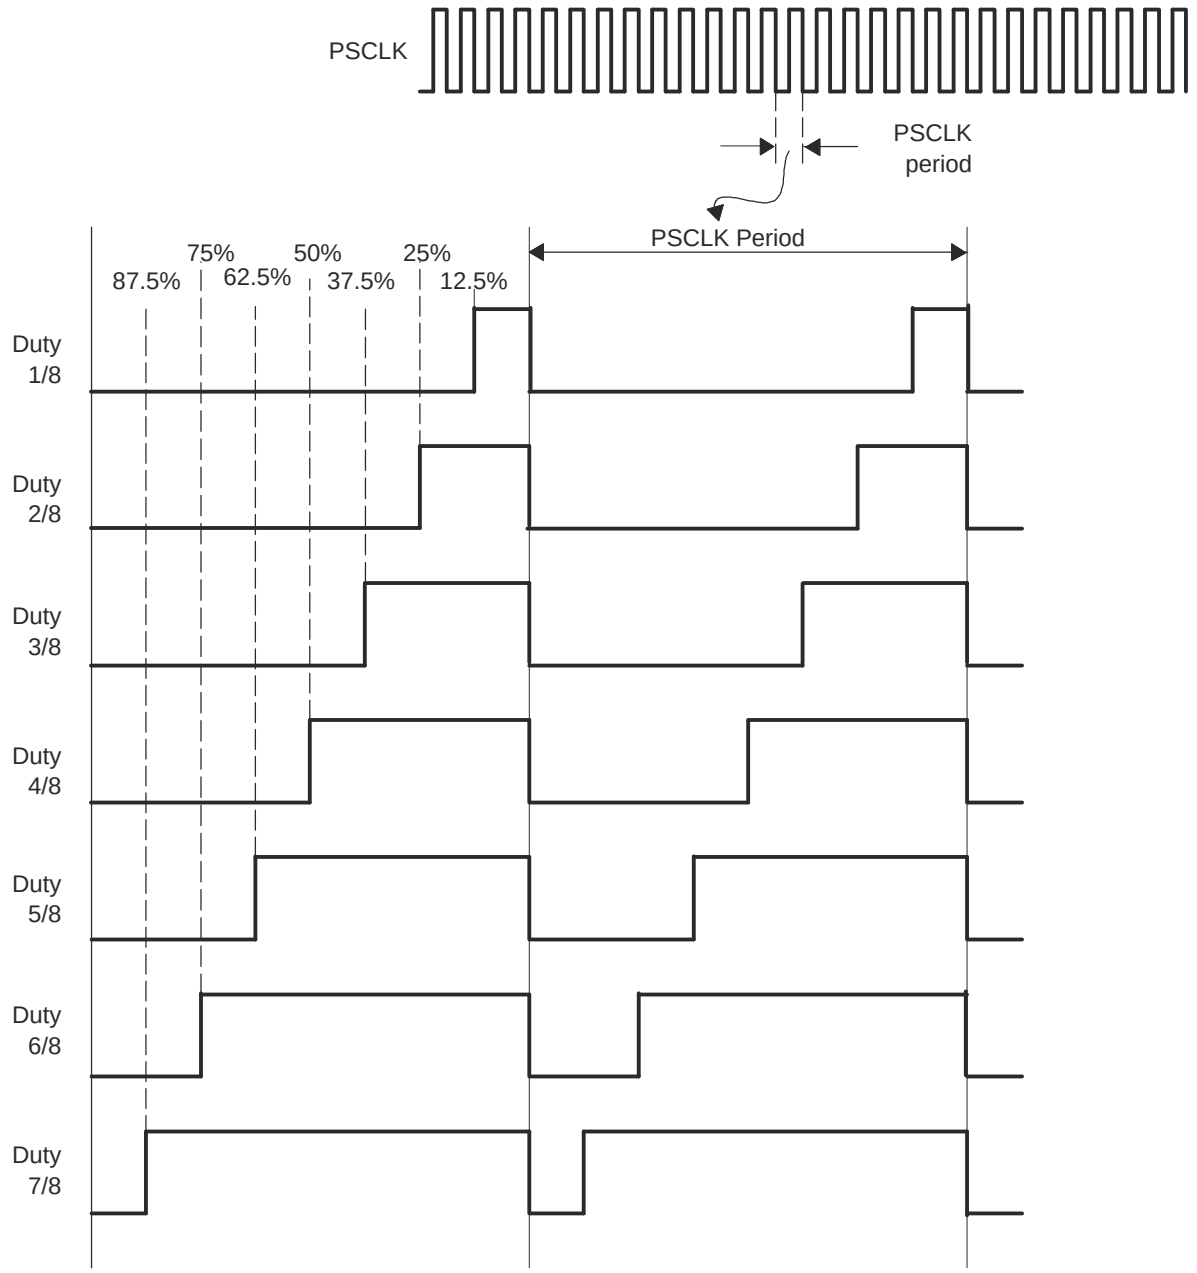

Figure 19-34. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

19.2.7 Trip-Zone (TZ) Submodule

Figure 19-35 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six $\overline{TZn}$ signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from a combination of EQEP1ERR and EQEP2ERR signals. $\overline{TZ5}$ is connected to the system oscillator or PLL clock fail logic, and $\overline{TZ6}$ is sourced from the debug mode halt indication output from the CPU. These signals indicate fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

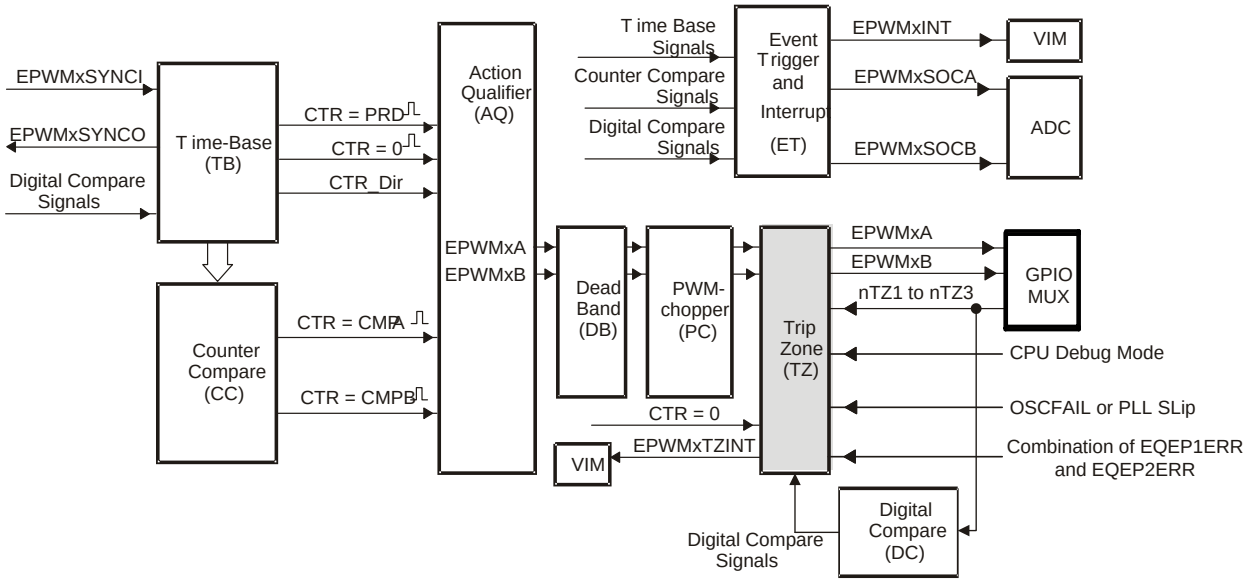

Figure 19-35. Trip-Zone Submodule

19.2.7.1 Purpose of the Trip-Zone Submodule

The key functions of the Trip-Zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ are mapped to all ePWM modules.
- Upon a fault indication, either no action is taken or the ePWM outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

19.2.7.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 19-18. Trip-Zone Submodule Registers

Register Name	Address Offset	Shadowed	Description [2]
TZSEL	0x0026	No	Trip-Zone Select Register
TZDCSEL	0x0024	No	Trip-zone Digital Compare Select Register [1]
TZCTL	0x002A	No	Trip-Zone Control Register
TZEINT	0x0028	No	Trip-Zone Enable Interrupt Register
TZFLG	0x002E	No	Trip-Zone Flag Register
TZCLR	0x002C	No	Trip-Zone Clear Register
TZFRC	0x0032	No	Trip-Zone Force Register

(1) This register is discussed in more detail in Section 19.2.9.
(2) All trip-zone registers are writable only in privileged mode.

19.2.7.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as $\overline{TZn}$) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the system clock (VCLK4) and digitally filtered within the GPIO MUX block. A minimum of 3*TBCLK low pulse width on $\overline{TZn}$ inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on $\overline{TZn}$ inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the IOMM chapter of the device technical reference manual.

Each $\overline{TZn}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAVET2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

  When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 19-19 lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

  If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

  The specified condition on the inputs is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):**

  When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 19-19 lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

  If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.
- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

  A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRIPSEL register and can be either trip zone input pins. For more information on the digital compare submodule signals, see Section 19.2.9.

  When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 19-19 lists the possible actions. In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

  The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL register bit fields. One of four possible actions, shown in Table 19-19, can be taken on a trip event.

Table 19-19. Possible Actions On a Trip Event

TZCTL Register bit-field Settings	EPWMxA and/or EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

Example 19-7. Trip-Zone Configurations

Scenario A:
A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

Scenario B:
A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.
A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

19.2.7.4 Generating Trip Event Interrupts

Figure 19-36 and Figure 19-37 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 19.2.9.

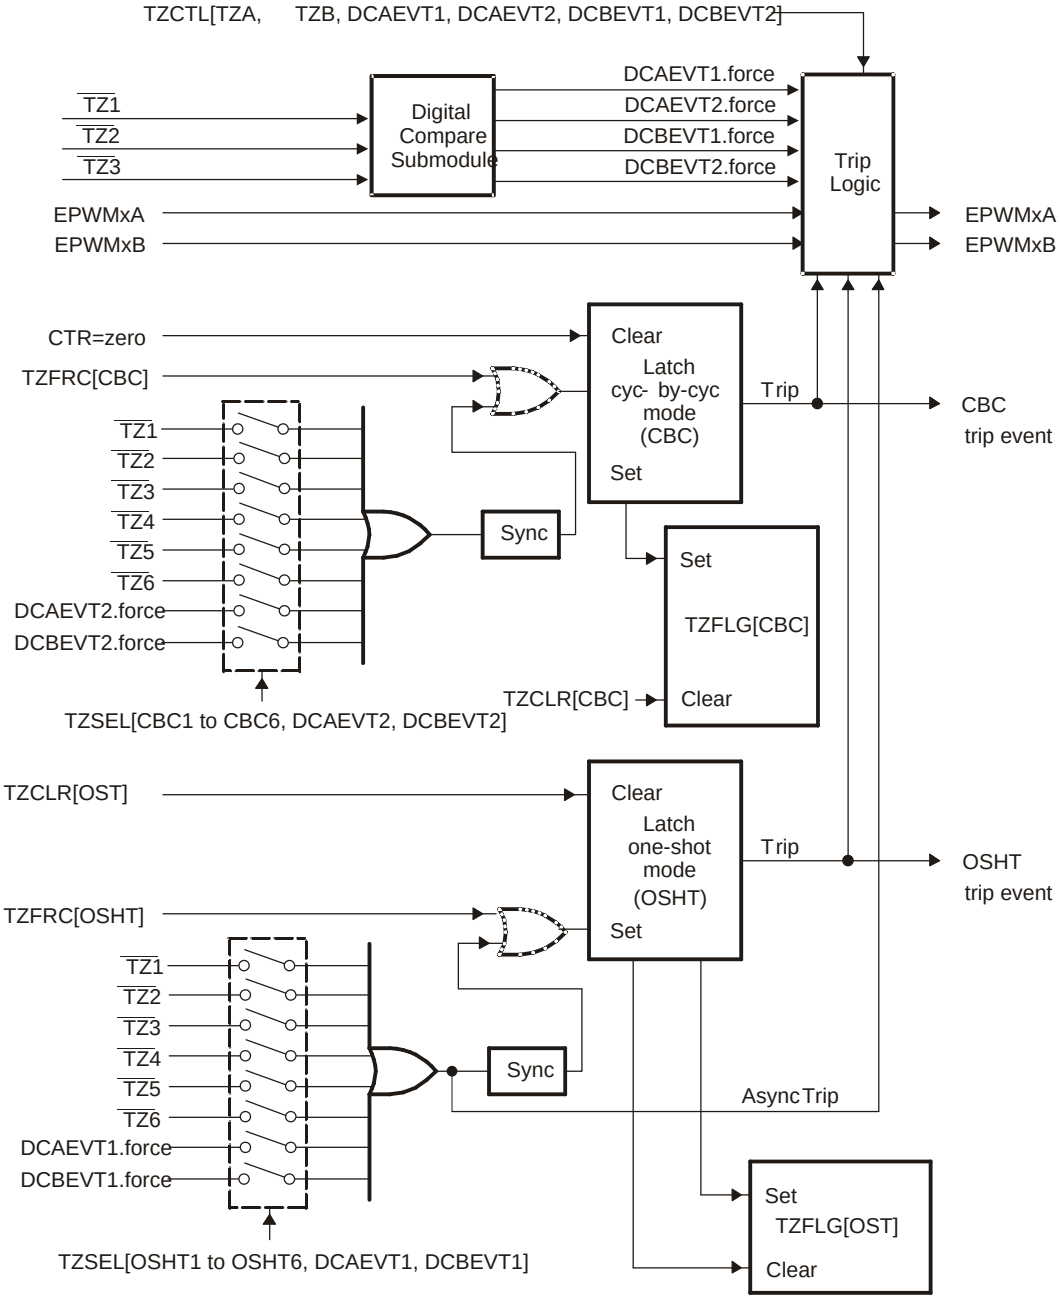

Figure 19-36. Trip-Zone Submodule Mode Control Logic

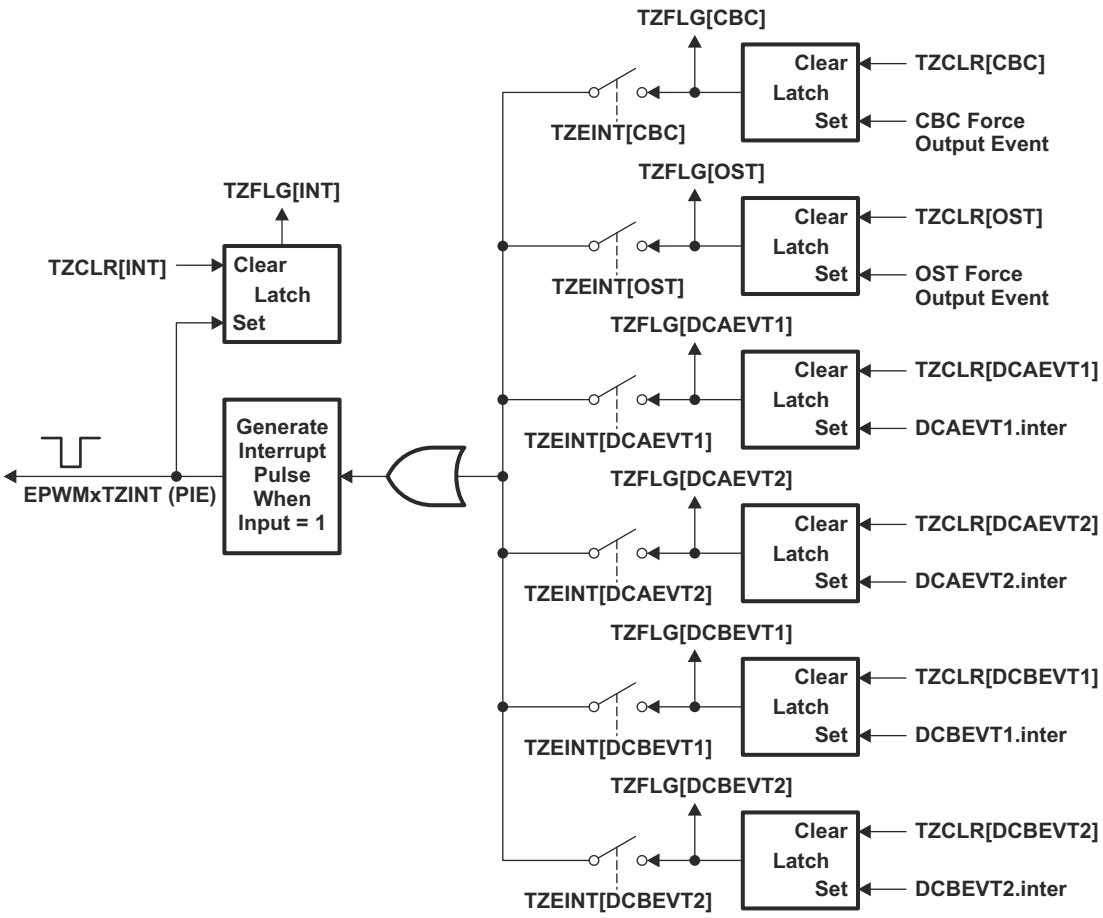

Figure 19-37. Trip-Zone Submodule Interrupt Logic

19.2.8 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. Figure 19-38 illustrates where the event-trigger submodule fits within the ePWM system.

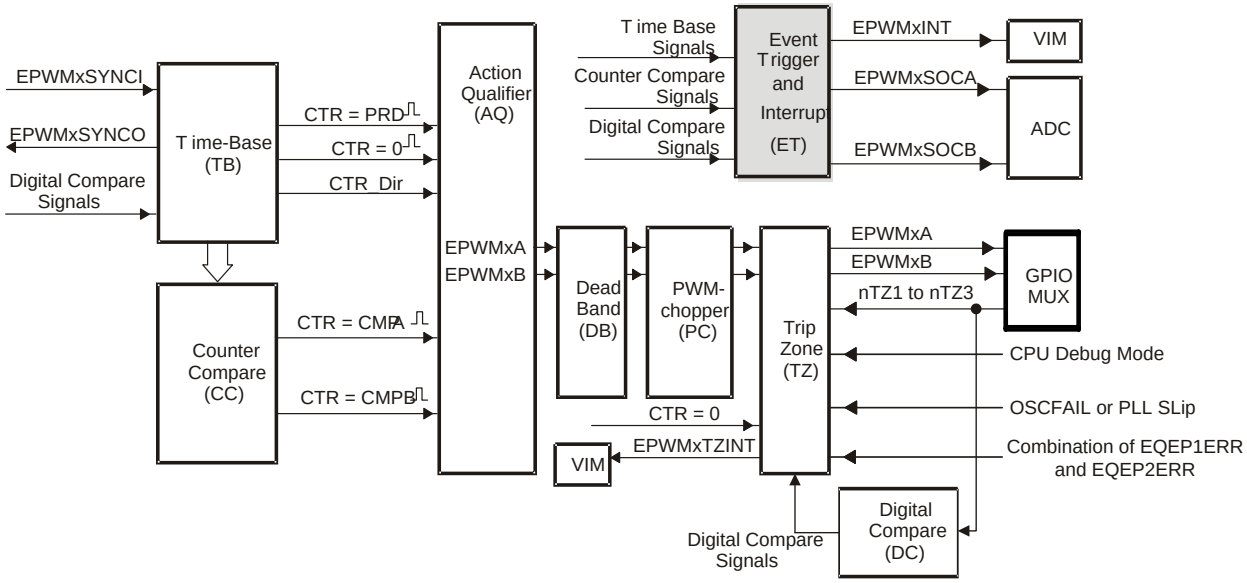

Figure 19-38. Event-Trigger Submodule

19.2.8.1 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the VIM and two start of conversion signals connected to the ADC module. As shown in Figure 19-39, the ePWMxSOCA and ePWMxSOCB signals are combined to generate four special signals that can be used to trigger an ADC start of conversion, and hence multiple modules can initiate an ADC start of conversion via the ADC trigger inputs.

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 19-40) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Every third event

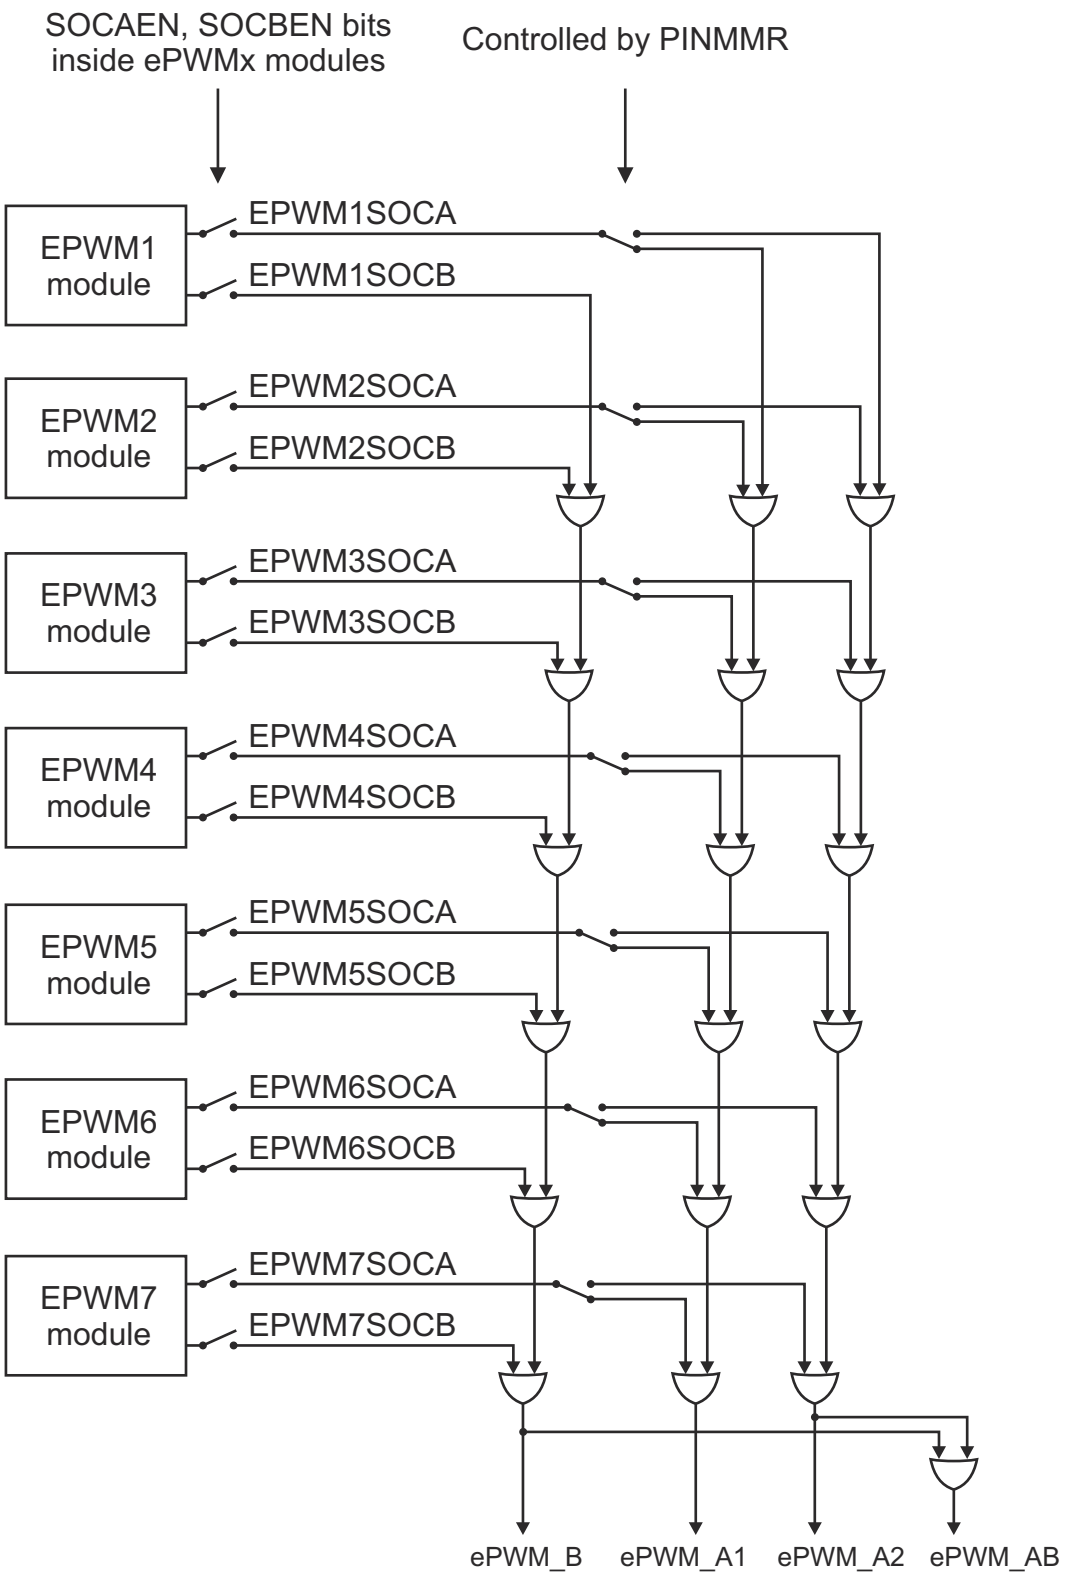

Figure 19-39. Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion

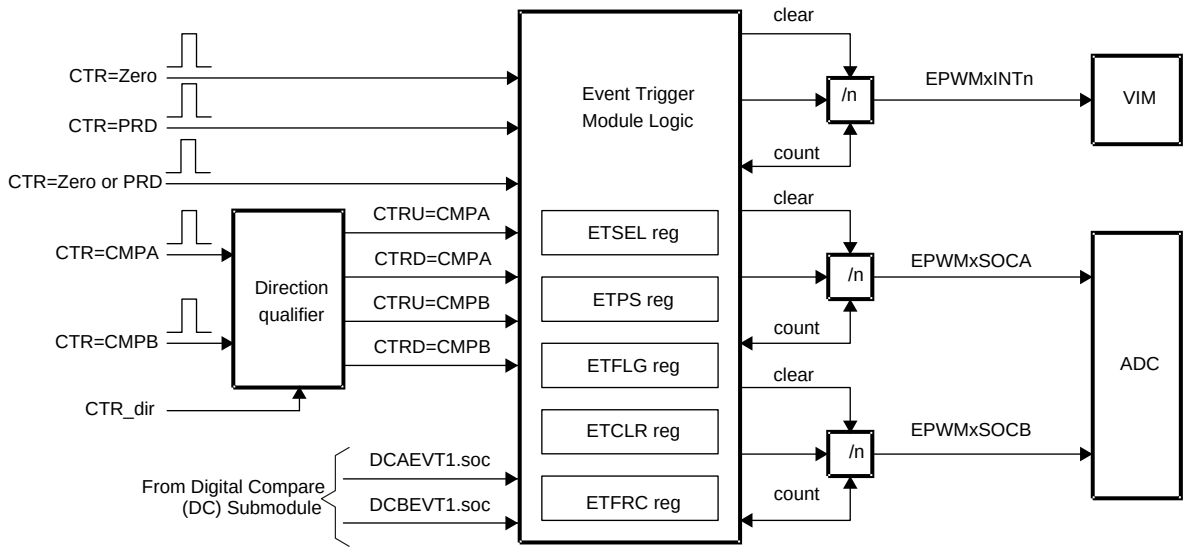

Figure 19-40. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

The key registers used to configure the event-trigger submodule are shown in Table 19-20.

Table 19-20. Event-Trigger Submodule Registers

Register Name	Address Offset	Shadowed	Description
ETSEL	0x0030	No	Event-trigger Selection Register
ETPS	0x0036	No	Event-trigger Prescale Register
ETFLG	0x0034	No	Event-trigger Flag Register
ETCLR	0x003A	No	Event-trigger Clear Register
ETFRC	0x0038	No	Event-trigger Force Register

- ETSEL—This selects which of the possible events will trigger an interrupt or start an ADC conversion
- ETPS—This programs the event prescaling options mentioned above.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or s/w intervention.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 19-41, Figure 19-42, and Figure 19-43.

Figure 19-41 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x0000).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x0000 || TBCTR = TBPRD)
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.

- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the VIM.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event. An interrupt cannot be generated on every fourth or more events.

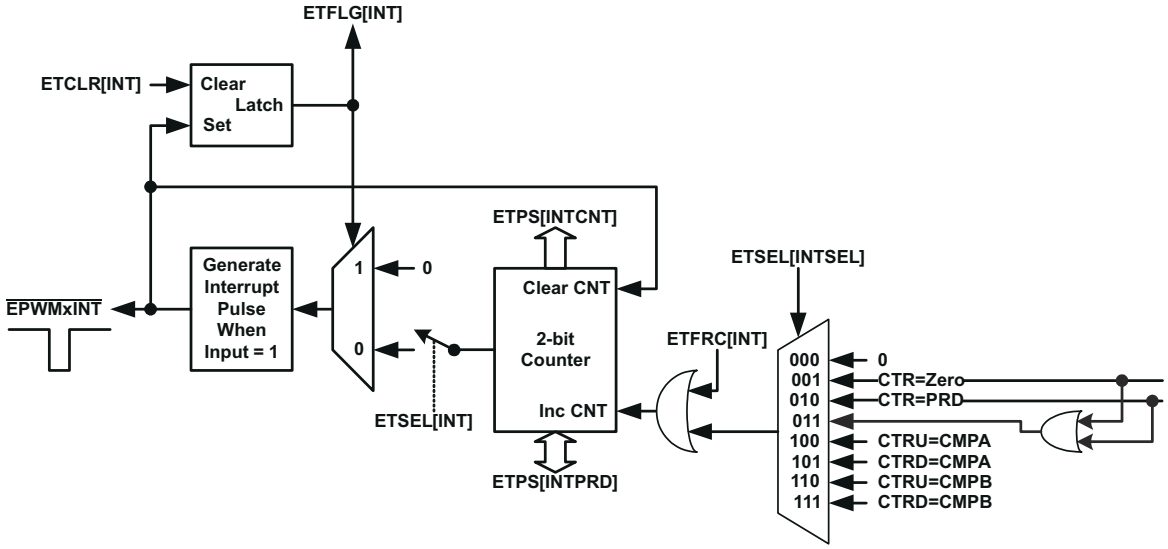

Figure 19-41. Event-Trigger Interrupt Generator

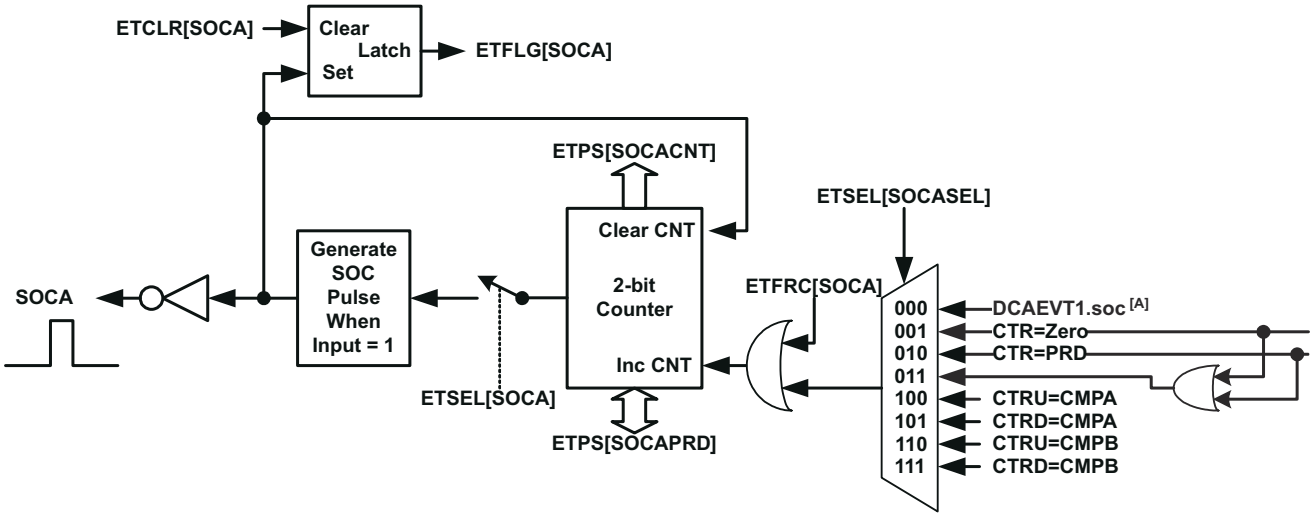
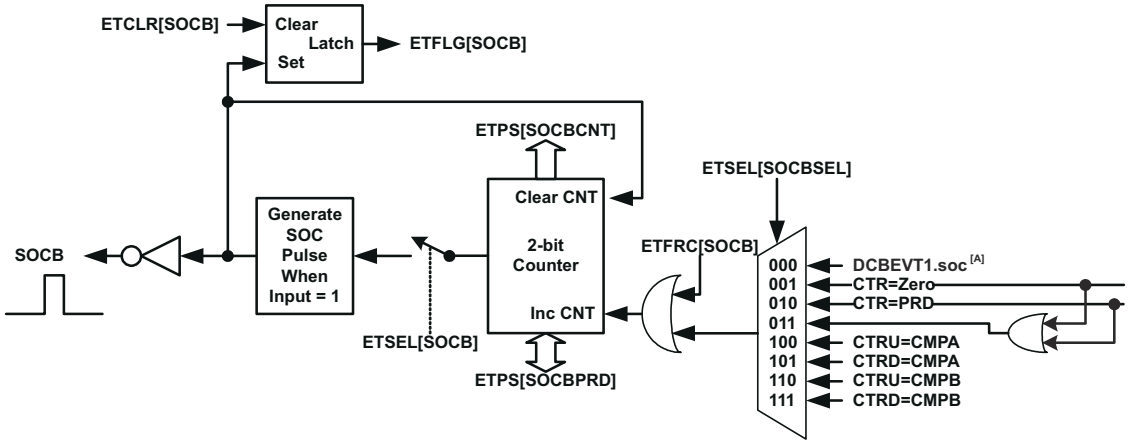
Figure 19-42 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule.



A. The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in Section 19.2.9.

Figure 19-42. Event-Trigger SOCA Pulse Generator

Figure 19-43 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.



A. The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in Section 19.2.9.

Figure 19-43. Event-Trigger SOCB Pulse Generator

19.2.9 Digital Compare (DC) Submodule

Figure 19-44 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The digital compare (DC) submodule compares signals external to the ePWM module to directly generate PWM events/actions that then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

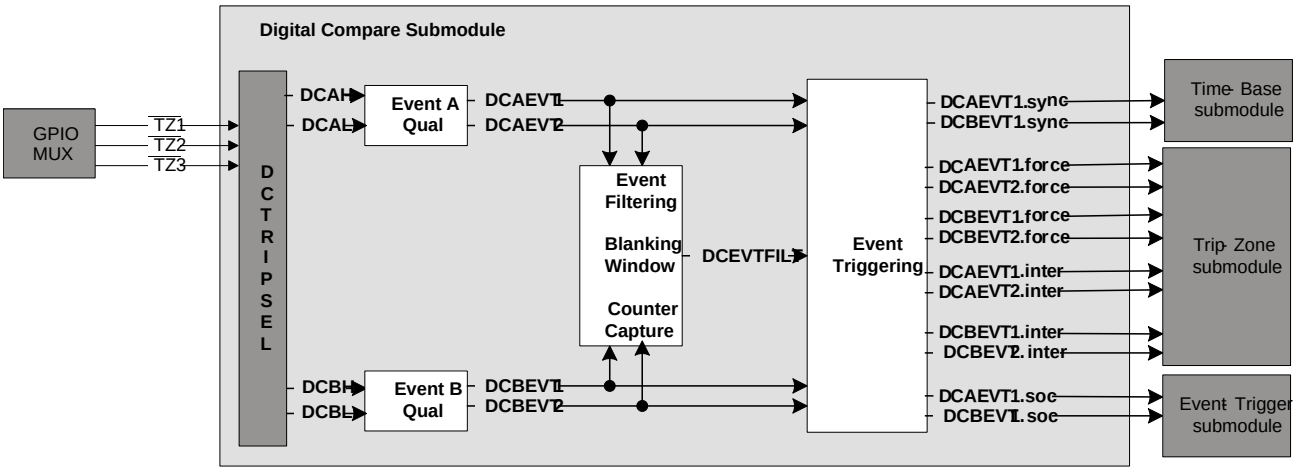


Figure 19-44. Digital-Compare Submodule High-Level Block Diagram

19.2.9.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- $\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

19.2.9.2 Controlling and Monitoring the Digital Compare Submodule

The digital compare submodule operation is controlled and monitored through the following registers:

Table 19-21. Digital Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
TZDCSEL(1) (2)	0x0024	No	Trip Zone Digital Compare Select Register
DCTRIPSEL(1)	0x0062	No	Digital Compare Trip Select Register
DCACTL(1)	0x0060	No	Digital Compare A Control Register
DCBCTL(1)	0x0066	No	Digital Compare B Control Register
DCFCTL(1)	0x0064	No	Digital Compare Filter Control Register
DCCAPCTL(1)	0x006A	No	Digital Compare Capture Control Register
DCFOFFSET	0x0068	Writes	Digital Compare Filter Offset Register
DCFOFFSETCNT	0x006E	No	Digital Compare Filter Offset Counter Register
DCFWINDOW	0x006C	No	Digital Compare Filter Window Register
DCFWINDOWCNT	0x0072	No	Digital Compare Filter Window Counter Register
DCCAP	0x0070	Yes	Digital Compare Counter Capture Register

(1) These registers are writable only in privileged mode.
(2) The TZDCSEL register is part of the trip-zone submodule but is mentioned again here because of its functional significance to the digital compare submodule.

19.2.9.3 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

19.2.9.3.1 Digital Compare Events

As illustrated in Figure 19-44, trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

Note

The $\overline{TZn}$ signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. EPWM outputs are asynchronously tripped when either the $\overline{TZn}$, DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3 × TBCLK sync pulse width is required. If pulse width is < 3 × TBCLK sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in Section 19.2.9.3.2. Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

  DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL[DCAEVT1 or DCAEVT2] configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL[TZA] configuration. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

  The priority of conflicting actions on the TZCTL register is as follows (highest priority overrides lower priority):

  Output EPWMxA: TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)

  Output EPWMxB: TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
- **interrupt signal:**

  DCAEVT1/2.interrupt signals generate trip zone interrupts to the VIM. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.
- **soc signal:**

  The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.
- **sync signal:**

  The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCI input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

Figure 19-45 and Figure 19-46 show how the DCAEVT1, DCAEVT2, or DCEVTFLT signals are processed to generate the digital compare A event force, interrupt, soc and sync signals.

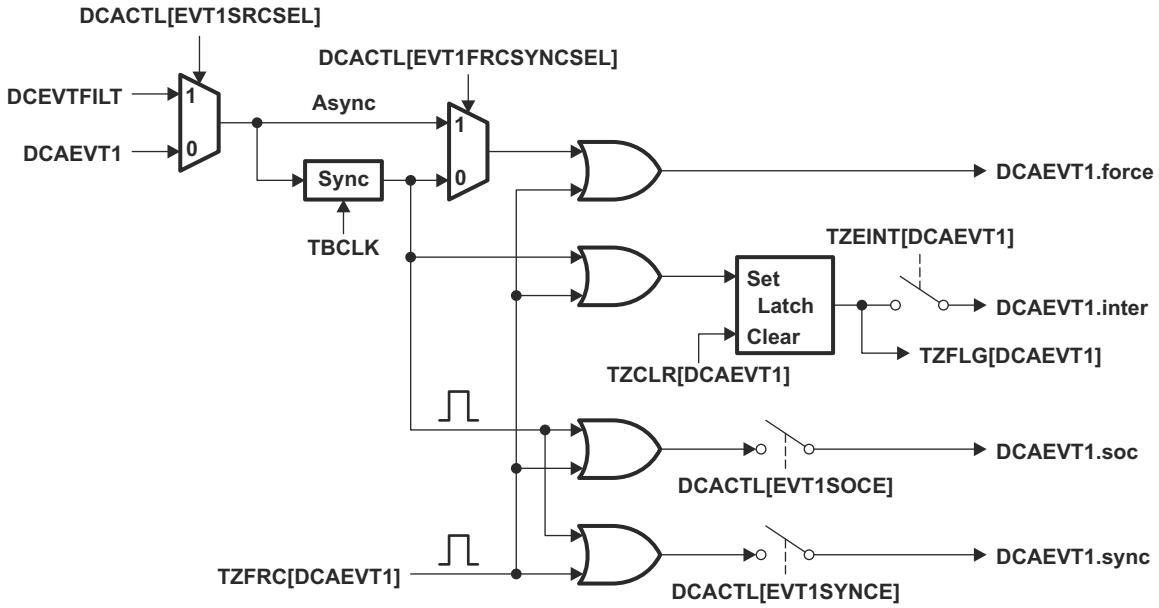

Figure 19-45. DCAEVT1 Event Triggering

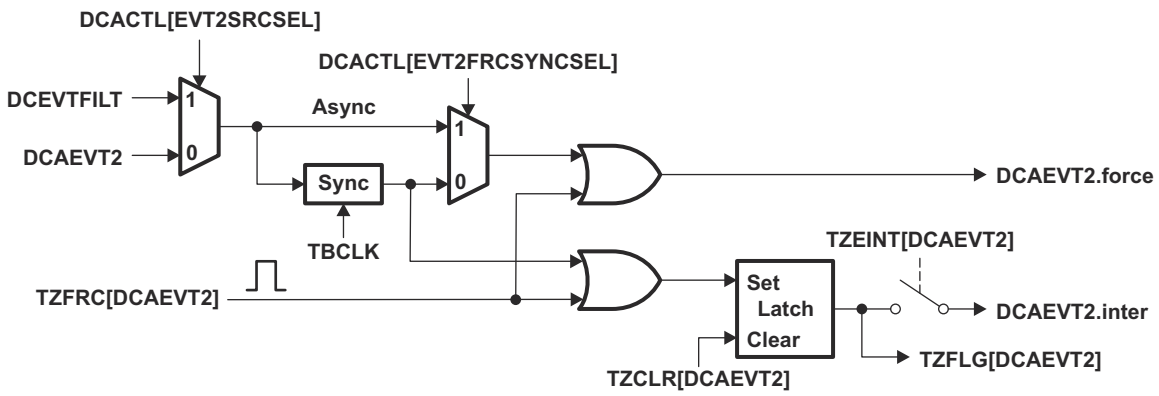

Figure 19-46. DCAEVT2 Event Triggering

Figure 19-47 and Figure 19-48 show how the DCBEVT1, DCBEVT2, or DCEVTFLT signals are processed to generate the digital compare B event force, interrupt, soc, and sync signals.

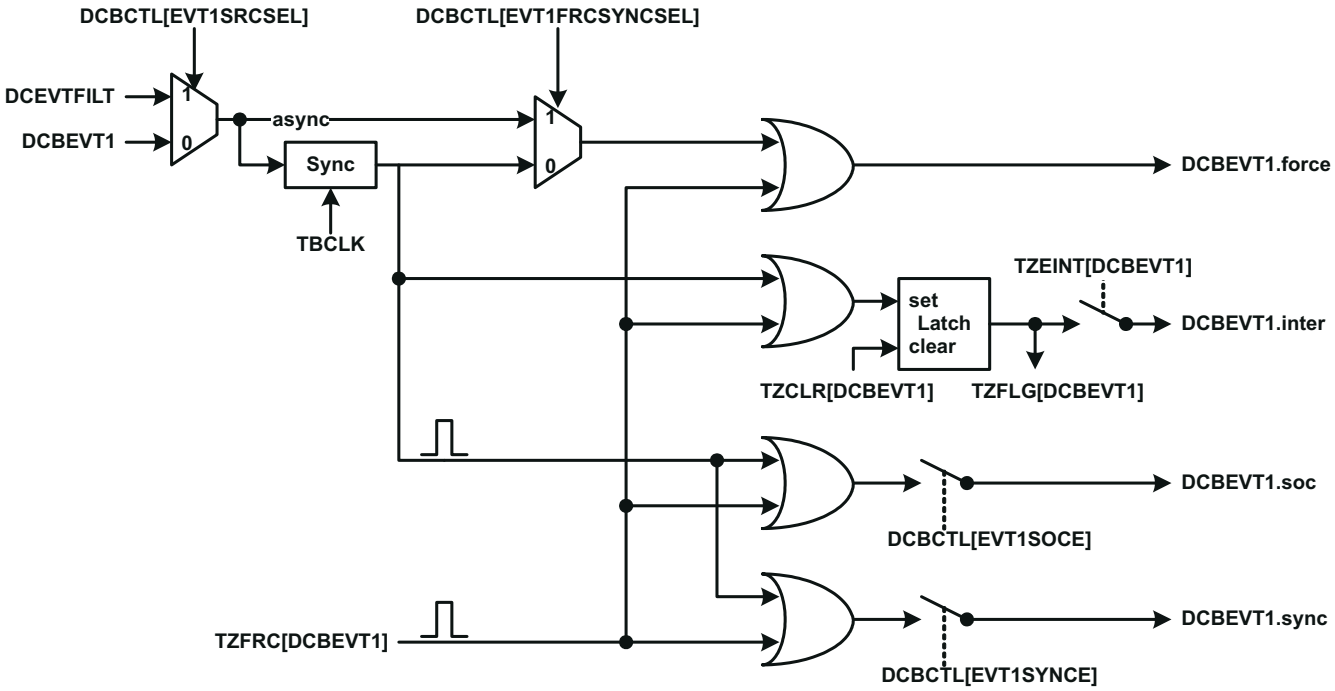

Figure 19-47. DCBEVT1 Event Triggering

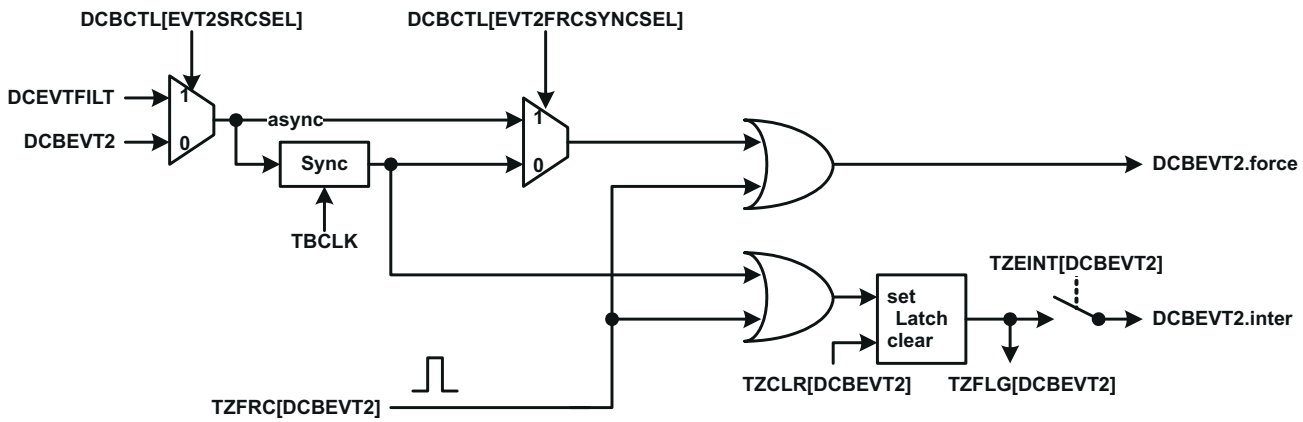

Figure 19-48. DCBEVT2 Event Triggering

19.2.9.3.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. Figure 19-49 shows the details of the event filtering logic.

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

Figure 19-50 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

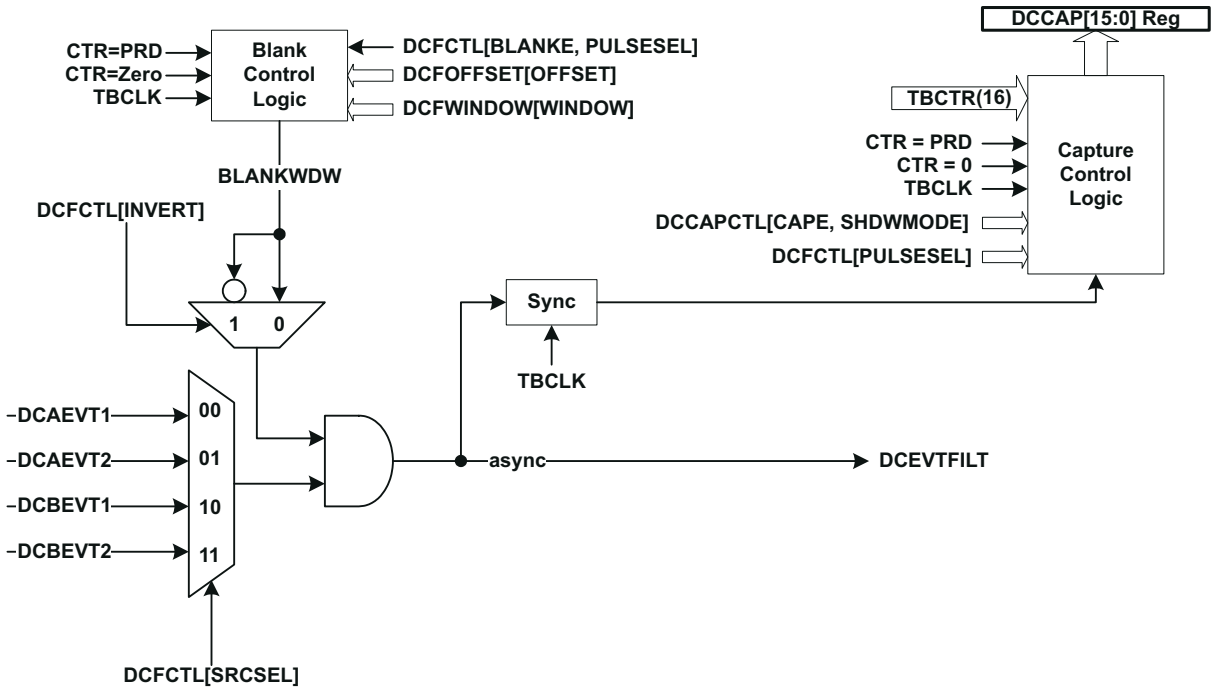

Figure 19-49. Event Filtering

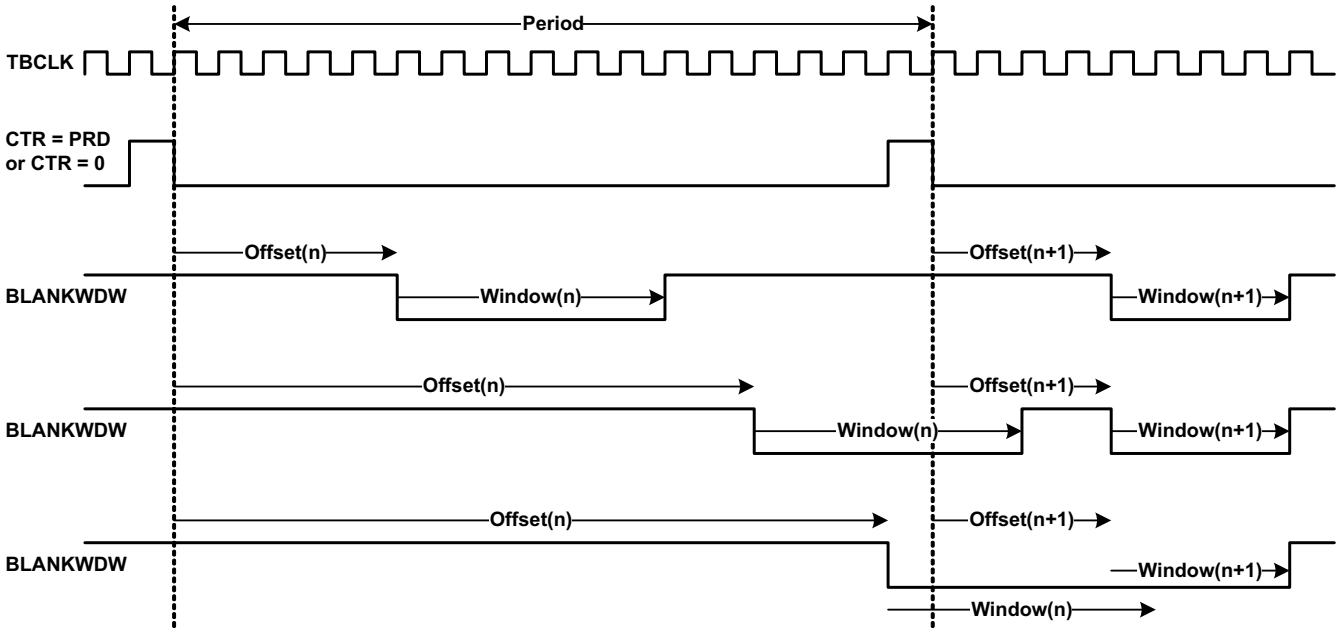

Figure 19-50. Blanking Window Timing Diagram

19.2.10 Proper Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is as follows:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Set TBCLKSYNC = 0
4. Initialize peripheral registers
5. Set TBCLKSYNC = 1
6. Clear any spurious ePWM flags (including interrupt flags)
7. Enable ePWM interrupts
8. Enable global interrupts

19.2.11

19.3 Application Examples

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

19.3.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 19-51. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

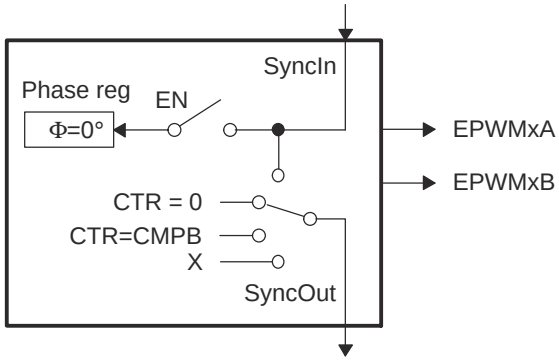

Figure 19-51. Simplified ePWM Module

19.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, that is, via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in Figure 19-52.

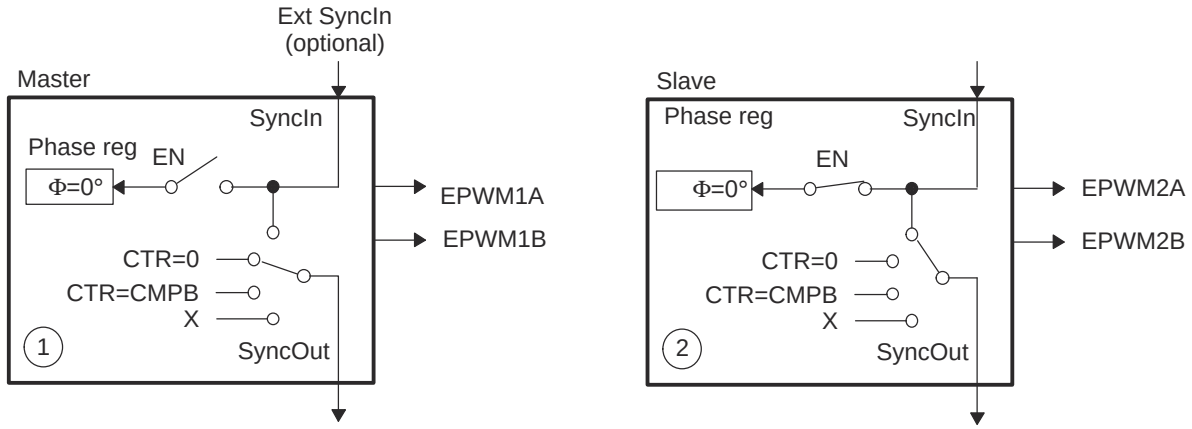

Figure 19-52. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave

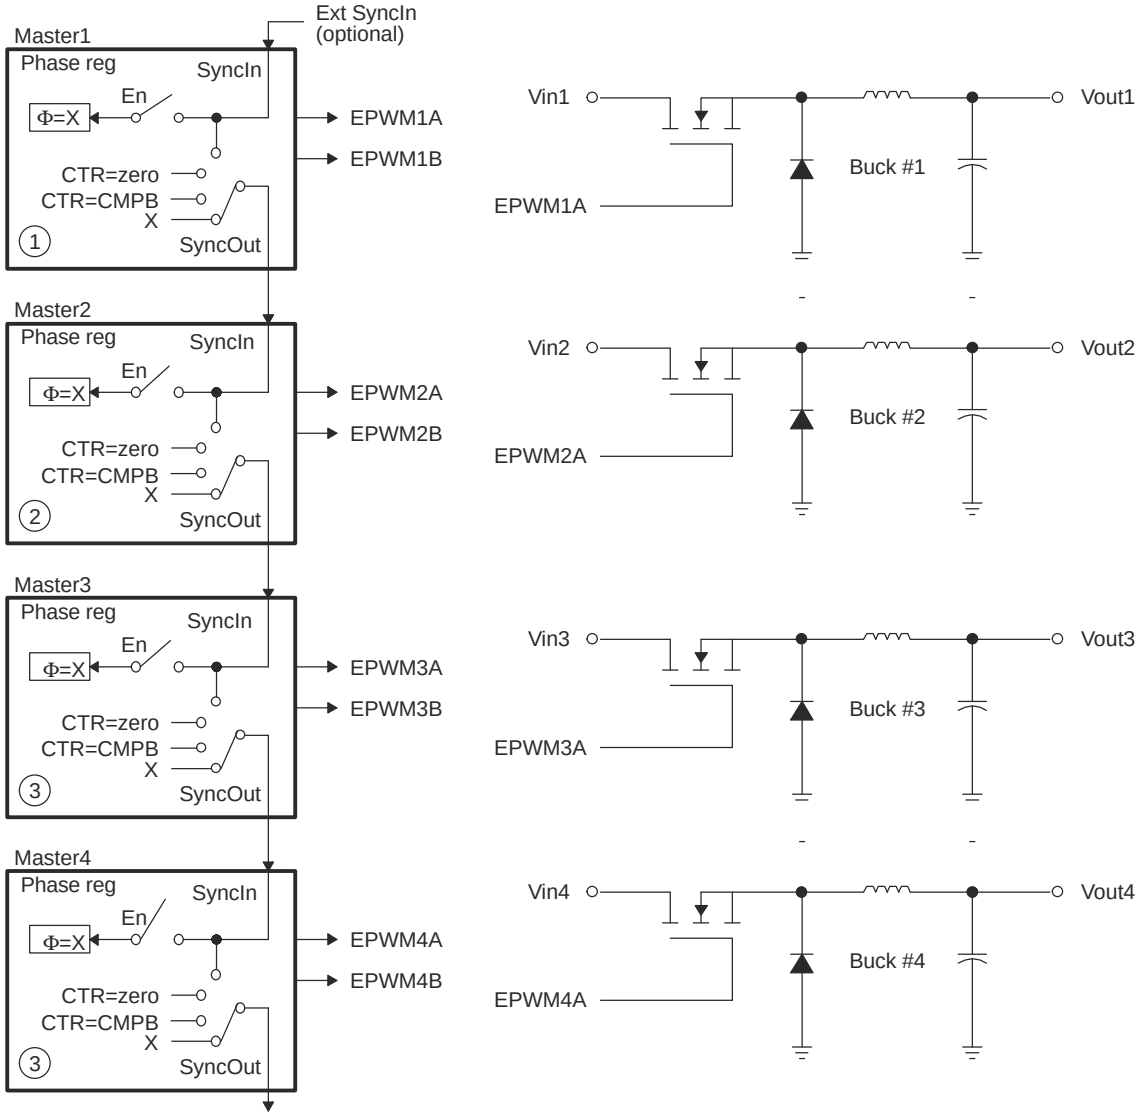
19.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 19-53 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 19-54 shows the waveforms generated by the setup shown in Figure 19-53; note that only three waveforms are shown, although there are four stages.



A. Θ = X indicates value in phase register is a "don't care"

Figure 19-53. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$

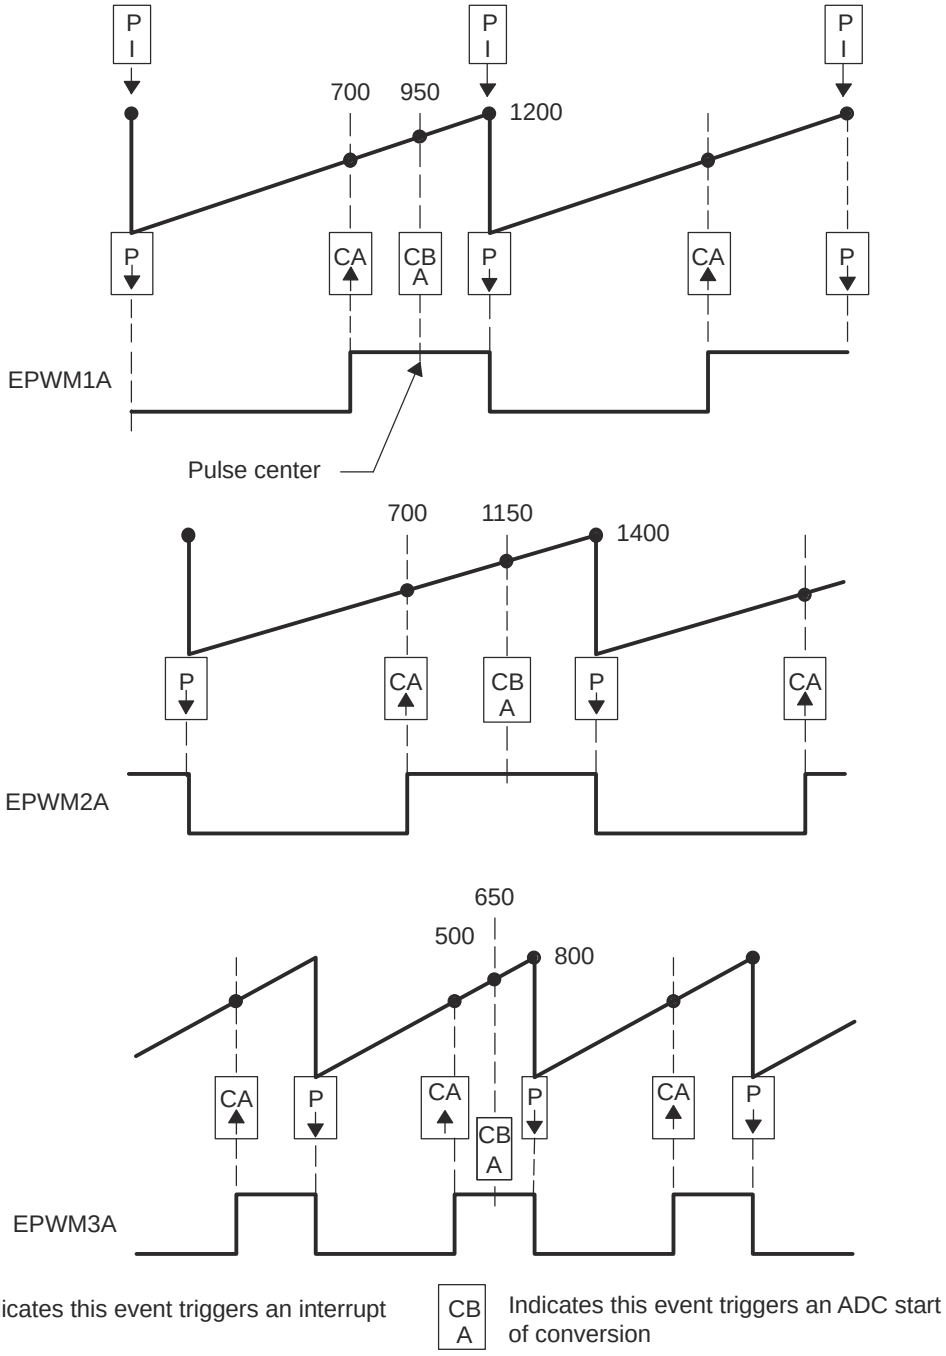


Figure 19-54. Buck Waveforms for Figure 19-53 (Note: Only three bucks shown here)

Example 19-8. Configuration for Example in Figure 19-54

```
//=====================================================================
// (Note: code for only 3 modules shown)
// Initialization Time
//=========================
// EPWM Module 1 config
   EPwm1Regs.TBPRD = 1200;                          // Period = 1201 TBCLK counts

   EPwm3Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;    // load on CTR=Zero
   EPwm3Regs.AQCTLA.bit.PRD = AQ_CLEAR;
   EPwm3Regs.AQCTLA.bit.CAU = AQ_SET;
//
// Run Time (Note: Example execution of one run-time instant)
//=====================================================
   EPwm1Regs.CMPA.half.CMPA = 700;                  // adjust duty for output EPWM1A
   EPwm2Regs.CMPA.half.CMPA = 700;                  // adjust duty for output EPWM2A
   EPwm3Regs.CMPA.half.CMPA = 500;                  // adjust duty for output EPWM3A
```

19.3.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 19-55 shows such a configuration; Figure 19-56 shows the waveforms generated by the configuration.

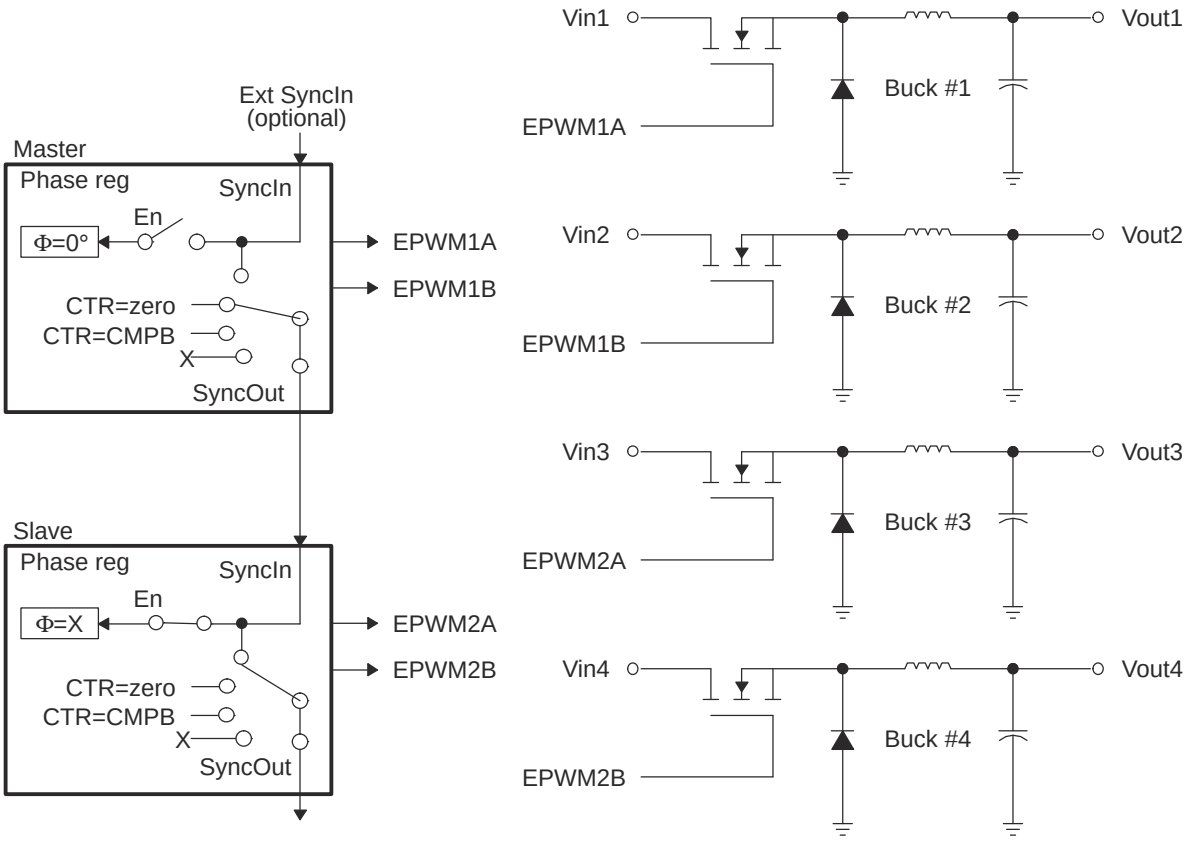

Figure 19-55. Control of Four Buck Stages. (Note: F_{PWM2} = N x F_{PWM1})

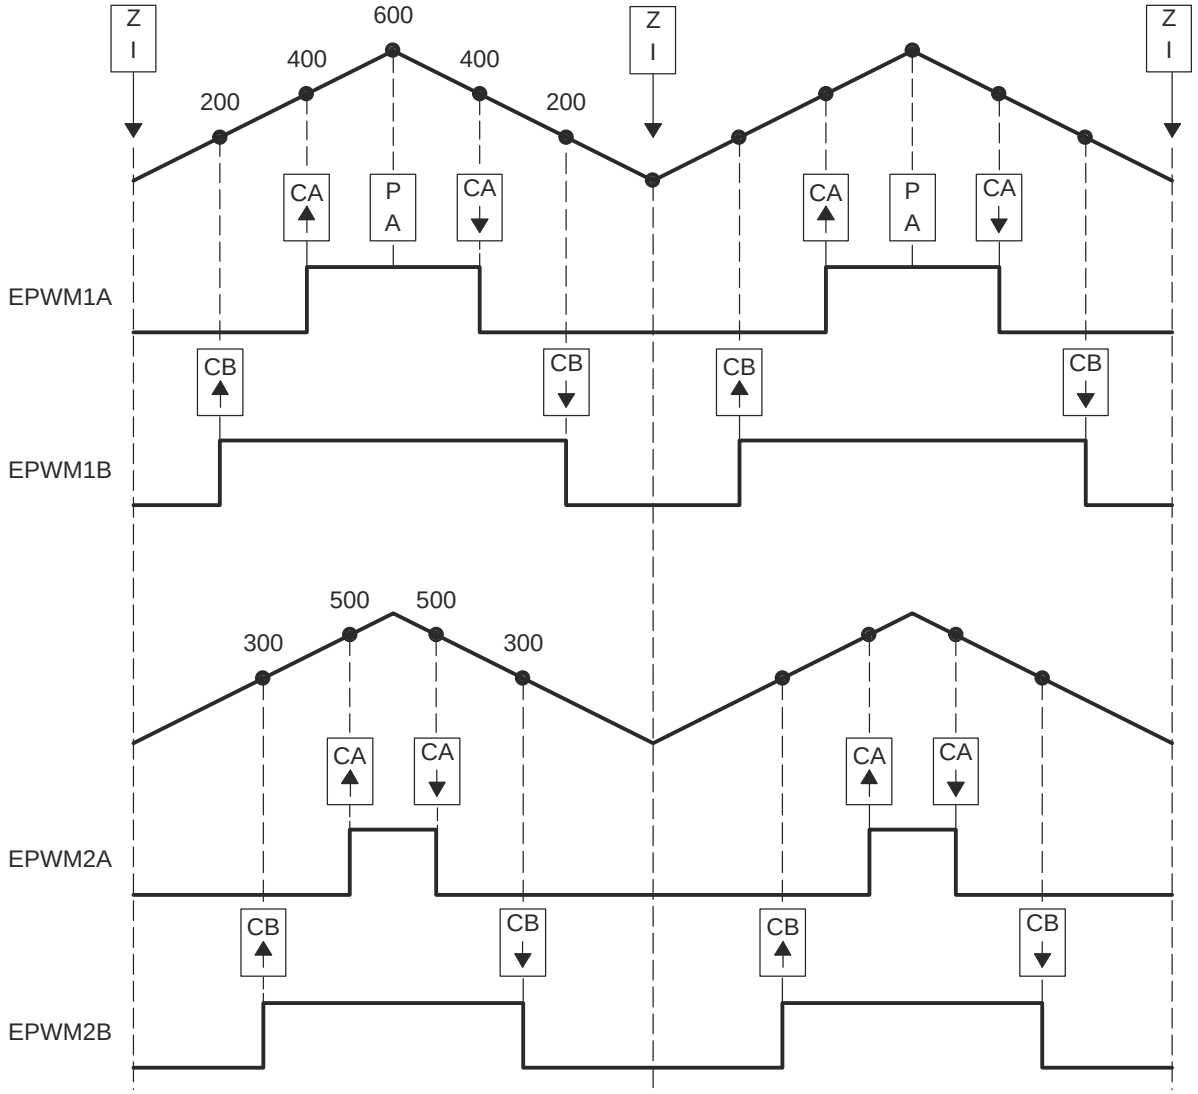

Figure 19-56. Buck Waveforms for Figure 19-55 (Note: $F_{PWM2} = F_{PWM1)}$)

Example 19-9. Code Snippet for Configuration in Figure 19-55

```
//=========================
// EPWM Module 1 config
     EPwm1Regs.TBPRD = 600;                          // Period = 1200 TBCLK counts
     EPwm1Regs.TBPHS.half.TBPHS = 0;                 // Set Phase register to zero
     EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
     EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;         // Master module
     EPwm1Regs.TBCTL.bit.PRDLD = TB_SHADOW;
     EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_CTR_ZERO;     // Sync down-stream module
     EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
     EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
     EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;              // set actions for EPWM1A
     EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
     EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;              // set actions for EPWM1B
     EPwm1Regs.AQCTLB.bit.CBD = AQ_CLEAR;
// EPWM Module 2 config
     EPwm2Regs.TBPRD = 600;                          // Period = 1200 TBCLK counts
     EPwm2Regs.TBPHS.half.TBPHS = 0;                 // Set Phase register to zero
     EPwm2Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
     EPwm2Regs.TBCTL.bit.PHSEN = TB_ENABLE;          // Slave module
     EPwm2Regs.TBCTL.bit.PRDLD = TB_SHADOW;
     EPwm2Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_IN;      // sync flow-through
     EPwm2Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.AQCTLA.bit.CAU = AQ_SET;              // set actions for EPWM2A
     EPwm2Regs.AQCTLA.bit.CAD = AQ_CLEAR;
     EPwm2Regs.AQCTLB.bit.CBU = AQ_SET;              // set actions for EPWM2B
     EPwm2Regs.AQCTLB.bit.CBD = AQ_CLEAR;
//
// Run Time (Note: Example execution of one run-time instance)
//=============================================================
    EPwm1Regs.CMPA.half.CMPA = 400;                // adjust duty for output EPWM1A
    EPwm1Regs.CMPB = 200;                          // adjust duty for output EPWM1B
    EPwm2Regs.CMPA.half.CMPA = 500;                // adjust duty for output EPWM2A
    EPwm2Regs.CMPB = 300;                          // adjust duty for output EPWM2B
```

19.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 19-57 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 19-58 shows the waveforms generated by the configuration shown in Figure 19-57.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

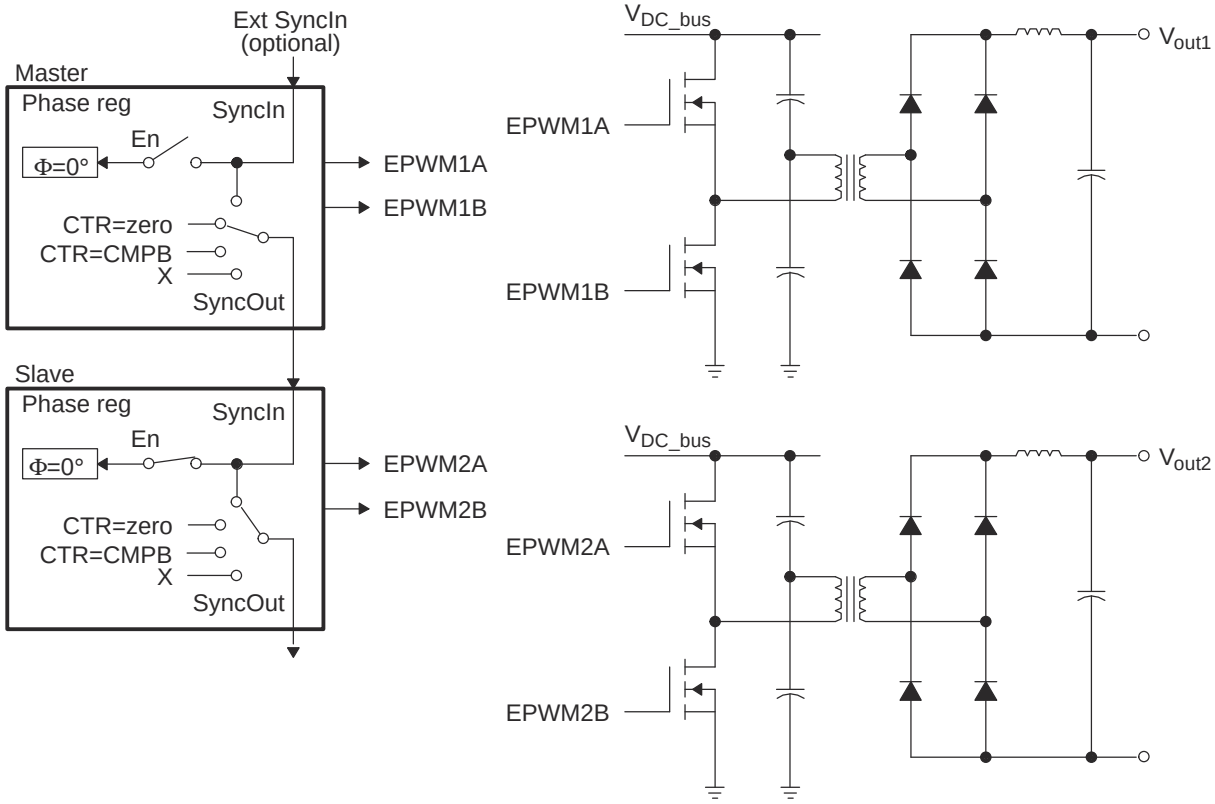

Figure 19-57. Control of Two Half-H Bridge Stages (F_{PWM2} = N x F_{PWM1})

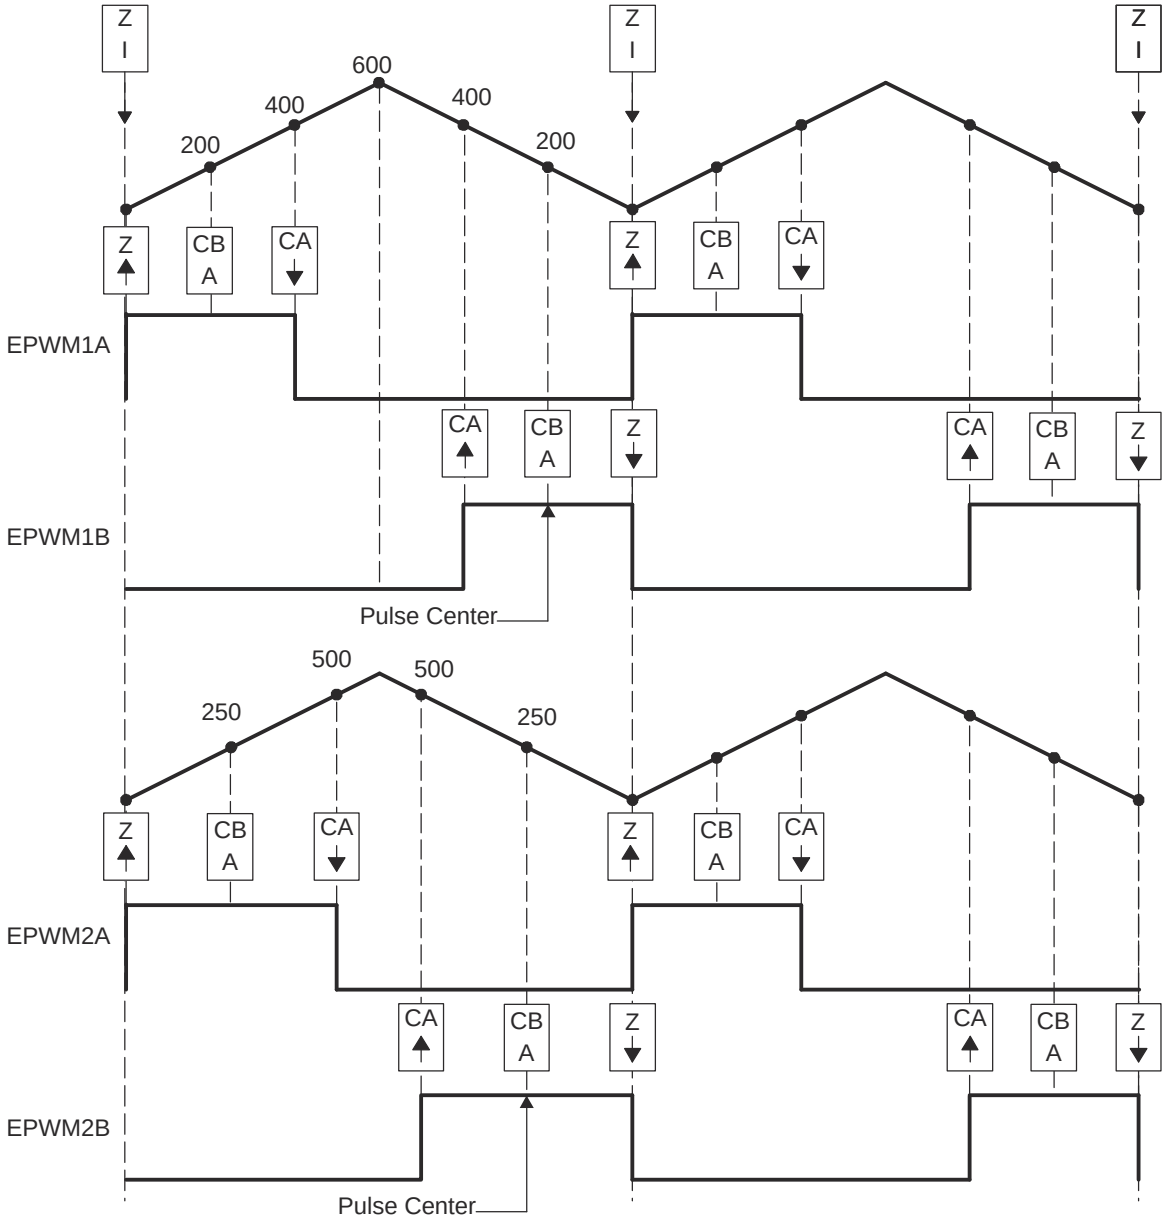

Figure 19-58. Half-H Bridge Waveforms for Figure 19-57 (Note: Here $F_{PWM2} = F_{PWM1}$)

     EPwm2Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.AQCTLA.bit.ZRO = AQ_SET;              // set actions for EPWM1A
     EPwm2Regs.AQCTLA.bit.CAU = AQ_CLEAR;
     EPwm2Regs.AQCTLB.bit.ZRO = AQ_CLEAR;            // set actions for EPWM1B
     EPwm2Regs.AQCTLB.bit.CAD = AQ_SET;
//=============================================================
     EPwm1Regs.CMPA.half.CMPA = 400;                 // adjust duty for output EPWM1A & EPWM1B
     EPwm1Regs.CMPB = 200;                           // adjust point-in-time for ADCSOC trigger
     EPwm2Regs.CMPA.half.CMPA = 500;                 // adjust duty for output EPWM2A & EPWM2B
     EPwm2Regs.CMPB = 250;                           // adjust point-in-time for ADCSOC trigger
```

19.3.5.1

19.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 19-59 shows how six PWM modules can control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 19-59), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

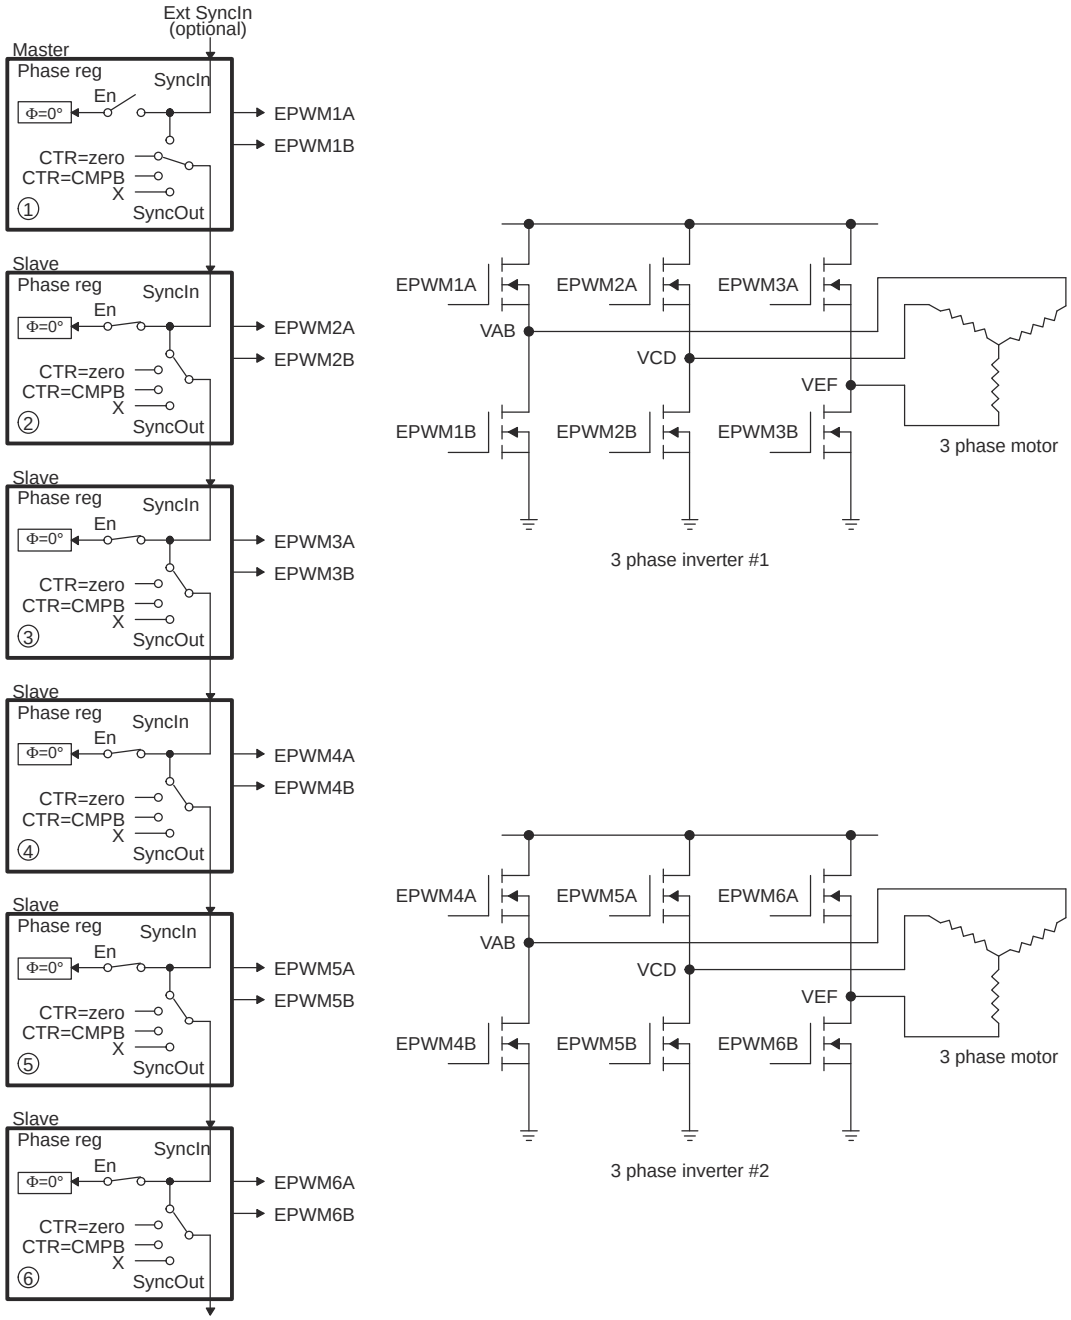

Figure 19-59. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

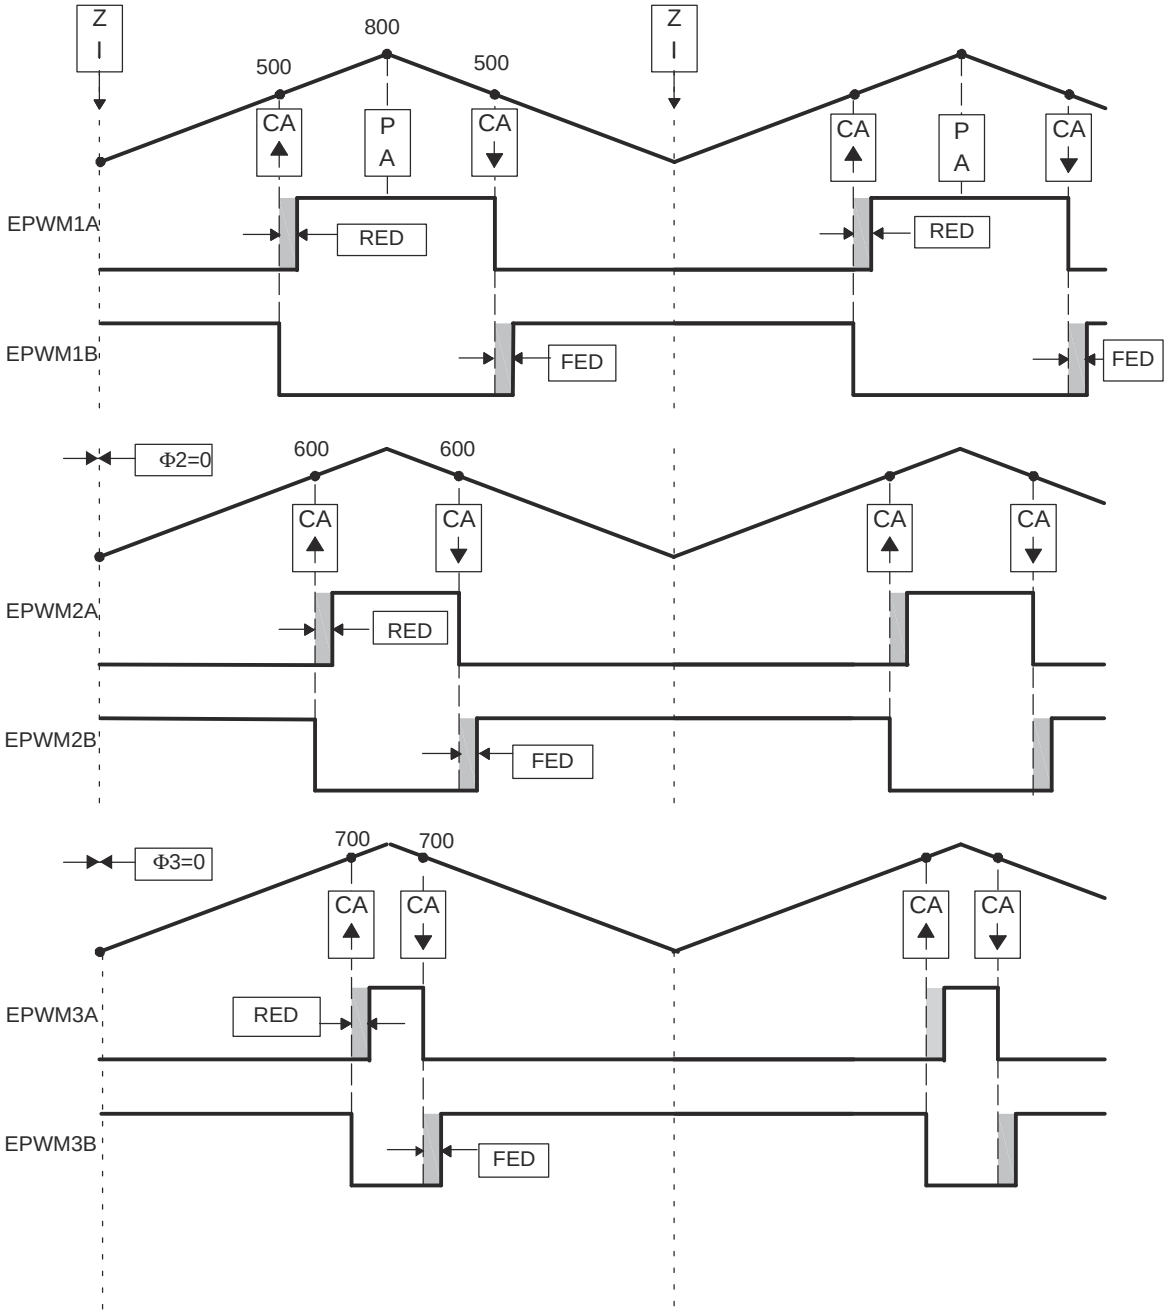

Figure 19-60. 3-Phase Inverter Waveforms for Figure 19-59 (Only One Inverter Shown)

19.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of applications that rely on phase relationship between stages for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, Figure 19-61 shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

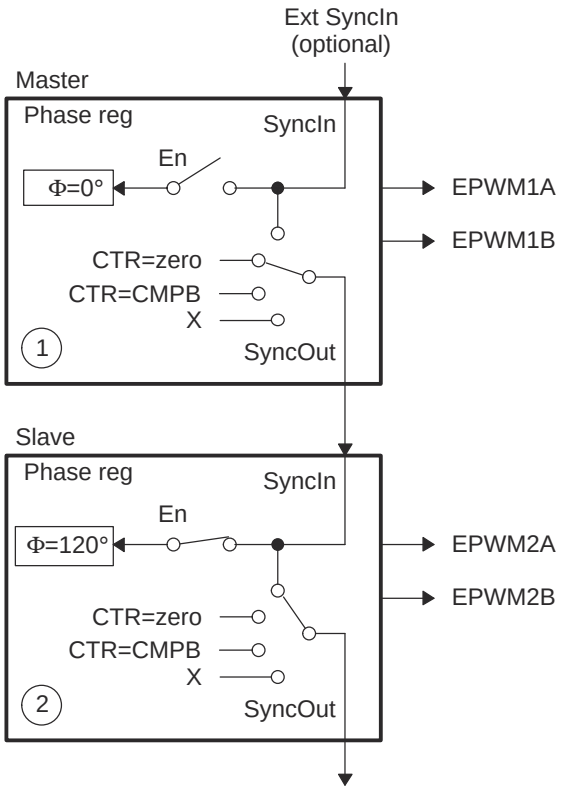

Figure 19-61. Configuring Two PWM Modules for Phase Control

Figure 19-62 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is, 200/600 X 360° = 120°). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120°.

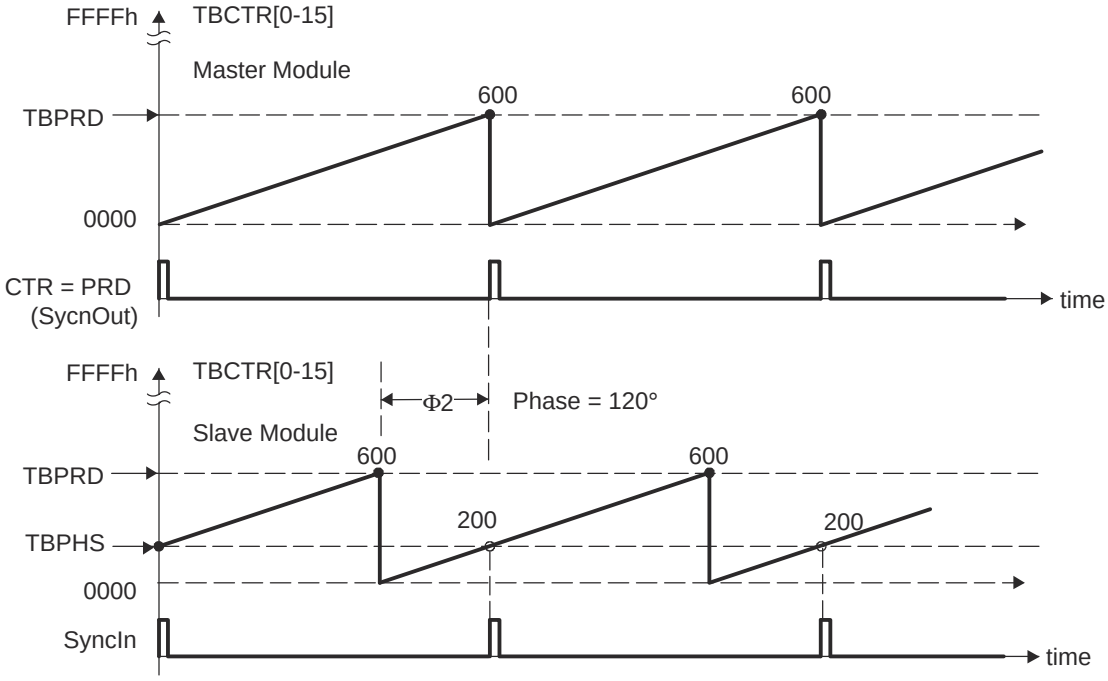

Figure 19-62. Timing Waveforms Associated With Phase Control Between 2 Modules

19.4 ePWM Module Control and Status Registers

Table 19-22 lists the memory-mapped registers for the ePWM Module Control and Status Registers. All register offset addresses not listed in Table 19-22 should be considered as reserved locations and the register contents should not be modified.

19.4.1 TBSTS Register (Offset = 0h) [reset = 1h]

TBSTS is shown in Figure 19-62 and described in Table 19-23.

Figure 19-62. TBSTS Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					CTRMAX	SYNCI	CTRDIR
R-0h					R-0h	R/W-0h	R-1h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 19-23. TBSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	CTRMAX	R	0h	Time-Base Counter Max Latched Status Bit 0h = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 1h = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.
1	SYNCI	R/W	0h	Input Synchronization Latched Status Bit 0h = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 1h = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCI). Writing a 1 to this bit will clear the latched event.
0	CTRDIR	R	1h	Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE]. 0h = Time-Base Counter is currently counting down. 1h = Time-Base Counter is currently counting up.

19.4.2 TBCTL Register (Offset = 2h) [reset = 83h]

TBCTL is shown in Figure 19-63 and described in Table 19-24.

Figure 19-63. TBCTL Register

Table 19-24. TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0h = Stop after the next time-base counter increment or decrement. 1h = Stop when counter completes a whole cycle. In up-count mode, stop when the time-base counter = period (TBCTR = TBPRD). In down-count mode, stop when the time-base counter = 0x0000 (TBCTR = 0x0000). In up-down-count mode, stop when the time-base counter = 0x0000 (TBCTR = 0x0000). 2h = Free run 3h = Free run
13	PHSDIR	R/W	0h	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event. In the up-count and down-count modes this bit is ignored. 0h = Count down after the synchronization event. 1h = Count up after the synchronization event.
12-10	CLKDIV	R/W	0h	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = VCLK4 / (HSPCLKDIV x CLKDIV) 0h = /1 (default on reset) 1h = /2 2h = /4 3h = /8 4h = /16 5h = /32 6h = /64 7h = /128

Table 19-24. TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = VCLK4 / (HSPCLKDIV x CLKDIV) 0h = /1 1h = /2 (default on reset) 2h = /4 3h = /6 4h = /8 5h = /10 6h = /12 7h = /14
6	SWFSYNC	R/W	0h	Software Forced Synchronization Pulse. This event is ORed with the EPWMxSYNCI input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCI is selected by SYNCOSEL = 0. 0h = Writing a 0 has no effect and reads always return a 0. 1h = Writing a 1 forces a one-time synchronization pulse to be generated.
5-4	SYNCOSEL	R/W	0h	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0h = EPWMxSYNC 1h = CTR = zero: Time-base counter equal to zero (TBCTR = 0x0000) 2h = CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB) 3h = Disable EPWMxSYNCO signal
3	PRDLD	R/W	0h	Active Period Register Load From Shadow Register Select 0h = The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to 0. A write or read to the TBPRD register accesses the shadow register. 1h = Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register.
2	PHSEN	R/W	0h	Counter Register Load From Phase Register Enable 0h = Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS) 1h = Load the time-base counter with the phase register when an EPWMxSYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit, or when a digital compare sync event occurs.
1-0	CTRMODE	R/W	3h	Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0h = Up-count mode 1h = Down-count mode 2h = Up-down-count mode 3h = Stop-freeze counter operation (default on reset)

19.4.3 TBPHS Register (Offset = 4h) [reset = 0h]

TBPHS is shown in Figure 19-64 and described in Table 19-25.

Figure 19-64. TBPHS Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 19-25. TBPHS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPHS	R/W	0h	These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. Valid values: 0-FFFFh If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization.

19.4.4 TBPRD Register (Offset = 8h) [reset = 0h]

TBPRD is shown in Figure 19-65 and described in Table 19-26.

Figure 19-65. TBPRD Register

Table 19-26. TBPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	These bits determine the period of the time-base counter. This sets the PWM frequency. Valid values: 0-FFFFh Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals 0. If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. The active and shadow registers share the same memory map address.

19.4.5 TBCTR Register (Offset = Ah) [reset = 0h]

TBCTR is shown in Figure 19-66 and described in Table 19-27.

Figure 19-66. TBCTR Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 19-29. CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	CMPA	R/W	0h	The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include: Do nothing, the event is ignored. Clear: Pull the EPWMxA and/or EPWMxB signal low Set: Pull the EPWMxA and/or EPWMxB signal high Toggle the EPWMxA and/or EPWMxB signal Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. In either mode, the active and shadow registers share the same memory map address.

19.4.8 AQCTLA Register (Offset = 14h) [reset = 0h]

AQCTLA is shown in Figure 19-69 and described in Table 19-30.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 19-34. DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit: 0h = Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1h = Half cycle clocking enabled. The dead-band counters are clocked at TBCLK x 2.
14-6	RESERVED	R	0h	Reserved
5-4	IN_MODE	R/W	0h	Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown in . This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 0h = EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 1h = EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 2h = EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 3h = EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.

Table 19-34. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	POLSEL	R/W	0h	Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch shown in . This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes. 0h = Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 1h = Active low complementary (ALC) mode. EPWMxA is inverted. 2h = Active high complementary (AHC). EPWMxB is inverted. 3h = Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.
1-0	OUT_MODE	R/W	0h	Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in . This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay. 0h = Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect. 1h = Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE]. 2h = The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE]. Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule. 3h = Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].

19.4.13 AQCSFRC Register (Offset = 1Eh) [reset = 0h]

AQCSFRC is shown in Figure 19-74 and described in Table 19-35.

19.4.17 TZSEL Register (Offset = 26h) [reset = 0h]

TZSEL is shown in Figure 19-78 and described in Table 19-39.

One-Shot (OSHT) Trip-zone enable/disable (bits 15-8). When any of the enabled pins go low, a one-shot trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. The one-shot trip condition remains latched until the user clears the condition via the TZCLR register. Cycle-by-Cycle (CBC) Trip-zone enable/disable (bits 7-0). When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero.

Table 19-46. ETFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3	SOCB	R	0h	Latched ePWM ADC Start-of-Conversion B (EPWMxSOCB) Status Flag 0h = Indicates no EPWMxSOCB event occurred. 1h = Indicates that a start of conversion pulse was generated on EPWMxSOCB. The EPWMxSOCB output will continue to be generated even if the flag bit is set.
2	SOCA	R	0h	Latched ePWM ADC Start-of-Conversion A (EPWMxSOCA) Status Flag. Unlike the ETFLG[INT] flag, the EPWMxSOCA output will continue to pulse even if the flag bit is set. 0h = Indicates no event occurred. 1h = Indicates that a start of conversion pulse was generated on EPWMxSOCA. The EPWMxSOCA output will continue to be generated even if the flag bit is set.
1	RESERVED	R	0h	Reserved
0	INT	R	0h	Latched ePWM Interrupt (EPWMx_INT) Status Flag 0h = Indicates no event occurred. 1h = Indicates that an ePWMx interrupt (EWPMx_INT) was generated. No further interrupts will be generated until the flag bit is cleared. Up to one interrupt can be pending while the ETFLG[INT] bit is still set. If an interrupt is pending, it will not be generated until after the ETFLG[INT] bit is cleared. Refer to Event-Trigger Interrupt Generator figure.

19.4.25 ETPS Register (Offset = 36h) [reset = 0h]

ETPS is shown in Figure 19-86 and described in Table 19-47.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 19-47. ETPS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	SOCBCNT	R	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Counter Register. These bits indicate how many selected ETSEL[SOCBSEL] events have occurred: 0h = No events have occurred. 1h = 1 event has occurred. 2h = 2 events have occurred. 3h = 3 events have occurred.
13-12	SOCBPRD	R/W	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Period Select. These bits determine how many selected ETSEL[SOCBSEL] events need to occur before an EPWMxSOCB pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCBEN] = 1). The SOCB pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCB] = 1). Once the SOCB pulse is generated, the ETPS[SOCBCNT] bits will automatically be cleared. 0h = Disable the SOCB event counter. No EPWMxSOCB pulse will be generated 1h = Generate the EPWMxSOCB pulse on the first event: ETPS[SOCBCNT] = 0,1 2h = Generate the EPWMxSOCB pulse on the second event: ETPS[SOCBCNT] = 1,0 3h = Generate the EPWMxSOCB pulse on the third event: ETPS[SOCBCNT] = 1,1
11-10	SOCACNT	R	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Counter Register. These bits indicate how many selected ETSEL[SOCASEL] events have occurred: 0h = No events have occurred. 1h = 1 event has occurred. 2h = 2 events have occurred. 3h = 3 events have occurred.

Table 19-47. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-8	SOCAPRD	R/W	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select. These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCAEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared. 0h = Disable the SOCA event counter. No EPWMxSOCA pulse will be generated 1h = Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1 2h = Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0 3h = Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1
7-4	RESERVED	R	0h	Reserved
3-2	INTCNT	R	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD]. 0h = No events have occurred. 1h = 1 event has occurred. 2h = 2 events have occurred. 3h = 3 events have occurred.
1-0	INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 0h = Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 1h = Generate an interrupt on the first event INTCNT = 01 (first event) 2h = Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 3h = Generate interrupt on ETPS[INTCNT] = 1,1 (third event)

19.4.26 ETFRC Register (Offset = 38h) [reset = 0h]

ETFRC is shown in Figure 19-87 and described in Table 19-48.

Table 19-55. DCFOFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	OFFSET	R	0h	Blanking Window Offset. Valid values: 0-FFFFh These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted.

19.4.34 DCCAPCTL Register (Offset = 6Ah) [reset = 0h]

DCCAPCTL is shown in Figure 19-95 and described in Table 19-56.

Figure 19-95. DCCAPCTL Register

Bit	Field	Type	Reset	Description
15-0	DCCAP	R	0h	Digital Compare Time-Base Counter Capture. Valid values: 0-FFFFh To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address.

19.4.38 DCFWINDOWCNT Register (Offset = 72h) [reset = 0h]

DCFWINDOWCNT is shown in Figure 19-99 and described in Table 19-60.

Figure 19-99. DCFWINDOWCNT Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
WINDOWCNT							
R-0h							

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 19-60. DCFWINDOWCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Any writes to these bit(s) must always have a value of 0.
7-0	WINDOWCNT	R	0h	Blanking Window Counter. Valid value: 0-FFh These 8 bits are read only and indicate the current value of the window counter. The counter counts down to zero and then stops until it is re-loaded when the offset counter reaches zero again.

Chapter 20

On-chip Debug

The debug subsystem contains one MCUDebugss at its core that allows the JTAG interface access to device components. The debug subsystem is designed to provide the following debug features:

- JTAG debug access to debug resources, mapped through an ARM SWJ-DP and TI ICEPickM scan module
- System memory access without halting the processor
- Trace for C66x DSP
- ETM-based trace for ARM R5F
- Cross trigger to halt and restart MSS and DSP, based on events such as watchdog, timers, DMA, and time-stamp events
- Capability to read the device ID

20.1 AWR294x DebugSS Architecture

20.1.1 DebugSS Overview

The OneMCU Debug Subsystem (OneMCUDebugSS) is used in the AWR294x platform. An overview of the interconnectivity of the debug ports and trace ports are shown in Figure 20-1.

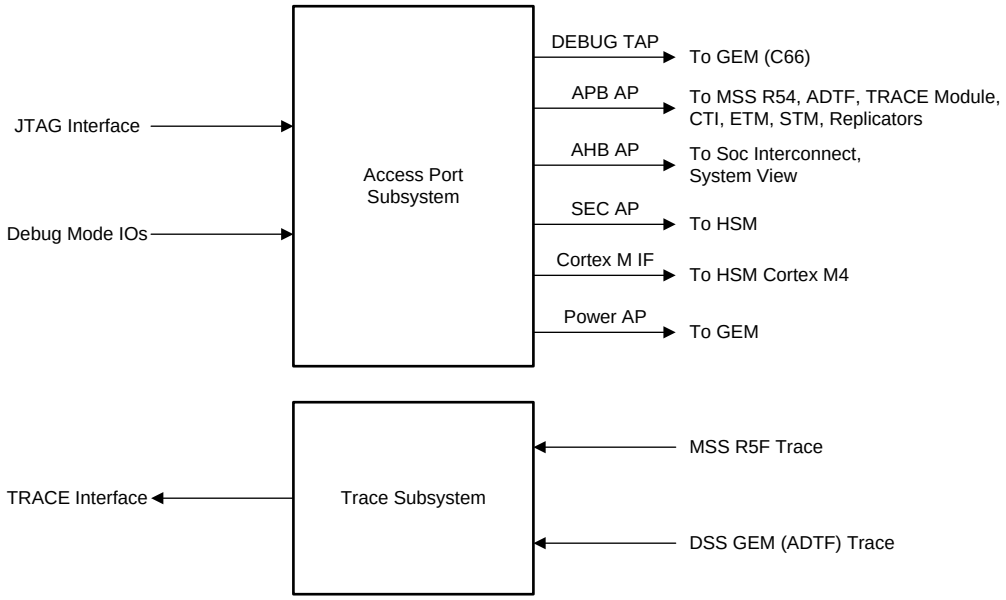

Figure 20-1. Debug SS Overview

20.1.2 DebugSS Architecture

The DebugSS architecture and the connectivity of the various debug components are shown in Figure 20-2.

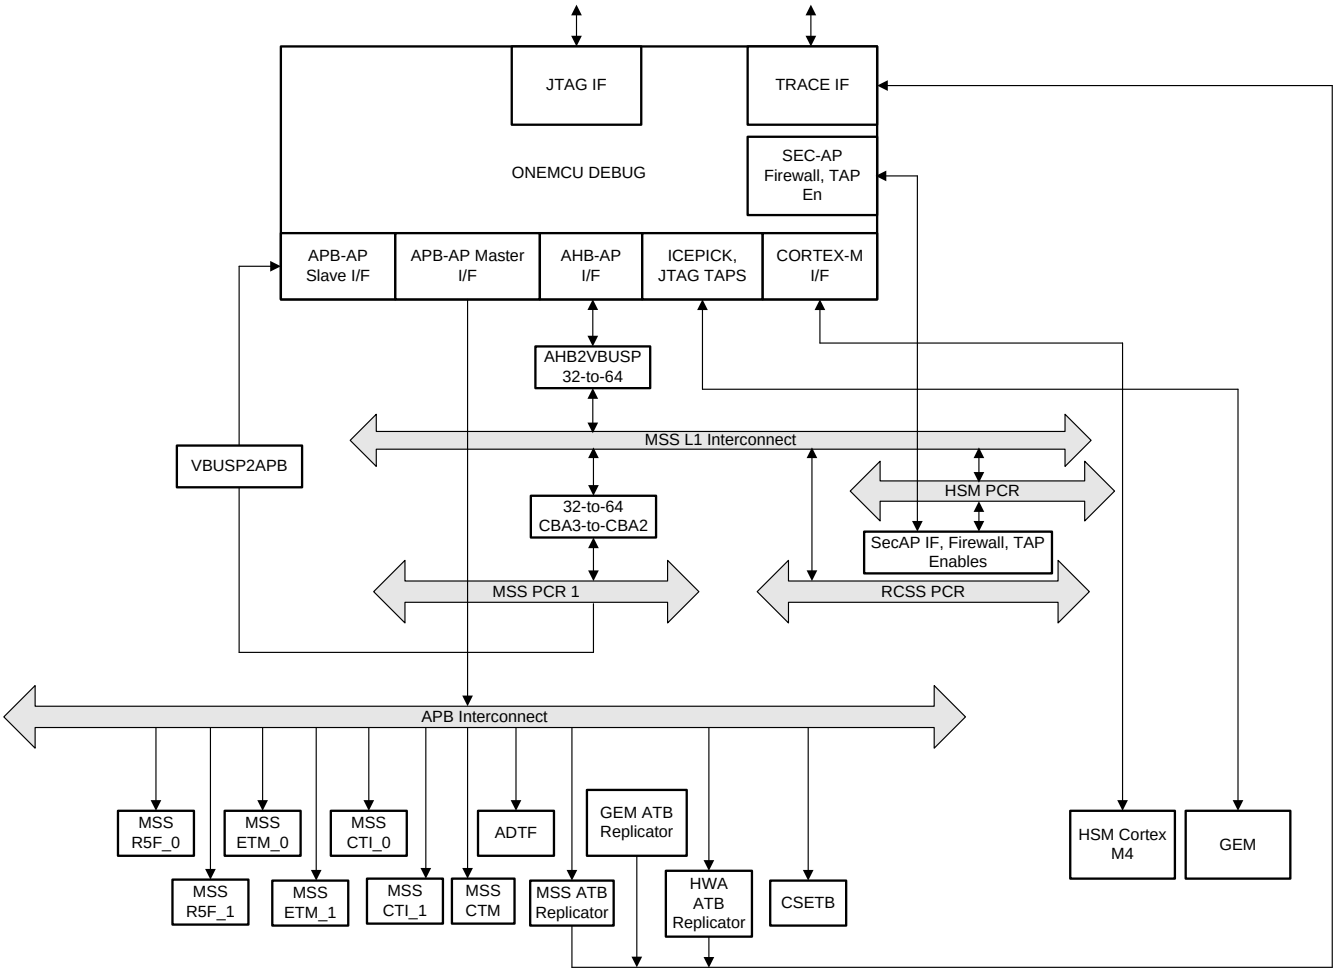

Figure 20-2. AWR294x DebugSS Architecture

20.1.3 Debug Subsystem Address Map

The memory map view for RS232 and DAP AHB is the same as MSS CortexR5. Table 20-1 shows the APB Port Address Map for the AWR294x.

Table 20-1. Debug Subsystem Address Map

APB Port	Block Name	Start Address Offset	End Address Offset
APB EXTERNAL PORT 0	C66x ADTF	0x00010000	0x00010FFF
APB EXTERNAL PORT 0	C66x ATB REPLICATOR	0x00011000	0x00011FFF
APB EXTERNAL PORT 0	MSS CR5 ATB REPLICATOR	0x00012000	0x00012FFF

APB EXTERNAL PORT 2	MSS CR5 C1 ETM	0x0003D000	0x0003DFFF

20.1.4 Trace Subsystem

20.1.4.1 Trace Infrastructure

The trace infrastructure is shown in Figure 20-3. Trace data from the MSS CR5 cores, C66x DSP core, and HWA Cortex M4 cores may be routed to the external trace lines over the TPIU-Trace interface. Alternately, there is an 8KB trace memory to store the configured (filtered) trace data onto the memory.

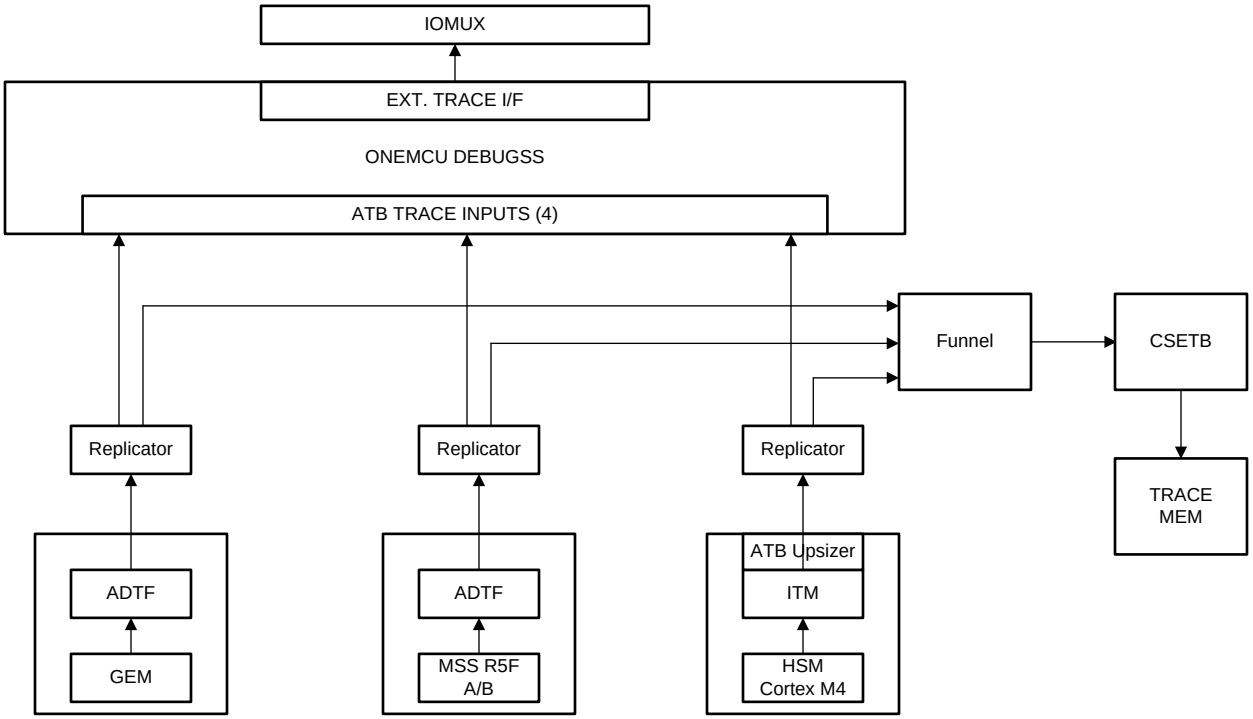

Figure 20-3. Trace Infrastructure

The CortexM4 ITM output requries an 8-bit to 32-bit ATB upsizer in the path to convert the signals to be compatible as input to the upstream layers/modules.

The maximum support frequency for the external interface trace clock is 125 MHz.

20.1.5 Cross Triggering

20.1.5.1 Cross Triggering Infrastructure

The cross triggering infrastructure is shown in Figure 20-4. The host processors involved in the cross triggering sequence are:

- MSS Cortex R5F cores, ETB
- C66x DSP cores, ADTF
- Host as suspend peripherals
  - HWA Accelerator

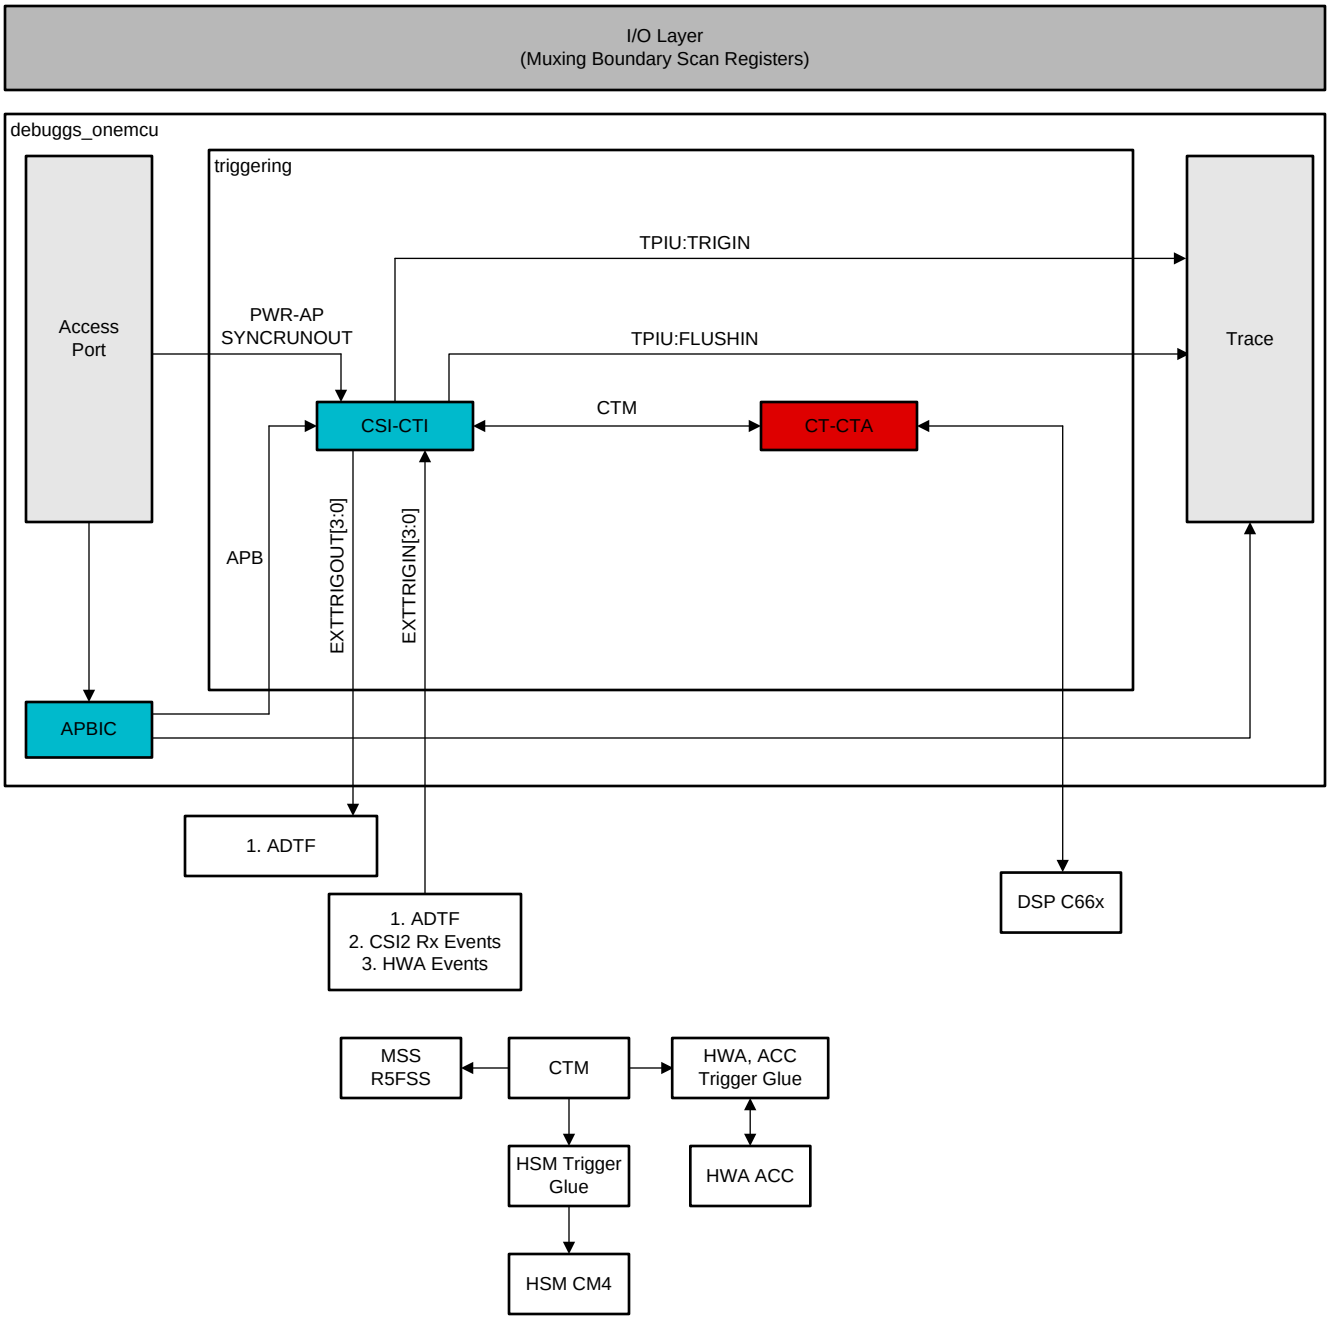

Figure 20-4. Cross Triggering Infrastructure

20.1.5.1.1 MSS CR5 CTI Trigger Input Connections

Table 20-2. MSS CR5 CTI Trigger Input Connections

CTI Trigger Input Bit	AWR294x Integration	Description
[7]	MSS_INT_MAP	MSS CR5 Interrupt. Select any of the 256 MSS CR5 Interrupts from Section 7.1. Configure the require interrupt as trigger by writing to MSS_CTRL:: MSS_CTI_TRIG_SEL:MSS_CTI_TRIG_SEL_TRIG8_SEL
[6]	ETMTRIGGER	ETM managed Trigger. Generated internal to Cortex R5 Susbsystem
[5]	COMMTX	Communications channel transmit. Generated internal to Cortex R5 Susbsystem
[4]	COMMRX	Communications channel receive. Generated internal to Cortex R5 Susbsystem

Table 20-2. MSS CR5 CTI Trigger Input Connections (continued)

CTI Trigger Output Bit	AWR294x Integration	Destination
[2]	Reserved	
[1]	TPIU:FLUSHIN	Internal TPIU
[0]	TPIU:TRIGIN	Internal TPIU

20.1.6 Suspend Peripherals

The device supports a suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters a debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

Table 20-6. Suspend Peripherals

Subsystems Peripherals	CPU Suspend	Peripherals	Peripheral Control Register
MSS Peripherals	MSS CR5 Cores	MSS_ CPSW	MSS_CTRL:DBG_ACK_CTL0_CPSW
		MSS_MCANA	MSS_CTRL:DBG_ACK_CTL1_DCAN
		MSS_MCANB	MSS_CTRL:DBG_ACK_CTL1_DCAN
		MSS_WDT	MSS_CTRL:DBG_ACK_CTL1_WDT
		MSS_RTIA	MSS_CTRL:DBG_ACK_CTL1_RTI
		MSS_RTIB	MSS_CTRL:DBG_ACK_CTL1_RTI
		MSS_RTIC	MSS_CTRL:DBG_ACK_CTL1_RTI
		MSS_MCRC	MSS_CTRL:DBG_ACK_CTL1_MCRC
		MSS_I2C	MSS_CTRL:DBG_ACK_CTL1_I2C
		MSS_SCIA	MSS_CTRL:DBG_ACK_CTL1_SCIA
		MSS_SCIB	MSS_CTRL:DBG_ACK_CTL1_SCIB
DSS Peripherals	DSP or MSS CR5 based on DSS_CTRL:: DBG_ACK_CPU_CTRL	DSS_ DCCA	DSS_CTRL:DBG_ACK_CTL0_ DSS_ DCCA
		DSS_ DCCB	DSS_CTRL:DBG_ACK_CTL0_ DSS_ DCCB
		DSS_RTIA	DSS_CTRL:DBG_ACK_CTL0_ DSS_RTIA
		DSS_RTIB	DSS_CTRL:DBG_ACK_CTL0_ DSS_RTIB
		DSS_RTIC	DSS_CTRL:DBG_ACK_CTL0_ DSS_RTIC

		DSS_WDT	DSS_CTRL:DBG_ACK_CTL0_ DSS_WDT
		DSS_MCRC	DSS_CTRL:DBG_ACK_CTL1_ DSS_MCRC
		DSS_HWA	DSS_CTRL:DBG_ACK_CTL1_ DSS_HWA

20.1.7 MSS_DEBUGSS Registers

MSS_DEBUGSS Registers lists the memory-mapped registers for the MSS_DEBUGSS registers. All register offset addresses not listed in MSS_DEBUGSS Registers should be considered as reserved locations and the register contents should not be modified.

Table 20-7. MSS_DEBUGSS Registers

Offset	Acronym	Register Name	Section
0h	ONEMCU_APB_BASE	Start Address of ROM Table	ONEMCU_APB_BASE Register (Offset = 0h) [Reset = 0h]
FFCh	ONEMCU_APB_BASE_END	End Address of ROM Table	ONEMCU_APB_BASE_END Register (Offset = FFCh) [Reset = 0h]
1000h	ONEMCU_CTI_CONTROL	http://infocenter.arm.com/help/topic/com.arm.doc.ddi0314h/Chdjefbi.html http://infocenter.arm.com/help/topic/com.arm.doc.ddi0314h/Chdefejc.html	ONEMCU_CTI_CONTROL Register (Offset = 1000h) [Reset = 0h]
1010h	ONEMCU_CTI_INTACK		ONEMCU_CTI_INTACK Register (Offset = 1010h) [Reset = 0h]
1014h	ONEMCU_CTI_APPSET		ONEMCU_CTI_APPSET Register (Offset = 1014h) [Reset = 0h]
1018h	ONEMCU_CTI_APPCLEAR		ONEMCU_CTI_APPCLEAR Register (Offset = 1018h) [Reset = 0h]
101Ch	ONEMCU_CTI_APPPULSE		ONEMCU_CTI_APPPULSE Register (Offset = 101Ch) [Reset = 0h]
1020h	ONEMCU_CTI_INEN0		ONEMCU_CTI_INEN0 Register (Offset = 1020h) [Reset = 0h]
1024h	ONEMCU_CTI_INEN1		ONEMCU_CTI_INEN1 Register (Offset = 1024h) [Reset = 0h]
1028h	ONEMCU_CTI_INEN2		ONEMCU_CTI_INEN2 Register (Offset = 1028h) [Reset = 0h]
102Ch	ONEMCU_CTI_INEN3		ONEMCU_CTI_INEN3 Register (Offset = 102Ch) [Reset = 0h]
1030h	ONEMCU_CTI_INEN4		ONEMCU_CTI_INEN4 Register (Offset = 1030h) [Reset = 0h]
1034h	ONEMCU_CTI_INEN5		ONEMCU_CTI_INEN5 Register (Offset = 1034h) [Reset = 0h]

Table 20-7. MSS_DEBUGSS Registers (continued)

Offset	Acronym	Register Name	Section

Complex bit access types are encoded to fit into small table cells. MSS_DEBUGSS Access Type Codes shows the codes that are used for access types in this section.

Table 20-8. MSS_DEBUGSS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		

Table 20-8. MSS_DEBUGSS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

ONEMCU_APB_BASE Register (Offset = 0h) [Reset = 0h]

ONEMCU_APB_BASE is shown in ONEMCU_APB_BASE Register and described in ONEMCU_APB_BASE Register Field Descriptions.

Return to the Summary Table.

Start Address of ROM Table

Table 20-255. STMTCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	
23	BUSY	R/W	0h	Indicates whether the STM is busy, for example the STM trace FIFO is not empty: 0b0 Not busy. 0b1 Busy.
22-16	TRACEID	R/W	0h	ATB trace ID. Setting this value to all zeroes or to a value greater than 0x6F might result in UNPREDICTABLE tracing. Reset value of this bit field is UNKNOWN.
15-6	RESERVED	R	0h	
5	COMPEN	R/W	0h	Compression enable for stimulus ports: 0b0 Disabled, the STM transmits data transfers based on the size of the transaction. 0b1 Enabled, the STM compresses data transfers to save bandwidth.
4-3	RESERVED	R	0h	
2	SYNCEN	R/W	0h	The STM implements the STMSYNCR, so this bit is Read As One. 0b1 The STM implements the STMSYNCR.
1	TSEN	R/W	0h	Determines whether to ignore timestamp requests: 0b0 Disable timestamping. The STM ignores requests for timestamp generation, and treats stimulus port writes that select timestamping as if timestamping were not selected. 0b1 Enable timestamping. If stimulus writes select timestamping, the STM outputs a timestamp according to STPv2.
0	EN	R/W	0h	Global STM enable: 0b0 Disabled 0b1 Enabled.

STMTSSTIMR Register (Offset = 00016E84h) [Reset = 0h]

STMTSSTIMR is shown in STMTSSTIMR Register and described in STMTSSTIMR Register Field Descriptions.

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7	QHWEVOVERRIDE	R/W	0h	Low-power interface override when hardware event tracing is enabled: 0b0 The STM can accept a quiescence request on the STM low-power interface when the STMHEMCR.EN bit is set to 0b1. 0b1 If the STMHEMCR.EN bit is set to 0b1, all quiescence requests on the STM low-power interface are denied. Reset value is 0b0.
6-3	RESERVED	R	0h	
2	PRIORINVDIS	R/W	0h	Controls arbitration between the AXI interface and the hardware event observation interface during flush: 0b0 Priority inversion. When the AXI flush completes, the hardware event observation interface gets priority until the hardware event observation interface flush completes. 0b1 Priority inversion disabled. The AXI always has priority over the hardware event observation interface. Reset value is 0b0.
1	ASYNCPE	R/W	0h	ASYNC priority: 0b0 Always lower than trace. 0b1 Escalates on second synchronization request. Reset value is 0b0.
0	FIFOAF	R/W	0h	Auto-flush: 0b0 Disabled. 0b1 Enabled. The STM automatically drains all data even if the ATB interface is not fully utilized. Reset value is 0b0.

STMFEAT1R Register (Offset = 00016EA0h) [Reset = 006587D1h]

STMFEAT1R is shown in STMFEAT1R Register and described in STMFEAT1R Register Field Descriptions.

Table 20-272. STMLSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	RESERVED	R	0h	
2	nTT	W	0h	Indicates whether the component implements the STMLAR as 8 bit or 32 bit. 0b0 32 bit.
1	SLK	W	0h	Returns the current status of the lock. 0b0 Enables write access to the STM. For read accesses to the STMLSR when the PADDRDBG31 signal is HIGH, this bit is always 0b0. 0b1 Blocks write access to the STM. The STM ignores all write accesses to the registers when the PADDRDBG31 signal is LOW. Reads are permitted
0	SLI	W	0h	Indicates that a lock control mechanism exists for the device. 0b0 No lock control mechanism exists. The STM ignores writes to the STMLAR. For read accesses to the STMLSR when the PADDRDBG31 signal is HIGH, this bit is always 0b0. 0b1 Lock control mechanism is present. For read accesses to the STMLSR when the PADDRDBG31 signal is LOW, this bit is always 0b1.

STMAUTHSTATUS Register (Offset = 00016FB8h) [Reset = AAh]

STMAUTHSTATUS is shown in STMAUTHSTATUS Register and described in STMAUTHSTATUS Register Field Descriptions.

Return to the Summary Table.

Authentication Status register

Table 20-274. STMDEVARCH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-21	ARCHITECT	R	23Bh	Defines the architect of the component: Bits[31:28] Indicates the JEP106 continuation code. Bits[27:21] Indicates the JEP106 identification code. See the Standard Manufacturer's Identification Code for information about JEP106. For the STM-500, ARM is the architect, and this 11-bit field returns 0x23B.
20	PRESENT	R	1h	Indicates the presence of the STMDEVARCH register: 0b1 The STMDEVARCH register is present.
19-16	REVISION	R	1h	Architecture revision. Returns the revision of the architecture that the ARCHID field specifies. For the STM, this value is 0x1, indicating the STMv1.1 architecture.
15-0	ARCHID	R	A63h	Architecture ID. Returns a value that identifies the architecture of the component. For the STM, this value is 0x0A63, indicating the STMv1.1 architecture.

STMDEVID Register (Offset = 00016FC8h) [Reset = 00010000h]

STMDEVID is shown in STMDEVID Register and described in STMDEVID Register Field Descriptions.

Return to the Summary Table.

Device Configuration register
