TAS2563 Schematic and Layout Guidelines

Ivan Salazar

ABSTRACT

In audio applications, it is always important to minimize the noise effects that may be induced by external conditions or even by the same components of the PCB. All the audio amplifiers require a clean and stable power supply to get the best performance. Any noise issue at the power supplies may be the cause of a high THD+N, SNR, and PSRR levels. In addition, the analog inputs and outputs require good noise immunity against the digital activity from nearby devices.

This document describes an optimized layout for the TAS2563 device in mono and stereo configuration. The goal of utilizing these layout guidelines is to minimize the noise issues and ensure the best device performance. The TAS2563EVM was taken as reference for the suggested guidelines.

1 Typical Application Block Diagram

Figure 1 shows the typical application block diagram for the mono TAS2563 device.

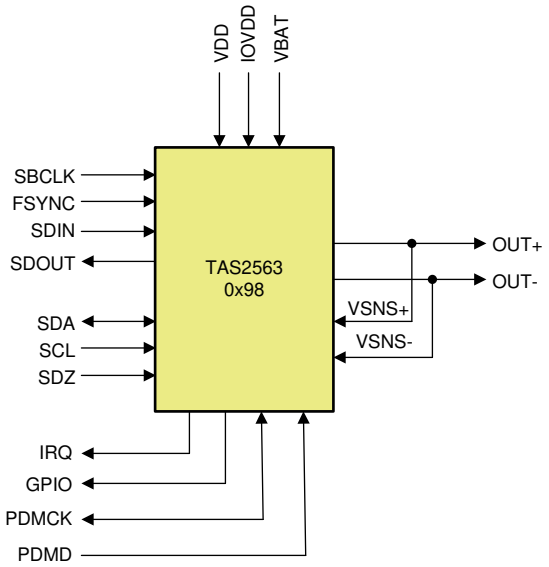

Figure 1. TAS2563 Block Diagram

Figure 2 shows the typical application block diagram for a stereo TAS253 device. Notice the devices share some of the signals like digital interface 1 (ASI1), I2C control, as well as GPIO and IRQ. Additionally, digital interface 2 (ASI2) must be interconnected for the stereo linking feature. The designer must also consider that each device has VSNS signals connected as close as possible to its respective speaker.

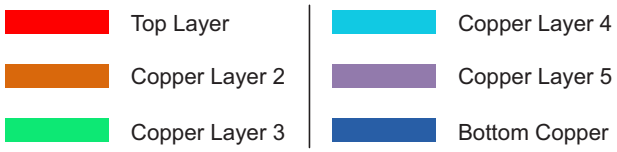

Figure 5. Layout Line Color Codes in This Document

For detailed information about the recommended external components, see Table 1.

2.2 GREG Pin

The GREG pin is the output of the high-side gate charge-pump regulator. As mentioned in the *TAS2563 6.1-W Boosted Class-D Audio Amplifier With Integrated DSP And IV Sense Data Sheet*, this pin must not be connected to an external load. A minimum of a 0.1-µF capacitor must be connected from the GREG pin to the PVDD pin (see Figure 3, for details).

TI recommends verifying that the PCB design does not generate a parasitic inductance higher than 200 pH. In addition, it is important to connect the GREG pin capacitor to PVDD with a star connection and not to the boost plane. This practice reduces the possibility of EMI radiation.

Similar to the ground pin connections, the layer changes should use multiple vias to minimize the parasitic inductance.

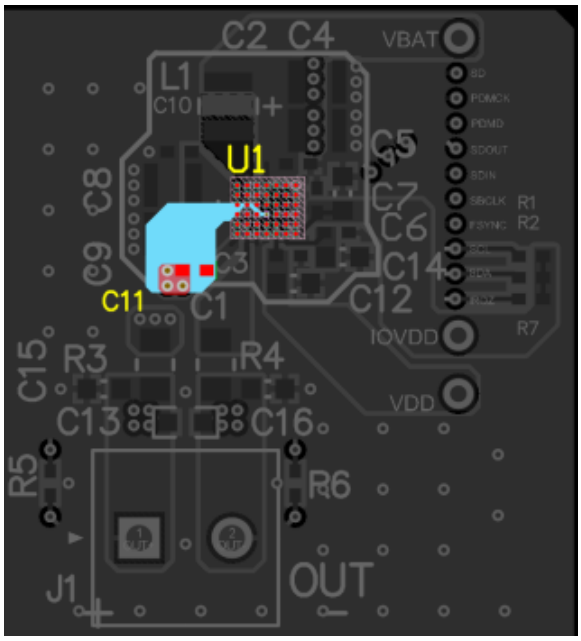

Figure 6. GREG Pin Connection

2.3 SW Pin

The boost inductor is selected to carry a high amount of current. Its saturation current should be higher than the limit current to deliver Class-D peak power. The PCB traces must be wide enough to handle this overcurrent limit.

The immediate layer below the top layer must be dedicated as a ground plane. A keepout region should be placed below the SW pin trace for noise reduction.

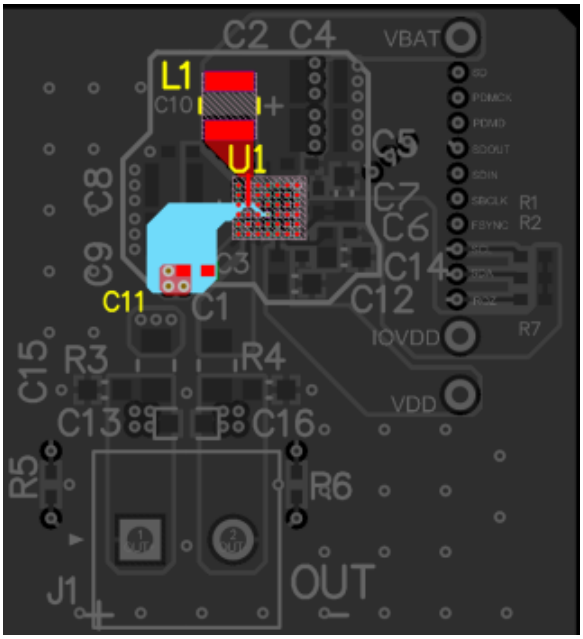

Figure 7. SW Pin Connection

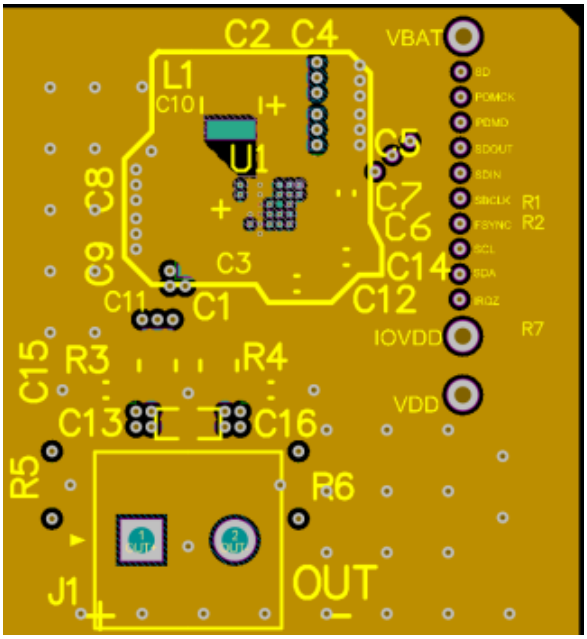

Figure 8. Ground Plane With Keepout Region

2.4 VBAT Pin

VBAT is the battery power supply input. This power pin supplies the internal boost. Since it carries a considerable amount of current, a decoupling capacitor is required. At least a 10-µF decoupling capacitor must be used to bypass VBAT to GND. See the *Decoupling Capacitors* section for details.

It is important to consider the following recommendations for VBAT:

1. Ensure that the parasitic inductance from the device pin to decoupling is below 500 pH.
2. Add an extra bulk decoupling capacitor to reduce overall THD+N at high power.
3. Have the VBAT traces wide enough to handle total output power.
4. Connect VBAT to and SW inductor through the thick plane.
5. Do not use vias between device pins and related capacitors and inductor.

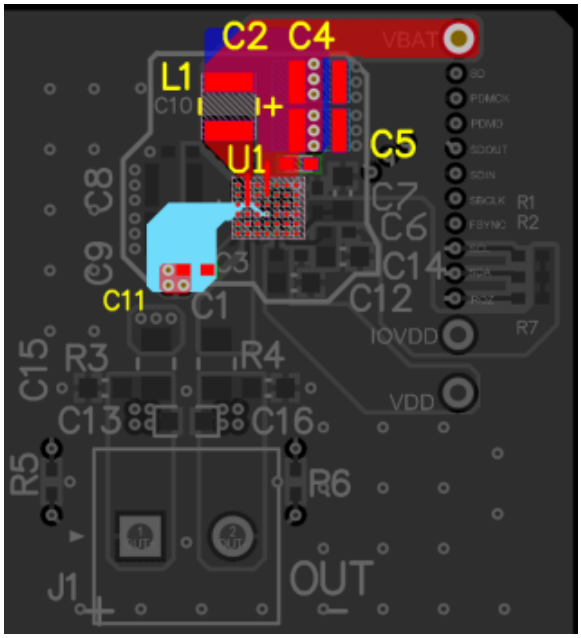

Figure 9. VBAT Pin Connection

2.5 DREG Pin

DREG is the digital core voltage regulator output. This pin must be bypassed to GND with a 1-µF capacitor and it must not be connected to an external load. TI recommends ensuring that both decoupling capacitor ends see as low inductance as possible between this DREG pin and GND. Multiple vias are suggested to reduce the inductance. See the *Decoupling Capacitors* section for details.

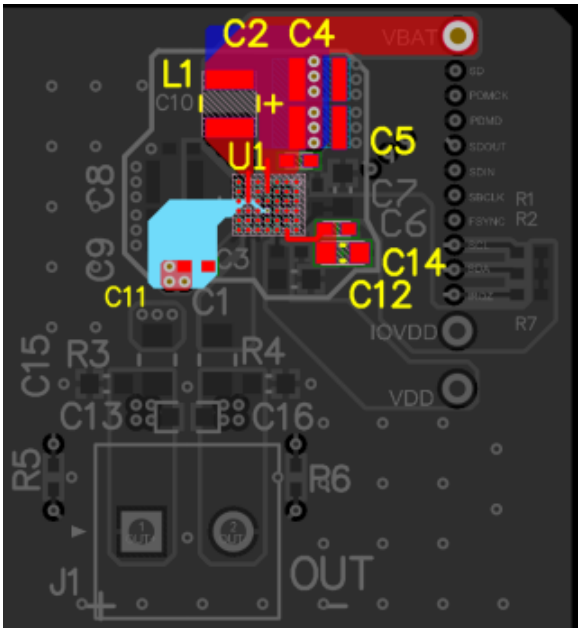

Figure 10. DREG Pin Connection

2.6 VBST and PVDD Pins

VBST is the internal boost converter output. This is the pin that will supply the power stage supply pin (PVDD). PVDD must be shorted to the VBST pin using a strong connection.

There are a few considerations that must be taken into account for the PVDD to VBST connection:

- VBST must not be connected to an external load. This pin should be bypassed to GND with a decoupling capacitor. The decoupling capacitor ends should see as low an inductance as possible between the VBST pin and the BGND pin. See the *Decoupling Capacitors* section for details.
- There should be a maximum parasitic inductance of 100 pH from the device pin to decoupling.
- VBST should be connected to PVDD through the tick plane (use multiple vias to reduce parasitic inductance).
- PVDD should be connected with a star connection to the GREG capacitor.
- VBST and PVDD traces carry a high amount of current. The traces should support currents up to the device overcurrent limit.
- Boost capacitor derating should satisfy the ratio with boost inductor: L/C < 1/3
- Ceramic capacitors derate with the applied DC voltage. Often, a 10-µF capacitor loses 80% of the nominal value at the 10-V to 12-V range (for example, a 10-µF capacitance value would result in 2 µF). Typically, TI recommends using a 20-µF capacitor (or a pair of two 10-µF capacitors) as decoupling capacitor.

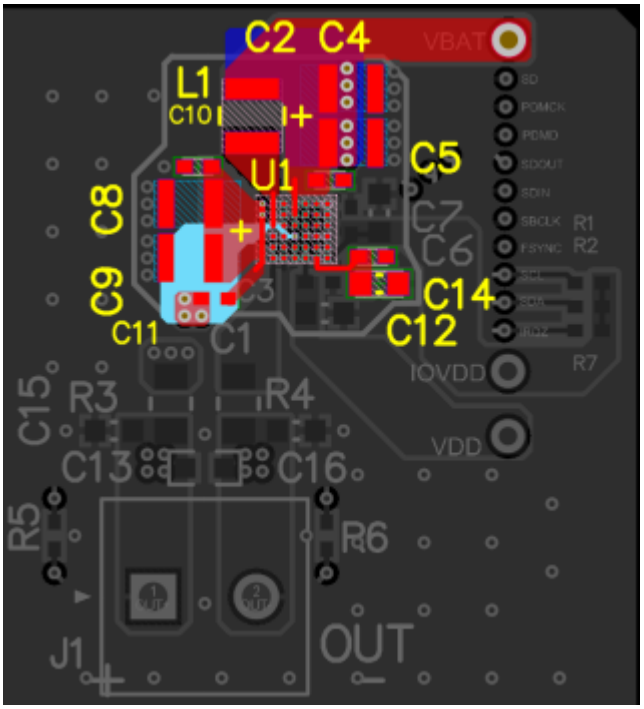

Figure 11. PVDD and VBST Pin Connections

2.7 VDD Pin

VDD is the analog, digital, and I/O power supply input. Similar to the VBAT pin, this power pin requires a decoupling capacitor. A minimum of 4.7-µF capacitor is suggested to bypass VDD to GND. See the *Decoupling Capacitors* section for details.

This pin requires having a maximum parasitic inductance of 200 pH.

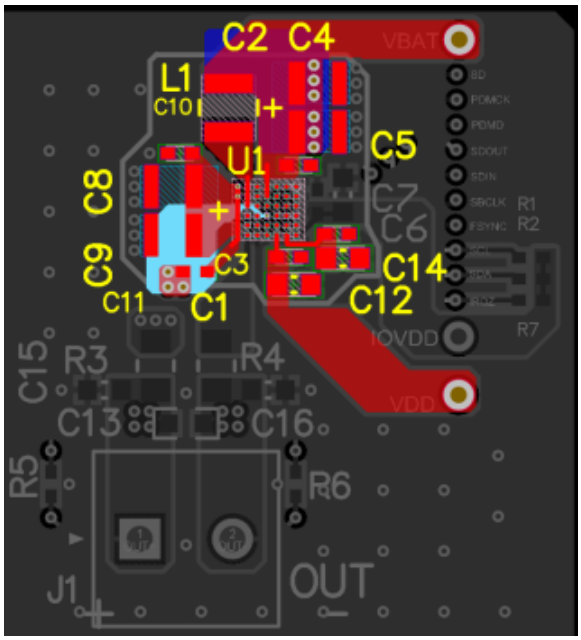

Figure 12. VDD Pin Connection

2.8 Output Pins (OUT_N and OUT_P)

OUT_N and OUT_P are the Class-D receiver channel negative and positive output, respectively. Due to its switching nature, TI recommends keeping the routing short to limit the emissions.

For optimal current flow, the PCB traces must be widened closely to the output pins. In addition, the outputs need to be routed on two layers using several vias to minimize parasitic impedance.

It is important to consider a few things when using an EMI filter (LC array):

- Inductance should be the first element in the filter.
- Capacitance to GND or other output will pull high-current spikes capable of triggering overcurrent protection.
- TI recommends fixing 1.5 MHz as the lower limit of the corner frequency to simplify the filter debug and noise issues.

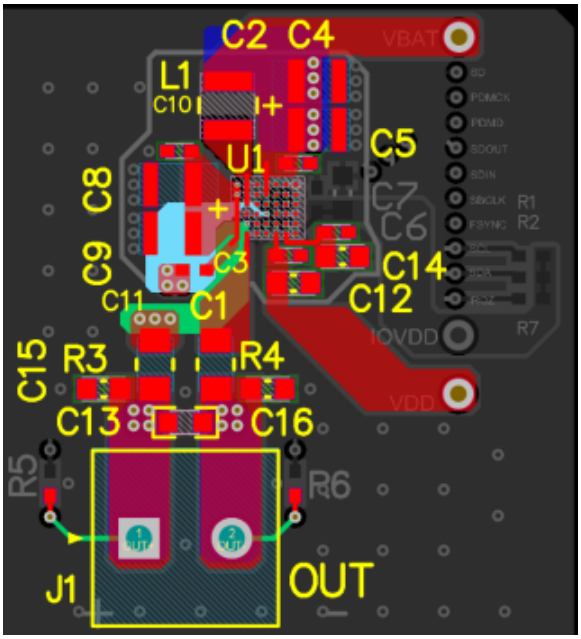

Figure 13. OUT_N and OUT_P Pin Connections

2.9 VSNS_N and VSNS_P Pins

VSNS_N and VSNS_P are the voltage sense negative and positive inputs, respectively. These inputs are connected to the Class-D outputs (VSNS_N to OUT_N and VSNS_P to OUT_P) after the ferrite bead filter.

When routing these pins to the ferrite bead filter, it is necessary to the make the connection to its respective output at the speaker terminal, not to a pin or trace. In addition, TI recommends adding a 1-kΩ resistor for each voltage sense path. This practice helps to reduce emissions and reduce ICN increments that result from the EMI filter.

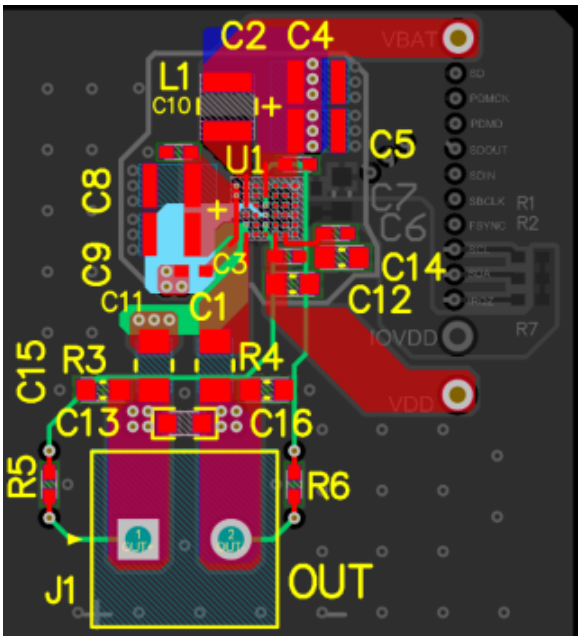

Figure 14. VSNS_N and VSNS_P Pin Connections

2.10 IOVDD and Digital Portion Connections

The TAS2563 device involves digital and analog activity. Care must be taken when routing the different signals since it may result in noise issues, especially from the digital lines to the analog portion.

The digital lines can reach frequencies up to 1 MHz for the I2C lines in *Fast-Mode Plus* and up to 50 MHz for the I2S lines. This high-frequency content can affect the performance of the analog signals. For measurement purposes, the digital noise level may affect the scope captures or a THD+N measurement.

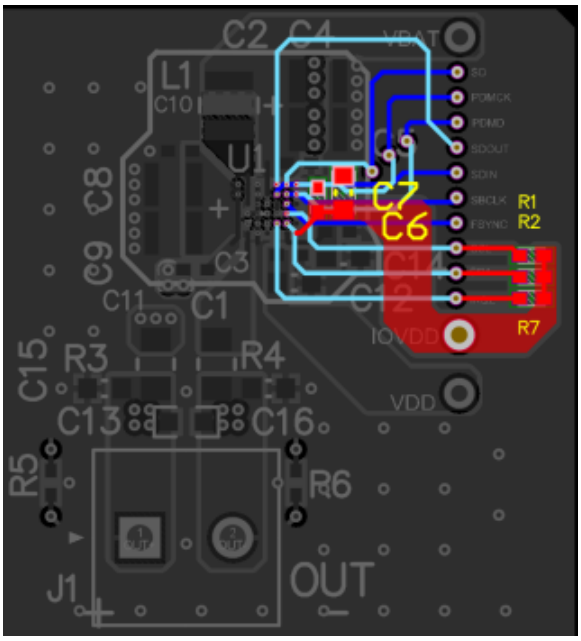

Figure 15. Digital Pin Connections

2.11 Ground Pins (BGND, GND, and PGND)

The ground plane routing is important when designing the PCB layout. These planes must be designed to have a proper thermal dissipation and minimize the parasitic impedance as much as possible. Design tips for the different ground pins are listed here:

- All the ground pins must be shorted below the package and connected to the PCB ground plane through multiple vias.
- The vias are the best way to carry heat from the different sections in the board. Since the GND plane will need to quickly dissipate all the elevated temperatures, it is necessary to add multiple vias close to the ground pins.
- A maximum 150 pH of parasitic inductance is recommended. Having many vias reduces the additional impedance and provides good conduction in both electrical and thermal perspective.
- An entire layer immediately below the top layer must be dedicated to GND, as best practice.

Table 1. Recommended External Components

Component	Description	Specification	MIN	TYP	MAX	Unit
L2, L3	Boost converter inductor	Inductance, 20% tolerance	0.47	1		µH
		Saturation current		4.5		A
N/A	EMI filter inductors (optional). These are not recommended because it degrades THD+N performance. The TAS2563 device is a filter-less class-D and does not require these bead inductors.	Impedance at 100 MHz		120		Ω
		DC resistance			0.095	Ω
		DC current			2	A
		Size		0402		EIA
C1, C2, C15, C16	Boost converter input capacitor	Capacitance, 20% tolerance	10			µF
C13, C14, C27, C28	Boost converter output capacitor	Type	X5R			
		Capacitance, 20% tolerance	10		47	µF
		Rated voltage	16			V
		Capacitance at 11.5 V derating	3.3			µF
N/A	EMI filter capacitors (optional, must use L2, L3 if C3, C4 used)	Capacitance		1		nF
C7, C21	VDD decoupling capacitor	Capacitance	4.7			µF
C9, C23	DREG decoupling capacitor	Capacitance	1			µF
C11, C25	GREG Fly capacitor	Capacitance	100			nF

For more information, see the *TAS2563 6.1-W Boosted Class-D Audio Amplifier with IV Sense Data Sheet*.

3.2 GREG Pin (Stereo)

The GREG pins for the stereo version have the same recommendations as stated in Section 2.2.

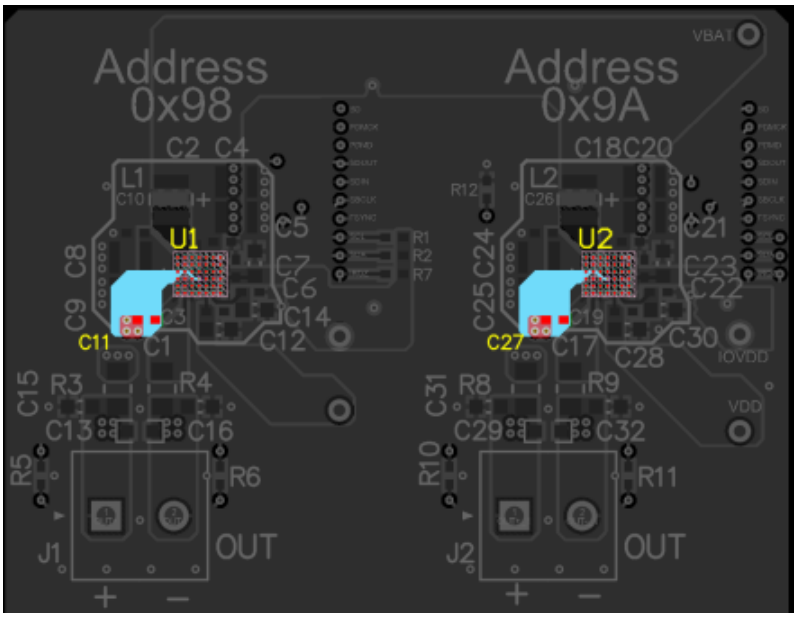

Figure 24. GREG Pin Connection (Stereo)

3.3 SW Pin (Stereo)

The GREG pins for the stereo version have the same considerations as stated in Section 2.3.

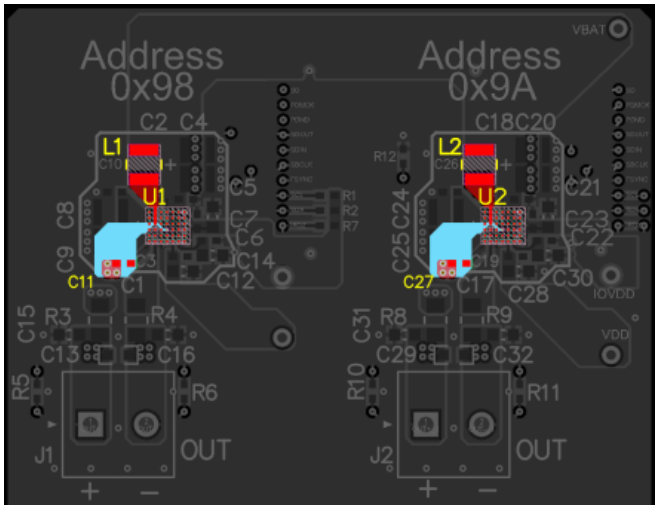

Figure 25. SW Pin Connection (Stereo)

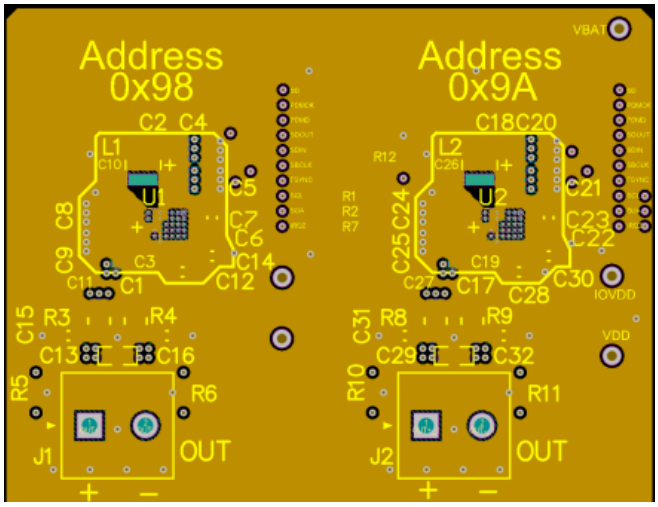

Figure 26. Ground Plane With Keepout Region (Stereo)

3.4 VBAT Pin (Stereo)

The VBAT pins for the stereo version have the same considerations as stated in Section 2.4.

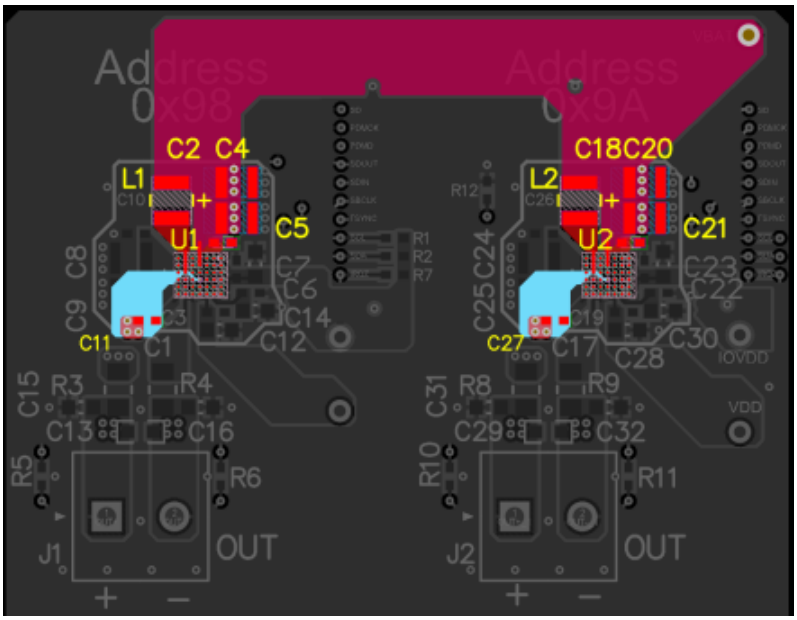

Figure 27. VBAT Pin Connection (Stereo)

3.5 DREG Pin (Stereo)

The DREG pins for the stereo version have the same considerations as stated in Section 2.5.

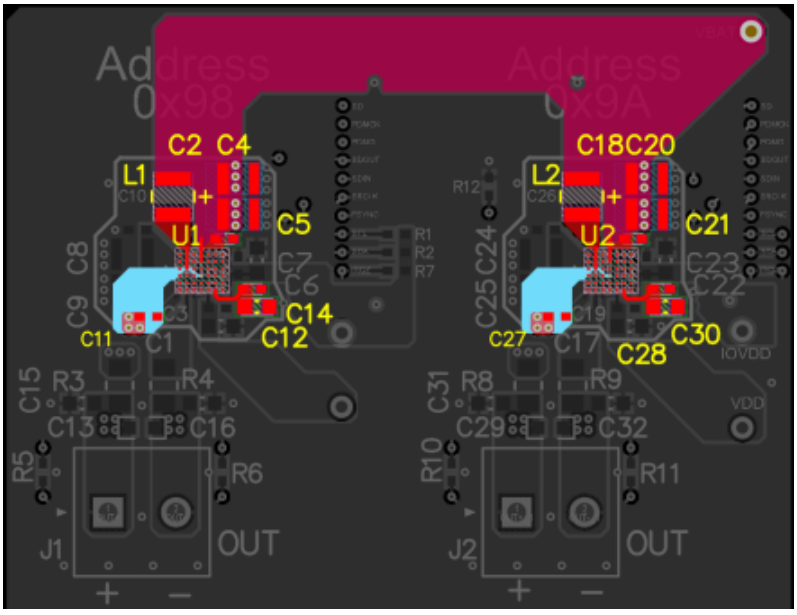

Figure 28. DREG Pin Connection (Stereo)

3.6 VBST and PVDD Pins (Stereo)

The VBST and PVDD pins for the stereo version have the same considerations as stated in BVST and PVDD Pins.

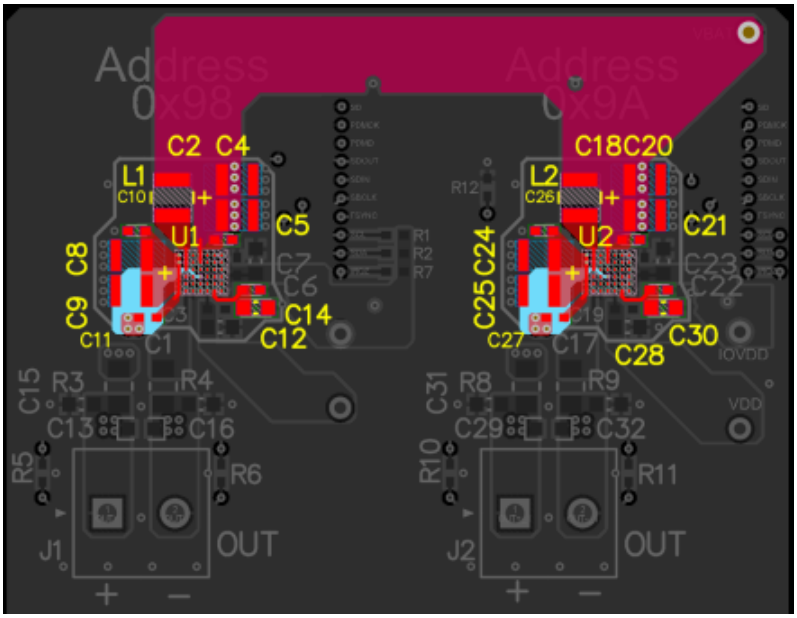

Figure 29. VBST and PVDD Pin Connection (Stereo)

3.7 VDD Pin (Stereo)

The VDD pin for the stereo version has the same considerations as stated in Section 2.7.

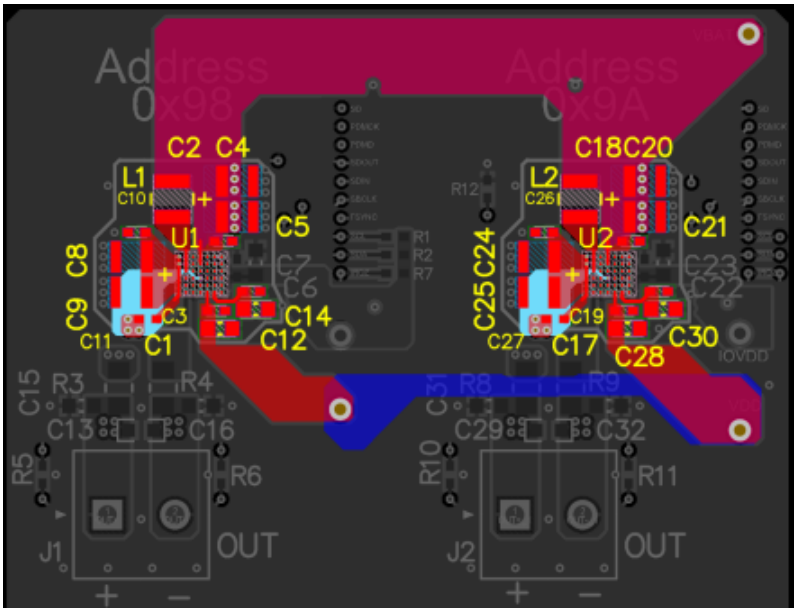

Figure 30. VDD Pin Connection (Stereo)

3.8 Output Pins (OUT_N and OUT_P, Stereo)

The output pins (OUT_N and OUT_P) for the stereo version have the same considerations as stated in Section 2.8.

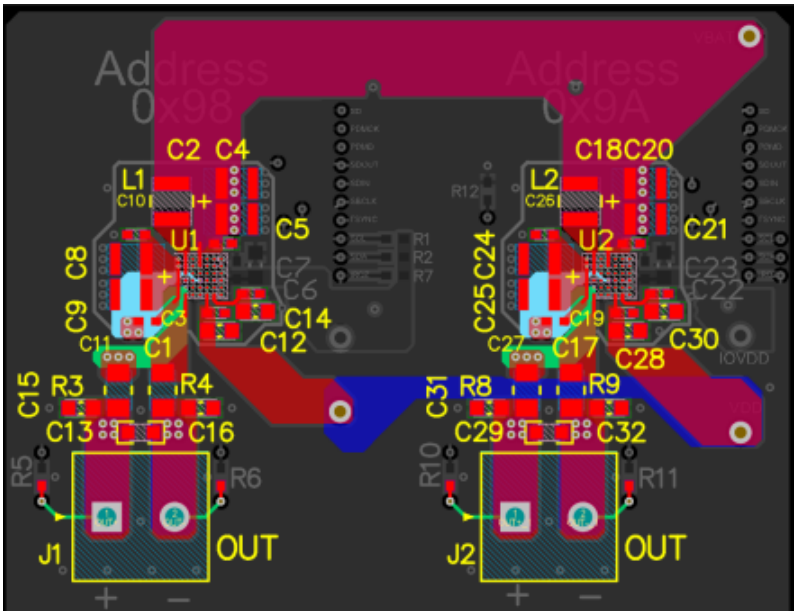

Figure 31. OUT_N and OUT_P Pins Connection (Stereo)

3.9 VSNS_N and VSNS_P Pins (Stereo)

The VSNS_N and VSNS_P pins for the stereo version have the same considerations as stated in Section 2.9.

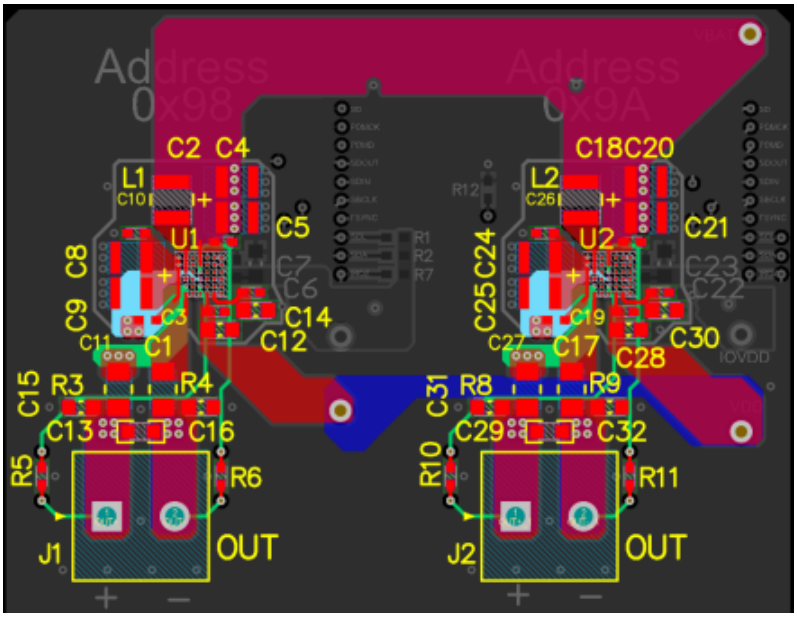

Figure 32. VSNS_N and VSNS_P Pin Connection (Stereo)

3.10 IOVDD and Digital Portion Connections (Stereo)

The digital portion connections for the stereo version have the same considerations as stated in Section 2.10.

In addition, care must be taken when routing the digital pins between both TAS2563 channels. Avoid routing the digital traces below the traces with switching activity such as the SW pin. Otherwise, there could be noise on the digital portion and may cause a wrong activity.

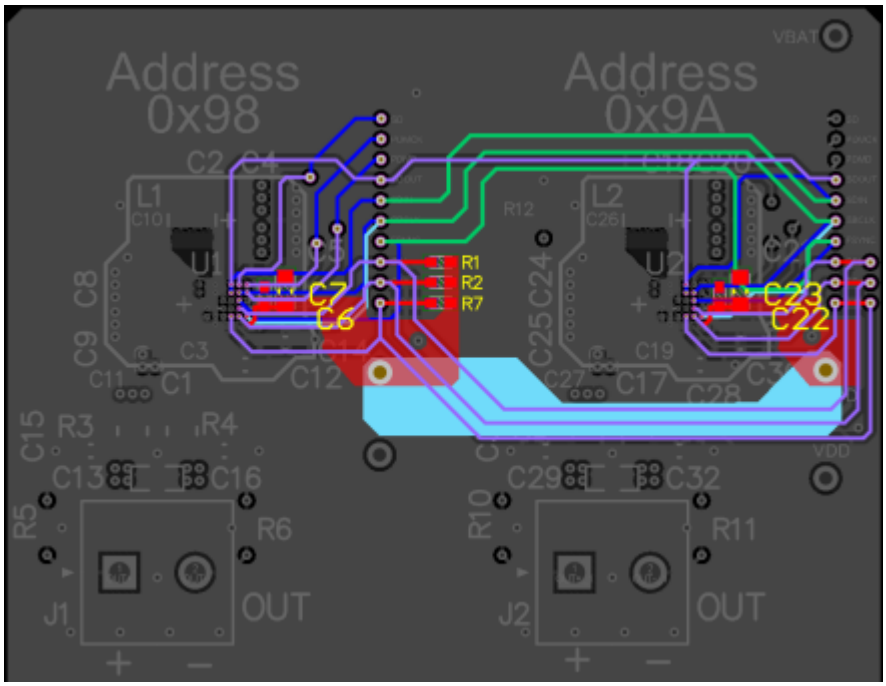

Figure 33. Digital Pin Connections (Stereo)

3.11 Ground Pins (BGND, GND, and PGND)

The ground pins (BGND, GND, and PGND) for the stereo version have the same considerations as stated in Section 2.11.

4 Decoupling Capacitors

All the PCB routes have defined impedance that must be considered during all design stages. These signal paths will act as additional components in the board. In addition, the PCB lines have a parasitic inductance and capacitance that result in a different power distribution.

To reduce the negative effects of all these parasitic impedances, TI recommends that the VBAT and VDD decoupling capacitor connections respect the following rules:

- **Place the decoupling capacitor close to the device pin in the same layer.** The decoupling capacitor stores local charge and supplies the large transient currents when it is required. The TAS2563 device has many switching activity and voltage fluctuations that demand large current transients in a short period of time. In addition, the parasitic effects caused by the vias, traces, and pads generate a voltage drop in the power supply. The proximity of the decoupling capacitors to the power pins compensates these effects and supplies the large transient currents when it is required. On a multi-layer board, the capacitors must be placed in the same layer where the TAS2563 device is located. Otherwise, the decoupling capacitor value may be reduced by the additional capacitance due to the vias connections.
- **Place the VDD and GND vias as close as possible to the decoupling capacitors.** If possible, place the vias directly or as close as possible to the capacitor mounting pads. The vias have defined impedance determined by its length and diameter. This impedance may cause a voltage drop (in high-frequency applications the signal integrity is greatly influenced) and a current flow that must be reduced or avoided. For that reason, TI recommends adding many vias around the mounting pads. This practice reduces the parasitic impedance.

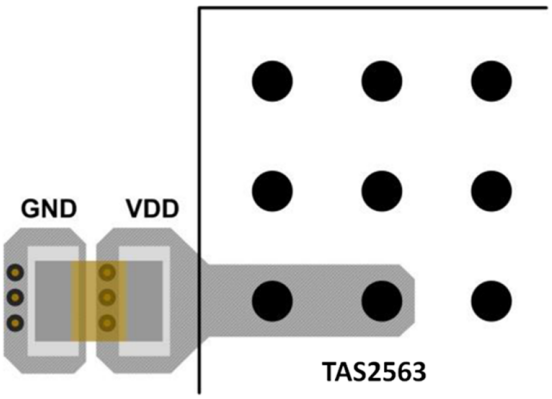

Figure 40. VIAS Placement

Refer all the pins that require a decoupling capacitor to this section for detailed information.

6 Layout Guidelines Summary

Table 3 summarizes the layout guidelines.

Table 3. Layout Guidelines Summary

Name	Pin	Description	Typical Component Value	Component Instructions	Layout Instructions	Priority
BGND	E1, E2, E3	Boost ground. Connect to PCB GND plane			Maximum 150-pH parasitic inductance. Short BGND, GND, GNDD, PGDN below the package and connect them to PCB ground plane strongly through multiple vias. Minimize inductance as much as possible	Critical
DGND	E4, F4	Digital ground. Connect to PCB GND plane.			Maximum 150-pH parasitic inductance. Short BGND, GND, GNDD, PGDN below the package and connect them to PCB ground plane strongly through multiple vias. Minimize inductance as much as possible	Critical
GNDP	E5, E6	Power stage ground. Connect to PCB GND plane			Maximum 150-pH parasitic inductance. Short BGND, GND, GNDD, PGDN below the package and connect them to PCB ground plane strongly through multiple vias. Minimize inductance as much as possible	Critical
VBAT	D1, D2	Battery power supply input. Connect to 2.7-V to 5.5-V supply and decouple with a capacitor.	10 µF	Extra bulk decoupling may help reduce overall THD+N at high power by preventing supply droop	Maximum 500-pH parasitic inductance from device pin to decoupling. Bypass to GND with a capacitor. Should be connected to inductor through thick plane. Both ends of the decoupling capacitor should see as low inductance as possible between VBAT pin and PGND pin. Routing from VBAT should be wide enough to handle total output power.	Critical
GREG	D4	High-side gate CP regulator output. Do not connect to external load.	100 nF	Connect between GREG and PVDD. Connection to PVDD should be a star connection instead of connecting to decoupling route. Layer changes should use multiple vias to minimize parasitic inductance.	Maximum 200-pH parasitic inductance. Connect it to PVDD with a star connection and not to boost plane. Do not connect to external load.	Critical
SW	F1, F2, F3	Boost converter switch input	1 µH	Inductor connects between SW and VBAT	Connect to VBAT with boost inductor. Reduce parasitic capacitor and resistance for efficiency. Boost inductor should be as close as possible to the SW pin. Inductor should be connected to SW through thick plane. Traces should support currents up to device overcurrent limit. Ground bounce can be reduced by placing a keep-out below this trace and preventing any signal from routing beneath. Do not route digital under this net.	Critical
PVDD	G4, G5, G6	Power stage supply	20 µF	Capacitor derating should satisfy ratio of L/C < 1/3 with respect to the Boost inductor. Considering component tolerances, should target no less than 3.3 µF at a typical 11.5 V Boost when using a 1-µH inductor. This requirement requires checking the DC bias derating of the capacitor. 16-V capacitors typically are derated by around 80% at the boost voltage.	Maximum 100-pH parasitic inductance from device pin to decoupling. Short it to VBST(boost) plane through a strong connection. Connect it to the GREG ping with a star connection and not to boost plane.	High

Table 3. Layout Guidelines Summary (continued)

Name	Pin	Description	Typical Component Value	Component Instructions	Layout Instructions	Priority
VBST	G1, G2, G3	Boost converter output. Do not connect to external load.	20 µF	Capacitor derating should satisfy the ratio of L/C < 1/3 with respect to the Boost inductor. Considering component tolerances, should target no less than 3.3 µF at a typical 11.5 V Boost when using a 1-µH inductor. This requirement requires checking the DC bias derating of the capacitor. 16-V capacitors typically are derated by around 80% at the boost voltage.	Maximum 100-pH parasitic inductance from device pin to decoupling. Do not connect to external load. Bypass to GND with a capacitor. Connect to PVDD through thick plane. Both ends of the decoupling capacitor should see as low inductance as possible between the VBST pin and BGND pin. Traces should support currents up to device overcurrent limit.	High
DREG	B6	Digital core voltage regulator output. Bypass to GND with a capacitor. Do not connect to external load.	1 µF		Maximum 500-pH parasitic inductance from device pin to decoupling. Bypass to GND with capacitor. Do not connect to external load. Both ends of the decoupling capacitor should see as low inductance as possible between this pin and gnd pins.	High
VDD	C6	Analog, digital, and IO power supply. Connect to 1.8-V supply and decouple to GND with capacitor.	4.7 µF		Maximum 200-pH parasitic inductance from the device pin to decoupling. Bypass to GND with capacitor. Both the end of decoupling capacitor should see as low inductance as possible between this pin and GND pin	High
OUT_N	F6	Class-D negative output for receiver channel		If using an EMI filter, inductance should be the first element in the filter. Capacitance to GND or other output will pull high current spikes capable of triggering overcurrent protection. TI recommends setting the filter corner frequency no lower than 1.5 MHz.	Route with wide traces to the speaker connection. Make Vsense connections as close to the speaker as possible. Keep the route short to limit emissions.	Medium
OUT_P	F5	Class-D positive output for receiver channel		If using an EMI filter, the inductance should be the first element in the filter. Capacitance to GND or other output will pull high current spikes capable of triggering overcurrent protection. TI recommends setting the filter corner frequency no lower than 1.5 MHz.	Route with wide traces to speaker connection. Make Vsense connections as close to the speaker as possible. Keep route short to limit emissions.	Medium
VSNS_N	D3	Voltage sense negative input. Connect to Class-D OUT_N output after Ferrite bead filter.	1 kΩ	Additional place holders for series resistance may be beneficial with limiting emissions	Make connection to OUTN at speaker terminal	Medium
VSNS_P	D5	Voltage sense positive input. Connect to Class-D OUT_P output after Ferrite bead filter.	1 kΩ	Additional place holders for series resistance may be beneficial with limiting emissions	Make connection to OUTP at speaker terminal	Medium
IOVDD	A6	3.3-V/1.8-V IOVDD supply	1 µF			Low
FSYNC	B3	I2S word clock or TDM frame sync for ASI1 and ASI2 channels				Low
SBCLK1	B2	ASI1 channel I2S/TDM serial bit clock				Low
SDA_MOSI	B5	I2C Mode: I 2C Data Pin. Pullup to VDD with a resistor. SPI Mode: Serial data input pin				Low
SDIN1	C2	ASI1 channel I2S/TDM serial data input				Low
SDOUT1	C1	ASI1 channel I2S/TDM serial data output				Low

Table 3. Layout Guidelines Summary (continued)

Name	Pin	Description	Typical Component Value	Component Instructions	Layout Instructions	Priority
SCL_SELZ	B4	I2C Mode: I2C clock pin. Pullup to IOVDD with a resistor. SPI Mode: active low chip select.				Low
IRQZ	C5	Open drain, active low interrupt pin. Pullup to VDDD with resistor if optional internal pullup is not used.	10 kΩ			Not critical
PDMCLK	A1	PDM clock			Tie to GND if unused	Not critical
PDMD	A2	PDM data			Tie to Gnd if unused	Not critical
SBCLK2	A5	ASI2 channel I2S/TDM serial bit clock			Connect to SBCLK1	Not critical
SDIN2	A4	ASI2 channel I2S/TDM serial data input			Connect to SDOUT2 of second amplifier when using in stereo mode. GND if unused.	Not critical
SDOUT2	A3	ASI2 channel I2S/TDM serial data output			Connect to SDIN2 of second amplifier when using in stereo mode. Float if unused.	Not critical
SDZ	B1	Active-low hardware shutdown				Not critical
SPIICZ_MISO	C3	Pin is queried on power-up. Short to GND for I2C Mode. Pull to IOVDD with resistor for SPI mode. SPI serial data output pin.				Not critical
ADDR_SPICLK	C4	I2C Mode - Address selection pin See General I2C operation. SPI Mode - SPI clock				Not critical
