A[16:1]/D[15:0]	gpmc_ad[15:0]	I/O	Multiplexed address/data
nCS[7:0]	gpmc_cs[7:0]	O	Chip-selects (active low)
CLK	gpmc_clk	O	Clock generated for the external memory or device
nADV/ALE	gpmc_advn_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	gpmc_oen_ren	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	gpmc_wen	O	Write enable (active low)
nBE0/CLE	gpmc_ben0	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	gpmc_ben1	O	Upper-byte enable (active low).
WAIT[1:0]	gpmc_wait[1:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.

⁽¹⁾ I = Input; O = Output

NOTE: For the gpmc_clk signal to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x register should be set to 0x1 because of retiming purposes.

Table 11-359 shows the use of address and data GPMC controller pins based on the type of external device.

⁽¹⁾ Used to effectively address 8-bit (only) non-multiplexed memories

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

- The NOR flash memory controller still supports nonmultiplexed address and data memory devices.
- Multiplexing mode can be selected through the `GPMC_CONFIG1_i[9:8]` MUXADDDATA bit field (where $i = 0$ to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

11.3.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No master standby protocol
- Supports slave idle protocol with device PRCM
- Supports Auto Idle
- No wake-up request
- One direct memory access request mapped to the device DMA crossbar (`DMA_CROSSBAR`)

- One interrupt request mapped via the device interrupt crossbar (IRQ_CROSSBAR) to all device integrated interrupt controllers
- One clock for functional and interface domains

Figure 11-16 shows GPMC integration.

Figure 11-16. GPMC Integration

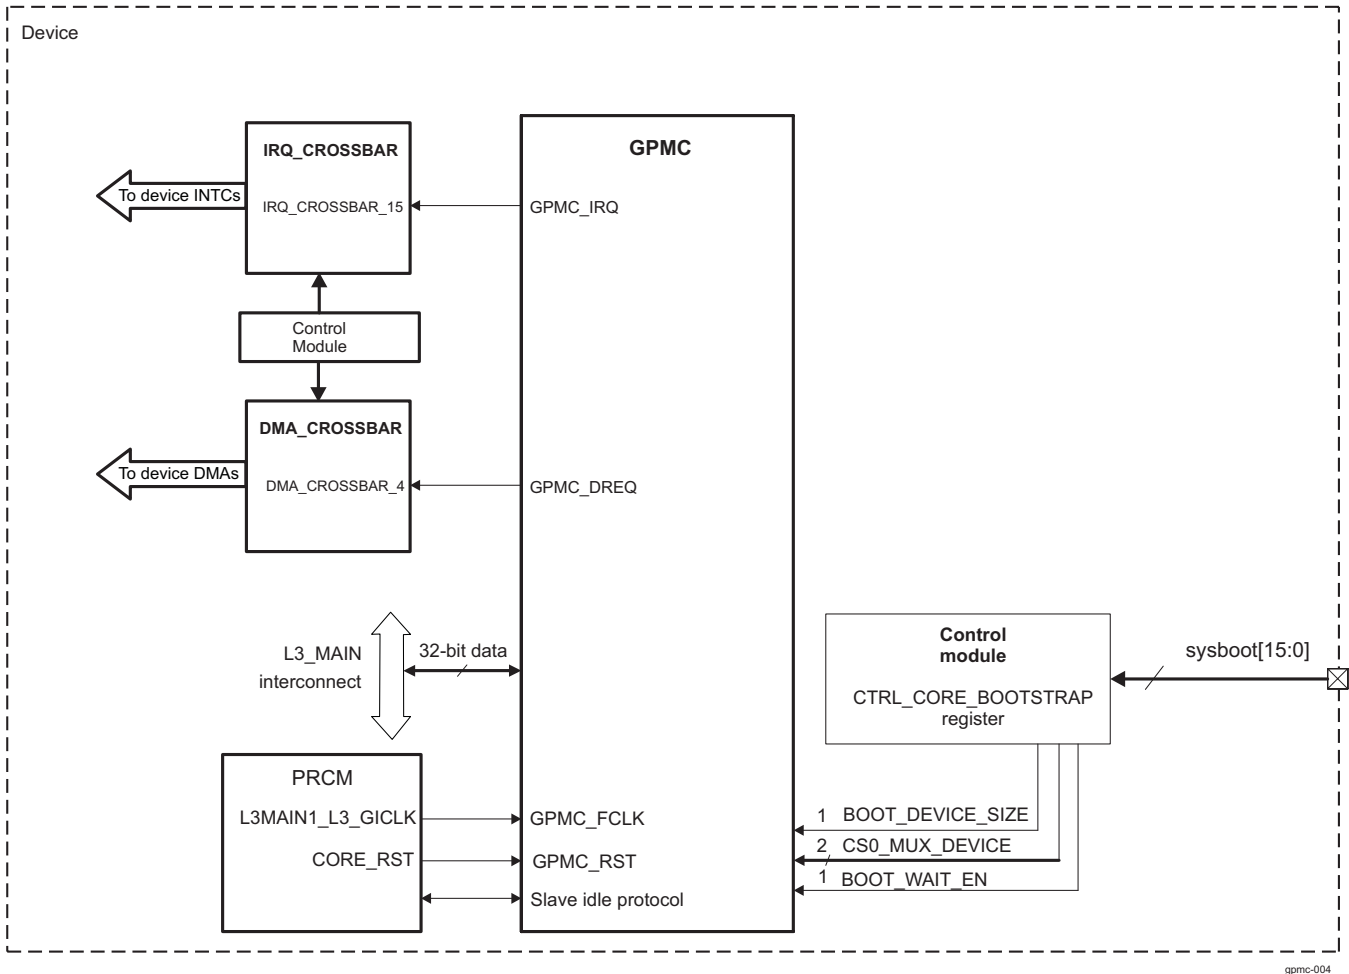

Table 11-360, Table 11-361 and Table 11-362 summarize the integration of the module in the device.

Table 11-360. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GPMC	PD_COREAON	No	L3_MAIN

NOTE:

- For the description of the operation performance point (OPP) configuration, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For information about frequencies associated with each OPP, see the device data manual.

Table 11-361. GPMC Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPMC	GPMC_FCLK	L3MAIN1_L3_GICLK	PRCM	Functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPMC	GPMC_RST	CORE_RET_RST	PRCM	GPMC reset

NOTE: For the clock description, see [Section 11.3.4.2, GPMC Clock Configuration](#).

Table 11-362. GPMC Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
GPMC	GPMC_IRQ	IRQ_CROSSBAR_15	DSP1_IRQ_46 DSP2_IRQ_46	GPMC interrupt
DMA Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
GPMC	GPMC_DREQ	DMA_CROSSBAR_4	DMA_EDMA_DREQ_3	DMA request from GPMC prefetch engine.

NOTE: The “Default Mapping” column in [Table 11-362 GPMC Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

NOTE: For the description of the interrupt source, see [Section 11.3.4.5, GPMC Interrupt Requests](#).

11.3.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

11.3.4.1 GPMC Block Diagram

[Figure 11-17](#) shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 11-17. GPMC Block Diagram

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

11.3.4.2 GPMC Clock Configuration

Table 11-363 describes the GPMC clocks.

Table 11-363. GPMC Clocks

Signal	I/O ⁽¹⁾	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices

⁽¹⁾ I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in [Table 11-361](#). The gpmc_clk is configured using the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field (where i = 0 to 7), as shown in [Table 11-364](#).

Table 11-364. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

11.3.4.3 GPMC Software Reset

The GPMC can be reset by software through the [GPMC_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The [GPMC_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. Software must ensure that the software reset completes before performing GPMC operations.

11.3.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

[Table 11-365](#) describes the power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
 - For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).
-

Table 11-365. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle and smart-idle wake-up modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

11.3.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt request (see [Figure 11-16](#)).

[Table 11-366](#) lists the event flags, and their mask, that can cause module interrupts.

Table 11-366. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS [9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE [9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG [9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS [8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE [8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG [8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS [1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE [1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS [0] FIFOEVENTSTATUS	GPMC_IRQENABLE [0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1 [2] DMAMODE must be set to 0.

11.3.4.6 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the [GPMC_CONFIG1](#)[_i][24:23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the [GPMC_CONFIG1](#)[_i][31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

11.3.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with an address range up to 256 MB (that is, 28 address bits in 8-bit mode or 27 address bits in 16-bit mode).

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: gpmc_a[27:16].
- 8-bit-wide NAND devices do not use GPMC I/O: gpmc_a[27:16] and GPMC I/O: gpmc_ad[15:8].

11.3.4.7.1 GPMC I/O Configuration Setting

NOTE: In this section and the following sections, the *i* in GPMC_CONFIGx_i stands for the GPMC chip-select *i*, where *i* = 0 to 7.

To select a NAND device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE = 0b10
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA = 0b01

To select an address/data-nonmultiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA = 0b00

11.3.4.7.2 GPMC CS0 Default Configuration at Device Reset

To ensure a correct, fast external boot with a GPMC access on device reset, several pins are sampled:

- The "sysboot0" through "sysboot5" pins (device boundary) define the sequence of interfaces and devices to use for booting (i.e. SYSBOOT[5:0] vector). They are sampled by the control module at reset and used later by the device ROM code. For more information, see [Section 25.2.4, Sysboot Configuration](#), in [Chapter 25, Initialization](#).
- Additional pins are used to configure reset values in the [GPMC_CONFIG1_i](#) register (where *i* = 0) as explained in the following and in [Table 11-367](#):
 - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 (CS0) and is used to configure the [GPMC_CONFIG1_i\[13:12\]](#) DEVICESIZE bit field (where *i* = 0). The BOOT_DEVICE_SIZE signal is propagated from the device Control Module. Its value 0b0 (8-bit memories) or 0b1 (16-bit memories) can be externally determined upon booting by **user hardware** via the device external input signal - "sysboot13".
 - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether or not the device attached to CS0 is an address/data-multiplexed device. The input pin is used to configure the [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit field (where *i* = 0). The CS0_MUX_DEVICE[1:0] signal is propagated from the Control Module. Its value 0x0 (**non-muxed memory attached**) or 0x2 (**Addr-Data Mux memory attached**) can be externally determined upon booting by **user hardware** via combining the device external input signals - "sysboot12" and "sysboot11", i.e. SYSBOOT[12:11].
 - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on CS0 of the wait pin at device reset release time for read accesses. The input pin is used to configure the [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit (where *i* = 0). The BOOT_WAIT_EN signal is

propagated from the Control Module. Its value 0x0 (**wait pin is not monitored for read accesses**) or 0x1 (**wait pin is monitored for read accesses**) can be externally determined upon booting by **user hardware** via the device external input signal - "sysboot10".

NOTE: If WAIT pin monitoring function is enabled upon booting (i.e. `BOOT_WAIT_EN="1"`), the default (power-on-reset) monitored input for CS0 is always the device `gpmc_wait0` input.

Table 11-367. Boot Control Interface Input Signals Description

Signal Name	Width	Description
BOOT_DEVICE_SIZE	1	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved (not used) 0b11: Reserved (not used)
CS0_MUX_DEVICE	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/data-multiplexed device on CS0 0b11: Reserved
BOOT_WAIT_EN	1	Wait monitoring on CS0 at device reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. For more information, see [Section 25.8, Memory Booting](#), and [Section 25.9, Image Format](#), in [Chapter 25, Initialization](#). This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed memory device attached to CS0

At reset time, the device can boot from the internal ROM.

The reset values of the timing control parameters are defined to cope with direct boot on address and data-multiplexed NOR flash devices, nonmultiplexed NOR flash devices, or any asynchronous device with large timing margins, assuming a low GPMC_FCLK frequency (for example, 19.2 MHz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto `gpmc_ad[15:0]`, while the high-order bits are presented onto `gpmc_a[26:16]`. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edges. The first rising edge latches the address most-significant bit (MSB) down to bit 17, while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXOFFTIME = 3

11.3.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 11.3.7, GPMC Register Manual](#), provides the GPMC register locations. For the map of GPMC memory locations, see [Chapter 2, Memory Mapping](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

11.3.4.8.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-MiB address space. For more information, see [Chapter 2, Memory Mapping](#).

NOTE: Even though GPMC supports total address space of 1GB, only 512MB are physically available in this device.

The GPMC 512-MiB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16 MiB to 256 MiB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in [Figure 11-18](#) (with A0 as the device system byte-address line). The base address is programmed through the `GPMC_CONFIG7_i[5:0] BASEADDRESS` bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the `GPMC_CONFIG7_i[11:8] MASKADDRESS` bit field.

Figure 11-18. Chip-Select Address Mapping and Decoding Mask

gpmc-006

Following is an example mapping that divides the 512MB memory reach into two 256MB regions:

- 1st 256MB region – 0x0000 0000 to 0x0FFF FFFF – program base address for that chip select equal to 0x0
- 2nd 256MB region – 0x1000 0000 to 0x1FFF FFFF – program base address for that chip select equal to 0x10

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the `GPMC_CONFIG7_i[6]` CSVALID bit (where *i* stands for the GPMC chip-select value, 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to eight chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines.

11.3.4.8.2 Access Protocol

11.3.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the `GPMC_CONFIG1_i[11:10]` DEVICETYPE parameter (where *i* = 0 to 7) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM

- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 11.3.4.12, NAND Device Basic Programming Model](#), and [Section 11.3.4.12.1, NAND Memory Device in Byte or Word16 Stream Mode](#).

11.3.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the [GPMC_CONFIG1_i\[13:12\]](#) DEVICESIZE bit field (where $i = 0$ to 7) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

11.3.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit field (where $i = 0$ to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 11.3.3, GPMC Integration](#).

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See [Section 11.3.4.12, NAND Device Basic Programming Model](#).

11.3.4.8.3 External Signals

NOTE: The "DIR" (direction control) output signal is NOT pinned out on any of the device pads. It is an internal signal only representing a signal direction on the GPMC data bus.

11.3.4.8.3.1 Wait Pin Monitoring Control

GPMC access time can be dynamically controlled using an external `gpmc_wait` pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features two input wait pins: `gpmc_wait1`, and `gpmc_wait0`. These pins allow control of external devices with different wait pin polarity. They also allow the overlap of wait pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The [GPMC_CONFIG1_i\[17:16\]](#) WAITPINSELECT bit field (where $i = 0$ to 7) selects which input `gpmc_wait` pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the [GPMC_CONFIG](#) register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a wait pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the wait pin of the external memory device, based on the access type: read or write.

- The [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit defines whether or not the wait pin must be monitored during read accesses.
- The [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING bit defines whether or not the wait pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the [GPMC_CONFIG1_i\[29\]](#) READTYPE and [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bits).

11.3.4.8.3.1.1 Wait Monitoring During Asynchronous Read Access

When wait pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

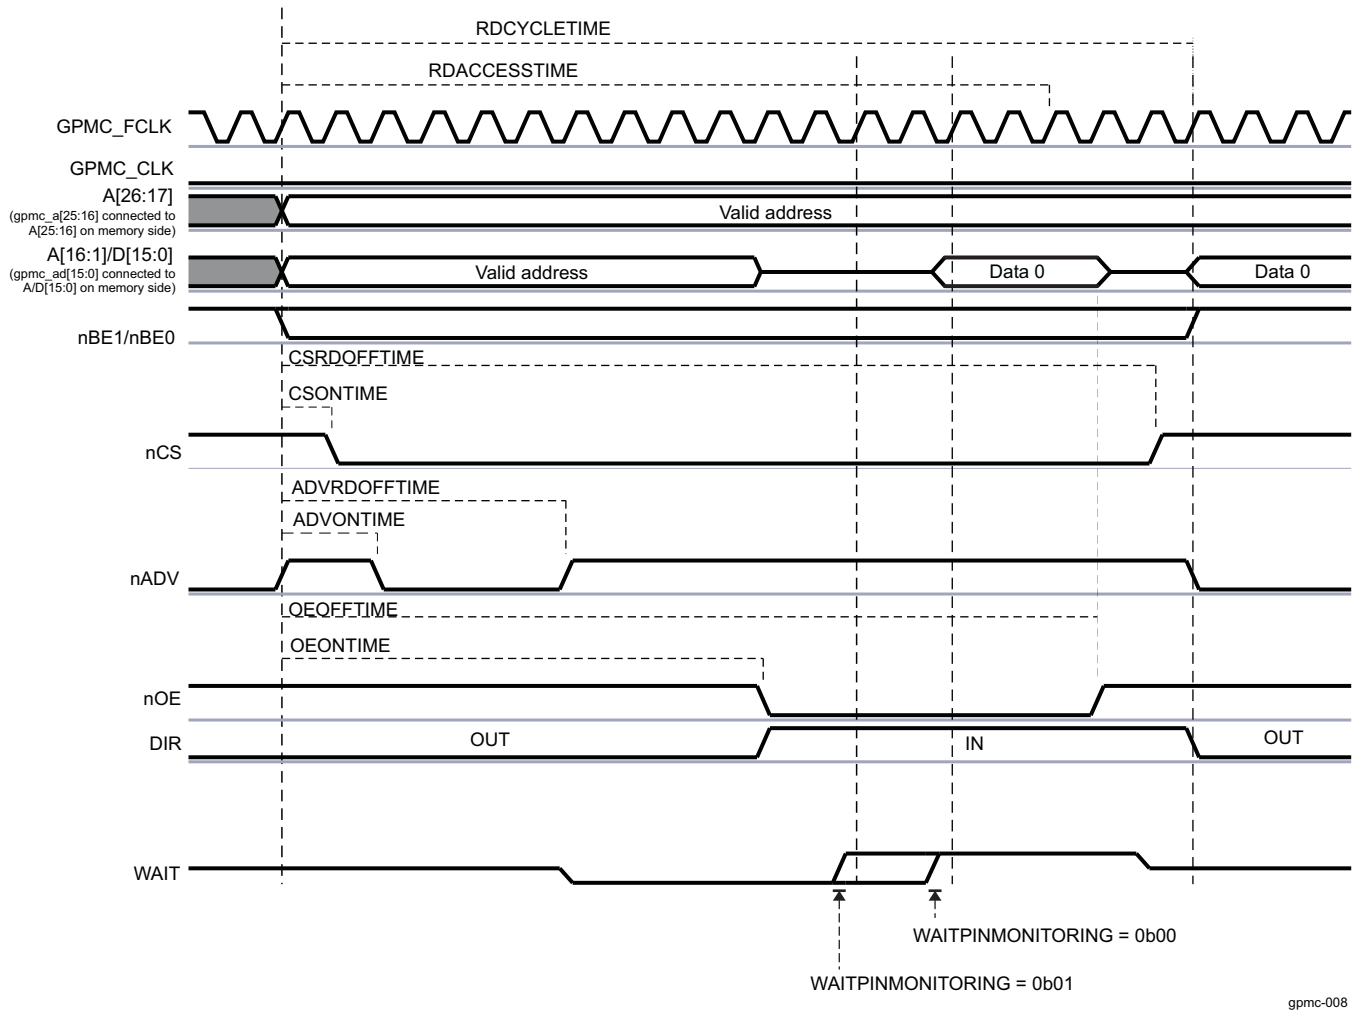

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME bit field (where i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
 - This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, because GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.
-

Figure 11-19 shows wait behavior during an asynchronous single read access.

Figure 11-19. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

gpmc-008

NOTE: The WAIT signal is active low. [GPMC_CONFIG1_i\[19:18\] WAITMONITORINGTIME = 0b00](#), or [0b01](#).

11.3.4.8.3.1.2 Wait Monitoring During Asynchronous Write Access

When wait pin monitoring is enabled for write accesses ([GPMC_CONFIG1_i\[21\] WAITWRITEMONITORING](#) bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME bit field (where $i = 0$ to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
 - This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.
-

11.3.4.8.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with wait pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME bit field (where $i = 0$ to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait pin monitoring is enabled (the [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the wait pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

[Figure 11-20](#) shows wait behavior during a synchronous read burst access.

Figure 11-20. Wait Behavior During a Synchronous Read Burst Access

gpmc-009

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

11.3.4.8.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with wait pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC_CLK capture edge of the effective memory device.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except `GPMC_CONFIG1_i[19:18]` `WAITMONITORINGTIME = 0x0` (where `i = 0` to `7`) for write bursts with a clock divider of `1` or `2` (the `GPMC_CONFIG1_i[1:0]` `GPMCFCLKDIVIDER` bit field is equal to `0x0` or `0x1`, respectively).

11.3.4.8.3.1.5 Wait With NAND Device

For information about the use of the wait pin for communication with a NAND flash external device, see [Section 11.3.4.12.2, NAND Device-Ready Pin](#).

11.3.4.8.3.1.6 Idle Cycle Control Between Successive Accesses

11.3.4.8.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the `GPMC_CONFIG6_i[3:0]` `BUSTURNAROUND` bit field (where `i = 0` to `7`).

After a read access to a chip-select with a nonzero `BUSTURNAROUND`, the next access is delayed until the `BUSTURNAROUND` delay completes, if the next access is one of the following:

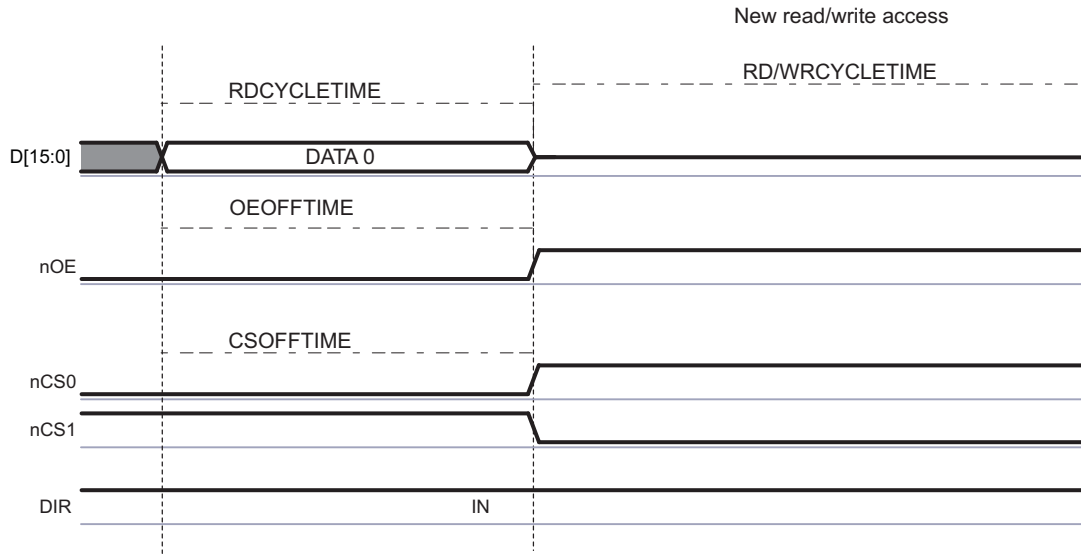

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that `DIR` changes from `IN` to `OUT` after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

`BUSTURNAROUND` delay runs in parallel with `GPMC_CONFIG6_i[3:0]` `CYCLE2CYCLEDELAY` bit field delays. `BUSTURNAROUND` is a timing parameter for the ending chip-select access, while `CYCLE2CYCLEDELAY` is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see [Figure 11-21](#) through [Figure 11-23](#)).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of `RDCYCLETIME`. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

Figure 11-21. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

gpmc-049

Figure 11-22. Read- to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround

gpmc-050

Figure 11-23. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround

11.3.4.8.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The [GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMECSSEN bit (where $i = 0$ to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the [GPMC_CONFIG6_i\[11:8\]](#) CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used ([GPMC_CONFIG1_i\[30\]](#) READMULTIPLE = 0 or [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

11.3.4.8.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the [GPMC_CONFIG6_i](#)[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the [GPMC_CONFIG6_i](#) registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see [Section 11.3.4.8.3.1.6.1, Bus Turnaround \(BUSTURNAROUND\)](#).

[Table 11-368](#) describes the configuration required for idle cycle insertion.

Table 11-368. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

11.3.4.8.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the [GPMC_CONFIG1_i](#)[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, 0 to 7). Increasing all access timing parameters allows support of slow devices.

11.3.4.8.3.2 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module provides an input pin, `global_rst_n`, to the GPMC:

- The `global_rst_n` pin is activated during device warm reset and cold reset.
- The `global_rst_n` pin initializes the internal state-machine and the internal configuration registers.

11.3.4.8.3.3 Byte Enable (*nBE1/nBE0*)

Byte enable signals (`nBE1/nBE0`) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

11.3.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the [GPMC_ERR_TYPE](#) register and the address of the illegal access is stored in the [GPMC_ERR_ADDRESS](#) register. The GPMC keeps only the first error abort information until the [GPMC_ERR_TYPE](#) register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the [GPMC_ERR_TYPE\[0\]](#) `ERRORVALID` bit.

- `ERRORNOTSUPPADD` occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KiB.
- `ERRORNOTSUPPMCMD` occurs when an unsupported command request is decoded at the L3 interconnect interface.
- `ERRORTIMEOUT`: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the [GPMC_TIMEOUT_CONTROL](#) register and enabled with the [GPMC_TIMEOUT_CONTROL\[0\]](#) `TIMEOUTENABLE` bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

11.3.4.9 Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about `GPMC_CLK` and `GPMC_FCLK` see [Section 11.3.4.9.6, GPMC_CLK](#).

NOTE: In the following sections, the start access time refers to the time at which the access begins.

11.3.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME and [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME bit fields (where $i = 0$ to 7) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select ([GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMECSSEN = 0 or [GPMC_CONFIG6_i\[6\]](#) CYCLE2CYCLEDIFFCSSEN = 0, where $i = 0$ to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSSEN = 1 or CYCLE2CYCLEDIFFCSSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

11.3.4.9.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME bit field (where $i = 0$ to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The [GPMC_CONFIG2_i\[12:8\]](#) CSRDOFFTIME (read access) and [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the [GPMC_CONFIG2_i\[7\]](#) CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

11.3.4.9.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME /

ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field (where $i = 0$ to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME (read access) and [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the [GPMC_CONFIG3_i\[7\]](#) ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

[GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME, [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME, and [GPMC_CONFIG3_i\[30:28\]](#) ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see [Section 11.3.4.12, NAND Access Description](#).

11.3.4.9.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME bit field (where $i = 0$ to 7) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user must ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the [GPMC_CONFIG4_i\[7\]](#) OEEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

11.3.4.9.5 *nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)*

The [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME bit field (where $i = 0$ to 7) defines the nWE signal-assertion time relative to start access time. The [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the [GPMC_CONFIG4_i\[23\]](#) WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

11.3.4.9.6 *GPMC_CLK*

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field (where $i = 0$ to 7), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device data manual.
- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME bit field (where $i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

11.3.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME bit field (where $i = 0$ to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADelay, ADVEXTRADelay, OEXTRADelay, or WEEXTRADelay parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

11.3.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME and [GPMC_CONFIG6_i\[28:24\]](#) WRACCESSTIME bit fields (where $i = 0$ to 7). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY bit.

11.3.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME bit field (where $i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see [Section 11.3.4.8.3.1, Wait Pin Monitoring Control](#).

11.3.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the [GPMC_CONFIG6_i\[28:24\]](#) WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see [Section 11.3.4.8.3.1, Wait Pin Monitoring Control](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see [Section 11.3.4.8.3.1, Wait Pin Monitoring Control](#).

11.3.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME bit field (where $i = 0$ to 7) can be set with a granularity of 1 or 2 through the [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY bit.

11.3.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see [Section 11.3.4.8.3.1, Wait Pin Monitoring Control](#).

11.3.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see [Section 11.3.4.8.3.1, Wait Pin Monitoring Control](#).

11.3.4.9.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

11.3.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the [GPMC_CONFIG1_i\[29\]](#) READTYPE bit (where $i = 0$ to 7). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bit where ($i = 0$ to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

11.3.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

11.3.4.10.1.1 Access on Address/Data Multiplexed Devices

11.3.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 11-24 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 11-24. Asynchronous Single Read on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see Section 11.3.5.6.1, GPMC Timing Parameters Formulas.

Table 11-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 11.3.4.8.2.3, Address/Data-Multiplexing Interface.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[27:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDFFTIME bit field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
 - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

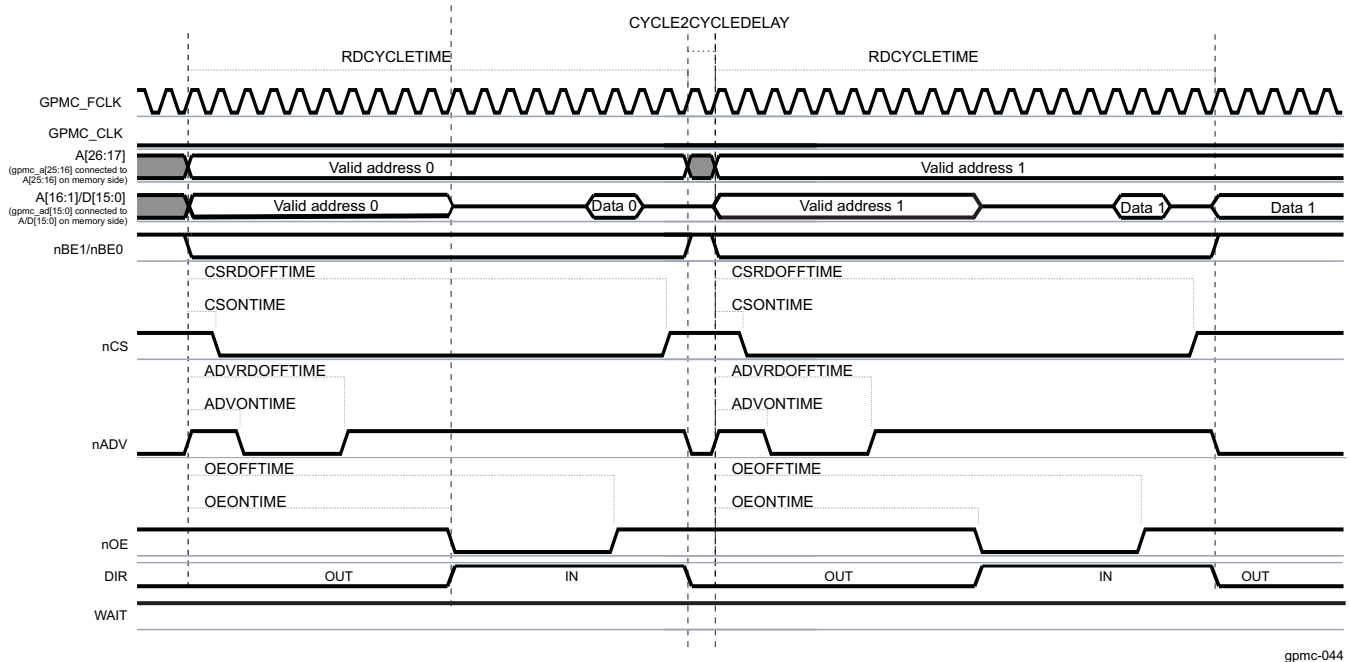

- Read data is latched when RDACCESSTIME completes. Access time is defined in the [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 11.3.4.10.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The [GPMC_CONFIG6_i\[11:8\]](#) CYCLE2CYCLEDELAY bit field can be programmed with the [GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMECSSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

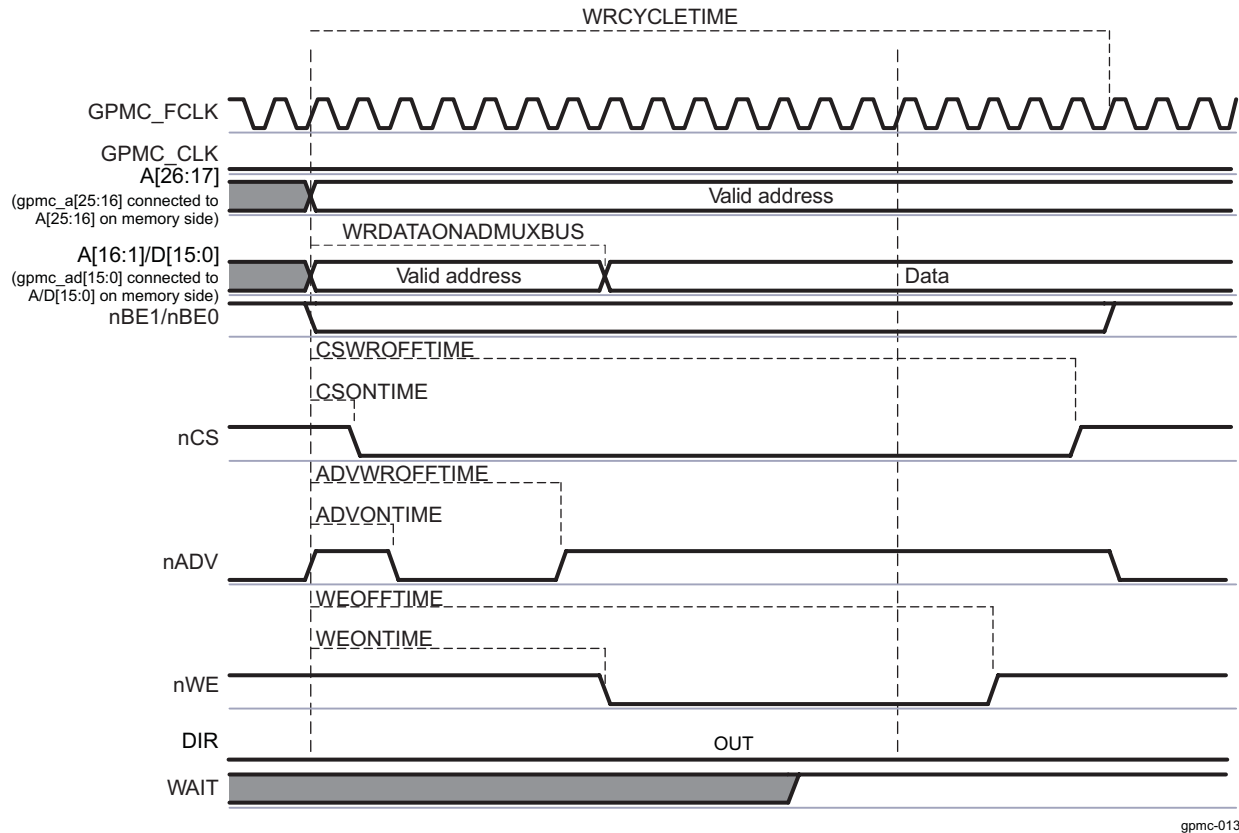

Figure 11-25. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)

11.3.4.10.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 11-26 shows an asynchronous single-write operation on an address/data-multiplexed device.

Figure 11-26. Asynchronous Single-Write on an Address/Data-Multiplexed Device

gpmc-013

For formulas to calculate timing parameters, see [Section 11.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 11-400](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 11.3.4.8.2.3, Address/Data-Multiplexing Interface](#).

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\] WEONTIME](#) bit field.
 - nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\] WEOFFTIME](#) bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the [GPMC_CONFIG5_i\[12:8\] WRCYCLETIME](#) parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a [GPMC_CONFIG6_i\[19:16\] WRDATAONADMUXBUS](#) time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 11.3.4.9.10, Bus Keeping Support](#).

11.3.4.10.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE bit is enabled (0x1) with the [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see [Section 11.3.4.10.3, Asynchronous and Synchronous Accesses in Nonmultiplexed Mode](#).

11.3.4.10.1.2 Access on Address/Address/Data-Multiplexed Devices

11.3.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 11-27 shows an asynchronous single-read operation on an AAD-multiplexed device.

Figure 11-27. Asynchronous Single Read on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 11.3.5.6.1, GPMC Timing Parameters Formulas.

Table 11-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

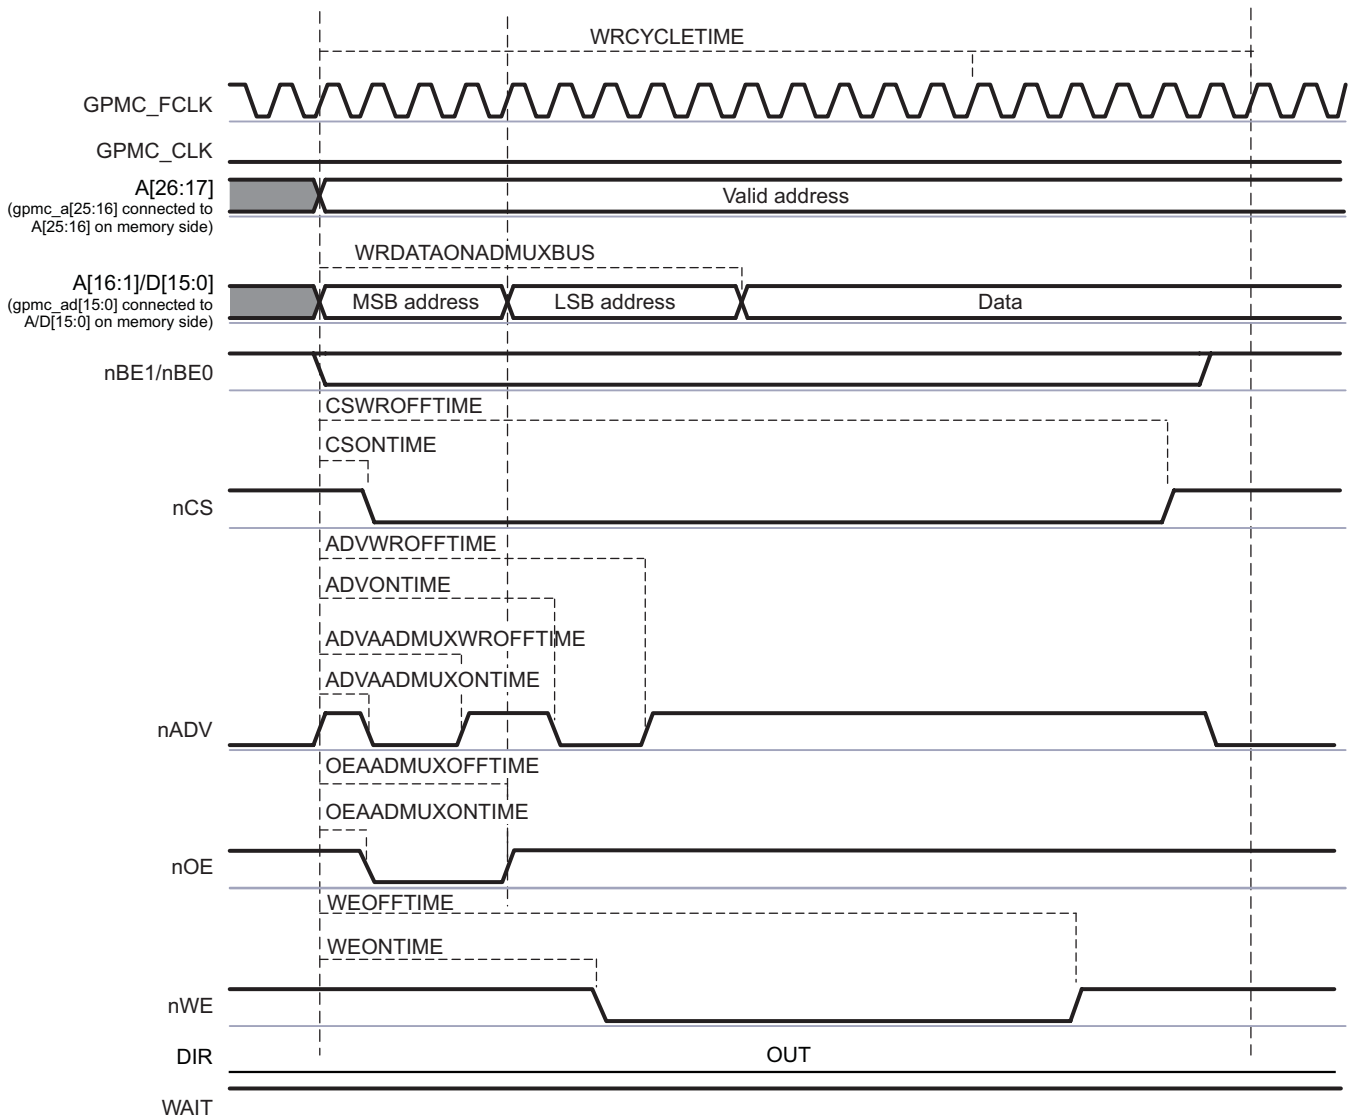

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.

- nADV first deassertion time is controlled by the `GPMC_CONFIG3_i[26:24]` ADVAADMUXRD OFFTIME bit field.
- nADV second assertion time is controlled by the `GPMC_CONFIG3_i[3:0]` ADVONTIME bit field.
- nADV second deassertion time is controlled by the `GPMC_CONFIG3_i[12:8]` ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the `GPMC_CONFIG4_i[6:4]` OEAADMUXONTIME bit field.
 - nOE first deassertion time is controlled by the `GPMC_CONFIG3_i[15:13]` OEAADMUXOFFTIME bit field.
 - nOE second assertion time is controlled by the `GPMC_CONFIG4_i[3:0]` OEONTIME bit field.
 - nOE second deassertion time is controlled by the `GPMC_CONFIG4_i[12:8]` OEOFFTIME bit field.

11.3.4.10.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 11-28 shows an asynchronous single-write operation on an AAD-multiplexed device.

Figure 11-28. Asynchronous Single Write on an AAD-Multiplexed Device

gpmc-042

For formulas to calculate timing parameters, see [Section 11.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 11-400](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See [Table 11-391](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME bit field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[30:28\]](#) ADVAADMUXWROFFTIME bit field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME bit field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
 - nOE assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME bit field.
 - nOE deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS parameter.

11.3.4.10.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE bit is enabled (0x1) with the [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see [Section 11.3.4.10.3, Asynchronous and Synchronous Accessed in Nonmultiplexed Mode](#).

11.3.4.10.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (nonmultiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on nonmultiplexed devices, see [Section 11.3.4.10.3, Asynchronous and Synchronous Accessed in Nonmultiplexed Mode](#).

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 7.
- The [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

11.3.4.10.2.1 Synchronous Single Read

[Figure 11-29](#) and [Figure 11-30](#) show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 11-29. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

Figure 11-30. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

For formulas to calculate timing parameters, see [Section 11.3.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 11-400](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 11.3.4.8.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME bit field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the [GPMC_CONFIG2_i\[12:8\]](#) CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME bit field.
 - nADV deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME bit field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME bit field.
 - nOE deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME bit field.
- Initial latency for the first read data is controlled by [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME bit field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME bit field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME bit field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME bit field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME bit field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME bit field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.3.4.9.10](#), *Bus Keeping Support*.

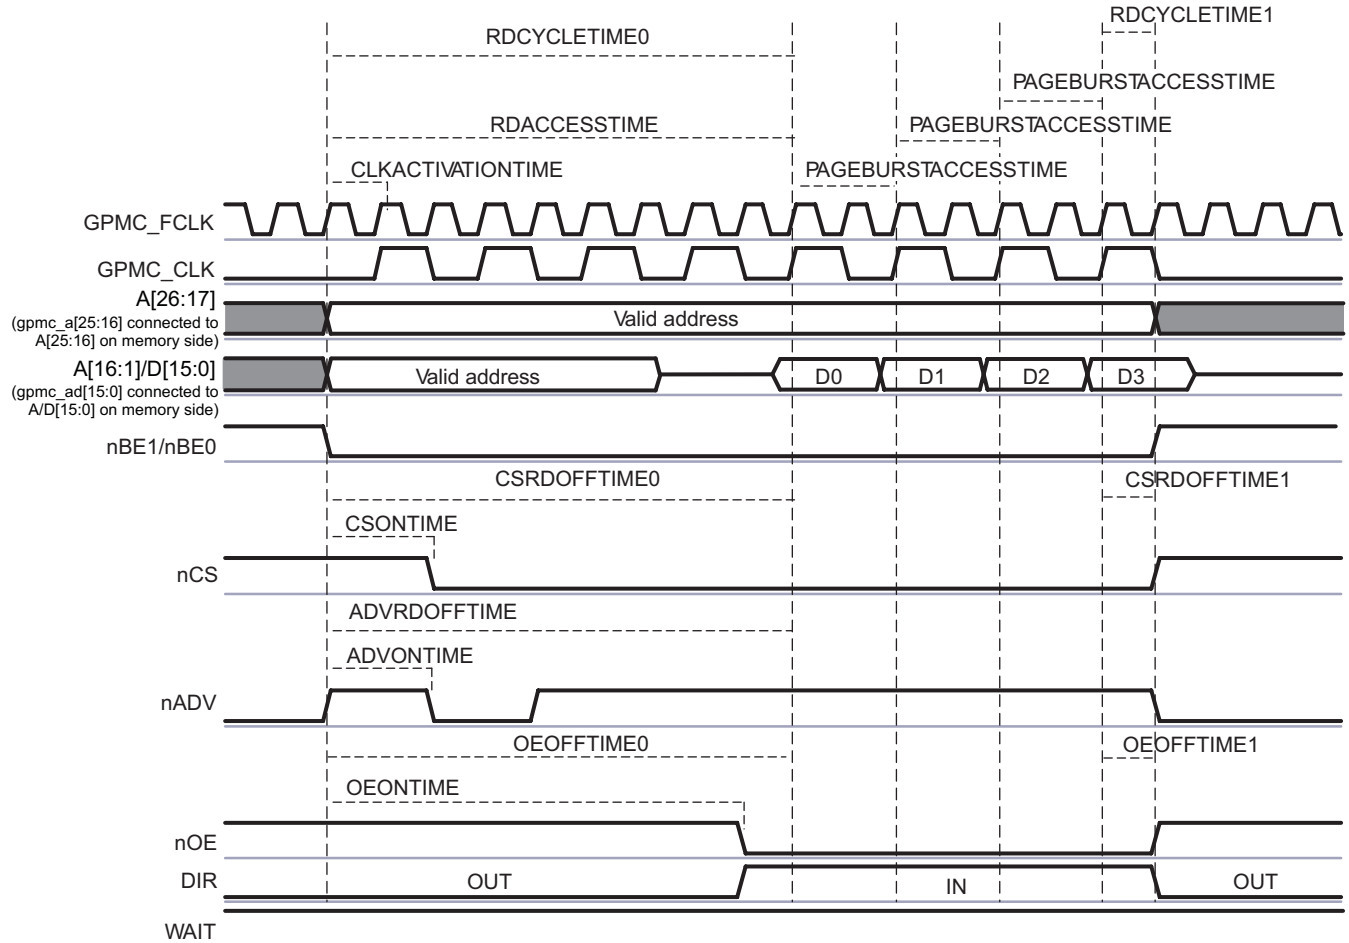

11.3.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

[Figure 11-31](#) and [Figure 11-32](#) show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 11-31. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-018

Figure 11-32. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

gpmc-019

When the [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See [Table 11-386](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 11-32](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.3.4.9.10, Bus Keeping Support](#).

Burst wraparound is enabled through the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH bit field.

11.3.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 11-33. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

11.3.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

[Figure 11-34](#) shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 11-34. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

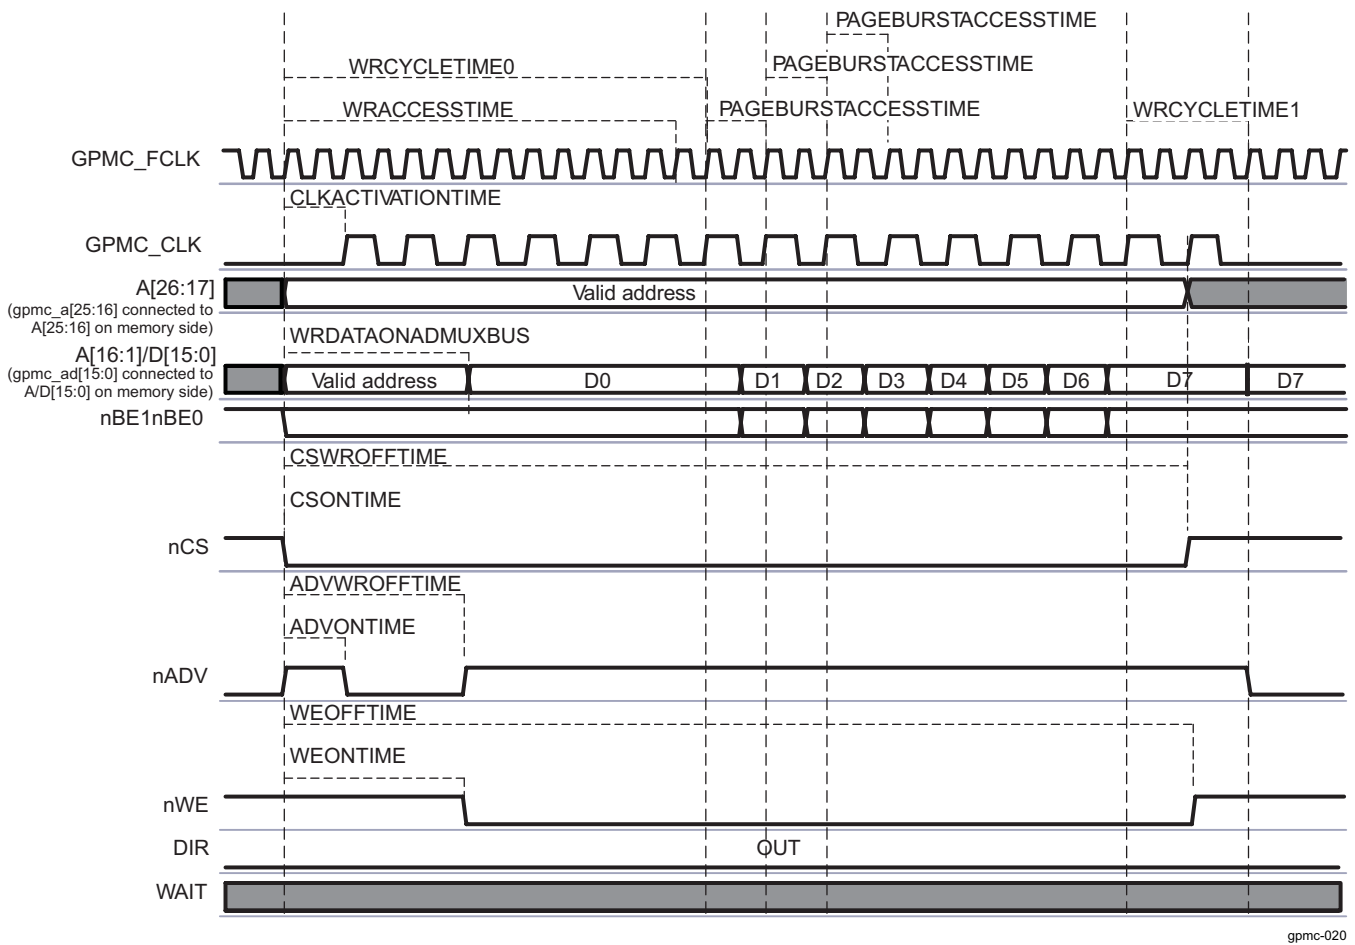

Figure 11-35 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Figure 11-35. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

gpmc-021

The first data of the burst is driven on the A/D bus at the [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 11.3.4.8.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME bit field (where i = 0 to 7) and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME bit field.

- nADV deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME bit field.
- Write enable signal nWE:
 - nWE assertion indicates a read cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME bit field.
 - nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME bit field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described..

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME bit field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME bit field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME bit field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME bit field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG4_i\[15:13\]](#) OEAADMUXOFFTIME bit field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME bit field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME bit field.

First write data is driven by the GPMC at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at $WRACCESSTIME + 1$ during [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME completes.

- WRACCESSTIME is defined in the [GPMC_CONFIG6_i\[28:24\]](#) bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 11-34](#), the programmed value of WRCYCLETIME equals $WRCYCLETIME0 + WRCYCLETIME1$. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 11.3.4.9.10, Bus Keeping Support](#).

11.3.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is available only in nonmultiplexed mode.

- Asynchronous single-read operation on a nonmultiplexed device
- Asynchronous single-write operation on a nonmultiplexed device
- Asynchronous multiple- (page mode) read operation on a nonmultiplexed device

- Synchronous operations on a nonmultiplexed device

11.3.4.10.3.1 Asynchronous Single-Read Operation on Nonmultiplexed Device

Figure 11-36 shows an asynchronous single-read operation on a nonmultiplexed device.

Figure 11-36. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

The 27-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at `GPMC_CONFIG1_5[20:16]` RDACCESSTIME completion time. The end of the access is defined by the `GPMC_CONFIG1_5[4:0]` RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 11-391](#)).

11.3.4.10.3.2 Asynchronous Single-Write Operation on Nonmultiplexed Device

Figure 11-37 shows an asynchronous single-write operation on a nonmultiplexed device.

Figure 11-37. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

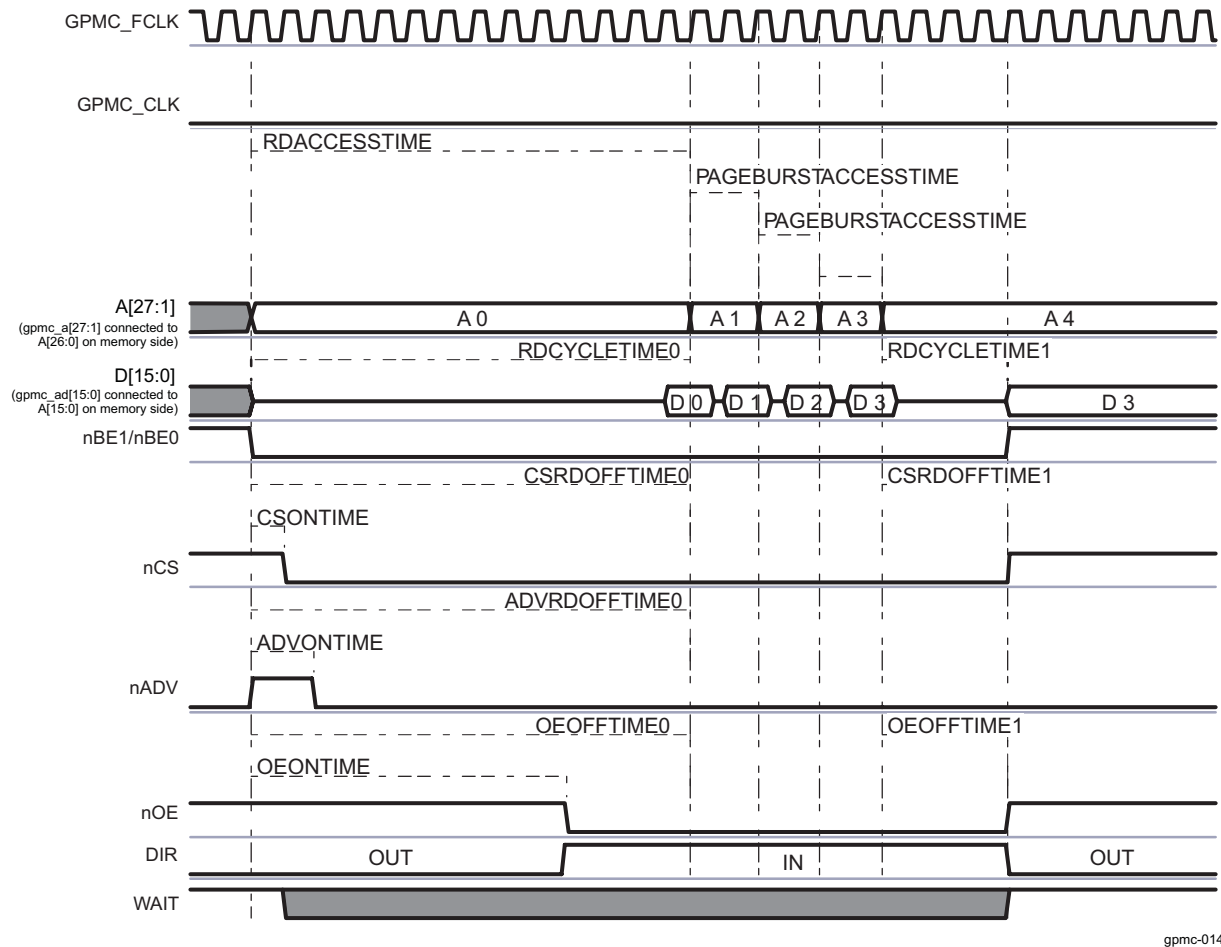

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 11-391](#)).

11.3.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on Nonmultiplexed Device

[Figure 11-38](#) shows an asynchronous multiple-read operation on a nonmultiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

Figure 11-38. Asynchronous Multiple (Page Mode) Read

gpmc-014

NOTE: The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 11-391](#)).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME completion time (where $i = 0$ to 7). The end of the access is defined by the [GPMC_CONFIG5_j\[4:0\]](#) RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the [GPMC_CONFIG5_j\[4:0\]](#) RDCYCLETIME bit field.
- In [Figure 11-38](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

11.3.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 11.3.5.3, GPMC Configuration in NOR Mode](#).

11.3.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC_CONFIG1_i\[30\]](#) READMULTIPLE and [GPMC_CONFIG1_i\[28\]](#) WRITMULTIPLE bits (where $i = 0$ to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
 - 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
 - Not applicable to NAND device interfacing
-

11.3.4.10.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH bit field (where $i = 0$ to 7). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit (where $i = 0$ to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), wait pin monitoring must be enabled to dynamically control data access completion within the burst.

NOTE: When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

11.3.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE bit field (where $i = 0$ to 7) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

11.3.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices.

This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

11.3.4.12.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

11.3.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The [GPMC_CONFIG7_i](#) register (where $i = 0$ to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MiB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the [GPMC_CONFIG1_i](#) register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in [Table 11-369](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 11-369. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i [31] ⁽¹⁾	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i [30]	0	Single access
READTYPE	GPMC_CONFIG1_i [29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i [28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i [27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i [26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i [24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i [22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i [21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i [19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i [17:16]		Select which wait is monitored by edge detectors
DEVICESTYPE	GPMC_CONFIG1_i [13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i [11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i [9:8]	0b00	Nonmultiplexed mode

⁽¹⁾ $i = 0$ to 7

Table 11-369. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

The [GPMC_CONFIG1_i](#) to [GPMC_CONFIG4_i](#) registers (where $i = 0$ to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

11.3.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) register locations (where $i = 0$ to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) register locations must be posted for faster operations (where $i = 0$ to 7). The [GPMC_CONFIG\[0\]](#) NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An [GPMC_STATUS\[0\]](#) EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) registers (where $i = 0$ to 7) are 32-bit word locations, which means any 32- or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a [GPMC_NAND_COMMAND_i](#) and a [GPMC_NAND_ADDRESS_i](#) (where $i = 0$ to 7) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

11.3.4.12.1.3 Command Latch Cycle

Writing data at the [GPMC_NAND_COMMAND_i](#) location (where $i = 0$ to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

- ALE and nRE (nOE) are maintained inactive.

Figure 11-39 shows the NAND command latch cycle.

Figure 11-39. NAND Command Latch Cycle

NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

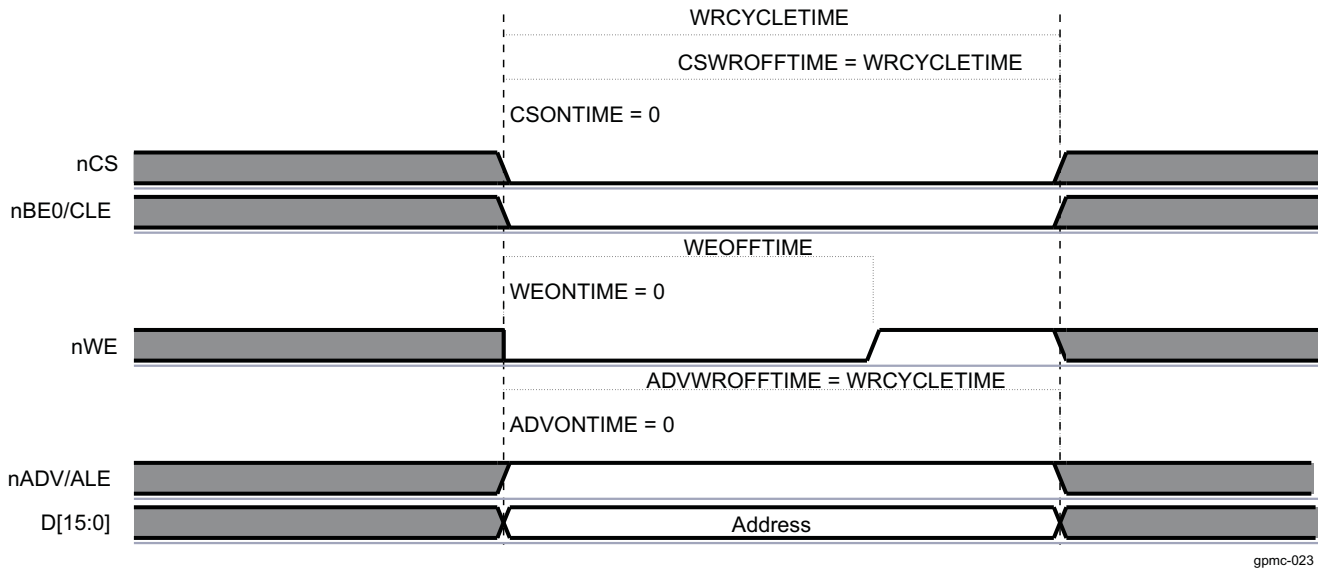

11.3.4.12.1.4 Address Latch Cycle

Writing data at the [GPMC_NAND_ADDRESS_i](#) location (where $i = 0$ to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 11-40 shows the NAND address latch cycle.

Figure 11-40. NAND Address Latch Cycle

NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

11.3.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the `GPMC_NAND_DATA_i` location (where $i = 0$ to 7) mapped in the chip-select-associated control register region. `GPMC_NAND_DATA_i` is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the `GPMC_NAND_DATA_i` location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 11-41 shows the NAND data read cycle.

Figure 11-41. NAND Data Read Cycle

gpmc-024

Writing data to the [GPMC_NAND_DATA_i](#) location or to any location in the associated chip-select memory region activates an asynchronous write access.

- **nCS** is controlled by the **CSONTIME** and **CSWROFFTIME** timing parameters.
- **nWE** is controlled by the **WEONTIME** and **WEOFFTIME** timing parameters.
- **ALE**, **CLE**, and **nRE** (**nOE**) are maintained inactive.

Figure 11-42 shows the NAND data write cycle.

Figure 11-42. NAND Data Write Cycle

gpmc-025

11.3.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by **nCS**-to-data-valid timing and has faster **nRE**-to-data-valid timing. Successive accesses with **nCS** deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that **nCS** always stays low between two accesses to the same chip-select. Moreover, an **nCS** deassertion time between the same chip-select NAND accesses is likely to be required as follows: the **nCS** deassertion requires programming **CYCLETIME** and **RDACCESSTIME** according to the **nCS**-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see [Section 11.3.4.12.4](#), *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

11.3.4.12.1.7 Read and Write Access Size Adaptation

11.3.4.12.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

11.3.4.12.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

11.3.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING and [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bits to 0, where $i = 0$ to 7), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where $x = 0$ to 2) of the [GPMC_STATUS](#).
- Configure an interrupt that is generated on the WAIT signal change (through the [GPMC_IRQENABLE](#) register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the [GPMC_STATUS](#) register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

11.3.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the [GPMC_STATUS](#) WAITxSTATUS bit (where $x = 0$ to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

11.3.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the [GPMC_CONFIG](#) WAITxPINPOLARITY bits (where $x = 0$ to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where $x = 0$ to 2) of the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two [GPMC_FCLK](#) cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the [GPMC_IRQENABLE](#) register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for NAND device ready signal monitoring.

11.3.4.12.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhuri-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the [GPMC_ECC_CONFIG\[3:1\]](#) ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

11.3.4.12.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

11.3.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers ([GPMC_ECCj_RESULT](#), where $j = 1$ to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the [GPMC_ECCj_RESULT](#) register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The [GPMC_ECC_CONTROL](#)[3:0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the [GPMC_ECCj_RESULT](#) register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the [GPMC_ECCj_RESULT](#) register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The [GPMC_ECC_CONTROL](#)[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each [GPMC_ECCj_RESULT](#) register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZe bits (where j = 1 to 9) in the [GPMC_ECC_SIZE_CONFIG](#) register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the [GPMC_ECCj_RESULT](#) register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KiB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine [GPMC_ECCj_RESULT](#) registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8] RESULTSIZe bits are set to 0, and the ECC9RESULTSIZe bit is set to 1.

11.3.4.12.3.1.2 ECC Enabling

The [GPMC_ECC_CONFIG](#)[3:1] ECCCS bit field selects the allocated chip-select. The [GPMC_ECC_CONFIG](#)[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZe (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 11-370](#) describes the ECC enable settings.

Table 11-370. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Table 11-370. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

11.3.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 11-43 and Figure 11-44. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

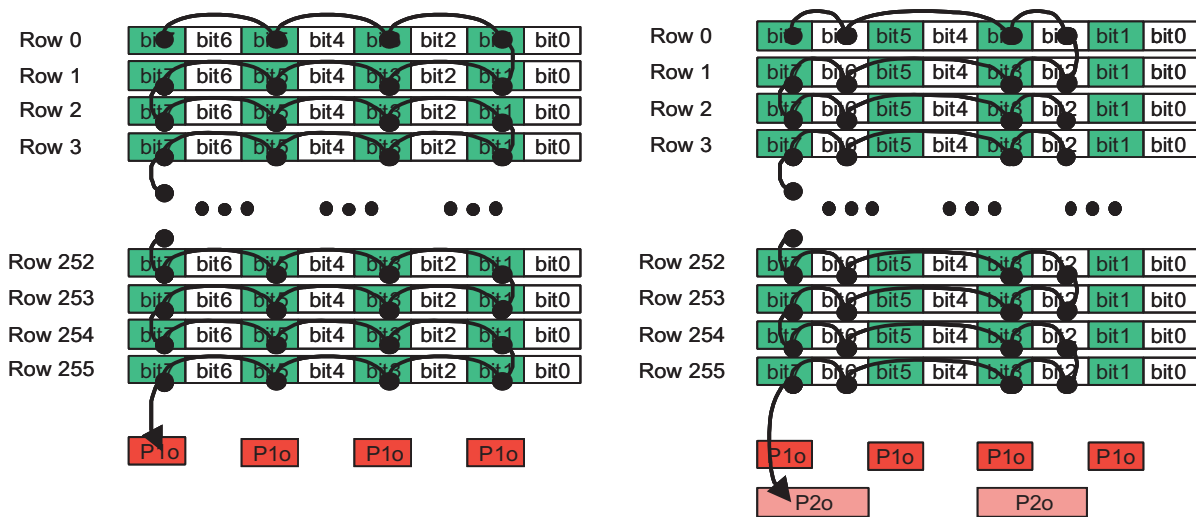

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 11-43. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Figure 11-44. Hamming Code Accumulation Algorithm (2/2)

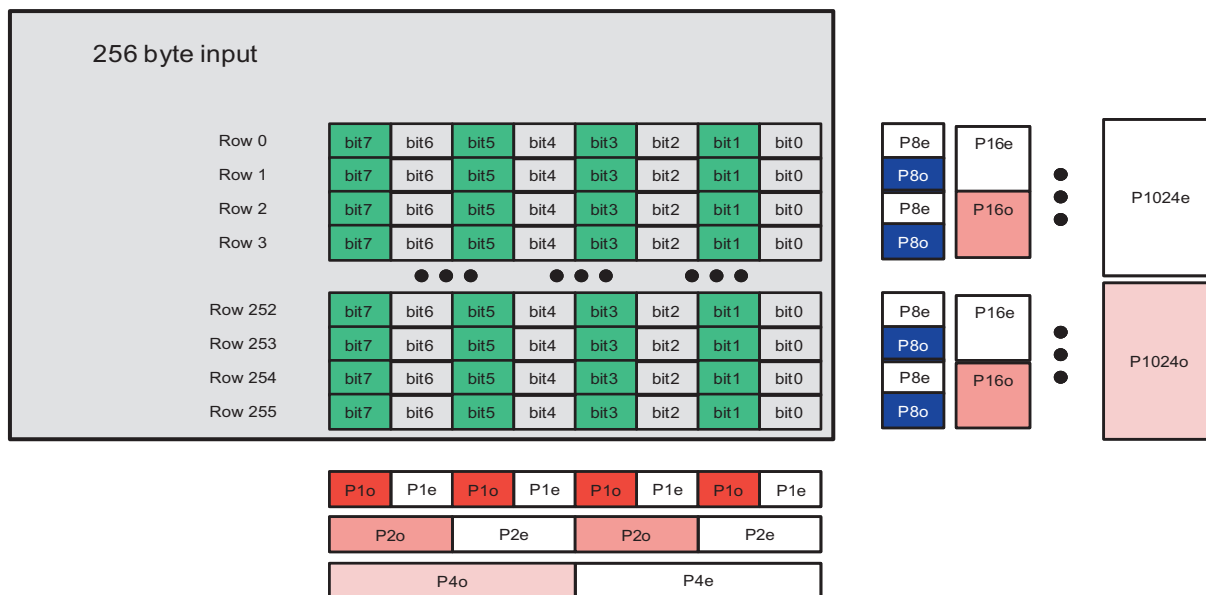

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 11-45 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 11-45. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 11-46 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 11-46. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2-KiB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the [GPMC_ECCj_RESULT](#) registers (where j = 1 to 9).

11.3.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

11.3.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

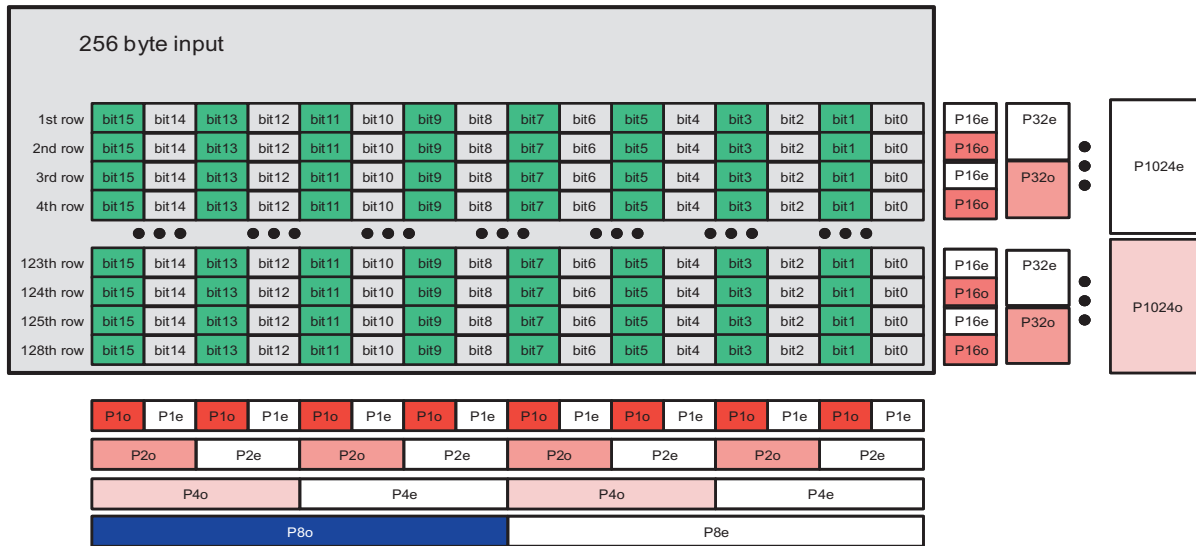

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

11.3.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the [GPMC_ECC_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

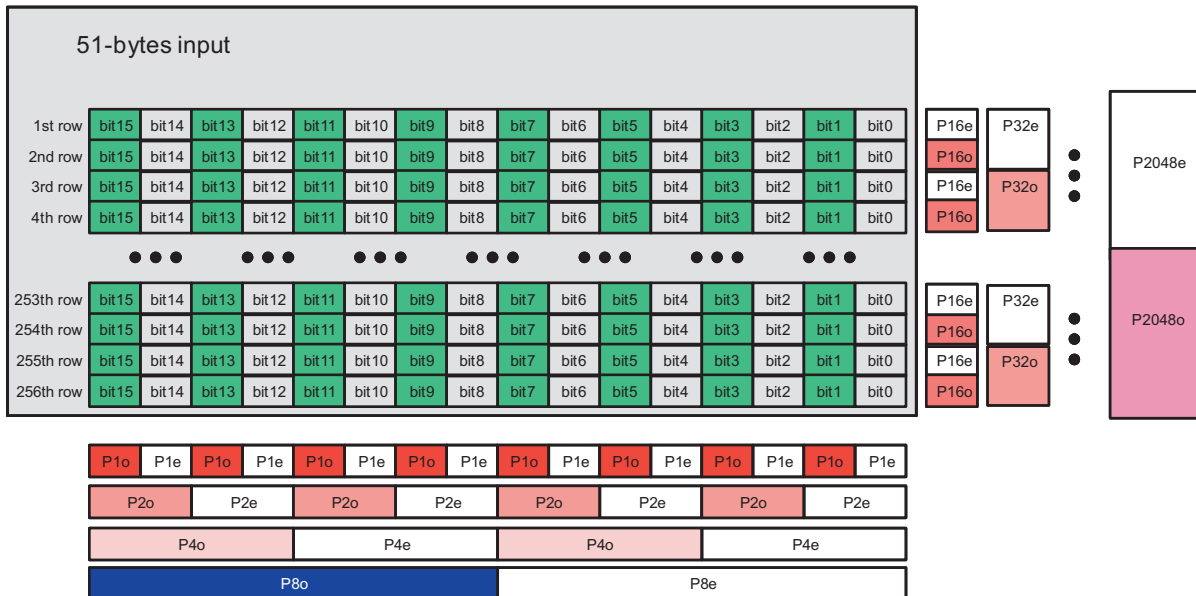

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. [Figure 11-47](#) and [Figure 11-48](#) show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 11-47. 128 Word16 ECC Computation

gpmc-030

Figure 11-48. 256 Word16 ECC Computation

gpmc-031

11.3.4.12.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

11.3.4.12.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
 - Typical page write sequence:
 - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy

- accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.
- Typical page read sequence:
 - Sequential read of a page. ECC is calculated on the fly.
 - The status of the ECC module buffers determines the presence of errors.
2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
 3. Each page can hold up to 4KiB of data, spare bytes not included. This means up to 8×512 -byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time. The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
 5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

11.3.4.12.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M_0 to M_{4095} . For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$, as described in [Table 11-371](#).

Table 11-371. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

Bit Number	Message $M(x)$			ECC $R(x)$		
	M_{4095}	...	M_0	R_{103}	...	R_0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) \times 8) - 1 = 4119$, for a total of $3 + 13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where $i = 0$ to 7):

- [GPMC_BCH_RESULT0_i](#)
- [GPMC_BCH_RESULT1_i](#)
- [GPMC_BCH_RESULT2_i](#)
- [GPMC_BCH_RESULT3_i](#)

11.3.4.12.3.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + \dots + b0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 11-372 and Table 11-373 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2¹²-1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 11-372. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 11-373. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 11-374 through Table 11-379 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 11-374. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...
$S/2 - 2$	Nibble 3	Nibble 2
$S/2 - 1$	Nibble 1	Nibble 0 (LSB)

Table 11-375. Misaligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...
$(S + 1) / 2 - 2$	Nibble 2	Nibble 1
$(S + 1) / 2 - 1$	Nibble 0 (LSB)	

Table 11-376. Aligned Nibble Mapping of Message in 16-Bit NAND

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

11.3.4.12.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

11.3.4.12.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see [Section 11.3.4.12.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for $t = 4$ ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

11.3.4.12.3.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in `GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1`. In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 x 16-bit accesses. Software must set:

- `GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5`
- `GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3`

NOTE: In the following figures, size and size0 are the same parameter.

Figure 11-49. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

11.3.4.12.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

11.3.4.12.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

11.3.4.12.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $S - (size0 + size1)$

11.3.4.12.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $size0 + (S - size1)$

11.3.4.12.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $size0 + (S - size1)$

11.3.4.12.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $size0 + (S - (1 + size1))$

11.3.4.12.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)

- size0 nibbles spare, processing OFF
 - Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON
- Checksum: Spare area size (nibbles) = size0 + (S – size1)

11.3.4.12.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

11.3.4.12.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

11.3.4.12.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

11.3.4.12.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $S - (\text{size0} + \text{size1})$

11.3.4.12.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 11.3.4.12.3.2.2.1, Memory Mapping of Data Message](#).

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 11-50](#) through [Figure 11-52](#), the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KiB + spares; that is, $S = 2$ sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - All sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - Sector 0 codeword: $(512) + P + E$
 - Other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - All codewords $(512) + E$

11.3.4.12.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

Figure 11-50. NAND Page Mapping and ECC: Per-Sector Schemes

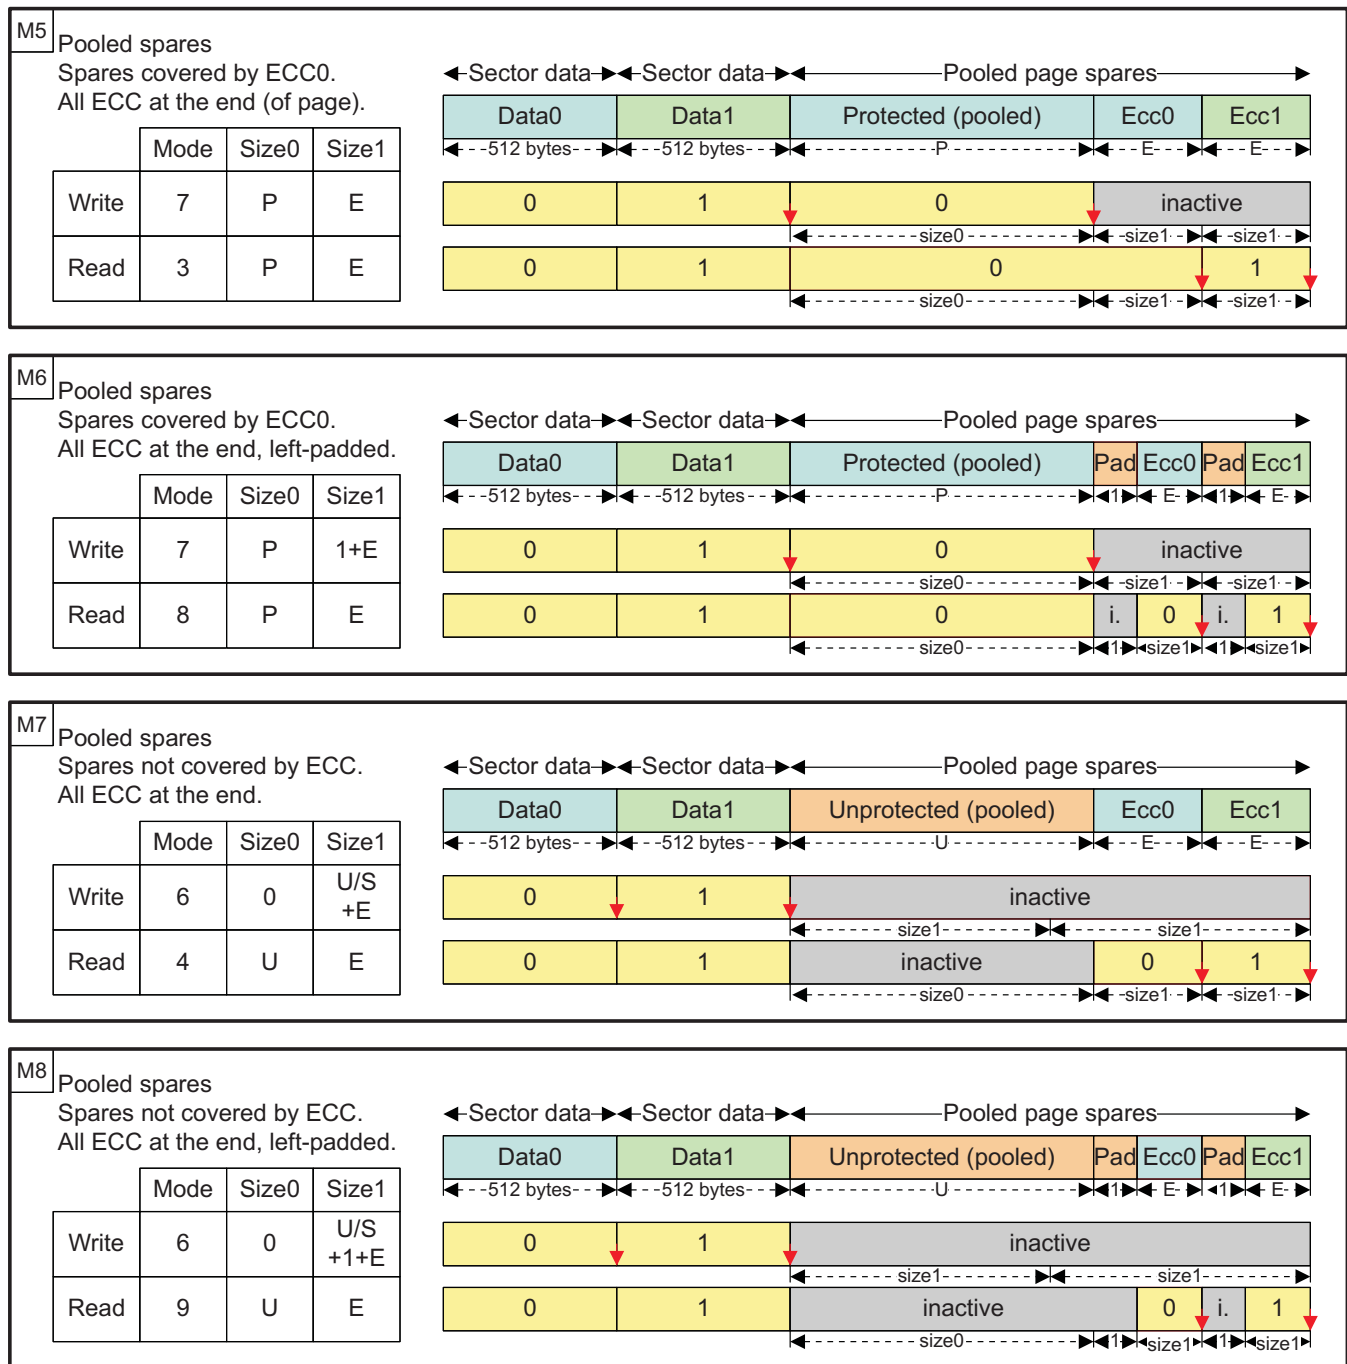

gpmc-033

11.3.4.12.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

Figure 11-51. NAND Page Mapping and ECC: Pooled Spare Schemes

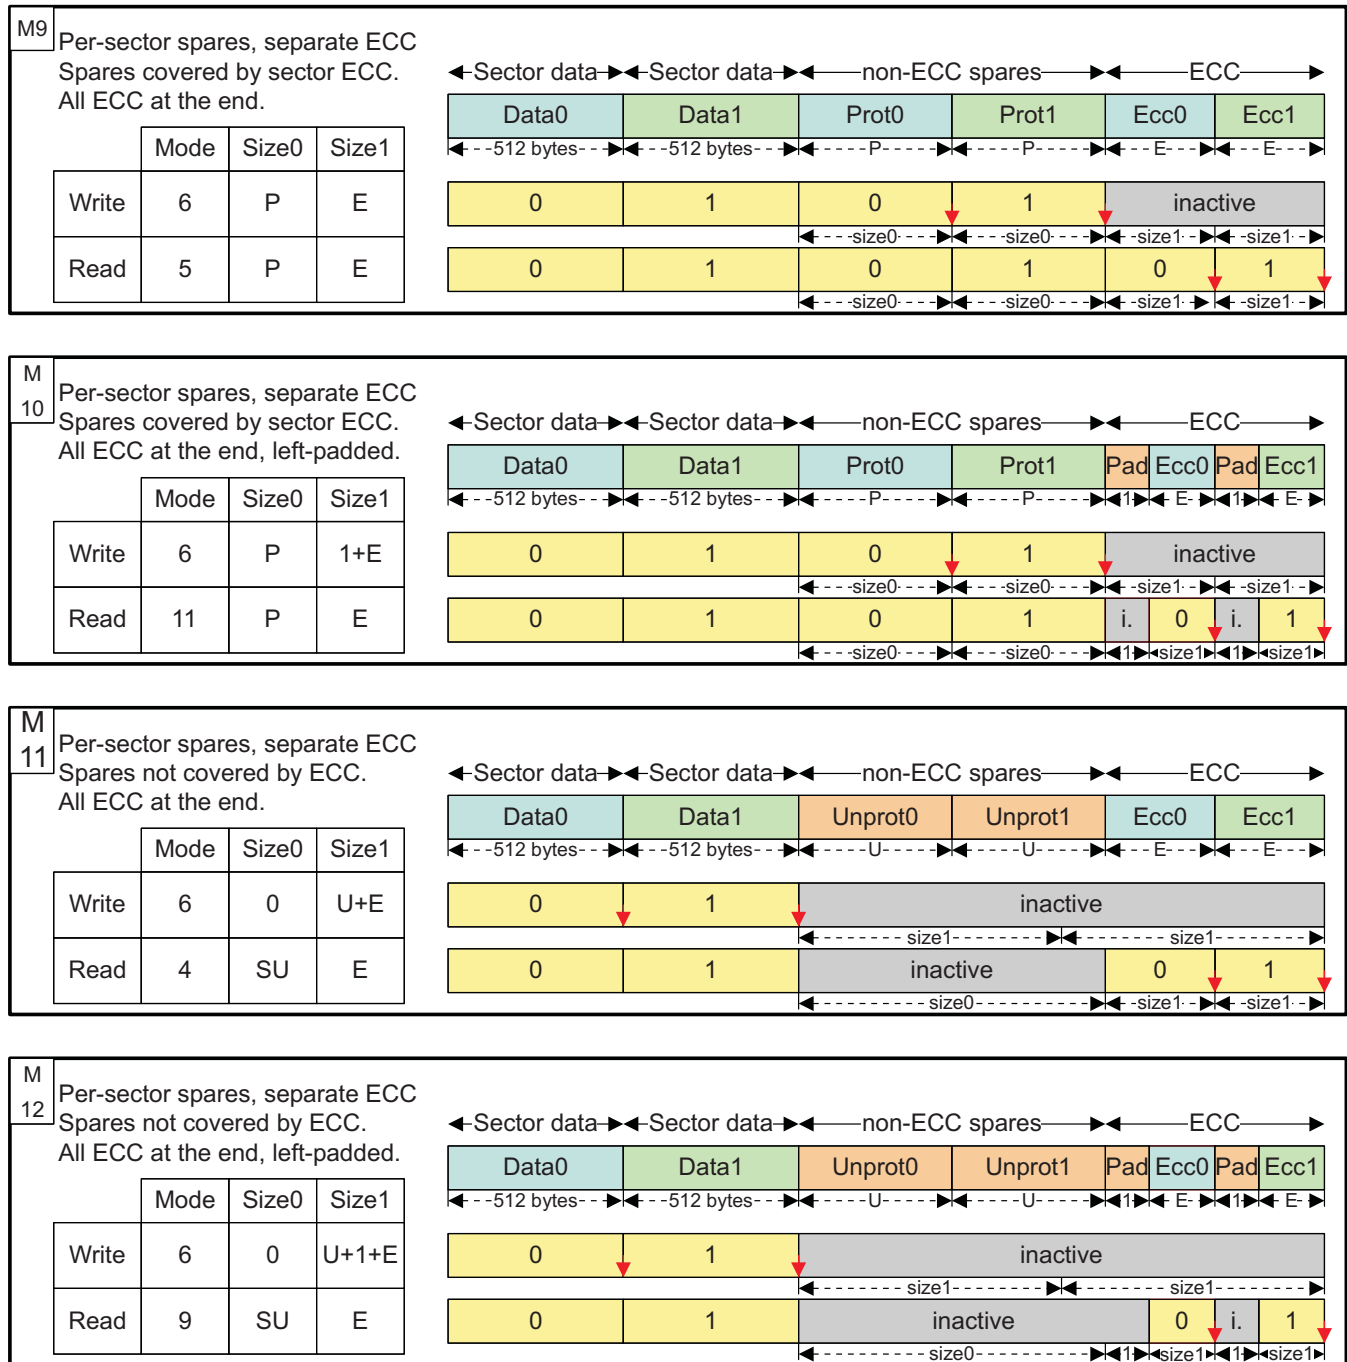

gpmc-034

11.3.4.12.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

Figure 11-52. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC

gpmc_035

11.3.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the IPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine relies on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the [GPMC_PREFETCH_CONFIG1\[23\] PFPWENROUNDROBIN](#) bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\] PFPWWEIGHTEDPRIO](#) bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

11.3.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the [GPMC_PREFETCH_CONTROL\[0\] STARTENGINE](#) bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the [GPMC_PREFETCH_CONFIG1\[26:24\] ENGINECSSELECTOR](#) bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The [FIFOTHRESHOLD](#) and [TRANSFERCOUNT](#) bit fields must be programmed accordingly as a number of bytes.

When the [GPMC_PREFETCH_CONFIG1\[7\] ENABLEENGINE](#) bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the [ENABLEENGINE](#) bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where $i = 0$ to 7):

- [GPMC_NAND_COMMAND_i](#)
- [GPMC_NAND_ADDRESS_i](#)
- [GPMC_NAND_DATA_i](#)

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the [FIFOTHRESHOLD](#) bit field. The [GPMC_PREFETCH_STATUS\[30:24\] FIFOPointer](#) bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The [GPMC_PREFETCH_STATUS\[13:0\] COUNTVALUE](#) bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the [TRANSFERCOUNT](#) bit field. The [FIFOPointer](#) and [COUNTVALUE](#) bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the [FIFOPointer](#) equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the [FIFOPointer](#) equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

11.3.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\] ACCESSMODE](#) bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the [GPMC_PREFETCH_CONTROL\[0\] STARTENGINE](#) bit. The [STARTENGINE](#) bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the [GPMC_PREFETCH_CONFIG1\[3\] SYNCHROMODE](#) bit is cleared, the prefetch engine starts requesting data as soon as the [STARTENGINE](#) bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the [STARTENGINE](#) bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the [SYNCHROMODE](#) bit is set, the prefetch engine starts requesting data when an active-to-inactive [WAIT](#) signal transition is detected. The transition detector must be cleared before any transition detection (see [Section 11.3.4.12.2.2, Ready Pin Monitored by Hardware Interrupt](#)). The [GPMC_PREFETCH_CONFIG1\[5:4\] WAITPINSELECTOR](#) bit field selects which [gpmc_wait](#) pin edge detector triggers the prefetch engine in this synchronized mode.

If the [STARTENGINE](#) bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the [STARTENGINE](#) bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive [WAIT](#) signal transition is detected. The [STARTENGINE](#) bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the [GPMC_PREFETCH_CONFIG2\[13:0\] TRANSFERCOUNT](#) bit field.

[Table 11-380](#) describes the prefetch mode configuration.

Table 11-380. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1 [26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1 [0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1 [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1 [17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1 [3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 11.3.4.12.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

11.3.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the [GPMC_PREFETCH_STATUS](#)[30:24] FIFOPointer bit field or through the [GPMC_PREFETCH_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPointer indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC_PREFETCH_CONFIG1\[2\]](#) DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

11.3.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\]](#) ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the [GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the [GPMC_PREFETCH_CONFIG1\[3\]](#) SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed [GPMC_PREFETCH_CONFIG2\[13:0\]](#) TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

[Table 11-381](#) describes the write-posting configuration.

Table 11-381. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

Table 11-381. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1 [26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1 [0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1 [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 11.3.4.12.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine.
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

11.3.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the [FIFOPOINTER](#) or through the [GPMC_PREFETCH_STATUS](#)[16] [FIFOTHRESHOLDSTATUS](#) bit. [FIFOPOINTER](#) indicates the current number of available free byte places in the FIFO, and the [FIFOTHRESHOLDSTATUS](#) bit, when set, indicates that at least [FIFOTHRESHOLD](#) free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the [GPMC_IRQENABLE](#)[0] [FIFOEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[0] [FIFOEVENTSTATUS](#) bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the [FIFOEVENTSTATUS](#) bit must be cleared to get further interrupt events. The [FIFOEVENTSTATUS](#) bit must always be cleared before asserting the [FIFOEVENTENABLE](#) bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the [STARTENGINE](#) bit.

The posting completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] [COUNTVALUE](#) bit field. [COUNTVALUE](#) indicates the current number of remaining data to be written based on the value of the [TRANSFERCOUNT](#) bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, [COUNTVALUE](#) equal to 0) if the [GPMC_IRQENABLE](#)[1] [TERMINALCOUNTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[1] [TERMINALCOUNTSTATUS](#) bit is set. To clear the interrupt, the [TERMINALCOUNTSTATUS](#) bit must be cleared. The [TERMINALCOUNTSTATUS](#) bit must always be cleared before asserting the [TERMINALCOUNTENABLE](#) bit to clear any out-of-date logged interrupt event.

NOTE: The value of the [COUNTVALUE](#) bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when [COUNTVALUE](#) reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the [DMAMode](#) bit field in the [GPMC_PREFETCH_CONFIG1](#)[2] [DMAMODE](#) bit must be set so that the GPMC issues a DMA hardware request when at least [FIFOTHRESHOLD](#) bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the [FIFOTHRESHOLD](#) bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or IPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

11.3.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMEECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the [GPMC_NAND_DATA_i](#) location, where i = 0 to 7) are never optimized.

The [GPMC_PREFETCH_CONFIG1](#)[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

[Figure 11-53](#) shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMEECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION bit field.

Figure 11-53. NAND Read Cycle Optimization Timing Description

11.3.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the [GPMC_PREFETCH_CONFIG1\[23\] PFPWENROUNDROBIN](#) bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\] PFPWWEIGHTEDPRIO](#) bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

11.3.5 GPMC Basic Programming Model

11.3.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

[Figure 11-54](#) and [Table 11-382](#) through [Table 11-384](#) show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

Figure 11-54. Programming Model Top-Level Diagram

gpmc-uc-001

Table 11-382. GPMC Initialization

Step	Description
Enable GPMC clocks.	Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management .
Enable GPMC pads.	Module-specific pad multiplexing and configuration must be set in the control module. See Section 14.4.6.1, Pad Configuration Registers in Chapter 14, Control Module .
Reset GPMC.	See Table 11-385 .

Table 11-383. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 11-386 .
NOR Chip-Select Configuration	See Table 11-387 .
NOR Timings Configuration	See Table 11-388 .
Wait Pin Configuration	See Table 11-396 .
Enable Chip-Select	See Table 11-397 .

Table 11-384. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 11-391 .
NAND Chip-Select Configuration	See Table 11-392 .
Write Operations (Asynchronous)	See Table 11-393 .
Read Operations (Asynchronous)	See Table 11-393 .
ECC Engine	See Table 11-394 .
Prefetch and Write-Posting Engine	See Table 11-395 .
Wait Pin Configuration	See Table 11-396 .
Enable Chip-Select	See Table 11-397 .

11.3.5.2 GPMC Initialization

[Table 11-413](#) describes the settings required to prepare the GPMC; that is enabling its clock and pads, and proceeding to a GPMC reset.

Table 11-385. Reset GPMC

Subprocess Name	Register/Bit Field	Value
Start a software reset.	GPMC_SYSCONFIG [1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS [0] RESETDONE =	0x1

11.3.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 11-386. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1 _ <i>i</i> [11:10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1 _ <i>i</i> [13:12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1 _ <i>i</i> [9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1 _ <i>i</i> [24:23] ATTACHEDDEVICEPAGELENGTH	x

Table 11-386. NOR Memory Type (continued)

Subprocess Name	Register / Bit Field	Value
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency ⁽¹⁾ .	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time ⁽¹⁾ .	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations ⁽¹⁾ .	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

⁽¹⁾ Applies only to synchronous configurations (or nonmultiplexed asynchronous for multiple access one)

Table 11-387. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 11-388. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 11.3.5.6, GPMC Timing Parameters	

Table 11-389. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable wait pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time.	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select.	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 11-390. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

11.3.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 11-391. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x

Table 11-391. NAND Memory Type (continued)

Subprocess Name	Register/Bit Field	Value
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 11.3.5.5, Set Memory Access.	x

Table 11-392. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16MiB).	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 11-393. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 11.3.5.6, GPMC Timing Parameters.	

Table 11-394. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x ⁽¹⁾
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x ⁽²⁾
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

⁽¹⁾ This parameter depends on the numbers of sectors in a page.

⁽²⁾ Depends on the size of each sector in the NAND page

Table 11-395. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request.	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 11-395. Prefetch and Write-Posting Engine (continued)

Subprocess Name	Register/Bit Field	Value
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30:28] CYCLOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 11-396. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 11-397. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_[i][6] CSVALID	x

11.3.5.5 Set Memory Access

This section describes the bit field to configure to set the GPMC in various memory modes. [Table 11-398](#) and [Table 11-399](#) provide check lists for mode parameters and access type parameters, respectively.

Table 11-398. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	–	0x1 ⁽¹⁾	N/S	0x0	–	0x1	–
GPMC_CONFIG1_i	29	READTYPE	0x0	–	0x0 ⁽¹⁾	N/S	0x1	–	0x1	–
GPMC_CONFIG1_i	28	WRITEMULTIPLE	–	0x0	- ⁽¹⁾	N/S	–	0x0	–	0x1
GPMC_CONFIG1_i	27	WRITETYPE	–	0x0	- ⁽¹⁾	N/S	–	0x1	–	0x1

⁽¹⁾ Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in nonmultiplexed mode.

Table 11-399. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			Nonmultiplexed	Address/Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1

11.3.5.6 GPMC Timing Parameters

Figure 11-55 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 11-55. NOR Interfacing Timing Parameters Diagram

gpmc-uc-002

Table 11-400 lists the bit fields to configure adequate timing parameters in various memory modes.

Table 11-400. Timing Parameters

Register	Bit	Name	Asynchronous			Synchronous				Access Type		
			Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiple xed	Address / Data-Multiple xed	AAD Multiple xed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	27	WRITETYPE		y			y		y	y	y	y
GPMC_CONFIG1_i	28	WRITEMULTIPLE		y			y		y	y	y	y
GPMC_CONFIG1_i	31	WRAPBURST						y	y	y	y	y
GPMC_CONFIG1_i	26:25	CLKACTIVATIONTIME				y	y	y	y	y	y	y
GPMC_CONFIG1_i	19:18	WAITMONITORINGTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	4	TIMEPARAGRANULARITY	y	y	y	y	y	y	y	y	y	y

11.3.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device data manual.

11.3.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when [GPMC_CONFIG1_j\[11:10\] DEVICETYPE = 0x2](#). [Table 11-401](#) describes the NAND timing parameters.

Table 11-401. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_wen valid time
B	ns	Delay time – gpmc_cs valid to gpmc_wen valid
C	ns	Delay time – gpmc_ben0/gpmc_advn_ale high to gpmc_wen valid
D	ns	Delay time – gpmc_ad[15:0] valid to gpmc_wen valid
E	ns	Delay time – gpmc_wen invalid to gpmc_ad[15:0] invalid
F	ns	Delay time – gpmc_wen invalid to gpmc_ben0/gpmc_advn_ale invalid
G	ns	Delay time – gpmc_wen invalid to gpmc_cs invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
J	ns	Setup time – gpmc_ad[15:0] valid to gpmc_oen_ren invalid
K	ns	Pulse duration – gpmc_oen_ren valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – gpmc_oen_ren invalid to gpmc_cs invalid

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

$$A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK \text{ period}$$

$$B = ((WEOnTime - CSONTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - ADVExtraDelay)) * GPMC_FCLK \text{ period}$$

$$D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - WEEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$I = ((OEOnTime - CSONTime) * (TimeParaGranularity + 1) + 0.5 * (OEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$J = ((RdAccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - OEEExtraDelay) * GPMC_FCLK \text{ period}$$

Figure 11-56 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

11.3.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to synchronous mode. Table 11-402 describes the synchronous NOR formulas.

Table 11-402. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – address bus valid to gpmc_clk first edge Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_clk first edge
C	ns	Pulse duration – gpmc_ben0/gpmc_ben1 low
D	ns	Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 invalid Delay time – gpmc_clk rising edge to gpmc_advn_ale invalid
E	ns	Delay time – gpmc_clk rising edge to gpmc_cs invalid Delay time – gpmc_clk rising edge to gpmc_oen_ren invalid
F	ns	Delay time – gpmc_clk rising edge to gpmc_cs transition
G	ns	Delay time – gpmc_clk rising edge to gpmc_advn_ale transition
H	ns	Delay time – gpmc_clk rising edge to gpmc_oen_ren transition
I	ns	Delay time – gpmc_clk rising edge to gpmc_wen transition
J	ns	Delay time – gpmc_clk rising edge to gpmc_ad data bus transition Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 transition
K	ns	Pulse duration – gpmc_advn_ale low
L	ns	Delay time – gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

- For single read accesses:

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$C = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$D = (\text{RDCYCLETIME} - \text{RDACCESSTIME}) * \text{GPMC_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - \text{RDACCESSTIME}) * \text{GPMC_FCLK period}$$

- For burst read accesses (where n is the page burst access number):

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$C = (\text{RDCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$D = (\text{RDCYCLETIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

- For burst write accesses (where n is the page burst access number):

$$A = (\text{CSWROFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$C = (\text{WRCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$D = (\text{WRCYCLETIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

$$E = (\text{CSWROFFTIME} - (\text{RDACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

- For all accesses:

For nCS falling edge (chip-select activated):

- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:

$$F = 0.5 * \text{CSEXTRADelay} * \text{GPMC_FCLK period}$$

- Case where GPMCFCLKDIVIDER = 0x1:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)

$$F = (1 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period otherwise.}$$

- Case where GPMCFCLKDIVIDER = 0x2:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3

$$F = (1 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3}$$

$$F = (2 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3}$$

- Case where GPMCFCLKDIVIDER = 0x3:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 4

$$F = (1 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 4}$$

$$F = (2 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 4}$$

$$F = (3 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 3) is a multiple of 4}$$

For nCS rising edge (chip-select deactivated) in reading mode:

- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:

$$F = 0.5 * \text{CSEXTRADelay} * \text{GPMC_FCLK period}$$

- Case where GPMCFCLKDIVIDER = 0x1:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)

$$F = (1 + 0.5 * \text{CSEXTRADelay}) * \text{GPMC_FCLK period otherwise.}$$

- Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
 - Case where GPMCFCLKDIVIDER = 0x3:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 4$
 $F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 4$
 $F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 4$
 $F = (3 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 3) \text{ is a multiple of } 4$
- For nCS rising edge (chip-select deactivated) in writing mode:
- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period}$
 - Case where GPMCFCLKDIVIDER = 0x1:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } CSWROFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } CSWROFFTIME \text{ are even})$
 $F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period otherwise.}$
 - Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
 - Case where GPMCFCLKDIVIDER = 0x3:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 4$
 $F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 4$
 $F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 4$
 $F = (3 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 3) \text{ is a multiple of } 4$
- For nADV falling edge (nADV activated):
- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period}$
 - Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period otherwise.}$
 - Case where GPMCFCLKDIVIDER = 0x2:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $G = (2 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
 - Case where GPMCFCLKDIVIDER = 0x3:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 4$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVONTIME -$

$\text{CLKACTIVATIONTIME} - 1$ is a multiple of 4
 $G = (2 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVONTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 4
 $G = (3 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVONTIME} - \text{CLKACTIVATIONTIME} - 3)$ is a multiple of 4

For nADV rising edge (nADV deactivated) in reading mode:

- Case where $\text{GPMC_CONFIG1_j}[1:0] \text{GPMCFCLKDIVIDER} = 0x0$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$
- Case where $\text{GPMCFCLKDIVIDER} = 0x1$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and ADVRDOFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and ADVRDOFFTIME are even)
 $G = (1 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$ otherwise.
- Case where $\text{GPMCFCLKDIVIDER} = 0x2$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $G = (1 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $G = (2 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3
- Case where $\text{GPMCFCLKDIVIDER} = 0x3$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 4
 $G = (1 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 4
 $G = (2 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 4
 $G = (3 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 3)$ is a multiple of 4

For nADV rising edge (nADV deactivated) in writing mode:

- Case where $\text{GPMC_CONFIG1_j}[1:0] \text{GPMCFCLKDIVIDER} = 0x0$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$
- Case where $\text{GPMCFCLKDIVIDER} = 0x1$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and ADVWROFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and ADVWROFFTIME are even)
 $G = (1 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$ otherwise.
- Case where $\text{GPMCFCLKDIVIDER} = 0x2$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $G = (1 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $G = (2 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3
- Case where $\text{GPMCFCLKDIVIDER} = 0x3$:
 $G = 0.5 * \text{ADVEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 4
 $G = (1 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 4
 $G = (2 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 4
 $G = (3 + 0.5 * \text{ADVEXTRADELAY}) * \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 3)$ is a multiple of 4

For nOE falling edge (nOE activated):

- Case where $\text{GPMC_CONFIG1_j}[1:0] \text{GPMCFCLKDIVIDER} = 0x0$:
 $H = 0.5 * \text{OEEXTRADELAY} * \text{GPMC_FCLK period}$
- Case where $\text{GPMCFCLKDIVIDER} = 0x1$:
 $H = 0.5 * \text{OEEXTRADELAY} * \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and OEONTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and OEONTIME are even)

$H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period otherwise.

- Case where $GPMCFCLKDIVIDER = 0x2$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3
 - Case where $GPMCFCLKDIVIDER = 0x3$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME)$ is a multiple of 4
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 4
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 4
 $H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEONTIME - CLKACTIVATIONTIME - 3)$ is a multiple of 4
- For nOE rising edge (nOE deactivated):
- Case where $GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK$ period
 - Case where $GPMCFCLKDIVIDER = 0x1$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK$ period, when $(CLKACTIVATIONTIME$ and $OEOFFTIME$ are odd) or $(CLKACTIVATIONTIME$ and $OEOFFTIME$ are even)
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period otherwise.
 - Case where $GPMCFCLKDIVIDER = 0x2$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3
 - Case where $GPMCFCLKDIVIDER = 0x3$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME)$ is a multiple of 4
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 4
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 4
 $H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK$ period, when $(OEOFFTIME - CLKACTIVATIONTIME - 3)$ is a multiple of 4
- For nWE falling edge (nWE activated):
- Case where $GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period
 - Case where $GPMCFCLKDIVIDER = 0x1$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(CLKACTIVATIONTIME$ and $WEONTIME$ are odd) or $(CLKACTIVATIONTIME$ and $WEONTIME$ are even)
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period otherwise.
 - Case where $GPMCFCLKDIVIDER = 0x2$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3
 - Case where $GPMCFCLKDIVIDER = 0x3$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME)$ is a multiple of 4

$I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 4

$I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 4

$I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEONTIME - CLKACTIVATIONTIME - 3)$ is a multiple of 4

For nWE rising edge (nWE deactivated):

- Case where $GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period
- Case where $GPMCFCLKDIVIDER = 0x1$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(CLKACTIVATIONTIME$ and $WEOFFTIME$ are odd) or $(CLKACTIVATIONTIME$ and $WEOFFTIME$ are even)
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period otherwise.
- Case where $GPMCFCLKDIVIDER = 0x2$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3
- Case where $GPMCFCLKDIVIDER = 0x3$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME)$ is a multiple of 4
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 4
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 4
 $I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 3)$ is a multiple of 4

For gpmc_nadv low pulse duration:

- Read operation:
 $K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK$ period
- Write operation:
 $K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK$ period

For gpmc_wait invalid to first data latching gpmc_clk edge:

- $L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK$ period + $GPMC_CLK$ period

Figure 11-57 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

gpmc-046

11.3.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 11-403 describes the asynchronous NOR formulas.

Table 11-403. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – gpmc_cs valid to gpmc_advn_ale invalid
C	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – gpmc_cs valid to gpmc_wen valid
F	ns	Delay time – gpmc_cs valid to gpmc_wen invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before gpmc_oen_ren high
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (burst read)
J	ns	Delay time – address bus valid to gpmc_cs valid Delay time – data bus valid to gpmc_cs valid Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_cs valid
K	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid
L	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
M	ns	Delay time – gpmc_cs valid to first data latching edge
N	ns	Pulse duration – gpmc_ben0/gpmc_ben1 valid time

Table 11-403. Asynchronous NOR Formulas Description (continued)

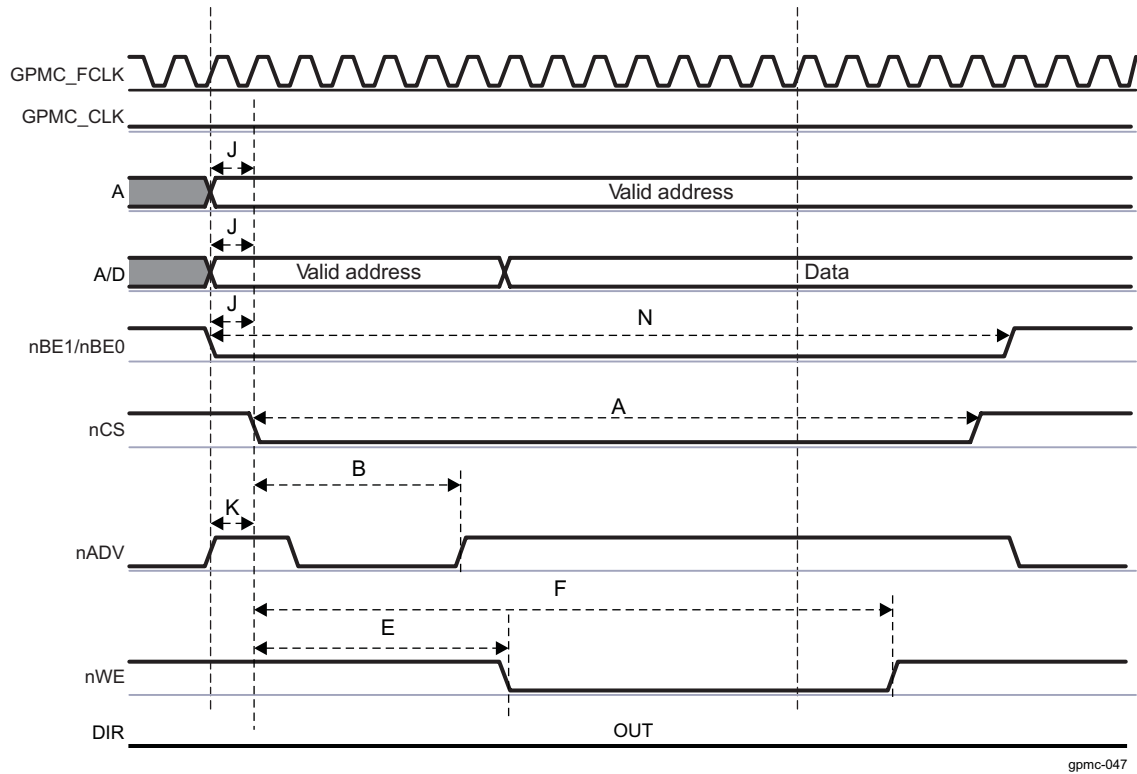

Configuration Parameter	Unit	Description
O	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device data manual.

- gpmc_cs low pulse:
For single read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For single write: $A = (\text{CSWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst write: $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- gpmc_cs valid to gpmc_advn_ale invalid delay:
For reading: $B = ((\text{ADVRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
For writing: $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $C = ((\text{OEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $D = \text{PAGEBURSTACCESSTIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
- $E = ((\text{WEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $F = ((\text{WEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $G = \text{CYCLE2CYCLEDELAY} * \text{GPMC_FCLK period}$
- $H = ((\text{OEOFFTIME} - \text{RDACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{OEEXTRADELAY}) * \text{GPMC_FCLK period}$
- $I = ((\text{OEOFFTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$, where N = page burst access number
- $J = (\text{CSONTIME} * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- $K = ((\text{ADVONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $L = ((\text{OEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $M = ((\text{RDACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) - 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- gpmc_ben0/gpmc_ben1 pulse:
For single read: $N = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $N = (\text{RDCYCLETIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For burst write: $N = (\text{WRCYCLETIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- $O = ((\text{WRCYCLETIME} + (N - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$

Figure 11-58 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

Figure 11-58. Asynchronous NOR Single Write Simplified Example

NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

11.3.6 GPMC Use Cases and Tips

11.3.6.1 How to Set GPMC Timing Parameters for Typical Accesses

11.3.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

11.3.6.1.2 Typical GPMC Setup

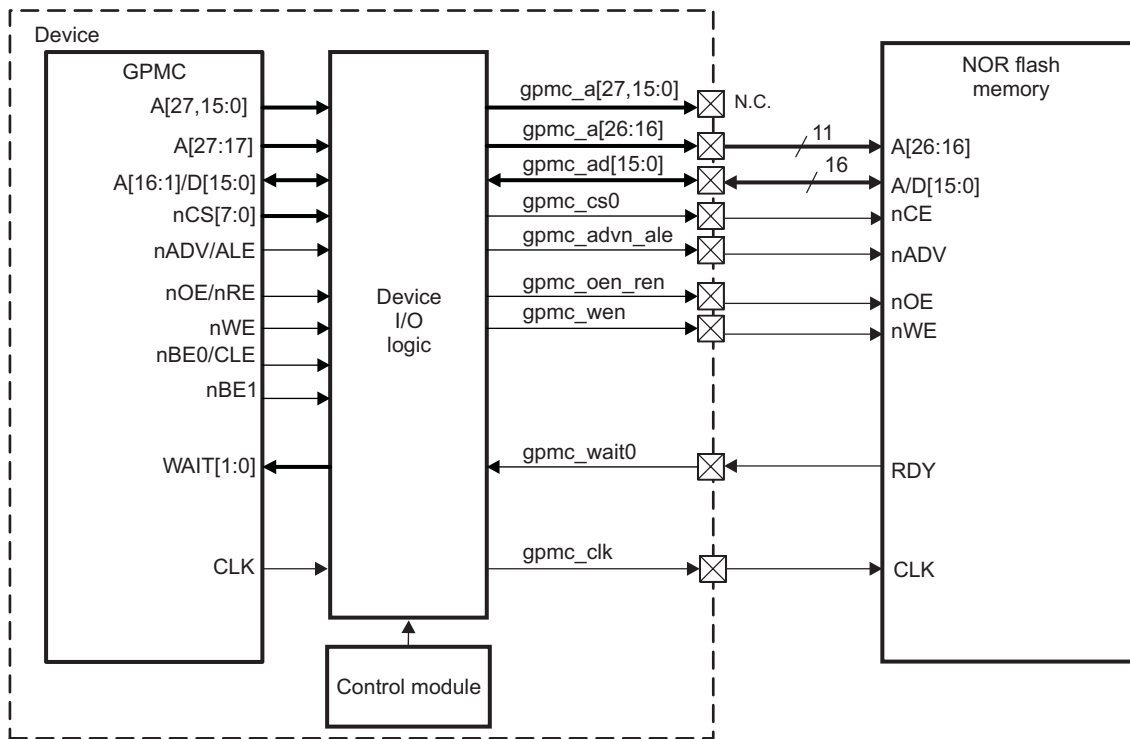

Table 11-404 lists some of the I/Os of the GPMC module.

Table 11-404. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[26:16]	O	Address
gpmc_ad[15:0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_csx	O	Chip-select (where x = 0, or 1)
gpmc_advn_ale	O	Address valid enable
gpmc_oen_ren	O	Output enable (read access only)
gpmc_wen	O	Write enable (write access only)
gpmc_wait[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 11-59 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 11-59. GPMC Connection to an External NOR Flash Memory

gpmc-037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

11.3.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

NOTE: The examples in Section 11.3.6.1.2.1 through Section 11.3.6.1.2.3 are based on a clock rate of 104 MHz. Refer to the device Data Manual for the maximum frequency appropriate for this device and to the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

Table 11-405 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-406 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-60 shows the synchronous burst read access.

Table 11-405. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

Table 11-405. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ($T = 9,615$ ns). The read access time between two bursts of data is $tBACC = 5.2$ ns. Therefore, data setup time is a clock period – $tBACC = 4,415$ ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 11-406. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	$\min(tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94.03: (9,615 + 80 + 4,415)	10: $\text{roundmax}(94.03 / 9,615)$	RDACCESSTIME = 0x0A
PageBurst RdAccessTime	$\text{roundmax}(tBACC)$	$\text{roundmax}(5.2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{RdAccess time} + \max(tCEZ, tOEZ)$	101.03: (94.03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC ⁽¹⁾	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC ⁽²⁾	12	2	ADVRDOFFTIME = 0x02
OeOnTime ⁽³⁾	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime}(\text{ClkActivationTime} + tIACC)$	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0x0B

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$; thus, $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$.

⁽³⁾ OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

Figure 11-60. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

gpmc-038

11.3.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 11-407 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-408 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-61 shows the asynchronous read access.

Table 11-407. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 \text{ clock cycle} + tOEZ:$$

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 11-407: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.
The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).

4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 11-408. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0x0A
PageBurstAccess Time	N/A (single access)			
RdCycleTime	RdAccessTime + 1 cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1 cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 11-61. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

gpmc-039

11.3.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 11-410 shows how to calculate timings for the GPMC using the memory parameters.

Table 11-409 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 11-62 shows the synchronous burst write access.

Table 11-409. AC Characteristics for Asynchronous Single Write (Memory Side)

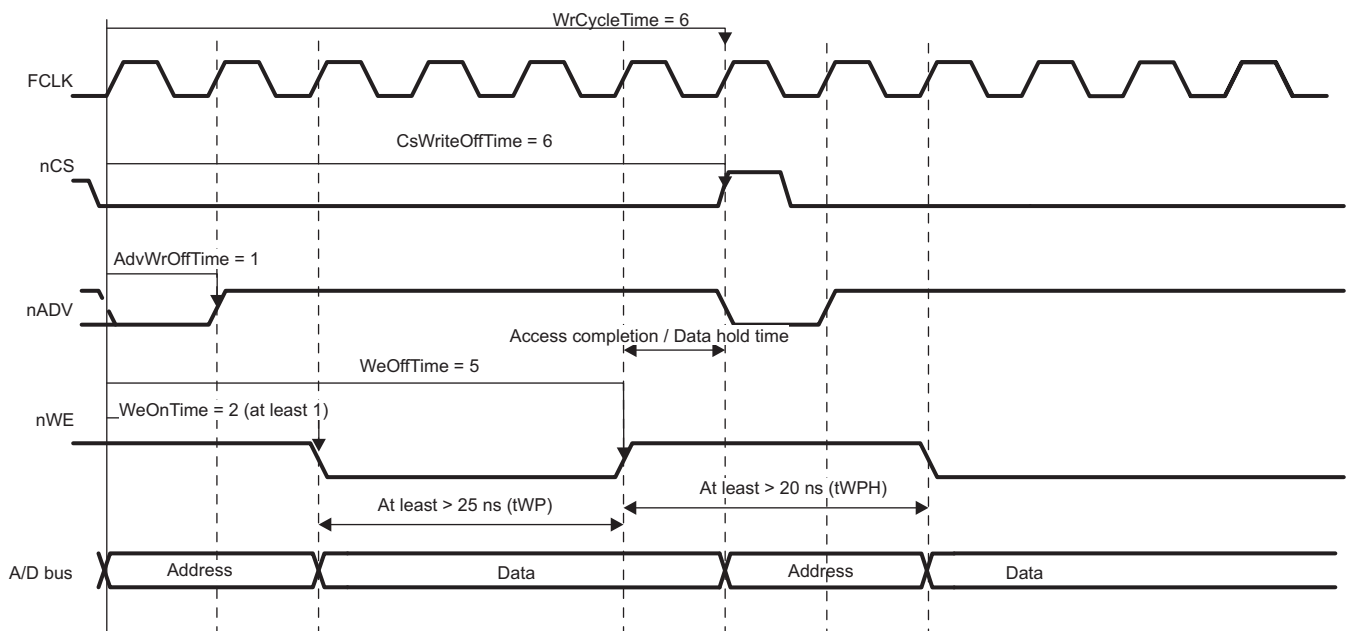

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device data manual.

Table 11-410. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		N/A (asynchronous mode)		
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		N/A (single access)		
WrCycleTime	$WeOffTime + AccessCompletion$	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	$WeOffTime + 1$	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	$tAVSC + tAVDP$	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	$tCS + tWP + tWPH$	48	5	WEOFFTIME = 0x05

11.3.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

11.3.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, etc.)
- 8- and 16-bit NAND flash devices

11.3.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 11-411. Supported Memories Interfaces

11.3.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 11-412 summarizes the NAND interface signals level applied to external device or memories.

Table 11-412. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾
Read (cmd input)	H	L	L	RE	H
Read (add input)	L	H	L	RE	H

⁽¹⁾ RE stands for rising edge; FE stands for falling edge

Table 11-412. NAND Interface Bus Operations Summary (continued)

Bus Operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾
Write (cmd input)	H	L	L	RE	H
Write (add input)	L	H	L	RE	H
Data input	L	L	L	RE	H
Data output	L	L	L	H	FE
Busy (during read)	x	x	H ⁽²⁾	H ⁽²⁾	H ⁽²⁾
Busy (during program)	x	x	x	x	x
Busy (during erase)	x	x	x	x	x
Standby	x	x	H	x	x

⁽²⁾ Can be nCE high, or WE and nRE high.

11.3.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 11-413 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 11-413. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

11.3.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

11.3.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read burst access with wrap capability (4, 8, 16 Word16)

11.3.6.2.2 GPMC Features and Settings

The features and settings of the GPMC are:

- Supported device type: Up to four NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V, 3.3 V
- Maximum operating frequency provided externally: See the device data manual for precise information.
- Maximum GPMC addressing capability: 512MiB divided into eight chip-selects
- Maximum supported memory size: 256MiB (must be a power-of-two)
- Minimum supported memory size: 16MiB (must be a power-of-two). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8, 16 bits wide
- Burst and page access: burst of 4, 8, 16 Word16
- Supports bus keeping
- Supports bus turnaround

11.3.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. [Table 11-415](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

11.3.7.1 GPMC Register Summary

Table 11-414. GPMC Instance Summary

Module Name	Base Address	Size

11.3.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC_NAND_DATA_i](#) register, are little-endian. If the [GPMC_NAND_DATA_i](#) register location is accessed, the endianness is access-dependent.

In this section *i* corresponds to the chip-select number, where *i* = 0 to 7.

Table 11-416. GPMC_REVISION

Address Offset	0x0000 0000	Instance	GPMC
Physical Address	0x5000 0000		
Description	This register contains the IP revision code.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	T1 internal data

Table 11-418. GPMC_SYSCONFIG

Address Offset	0x0000 0010	Instance	GPMC
Physical Address	0x5000 0010		
Description	This register controls the various parameters of the interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Do not use.	RW	0x0
2	RESERVED	Write 0 for future compatibility Read returns 0.	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied, based on the interconnect activity.	RW	0x0

Table 11-422. GPMC_IRQSTATUS

Address Offset	0x0000 0018	Instance	GPMC
Physical Address	0x5000 0018		
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WAIT1EDGEDETECTIONSTATUS		WAIT0EDGEDETECTIONSTATUS		RESERVED						TERMINALCOUNTSTATUS		FIFOEVENTSTATUS			

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONSTATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected. Write 0x0: WAIT1EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT1 input pin has been detected. Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset.	RW	0x0
8	WAIT0EDGEDETECTIONSTATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected. Write 0x0: WAIT0EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT0 input pin has been detected. Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit is unchanged. Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset.	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates that less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x0: FIFOEVENTSTATUS bit is unchanged. Read 0x1: Indicates that at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x1: FIFOEVENTSTATUS bit is reset.	RW	0x0

Description	This register is not a true register, only an address location.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPMC_NAND_COMMAND																															

Bits	Field Name	Description	Type	Reset
31:0	GPMC_NAND_COMMAND	This register is not a true register, only an address location. Writing data at the GPMC_NAND_COMMAND_i location places the data as the NAND command value on the bus, using a regular asynchronous write access.	W	0x-

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:28	CYCLEOPTIMIZATION	Define the number of GPMC_FCLK cycles to be subtracted from RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, WEOFFTIME 0x0: 0 GPMC_FCLK cycle 0x1: 1 GPMC_FCLK cycle ... 0x7: 7 GPMC_FCLK cycles	RW	0x0
27	ENABLEOPTIMIZEDACCESS	Enables access cycle optimization 0x0: Access cycle optimization is disabled. 0x1: Access cycle optimization is enabled.	RW	0x0
26:24	ENGINECSSELECTOR	Selects the chip-select where Prefetch Postwrite engine is active 0x0: CS0 0x1: CS1 0x2: CS2 0x3: CS3 0x4: CS4 0x5: CS5 0x6: CS6 0x7: CS7	RW	0x0
23	PFPWENROUNDROBIN	Enables the PFPW RoundRobin arbitration 0x0: Prefetch Postwrite engine round robin arbitration is disabled. 0x1: Prefetch Postwrite engine round robin arbitration is enabled.	RW	0x0
22:20	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
19:16	PFPWWEIGHTEDPRIO	When an arbitration occurs between a DMA and a PFPW engine access, the DMA is always serviced. If the PFPWEnRoundRobin is enabled, 0x0: The next access is granted to the PFPW engine. 0x1: The next two accesses are granted to the PFPW engine. ... 0xF: The next 16 accesses are granted to the PFPW engine.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
14:8	FIFOTHRESHOLD	Selects the maximum number of bytes read from the FIFO or written to the FIFO by the host on a DMA or interrupt request 0x00: 0 byte 0x01: 1 byte ... 0x40: 64 bytes	RW	0x40
7	ENABLEENGINE	Enables the Prefetch Postwrite engine 0x0: Prefetch Postwrite engine is disabled. 0x1: Prefetch Postwrite engine is enabled.	RW	0x0
6	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
5:4	WAITPINSELECTOR	Select which wait pin edge detector should start the engine in synchronized mode 0x0: Selects Wait0 EdgeDetection 0x1: Selects Wait1 EdgeDetection 0x2, 0x3: Reserved	RW	0x0
3	SYNCHROMODE	Selects when the engine starts the access to chip-select 0x0: Engine starts the access to chip-select as soon as STARTENGINE is set 0x1: Engine starts the access to chip-select as soon as STARTENGINE is set AND wait to nonwait edge detection on the selected wait pin	RW	0x0

Bits	Field Name	Description	Type	Reset
2	DMAMODE	Selects interrupt synchronization or DMA request synchronization 0x0: Interrupt synchronization is enabled. Only interrupt line is activated on FIFO threshold crossing. 0x1: DMA request synchronization is enabled. A DMA request protocol is used.	RW	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ACCESSMODE	Selects prefetch read or write-posting accesses 0x0: Prefetch read mode 0x1: Write-posting mode	RW	0x0

11.4 Error Location Module

11.4.1 Error Location Module Overview

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

The ELM has the following features:

- 4, 8 and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode

Figure 11-63 shows the ELM overview.

Figure 11-63. ELM Overview

elm-001

11.4.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 11-64 shows the integration of the ELM subsystem in the device.

Figure 11-64. ELM Integration

Table 11-488 through Table 11-490 summarize the integration of the module in the device.

Table 11-488. ELM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_COREAON	No	L4_PER1

Table 11-489. ELM Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_FCLK	L4PER_L4_GICLK	PRCM	Functional clock
	ELM_ICLK	L4PER_L3_GICLK	PRCM	Interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_RST	L4PER_RST	PRCM	Module hardware reset

Table 11-490. ELM Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR	Default Mapping	Description
ELM	ELM_IRQ	IRQ_CROSSBAR_1	DSP1_IRQ_32	BCH error-location module interrupt
			DSP2_IRQ_32	
			EVE_IRQ_0	

NOTE: The “Default Mapping” column in [Table 11-490 ELM Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

11.4.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

11.4.3.1 ELM Software Reset

To perform a software reset, set the [ELM_SYSCONFIG\[1\] SOFTRESET](#) bit to 1. The [ELM_SYSSTATUS\[0\] RESETDONE](#) bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [ELM_SYSCONFIG\[1\] SOFTRESET](#) bit is automatically reset.

11.4.3.2 ELM Power Management

[Table 11-491](#) describes the power-management features available to the ELM.

NOTE:

- For information about source clock gating and a description of the sleep/wake-up transitions, see the [Section 3.6.4.5, CD_L4_PER1 Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#)

Table 11-491. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG [0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG [4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG [8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see [Chapter 3, Power, Reset, and Clock Management](#).

11.4.3.3 ELM Interrupt Requests

[Table 11-492](#) lists the event flags, and their masks, that can cause module interrupts.

Table 11-492. Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS [8] PAGE_VALID	ELM_IRQENABLE [8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS [7] LOC_VALID_7	ELM_IRQENABLE [7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS [6] LOC_VALID_6	ELM_IRQENABLE [6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS [5] LOC_VALID_5	ELM_IRQENABLE [5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS [4] LOC_VALID_4	ELM_IRQENABLE [4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS [3] LOC_VALID_3	ELM_IRQENABLE [3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS [2] LOC_VALID_2	ELM_IRQENABLE [2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS [1] LOC_VALID_1	ELM_IRQENABLE [1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS [0] LOC_VALID_0	ELM_IRQENABLE [0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

11.4.3.4 Processing Initialization

[ELM_LOCATION_CONFIG](#) global setting parameters must be set before using the error-location engine. The [ELM_LOCATION_CONFIG](#)[1:0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-, 8-, or 16-bit error correction). The [ELM_LOCATION_CONFIG](#)[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all [ELM_PAGE_CTRL](#)[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all [ELM_IRQENABLE\[i\]](#) LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the [ELM_IRQENABLE\[8\]](#) PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: [ELM_SYNDROME_FRAGMENT_0_i](#) to [ELM_SYNDROME_FRAGMENT_6_i](#). The first six registers can be written in any order, but [ELM_SYNDROME_FRAGMENT_6_i](#) must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit).

As soon as one validity bit is asserted ([ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated [ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is set.

11.4.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) ECC_CORRECTABLE bit is set to 1 and the [ELM_LOCATION_STATUS_i\[4:0\]](#) ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) ECC_CORRECTABLE bit is set to 0 while the [ELM_LOCATION_STATUS_i\[4:0\]](#) ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the [ELM_ERROR_LOCATION_0_i\[12:0\]](#) ECC_ERROR_LOCATION bit field; the second is logged in the [ELM_ERROR_LOCATION_1_i\[12:0\]](#) ECC_ERROR_LOCATION bit field, and so on.

Table 11-493 describes the [ELM_LOCATION_STATUS_i](#) value decoding.

Table 11-493. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

11.4.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, [ELM_LOCATION_STATUS_i](#) (where $i = 0$ to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit (where $i = 0$ to 7) is set. The processing exit status is available from the associated [ELM_LOCATION_STATUS_i](#) register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in [ELM_PAGE_CTRL](#) are reset), an interrupt is triggered whenever a [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is asserted. Software must read the [ELM_IRQSTATUS](#) register to determine which polynomial is processed and retrieve the exit status and error locations ([ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#)). When done, software must clear the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the [ELM_IRQSTATUS\[8\]](#) PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the [ELM_IRQENABLE\[i\]](#) LOCATION_MASK_i bits are cleared. A page is defined using the [ELM_PAGE_CTRL](#) register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bits. The module triggers an [ELM_IRQSTATUS\[8\]](#) PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the [ELM_IRQSTATUS](#) register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the [ELM_PAGE_CTRL](#) register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the [ELM_PAGE_CTRL\[i\]](#) SECTOR_i bits (where $i = 0$ to 7) are processed as usual, but are essentially ignored. Software must manually poll the [ELM_IRQSTATUS](#) bits to check for their status.

11.4.4 ELM Basic Programming Model

11.4.4.1 ELM Low-Level Programming Model

11.4.4.1.1 Processing Initialization

Table 11-494. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value.
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value.
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value.
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value.
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (where $i = 0$ to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1

Table 11-494. ELM Processing Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
else (page mode is used)	One syndrome polynomial <i>i</i> is set ELM_PAGE_CTRL[i] SECTOR_ <i>i</i> (where <i>i</i> = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_ <i>i</i> = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value.
endif		Set value.
Set the input syndrome polynomial <i>i</i> .	ELM_SYNDROME_FRAGMENT_0_i	Set value.
	ELM_SYNDROME_FRAGMENT_1_i	Set value.
	ELM_SYNDROME_FRAGMENT_5_i	Set value.
	ELM_SYNDROME_FRAGMENT_6_i	Set value.
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

11.4.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 11-495](#) and [Table 11-496](#) describe the processing completion for continuous and page modes, respectively.

Table 11-495. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial <i>i</i> : Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which <i>i</i> the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_ <i>i</i>	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial <i>i</i> of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding <i>i</i> interrupt.	ELM_IRQSTATUS[i] LOC_VALID_ <i>i</i>	0x1

A new syndrome polynomial can be processed after the end of processing ([ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID = 0x0) and after the exit status register check ([ELM_LOCATION_STATUS_i](#)).

Table 11-496. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial <i>i</i> : Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		

Table 11-496. ELM Processing Completion for Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the process exit status.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	
if the process fails (too many errors) It is software dependent.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	0x0
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial <i>i</i> of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i [12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i [12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i [12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed ([ELM_IRQSTATUS](#)[*i*] LOC_VALID_0 = 0x1 for all syndrome polynomials *i* used in the page).

11.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see [Table 11-497](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 11-497. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG [1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS [0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG [4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG [1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2 × 528 = 1056)	ELM_LOCATION_CONFIG [26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE [0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where <i>i</i> = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where <i>i</i> = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where <i>i</i> = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where <i>i</i> = 0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i [16] SYNDROME_VALID (where <i>i</i> = 0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS [0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE (where <i>i</i> = 0)	0x1

Table 11-497. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 11-498](#) are given in decimal format.

Table 11-498. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216

260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

11.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see [Table 11-499](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB

- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 11-499. Use Case: Page Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x2
Defines the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xA329AA05

	ELM_SYNDROME_FRAGMENT_5_i (where i = 1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (where i = 1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (where i = 2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (where i = 2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (where i = 2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 2)	0xA6498FEE
	ELM_SYNDROME_FRAGMENT_4_i (where i = 2)	0xEC3697FA
	ELM_SYNDROME_FRAGMENT_5_i (where i = 2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1

Table 11-499. Use Case: Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i [16] SYNDROME_VALID (where i = 3)	0x1
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS [8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0) ELM_ERROR_LOCATION_1_i (where i = 0) ELM_ERROR_LOCATION_2_i (where i = 0) ELM_ERROR_LOCATION_3_i (where i = 0)	0x1FE 0x617 0x650 0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1) ELM_ERROR_LOCATION_1_i (where i = 1)	0x4 0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

11.5 On-Chip Memory (OCM) Subsystem

11.5.1 OCM Subsystem Overview

The OCM subsystem consists of one OCM Controller (OCMC) that is associated with the on-chip RAM. This is the OCMC_RAM with 512 KiB of dedicated memory space. The OCM controller is also introduced in [Section 11.1.4, OCM Overview](#) of [Section 11.1, Memory Subsystem Overview](#).

[Figure 11-65](#) shows the OCMC_RAM controller.

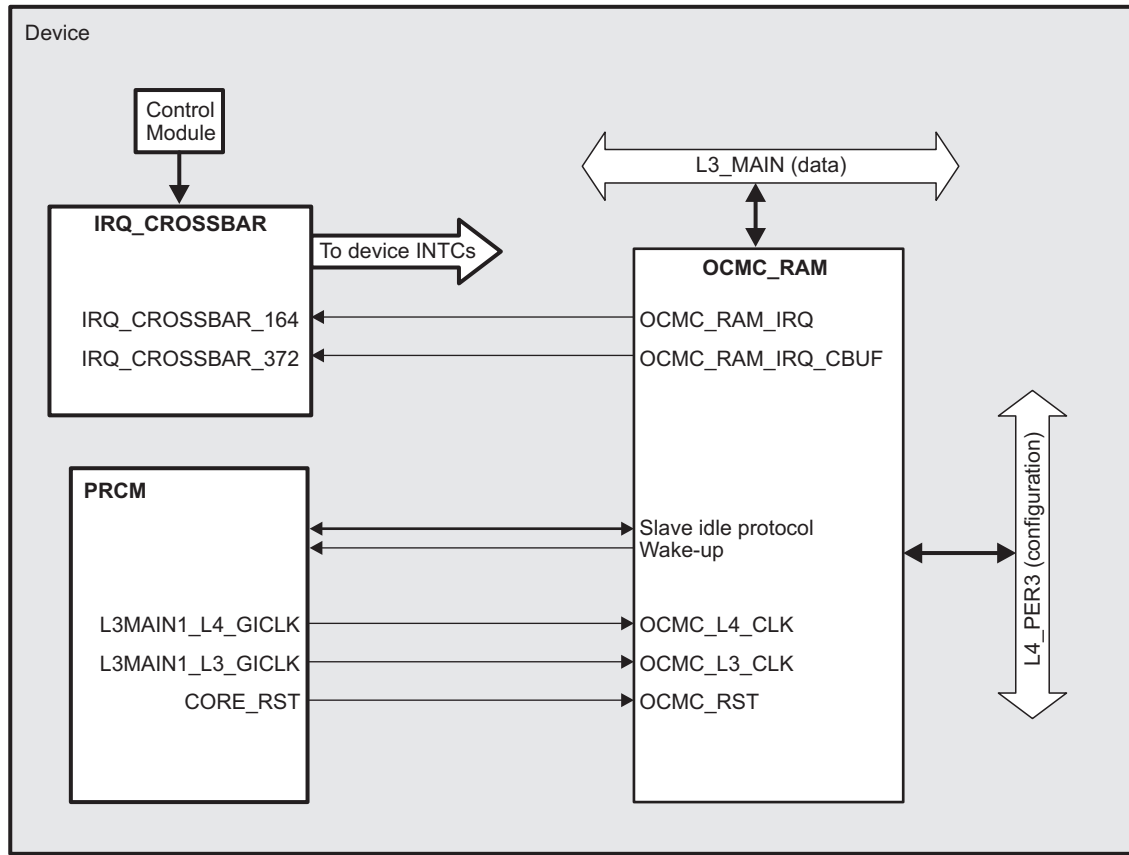

Figure 11-65. OCMC_RAM Overview

11.5.2 OCM Subsystem Integration

[Figure 11-66](#) shows the integration of the OCMC_RAM in the device.

Figure 11-66. OCMC_RAM Integration

ocmc-003

Table 11-564 through Table 11-566 summarize the integration of the OCMC_RAM in the device.

Table 11-564. OCMC_RAM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
OCMC_RAM	PD_COREAON	Yes	L3_MAIN L4_PER3

Table 11-565. OCMC_RAM Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM	OCMC_RST	CORE_RST	PRCM	Reset signal for the OCMC_RAM

Table 11-566. OCMC_RAM Hardware Requests

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
OCMC_RAM	OCMC_RAM_IRQ	IRQ_CROSSBAR_164	-	First OCMC_RAM interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM_IRQ_CBUF	IRQ_CROSSBAR_372	-	Second OCMC_RAM interrupt request. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “Default Mapping” column in [Table 11-566 OCMC_RAM Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For description of the interrupt sources, see [Section 11.5.3.4, Interrupt Requests](#).

11.5.3 OCM Subsystem Functional Description

11.5.3.1 Block Diagram

[Figure 11-67](#) shows the OCMC block diagram.

Figure 11-67. OCMC Block Diagram

The module is composed by the following main blocks:

- L3 interface used for data transactions
- L4 interface used for configuration
- CBUF address translator which converts the L3_MAIN VBUF addresses into SRAM addresses
- ECC logic to support single error correction and double error detection
- SRAM used for storing data and the corresponding for each 128-bit word ECC
- Interrupt logic used for generating interrupt requests
- Configuration logic in which reside the registers used for configuring the OCM controller operation modes

11.5.3.2 Resets

The OCMC_RST is the reset signal for the OCM controller which asynchronously resets the whole internal logic of the controller, including all configuration registers. It does not reset the SRAM. In addition, the [OCMC_SYSCONFIG_RST\[0\]](#) SW_RST bit provides a software way to reset the OCM controller. In this case all of its internal logic is reset except the configuration registers accessible through the L4_PER3.

11.5.3.3 Clock Management

The OCM controller complies with the PRCM slave idle protocol. The OCMC_L3_CLK and OCMC_L4_CLK clocks are gated based on the values loaded in the [OCMC_SYSCONFIG_PM\[3:2\]](#) IDLEMODE bit field.

11.5.3.4 Interrupt Requests

The OCM controller generates two interrupt requests, OCMC_RAM_IRQ and OCMC_RAM_IRQ_CBUF.

The OCMC_RAM_IRQ line is associated with the following registers:

- [INTR0_STATUS_RAW_SET](#) - interrupt raw status register
- [INTR0_STATUS_ENABLED_CLEAR](#) - interrupt status register
- [INTR0_ENABLE_SET](#) - interrupt enable register
- [INTR0_ENABLE_CLEAR](#) - interrupt disable register

The OCMC_RAM_IRQ_CBUF line is associated with the following registers:

- [INTR1_STATUS_RAW_SET](#) - interrupt raw status register
- [INTR1_STATUS_ENABLED_CLEAR](#) - interrupt status register
- [INTR1_ENABLE_SET](#) - interrupt enable (event unmask) register
- [INTR1_ENABLE_CLEAR](#) - interrupt disable (event mask) register

Both the register groups previously described have identical bits. When for example, only one event occurs one or the two IRQ lines will be asserted depending on the masks applied to the [INTR0_ENABLE_SET](#) and [INTR1_ENABLE_SET](#) registers. When for example, a short frame detection event occurs and if both the [INTR0_ENABLE_SET\[14\]](#) CBUF_SHORT_FRAME_DETECT_FOUND and [INTR1_ENABLE_SET\[14\]](#) CBUF_SHORT_FRAME_DETECT_FOUND bits are set to 0x1, then both the OCMC_RAM_IRQ and OCMC_RAM_IRQ_CBUF lines are asserted. If only the [INTR0_ENABLE_SET\[14\]](#) CBUF_SHORT_FRAME_DETECT_FOUND bit is set to 0x1, then only the OCMC_RAM_IRQ line is asserted and the OCMC_RAM_IRQ_CBUF line remains inactive (deasserted). Thus depending on the mask applied one IRQ line of the OCM controller can be associated only with CBUF events for example, and the other one IRQ line can be associated with ECC events. In other words, two unique interrupts can be provided.

[Table 11-567](#) lists the interrupt events which can assert the two interrupt lines of the OCM controller.

The OCM controller asserts each of its interrupt lines only if the interrupts are enabled by setting to 0x1 the corresponding bits in the [INTR0_ENABLE_SET/INTR1_ENABLE_SET](#) register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the [INTR0_ENABLE_CLEAR/INTR1_ENABLE_CLEAR](#) register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the [INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR](#) register which also

clears the corresponding bit in the [INTRO_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register. The status flags in the [INTRO_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register are set even if the corresponding interrupt is disabled as opposed to those in the [INTRO_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR](#) register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the OCM controller, if certain bit in the [INTRO_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register is set to 0x1 and the corresponding interrupt is enabled through the [INTRO_ENABLE_SET/INTR1_ENABLE_SET](#) register. This is useful when user software debugging is performed. Additionally, even if interrupts are not enabled, certain status bit in the [INTRO_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register can be cleared by setting to 0x1 the corresponding bit in the [INTRO_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR](#) register.

For additional details regarding the CBUF related events, see [Section 11.5.3.11, CBUF Mode Error Handling](#).

Table 11-567. OCMC_RAM Events

Event Flag	Event Mask	Description
INTRO_STATUS_RAW_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_RAW_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND and	INTRO_ENABLE_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND and	This bit indicates a short frame detection. It is set if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT register is set to 0x1.
INTRO_STATUS_ENABLED_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_ENABLED_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND	INTRO_ENABLE_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND	
INTRO_STATUS_RAW_SET [13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_STATUS_RAW_SET [13] CBUF_UNDERFLOW_ERR_FOUND and	INTRO_ENABLE_SET [13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_ENABLE_SET [13] CBUF_UNDERFLOW_ERR_FOUND and	Indicates CBUF underflow detection. This bit is set if at least one of the bits in the STATUS_CBUF_UNDERFLOW register is set to 0x1.
INTRO_STATUS_ENABLED_CLEAR [13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR [13] CBUF_UNDERFLOW_ERR_FOUND	INTRO_ENABLE_CLEAR [13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_ENABLE_CLEAR [13] CBUF_UNDERFLOW_ERR_FOUND	
INTRO_STATUS_RAW_SET [12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_STATUS_RAW_SET [12] CBUF_OVERFLOW_WRAP_ERR_FOUND and	INTRO_ENABLE_SET [12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_ENABLE_SET [12] CBUF_OVERFLOW_WRAP_ERR_FOUND and	Indicates Cbuf_Overflow_Wrap event
INTRO_STATUS_ENABLED_CLEAR [12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR [12] CBUF_OVERFLOW_WRAP_ERR_FOUND	INTRO_ENABLE_CLEAR [12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_ENABLE_CLEAR [12] CBUF_OVERFLOW_WRAP_ERR_FOUND	
INTRO_STATUS_RAW_SET [11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_STATUS_RAW_SET [11] CBUF_OVERFLOW_MID_ERR_FOUND and	INTRO_ENABLE_SET [11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_ENABLE_SET [11] CBUF_OVERFLOW_MID_ERR_FOUND and	Indicates Cbuf_Overflow_Mid event
INTRO_STATUS_ENABLED_CLEAR [11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR [11] CBUF_OVERFLOW_MID_ERR_FOUND	INTRO_ENABLE_CLEAR [11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_ENABLE_CLEAR [11] CBUF_OVERFLOW_MID_ERR_FOUND	
INTRO_STATUS_RAW_SET [10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET [10] CBUF_READ_SEQUENCE_ERR_FOUND and	INTRO_ENABLE_SET [10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_SET [10] CBUF_READ_SEQUENCE_ERR_FOUND and	This flag indicates that at least one CBUF read address is not incrementing in raster scan order ⁽¹⁾ .
INTRO_STATUS_ENABLED_CLEAR [10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR [10] CBUF_READ_SEQUENCE_ERR_FOUND	INTRO_ENABLE_CLEAR [10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_CLEAR [10] CBUF_READ_SEQUENCE_ERR_FOUND	

⁽¹⁾ The [LAST_ILLEGAL_OCMC_ADDR](#) register stores the last illegal L3_MAIN address caused the assertion of this event.

Table 11-567. OCMC_RAM Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and	INTR0_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and	This flag indicates when at least one of the CBUF read accesses does not start at the VBUF start address ⁽¹⁾ .
INTR0_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	INTR0_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND

Table 11-567. OCMC_RAM Events (continued)

Event Flag	Event Mask	Description
<p>INTRO_STATUS_RAW_SET[2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_SE T[2] ADDR_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND/INTR1_STATUS_ENABL ED_CLEAR[2] ADDR_ERR_FOUND</p>	<p>INTRO_ENABLE_SET[2] ADDR_ERR_FOUND/INTR1_ENABLE_SET[2] ADDR_ERR_FOUND and INTRO_ENABLE_CLEAR[2] ADDR_ERR_FOUND/INTR1_ENABLE_CLEAR[2] ADDR_ERR_FOUND</p>	<p>This status flag is set when the value of the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.</p>
<p>INTRO_STATUS_RAW_SET[1] DED_ERR_FOUND/INTR1_STATUS_RAW_SE T[1] DED_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND/INTR1_STATUS_ENABL E_CLEAR[1] DED_ERR_FOUND</p>	<p>INTRO_ENABLE_SET[1] DED_ERR_FOUND/INTR1_ENABLE_SET[1] DED_ERR_FOUND and INTRO_ENABLE_CLEAR[1] DED_ERR_FOUND/INTR1_ENABLE_CLEAR[1] DED_ERR_FOUND</p>	<p>This status flag is set when the value of the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.</p>
<p>INTRO_STATUS_RAW_SET[0] SEC_ERR_FOUND/INTR1_STATUS_RAW_SE T[0] SEC_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND/INTR1_STATUS_ENABL _CLEAR[0] SEC_ERR_FOUND</p>	<p>INTRO_ENABLE_SET[0] SEC_ERR_FOUND/INTR1_ENABLE_SET[0] SEC_ERR_FOUND and INTRO_ENABLE_CLEAR[0] SEC_ERR_FOUND/INTR1_ENABLE_CLEAR[0] SEC_ERR_FOUND</p>	<p>This status flag is set when the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.</p>

11.5.3.5 OCM Subsystem Memory Regions

The SRAM associated with the OCMC_RAM is accessible through the L3_MAIN interconnect. The start address is 0x4030 0000 and the end address is 0x4037 FFFF. That is address space of 512KiB. The configuration registers of the OCMC_RAM are accessible through the L4_PER3 starting at address 0x4880 4000.

11.5.3.6 OCM Controller Modes Of Operation

The OCM controller supports four modes of operation. Each of these modes is selected through the [CFG_OCMC_ECC\[2:0\] CFG_OCMC_MODE](#) bit field. The four supported modes are the following:

- Non-ECC mode (Data Access) - Accesses to the SRAM are non-ECC-enabled and an ECC is not calculated.
- Non-ECC mode (Code Access) - The L3_MAIN address is mapped to the SRAM memory space where the ECC code is stored. This mode allows read and write access to the 9-bit ECC word associated with each 128-bit data word. This mode is used for test purposes.
- Full-ECC mode - Accesses to the SRAM are ECC-enabled and a 9-bit ECC is calculated for each 128 bits of data.
- Block-ECC mode - A 9-bit ECC is calculated only for a 128KiB block of the SRAM. Accesses outside the 128KiB ECC-enabled block are non-ECC data accesses. In other words, a 9-bit ECC will be calculated not for each 128-bit data word of the whole SRAM space, but for each 128-bit data word within the boundaries of this 128KiB block of the SRAM. The selection of a 128KiB ECC-enabled block is done using bits[19:0] of the [CFG_OCMC_ECC_MEM_BLK](#) register. Each bit specifies which 128KiB block of the SRAM is ECC-enabled. 0x1 is the active value for each bit. In addition, more than one 128KiB ECC-enabled block can be selected.

The default mode of operation for the OCM controller is the non-ECC data access mode.

11.5.3.7 ECC Associated FIFOs

There are three FIFOs used when ECC mode is enabled. Each FIFO is four level deep. The FIFOs are the following:

- Address FIFO for single errors also referred to as SEC FIFO
- Address FIFO for double errors also referred to as DED FIFO
- Address FIFO for address errors also referred to as ADDRERR FIFO

The SEC FIFO stores the SRAM addresses at which a single error is detected. The FIFO is able to store up to four unique addresses of the single errors occurred. If there are more than four single errors associated with unique addresses, then only the first four addresses are stored in the FIFO. In case of occurrence of multiple correctable errors, the addresses are stored in the order the errors occurred. The SEC FIFO can be optionally configured to store all addresses of the single errors occurred including also the repeated addresses. This is done by setting to 0x0 the [CFG_OCMC_ECC_ERROR\[24\] CFG_DISCARD_DUP_ADDR](#) bit. The SEC FIFO can be cleared by setting to 0x1 the [CFG_OCMC_ECC_CLEAR_HIST\[0\] CLEAR_SEC_ERR_CNT](#) bit or by reading FIFO's content one by one through the [STATUS_SEC_ERROR_TRACE\[17:0\] ADDRESS_128BIT](#) bit field which points to the SEC FIFO. In addition, the [STATUS_SEC_ERROR_TRACE\[18\] VALID](#) bit shows whether the FIFO is empty or not. A value of 0x1 means that the SEC FIFO is not empty and valid address can be read.

The DED FIFO stores the SRAM addresses when a double error is detected. The FIFO is able to store up to four unique addresses, but it can also be configured to store the repeated addresses by setting to 0x0 the [CFG_OCMC_ECC_ERROR\[24\] CFG_DISCARD_DUP_ADDR](#) bit. The [STATUS_DED_ERROR_TRACE\[17:0\] ADDRESS_128BIT](#) bit field points to the DED FIFO. The [STATUS_DED_ERROR_TRACE\[18\] VALID](#) bit shows whether the FIFO is empty or not. The DED FIFO can be cleared by setting to 0x1 the [CFG_OCMC_ECC_CLEAR_HIST\[1\] CLEAR_DED_ERR_CNT](#) bit or by reading its content one by one through the [STATUS_DED_ERROR_TRACE\[17:0\] ADDRESS_128BIT](#).

The ADDRERR FIFO stores the SRAM addresses where the single error occurred is an address error. The [STATUS_ADDR_TRANSLATION_ERROR_TRACE\[17:0\] ADDRESS_128BIT](#) bit field points to the ADDRERR FIFO. The [STATUS_ADDR_TRANSLATION_ERROR_TRACE\[18\] VALID](#) bit shows whether the FIFO is empty or not. The ADDRERR FIFO can be cleared by setting to 0x1 the [CFG_OCMC_ECC_CLEAR_HIST\[2\] CLEAR_ADDR_ERR_CNT](#) bit or by reading its content one by one through the [STATUS_ADDR_TRANSLATION_ERROR_TRACE\[17:0\] ADDRESS_128BIT](#) pointer. The ADDRERR FIFO is also able to store up to four unique addresses and can also be configured to store repeated addresses by setting to 0x0 the [CFG_OCMC_ECC_ERROR\[24\] CFG_DISCARD_DUP_ADDR](#) bit.

11.5.3.8 ECC Counters And Corrected Bit Distribution Register

There are three counters which are used to count different types of errors occurred when the ECC mode is enabled. The counters are the following:

- SEC Counter - [STATUS_ERROR_CNT\[15:0\]](#) SEC_ERROR_CNT. This is the counter for the single errors occurred. It keeps track of all single errors. That is, even for those with error addresses that have already been logged.
- DED Counter - [STATUS_ERROR_CNT\[19:16\]](#) DED_ERROR_CNT. This is the counter for the double error detections.
- ADDRERR Counter - [STATUS_ERROR_CNT\[23:20\]](#) ADDR_ERROR_CNT. This is the counter for the address errors found when a single error occurs. That is, when the single error is an address error.

When a single error in the 128-bit data word occurs and this error is corrected, the OCM controller indicates for the corrected bit of this 128-bit word by setting to 0x1 a corresponding bit in the corrected bit distribution register. This is a 128-bit register composed by the following registers:

- [STATUS_SEC_ERROR_DISTR_0\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [31:0] of the corrected 128-bit data word.
- [STATUS_SEC_ERROR_DISTR_1\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [63:32] of the corrected 128-bit data word.
- [STATUS_SEC_ERROR_DISTR_2\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [95:64] of the corrected 128-bit data word.
- [STATUS_SEC_ERROR_DISTR_3\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [127:96] of the corrected 128-bit data word.

When a single error in the ECC itself occurs, the OCM controller indicates for this error by setting to 0x1 a corresponding bit in the [STATUS_SEC_ERROR_DISTR_4\[7:0\]](#) SEC_ECC_CODE_ERROR_FOUND bit field. The parity bit is not associated with this bit field.

11.5.3.9 ECC Support

The ECC mode is enabled through the [CFG_OCMC_ECC\[2:0\]](#) CFG_OCMC_MODE bit field. When enabled a 9-bit Hamming ECC is calculated and stored for each consecutive 128-bit block of the SRAM. The ECC is calculated based on a codeword constructed by concatenating the 128 bits of data with the address bits A21 through A4 of the L3_MAIN. The ECC generated is Hamming(155,146) code and has a Hamming distance of 4. The OCM controller uses this code to validate the content of the SRAM, to correct a single bit error that occurs within the 128-bit boundary or to determine if a non-correctable error has occurred within the 128-bit boundary.

During write transactions and when ECC is enabled, for every 128-bit data word, the ECC is calculated and stored in a 9-bit field of the SRAM associated only with the address where that 128-bit data word is written. If an initiator performs a write transaction which is less than 128 bits or it is non-128-bit aligned transaction, then the content of all 128 bits is read, the new sub-quanta of data is inserted and the ECC is calculated based on all 128 bits.

During read transactions and when ECC is enabled, the ECC is calculated based on the memory address (bits A21 through A4) and the 128-bit data word read from the SRAM. This ECC is then compared to the ECC stored at the address when the data was written to the SRAM. If the two ECCs are matching then the data is transferred to the requesting initiator without further exceptions. If the two ECCs are not matching then a check is made to determine if the error is correctable or not. If the error is not correctable, that is a double error, then the address of the erroneous word is stored in the DED FIFO, the [STATUS_ERROR_CNT\[19:16\]](#) DED_ERROR_CNT counter is incremented by 1 and the double error flag is asserted. The double error flag is indicated by the [INTR0_STATUS_RAW_SET\[1\]](#) DED_ERR_FOUND/[INTR1_STATUS_RAW_SET\[1\]](#) DED_ERR_FOUND bits, but its assertion depends on the threshold configured through the [CFG_OCMC_ECC_ERROR\[19:16\]](#) CFG_DED_CNT_MAX bit field. For more information see, [Table 11-567, OCMC_RAM Events](#).

In case of a single error, the OCM controller first determines whether the erroneous bit is in the data, address or the ECC itself. In this case the following applies:

- If the single error is located in the data read, then the erroneous bit is corrected and the data is passed to the requesting initiator. The erroneous bit is corrected also in the SRAM location by the auto re-write

feature of the OCM controller if this feature is enabled by setting to 0x1 the [CFG_OCMC_ECC\[3\]](#) [CFG_ECC_SEC_AUTO_CORRECT](#) bit field. In addition, the address of the corrected data word is pushed to the SEC FIFO and the [STATUS_ERROR_CNT\[15:0\]](#) [SEC_ERROR_CNT](#) counter is incremented by 1. The single error flag is asserted too, but only if the value of the [STATUS_ERROR_CNT\[15:0\]](#) [SEC_ERROR_CNT](#) counter reaches the threshold configured by the [CFG_OCMC_ECC_ERROR\[15:0\]](#) [CFG_SEC_CNT_MAX](#) bit field. The single error flag is indicated by the [INTR0_STATUS_RAW_SET\[0\]](#) [SEC_ERR_FOUND](#)/[INTR1_STATUS_RAW_SET\[0\]](#) [SEC_ERR_FOUND](#) bits. For more information see, [Table 11-567, OCMC_RAM Events](#).

- If the single error is located in the address portion of the quanta, then the data is passed to the requesting initiator unchanged and the [STATUS_ERROR_CNT\[23:20\]](#) [ADDR_ERROR_CNT](#) and [STATUS_ERROR_CNT\[15:0\]](#) [SEC_ERROR_CNT](#) counters are incremented by 1. The address associated with this error is stored in the ADDRERR FIFO and the address error flag is asserted. This flag is indicated by the [INTR0_STATUS_RAW_SET\[2\]](#) [ADDR_ERR_FOUND](#)/[INTR1_STATUS_RAW_SET\[2\]](#) [ADDR_ERR_FOUND](#) bits, but its assertion depends on the threshold configured through the [CFG_OCMC_ECC_ERROR\[23:20\]](#) [CFG_ADDR_ERR_CNT_MAX](#) bit field. For more information see, [Table 11-567, OCMC_RAM Events](#).
- If the single error is located in the ECC itself, then the data is passed to the initiator unchanged but the [STATUS_ERROR_CNT\[15:0\]](#) [SEC_ERROR_CNT](#) counter is incremented by 1 and the address associated with this error is stored in the SEC FIFO.

[Table 11-568](#) summarizes the actions taken by the OCM controller for the different error types.

Table 11-568. OCMC Error Handling In Case Of Different Error Types

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRERR Counter	ADDRERR FIFO	Error Bit Distribution
Single data error	Corrected	Data corrected/ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the corrected bit distribution register is updated
Single address error	Unchanged	ECC re-generated	Incremented by 1	-	-	-	Incremented by 1	Address written	-
Single ECC error	Unchanged	ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field is updated
Double error	Unchanged	-	-	-	Incremented by 1	Address written	-	-	-

If ECC has to be used, before performing SRAM read/write operations the following steps should be performed:

- Configuring the ECC registers
- Enabling the ECC
- Initializing the SRAM with data
- Clearing the status flags

[Table 11-569](#) describes in detail the steps to be performed.

Table 11-569. OCMC ECC Configuration

Step	Associated Register/ Bit Field	Value
(Optional) Enable the error response on L3_MAIN for a non-correctable error	CFG_OCMC_ECC[4] CFG_ECC_ERR_SRESP_EN	0x1
(Optional) Enable data auto correction in case of a single error	CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT	0x1
Enable the memory blocks to be ECC protected, if ECC block mode is used	CFG_OCMC_ECC_MEM_BLK[19:0] CFG_ECC_ENABLED_128K_BLK	0x-

Table 11-569. OCMC ECC Configuration (continued)

Step	Associated Register/ Bit Field	Value
(Optional) Configure the address errors count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX	0x-
(Optional) Configure the DED count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX	0x-
(Optional) Configure the SEC count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX	0x-
Enable ECC	CFG_OCMC_ECC[2:0] CFG_OCMC_MODE	0x2 for full ECC or 0x3 for block ECC mode
Initialize the memory with data		
Clear the error counters in the STATUS_ERROR_CNT register	CFG_OCMC_ECC_CLEAR_HIST[2:0]	0x7
Clear the SEC bit distribution history from the following registers:	CFG_OCMC_ECC_CLEAR_HIST[3] CLEAR_SEC_BIT_DISTR	0x1
• STATUS_SEC_ERROR_DISTR_0		
• STATUS_SEC_ERROR_DISTR_1		
• STATUS_SEC_ERROR_DISTR_2		
• STATUS_SEC_ERROR_DISTR_3		
• STATUS_SEC_ERROR_DISTR_4		

11.5.3.10 Circular Buffer (CBUF) Support

The OCM controller provides up to 12 programmable circular buffers that are mapped to virtual video frames to support sliced based on-the-fly video frame processing. Each circular buffer must be programmed with the following:

- Unique virtual frame start address - configured through CBUF_i_VBUF_START_ADDR[31:4] ADDR.
- Unique virtual frame end address - configured through CBUF_i_VBUF_END_ADDR[31:4] ADDR.
- SRAM start address - configured through CBUF_i_OCMC_START_ADDR[31:4] ADDR.
- SRAM size allocated for that circular buffer - configured through CBUF_i_OCMC_BUF_SIZE[19:4] BUF_SIZE.

The circular buffer mode is enabled when the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN bit is set to 0x1. In addition, to enable certain circular buffer the corresponding bit in the CFG_OCMC_CBUF_EN[27:16] bit field must be set to 0x1. For example, to enable CBUF_0 both the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN and CFG_OCMC_CBUF_EN[16] CBUF_EN_0 bits must be set to 0x1.

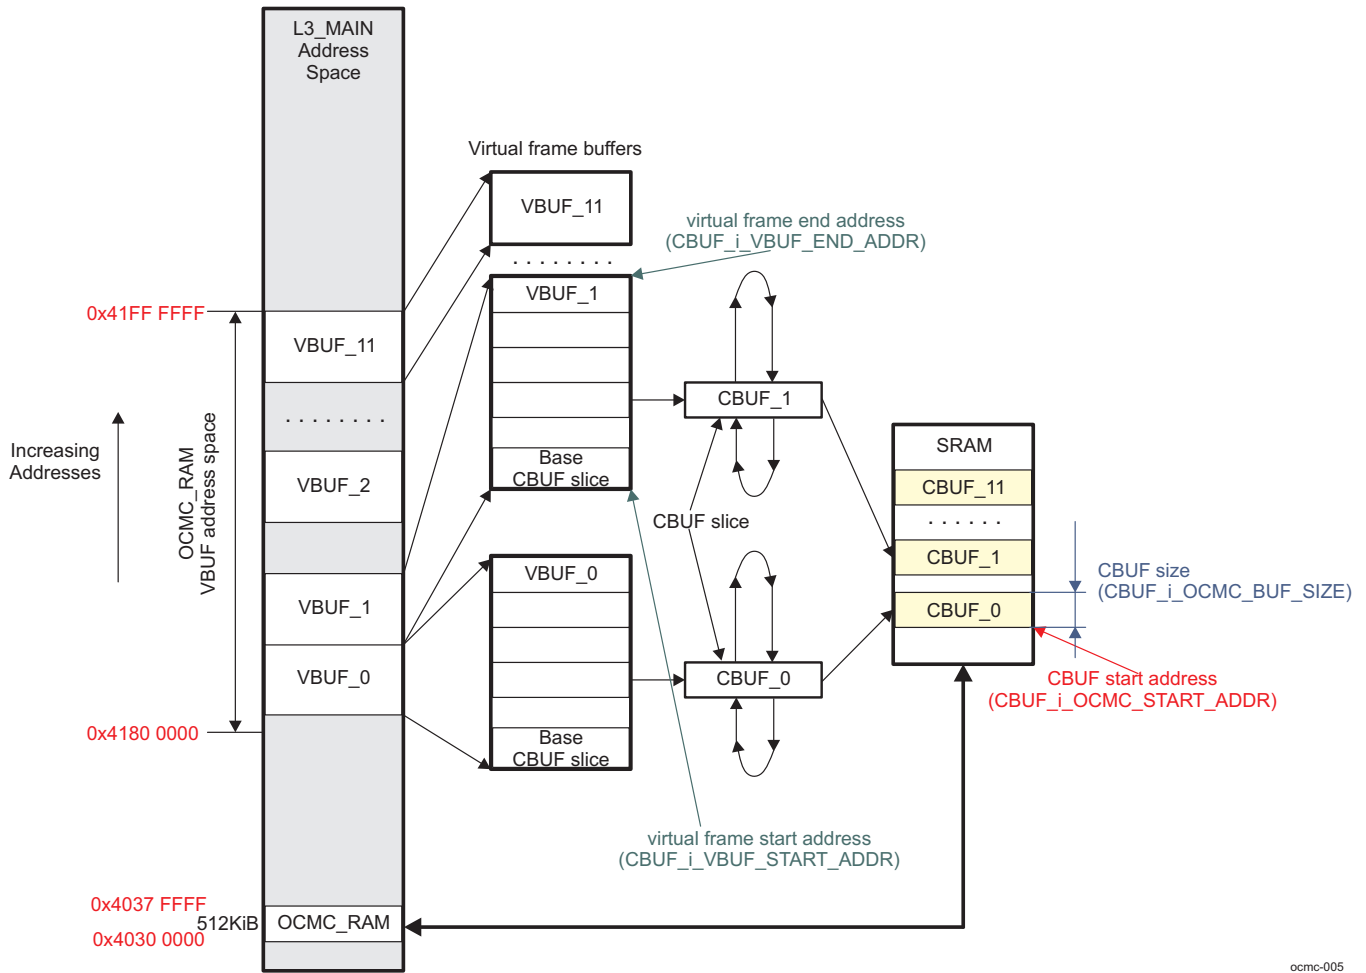

The data transfers are made to the virtual frame addresses. The OCM controller translates these virtual addresses to SRAM addresses allocated for the CBUF. The address translation is done on-the-fly without leading to any additional latency and therefore has no performance impact on the overall operation of the OCM controller.

The L3_MAIN address range associated with the virtual frame addresses is the following:

- For OCMC_RAM the start address is 0x4180 0000 and the end address is 0x41FF FFFF.

When an initiator performs an access to these L3_MAIN addresses, these virtual frame addresses will be translated automatically by the OCM controller into SRAM addresses. Figure 11-68 shows the address mapping of the virtual frame addresses to CBUF addresses.

Figure 11-68. VBUF to CBUF Address Mapping

It must be taken into account that the start address of a virtual frame always begins at the start of the CBUF. Since the virtual frame buffer size is not necessarily to be a multiple of the CBUF size, the last VBUF write location may not be the last line of the CBUF. As the CBUF read and write pointers are independently managed the initiators that are writing to and reading from the CBUF should be coordinated in order to avoid overflow and underflow conditions.

11.5.3.11 CBUF Mode Error Handling

For each L3_MAIN write or read access associated with the virtual frame buffer, the OCM controller performs various address error checks to prevent illegal CBUF accesses from causing false overflow and underflow conditions. Once the L3_MAIN VBUF address is determined as valid, the OCM controller further checks for overflow and underflow conditions to properly handle the access to the CBUF during each one of these conditions and to notify for error condition an external host.

For more information regarding all CBUF events see, [Table 11-567, OCMC_RAM Events](#).

11.5.3.11.1 VBUF Address Not Mapped to a CBUF Memory Space

The L3_MAIN VBUF address should be mapped to a valid CBUF region. If this address is mapped to none of the configured CBUF regions, then the OCM controller generates a virtual address error or out of range CBUF address error event. It is possible both virtual address error and out of range CBUF address error to be generated. The L3_MAIN VBUF address caused these two events can be read through the [LAST_ILLEGAL_OCMC_ADDR\[31:0\]](#) ADDR bit field.

Virtual address error is generated when the L3_MAIN VBUF address is lower than the virtual frame start address. This is indicated by asserting the [INTRO_STATUS_RAW_SET\[4\]](#) [CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET\[4\]](#) [CBUF_VIRTUAL_ADDR_ERR_FOUND](#) bit.

The out of range CBUF address error is generated when the L3_MAIN VBUF address is greater than the virtual frame end address. This error is an indication of an unexpected change in the frame size or a long frame and should be handled immediately to prevent further memory corruption. The out of range CBUF address error can be caused when performing write or read access. The out of range CBUF write address error is indicated by the [STATUS_CBUF_WR_OUT_OF_RANGE_ERR\[11:0\]](#) [CBUF_ERR](#) bit field. The out of range CBUF read address error is indicated by the [STATUS_CBUF_RD_OUT_OF_RANGE_ERROR\[11:0\]](#) [CBUF_ERR](#) bit field. Each bit in these registers is associated only with one CBUF. Bit 0 corresponds to CBUF_0, bit 1 corresponds to CBUF_1 and so on. A value of 0x1 for each bit means that there is an error (CBUF address is out of CBUF range) for the corresponding CBUF. Writing 0x1 for each bit clears the status.

The [INTRO_STATUS_RAW_SET\[5\]](#) [CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET\[5\]](#) [CBUF_WR_OUT_OF_RANGE_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_WR_OUT_OF_RANGE_ERR\[11:0\]](#) [CBUF_ERR](#) bit field is set to 0x1.

The [INTRO_STATUS_RAW_SET\[8\]](#) [CBUF_READ_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET\[8\]](#) [CBUF_READ_OUT_OF_RANGE_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_RD_OUT_OF_RANGE_ERROR\[11:0\]](#) [CBUF_ERR](#) bit field is set to 0x1.

11.5.3.11.2 VBUF Access Not Starting At The Base Address

After (hardware or software) reset or on a new frame start condition, a frame write or read access for any VBUF must start from its virtual frame start address ([CBUF_i_VBUF_START_ADDR\[31:4\]](#) [ADDR](#)). If this is not met the OCM controller ignores all accesses which don't start at address [CBUF_i_VBUF_START_ADDR\[31:4\]](#) [ADDR](#) and also generates an interrupt. The [STATUS_CBUF_WR_VBUF_START_ERR\[11:0\]](#) [CBUF_ERR](#) register contains the status bits of this interrupt which are associated with frame write access. The [STATUS_CBUF_VBUF_RD_START_ERROR\[11:0\]](#) [CBUF_ERR](#) register contains the status bits associated with frame read access. Each bit in these two registers is associated only with one CBUF. A value of 0x1 for each bit means that the read/write access does not start at the VBUF start address.

While this error condition exists, no updates to the CBUF channel status registers are made. An exception to this constraint is when the last read/write access is still within the base CBUF slice. The enforcing of a frame starting at VBUF starting address is not done in this case to allow random access within the same CBUF. However, this will be flagged and handled as a short frame occurrence.

The [INTRO_STATUS_RAW_SET\[6\]](#) [CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_STATUS_RAW_SET\[6\]](#) [CBUF_VBUF_WRITE_START_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_WR_VBUF_START_ERR\[11:0\]](#) [CBUF_ERR](#) bit field is set to 0x1.

The [INTRO_STATUS_RAW_SET\[9\]](#) [CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_RAW_SET\[9\]](#) [CBUF_VBUF_READ_START_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_VBUF_RD_START_ERROR\[11:0\]](#) [CBUF_ERR](#) bit field is set to 0x1.

11.5.3.11.3 Illegal Address Change Between Two Same Type Accesses

The OCM controller requires both read and write accesses to a virtual frame buffer to be performed in the positive raster scan order, that is, successive write or read accesses should be to a higher address except on a new frame start for which the address jumps back down to the beginning of the virtual frame buffer. The OCM controller checks to make sure that a virtual address meets one of the following conditions:

- It is within the same CBUF slice as the last access of the same type (read or write)
- It is within the next CBUF slice of the last access of the same type (read or write)
- The virtual address is to the VBUF frame start address

Based on these constraints, the OCM controller generates a write/read address sequence error interrupt and invalidates the access, that is, writes are disabled and reads return unknown data, if the following two conditions are met:

- The current access address is not to a current or next CBUF slice space
- The current access address is not to the base of the virtual frame buffer (the first CBUF slice)

The random accesses within the current CBUF slice are permitted to allow some variations in the line width of the captured video which often happens with weak video signal conditions.

To avoid illegal CBUF slice backward switching, the modules capturing the input video and sending it to the CBUF of the OCM controller should limit the maximum width of a line width to be less than the stride size (in pixels). This guarantees that a start of a new line does not point back to the previous CBUF slice.

If a write or read address sequence error event is detected on an access, the OCM controller will simply invalidate the accesses and will not update the CBUF status registers.

The bits in the [STATUS_CBUF_WR_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field indicate write address sequence error event.

The bits in the [STATUS_CBUF_RD_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field indicate read address sequence error event.

In both the registers each bit is associated only with one CBUF.

The [INTR0_STATUS_RAW_SET](#)[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/[INTR1_STATUS_RAW_SET](#)[7] CBUF_WRITE_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the [STATUS_CBUF_WR_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field is set to 0x1.

The [INTR0_STATUS_RAW_SET](#)[10] CBUF_READ_SEQUENCE_ERR_FOUND/[INTR1_STATUS_RAW_SET](#)[10] CBUF_READ_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the [STATUS_CBUF_RD_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field is set to 0x1.

11.5.3.11.4 Illegal Frame Size (Short Frame Detection)

If a frame write access for any VBUF begins from its virtual frame start address without a CBUF software reset and the last write address is not the virtual frame end address or is in the last CBUF slice, then the previous frame is considered to be short. This includes the case where a new frame write happens twice without a new frame read in between, which is an indication of an extremely short frame. When a short frame event is detected, the OCM controller generates a short frame detection interrupt and temporarily disables overflow checking on the write access, including also the current access, until a frame read happens in order to avoid false overflow indication on a suspended read side following the short frame detection.

If the last write address is in the last CBUF slice the short frame detection can be ignored if the [CFG_OCMC_CBUF_ERR_HANDLER](#)[1] SHORT_FRAME_PREV_EOF_SEL bit is set to 0x1.

The [STATUS_CBUF_SHORT_FRAME_DETECT](#)[11:0] CBUF_ERR bit field has status flags to indicate a short frame detection for each CBUF. When a short frame condition occurs the corresponding bit is set to 0x1.

The [INTR0_STATUS_RAW_SET](#)[14] CBUF_SHORT_FRAME_DETECT_FOUND/[INTR1_STATUS_RAW_SET](#)[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is asserted if at least one of the bits in the [STATUS_CBUF_SHORT_FRAME_DETECT](#)[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the short frame detection enabling/disabling is controlled by the [CFG_OCMC_CBUF_ERR_HANDLER](#)[0] SHORT_FRAME_DETECT_CHECK_EN bit.

11.5.3.11.5 CBUF Overflow

For each valid CBUF write access, the write address is compared to the last read address for an overflow condition. If an overflow is detected, the corresponding CBUF overflow status bit in the [STATUS_CBUF_OVERFLOW_MID](#) or [STATUS_CBUF_OVERFLOW_WRAP](#) registers is set to 0x1 and an interrupt is generated. This interrupt condition exists until the corresponding overflow status bit is cleared.

There are two types of overflow conditions referred to as `Cbuf_overflow_wrap` and `Cbuf_overflow_mid`.

`Cbuf_overflow_wrap` occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address < CBUF size
- VBUF write address – VBUF frame start address > VBUF last read address – Current VBUF start address

`Cbuf_overflow_mid` occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address > CBUF size
- VBUF write address – VBUF last read address > CBUF size

If an overflow condition is detected on a CBUF write access, the OCM controller generates a CBUF overflow (`Cbuf_overflow_wrap` or `Cbuf_overflow_mid`) interrupt and enter an overflow error handling state. In this state, the OCM controller do the following in the default error handling configuration:

- When a `Cbuf_Overflow_Wrap` condition occurs (write buffer wraparound with read from previous frame still remaining), writes are disabled but reads are serviced normally. This mechanism preserves the back end of the previous frame and discards the new frame which is already showing signs of overflowing. Writes will be re-enabled automatically on write to the virtual frame start address which indicates the next frame after the overflowed frame has begun. The overflow (and underflow) check for this CBUF will be disabled until detection of write to/read from the virtual frame start address. The module which reads should not start reading the next frame (which is being discarded) or stop reading the frame if the read of this new frame has already started. This mechanism allows both write and read sides to re-synchronize on the next frame after one-frame drop.
- When a `Cbuf_Overflow_Mid` condition occurs, writes and reads are serviced normally allowing the read side to catch up to the write side. The overflow (and underflow) check will be disabled until first a write to the virtual frame start address and then a read from the virtual frame start address is detected. This mechanism allows the frame with a “momentary” overflow condition to be saved. The reader side has an option to stop reading and discarding the data by just resetting its CBUF read pointer at the next frame start, if the read side is too far back.

These steps are taken to minimize the frame loss due to an overflow condition. To support the previously described behavior but to allow software to override the default error handling behavior the following controls are available:

- [CFG_OCMC_CBUF_ERR_HANDLER\[7:6\] OVERFLOW_CHECK_REENABLE_SEL](#)
- [CFG_OCMC_CBUF_ERR_HANDLER\[5:4\] OVERFLOW_WRITE_HANDLER_SEL](#)

In addition, the overflow check can be enabled or disabled through the [CFG_OCMC_CBUF_ERR_HANDLER\[2\] OVERFLOW_ERR_CHECK_EN](#) bit.

11.5.3.11.6 CBUF Underflow

According to the CBUF operation a read request can only be made when there are enough number of video lines written to the CBUF. Therefore, there should not be any underflow conditions due to normal processing speed variations. An underflow condition occurs when the VBUF read address is greater than the last VBUF write address. To detect an abnormal failure in the read/write mechanism which could cause an underflow condition, each valid CBUF read access is checked for an underflow condition and if detected, an underflow interrupt is generated for the selected CBUF. The [STATUS_CBUF_UNDERFLOW\[11:0\] CBUF_ERR](#) bit field has status flags indicating when underflow occurs. This interrupt condition exists until the corresponding underflow status bit in the [STATUS_CBUF_UNDERFLOW](#) register is cleared.

If an underflow is detected on a CBUF read access, the OCM controller generates an underflow interrupt and continues to perform reads and writes normally, but the return data will not be correct while the underflow condition exists.

To avoid a false underflow detection at the end of a frame (due to external decoders sending short last line or due to interlaced input video having different number of lines in even/odd fields), the [CFG_OCMC_CBUF_ERR_HANDLER\[8\]](#) UNDERFLOW_LAST_CBUF_SLICE_DISABLE bit can be set to 0x1 which disables the underflow checking in the last CBUF slice.

The [INTR0_STATUS_RAW_SET\[13\]](#) CBUF_UNDERFLOW_ERR_FOUND/[INTR1_STATUS_RAW_SET\[13\]](#) CBUF_UNDERFLOW_ERR_FOUND bit is asserted if at least one of the bits in the [STATUS_CBUF_UNDERFLOW\[11:0\]](#) CBUF_ERR bit field is set to 0x1.

In addition, the underflow check can be enabled or disabled through the [CFG_OCMC_CBUF_ERR_HANDLER\[3\]](#) UNDERFLOW_ERR_CHECK_EN bit.

11.5.3.12 Status Reporting

The OCM controller keeps a history of last valid write and read addresses for each CBUF. The [CBUF_k_LAST_WR_ADDR](#) register stores the address for the last valid write and the [CBUF_k_LAST_RD_ADDR](#) register stores the address for the last valid read access.

The OCMC_ECC generates also a general VBUF mode error event for an access made with illegal VBUF address. The [INTR0_STATUS_RAW_SET\[3\]](#) OUT_OF_RANGE_ERR_FOUND/[INTR1_STATUS_RAW_SET\[3\]](#) OUT_OF_RANGE_ERR_FOUND bit indicates for this event.

Table 11-628. CFG_OCMC_CBUF_RESET

Address Offset	0x0000 0204	Instance	OCMC_RAM
Physical Address	0x4880 4204		
Description	Writing 1 to bit n will set a reset bit to clear the corresponding CBUF_n address translation logic. Sliding CBUF frame tracking will be cleared so that the CBUF now points to the base of the virtual frame buffer. Normally, a reset is not required since the CBUF logic will clear itself when a VBUF access is to the base of the virtual frame.

Enhanced DMA

This chapter describes the Enhanced Direct Memory Access (EDMA) controller.

Topic	Page
12.1 EDMA Module Overview	4457
12.2 EDMA Controller Environment.....	4461
12.3 EDMA Controller Integration	4462
12.4 EDMA Controller Functional Description	4474
12.5 EDMA Transfer Examples	4523
12.6 EDMA Debug Checklist and Programming Tips	4544
12.7 EDMA Register Manual	4546

12.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA can also perform transfers between external memories and between device subsystems internal memories, with some performance loss caused by resource sharing between the read and write ports.

EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

The **TPCC** is a high flexible Channel Controller. It serves as an user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals as programmed in the "Active" and "Pending" set of the registers. The transfer controllers are responsible for data movement and issue read/write commands to the source and destination addresses that are programmed for a given transfer in the EDMA_TPCC.

The SoC integrates the following EDMA instances:

- One system-level EDMA
- One DSP internal EDMA (per DSP)
- One EVE internal EDMA (per EVE)

Each of these EDMA modules consists of:

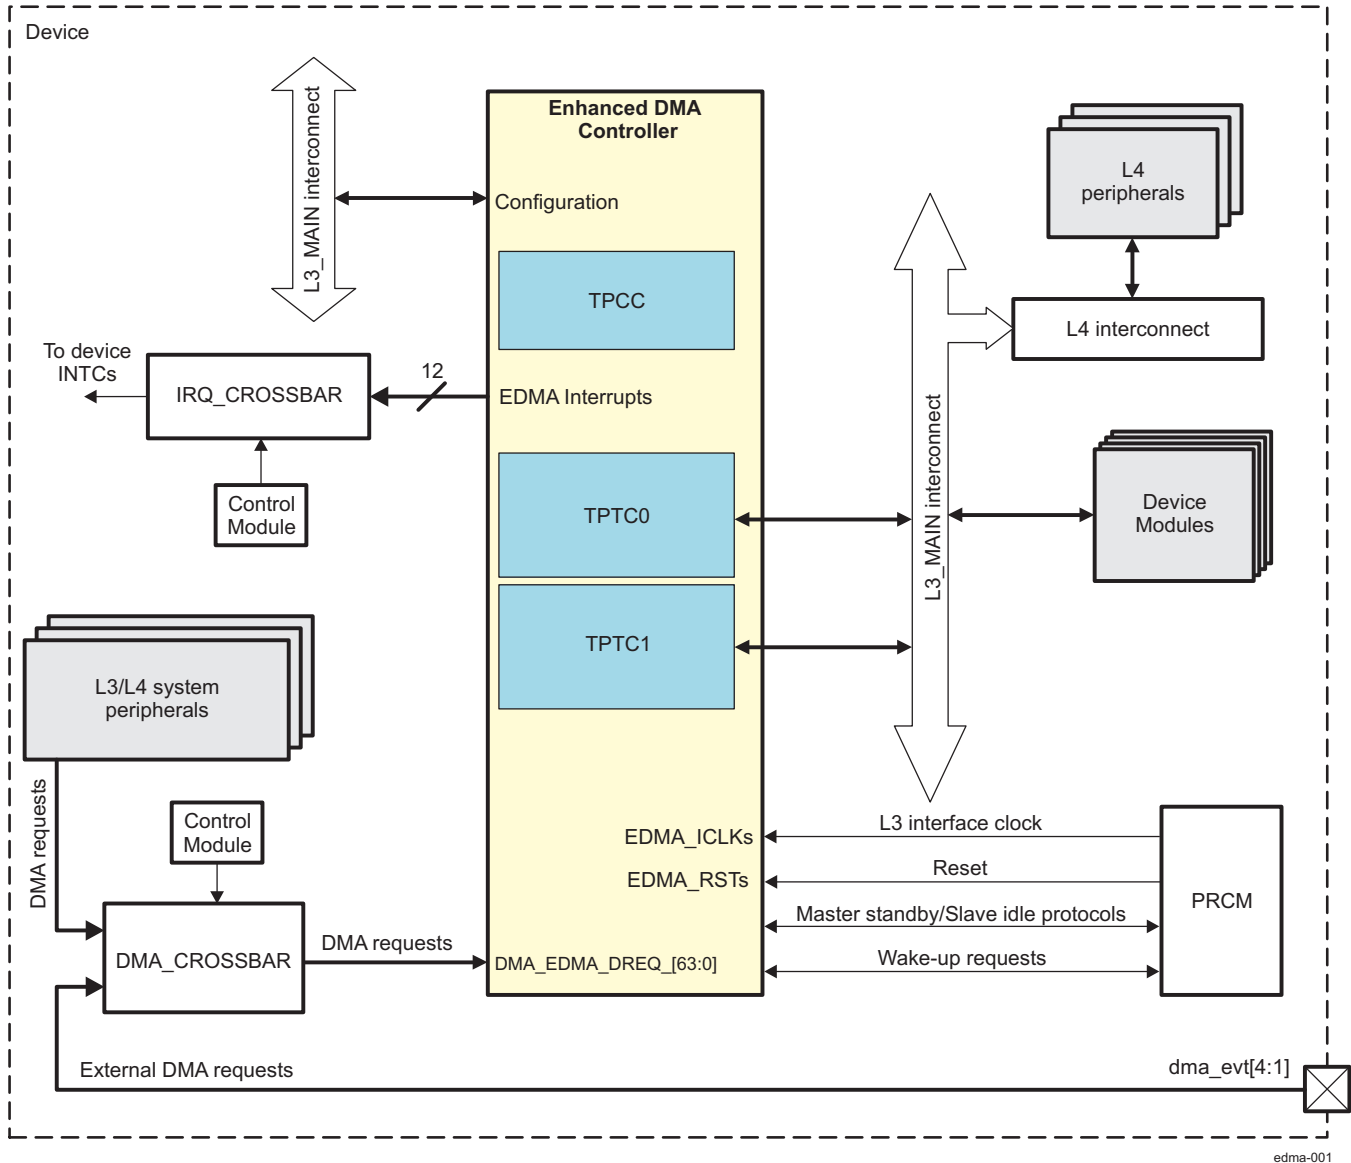

- One TPCC instance
- Two TPTC instances

NOTE: All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see [Section 12.1.2, EDMA Controllers Configuration](#)).

This chapter is mostly focused on describing the system-level EDMA module (in terms of configuration and integration in the SoC). For details on DSPx_EDMA / EVEx_EDMA integration, see their respective chapters.

[Figure 12-1](#) shows an overview of the EDMA module.

Figure 12-1. EDMA Module Overview

The device CPUs can configure the EDMA controller blocks through the L3_MAIN interconnect.

12.1.1 EDMA Features

The **EDMA_TPCC** channel controller has following features:

- Fully orthogonal transfer description:
 - Three transfer dimensions.
 - A-synchronized transfers: one-dimension serviced per event.
 - AB-synchronized transfers: two-dimensions serviced per event.
 - Independent indexes on source and destination.
 - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
 - Increment or FIFO transfer addressing modes.
 - Linking mechanism allows automatic PaRAM set update.

- Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
 - Transfer completion.
 - Error conditions.
- Debug visibility:
 - Queue water marking/threshold.
 - Error and status recording to facilitate debug.
- 64 DMA request channels:
 - Event synchronization.
 - Manual synchronization (CPU(s) write to event set registers [EDMA_TPCC_ESR](#) and [EDMA_TPCC_ESRH](#)).
 - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
 - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
 - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
 - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Two transfer controllers/event queues.
- 16 event entries per event queue.
- Memory protection support:
 - Proxy memory protection for TR submission.
 - Active memory protection for accesses to PaRAM and registers.

The **EDMA_TPTC** transfer controller has the following features:

- Two transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

EDMA controller uses the shared MMU1 module for transferring to and from DSP module. This provides several benefits including:

- Protection of Host CPU memory regions from accidental corruption by EDMA TPTCs.
- Direct allocation of buffers in user space without the need for translation between CPU and DSP applications utilizing EDMA TPTCs.

Accesses by the EDMA TPTCs (both TPTC0 and TPTC1) may optionally be routed through the MMU1.

The TPTC0 and TPTC1 routing allows EDMA transfer controller to be used to perform transfers using only the virtual addresses of the associated buffers.

For more information about MMU1 module refer to [Chapter 16 Memory Management Units](#).

NOTE: The device DSP integrated EDMA controller instances (DSP_EDMA_TPCC, DSP_EDMA_TPTC0 and DSP_EDMA_TPTC1) are functionally identical with the device EDMA controller instances (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1). The only difference is that the DSP_EDMA instances are located at different physical addresses.

For detail information about DSPSS refer to [Chapter 4 DSP Subsystem](#).

12.1.2 EDMA Controllers Configuration

[Table 12-1](#) summarizes the configuration for each of the EDMA channel controllers present on the SoC.

Table 12-1. EDMA Channel Controllers Configuration

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVE _x _EDMA CC Configuration
Number of DMA channels (NUM_DMACH)	64	64	16
Number of QDMA channels (NUM_QDMACH)	8	8	8
Number of interrupt channels (NUM_INTCH)	64	64	16
Number of PaRAM set entries (NUM_PARAMENTRY)	512	128	128
Number of event queues (NUM_EVQUE)	2	2	2
Number of transfer controllers (NUM_TC)	2	2	2
Memory protection existence (MPEXIST)	Yes	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes	Yes

[Table 12-2](#) summarizes the configuration of each of the EDMA transfer controllers present on the SoC.

Table 12-2. EDMA Transfer Controllers Configuration

Parameter	SYS_EDMA TC0 / TC1 Configuration	DSPx_EDMA TC0 / TC1 Configuration	EVE _x _EDMA TC0 / TC1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	2048 bytes	2048 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries
Default burst size (DBS)	Defined by CTRL_CORE_CONTROL_ IO_1 register	Defined by DSP_SYS_BUS_CONFIG register	Defined by EVE_BUS_CONFIG register

12.2 EDMA Controller Environment

The EDMA controller supports external DMA requests through the dma_evt[4:1] pins (see Table 12-3). A logical channel can be configured to respond to an external synchronization request.

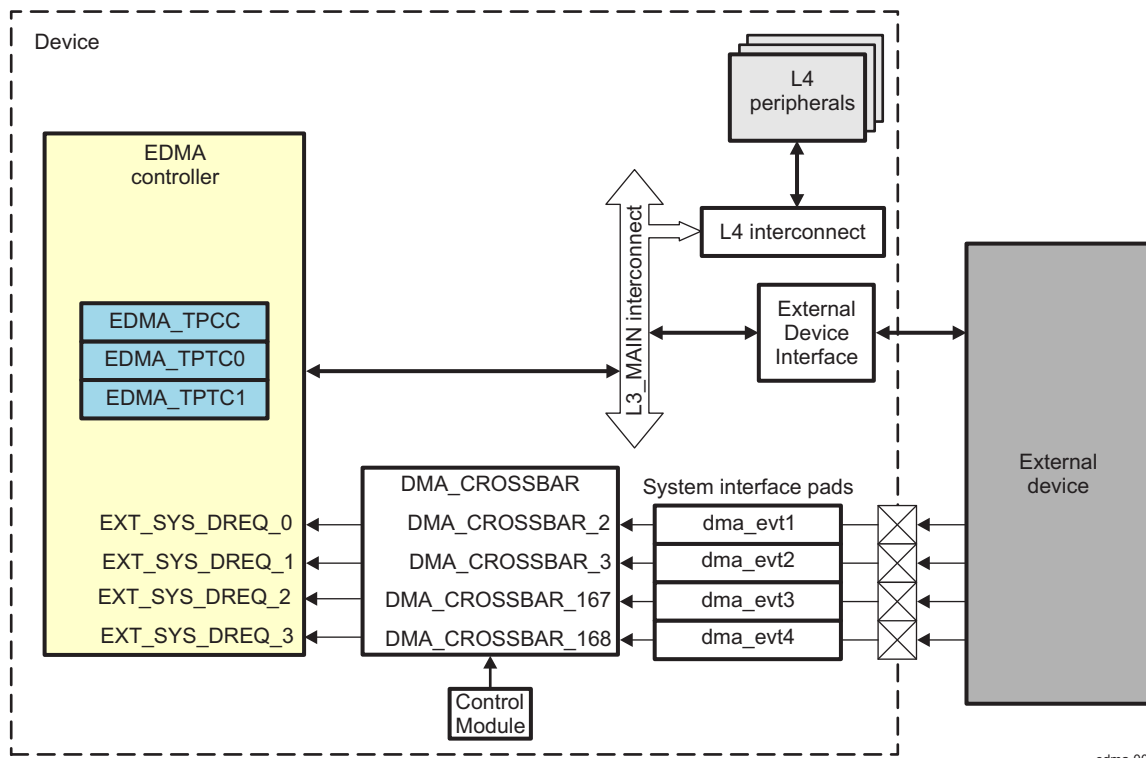

Table 12-3. External EDMA Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O ⁽¹⁾	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

⁽¹⁾ I = Input, O = Output

Figure 12-2 shows an example of how to use the external hardware DMA request pins in the EDMA environment.

Figure 12-2. Example of External DMA Requests Use

edma-005

An external device can use the external DMA request pins to start a logical channel transfer. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, refer to Chapter 14, Control Module.

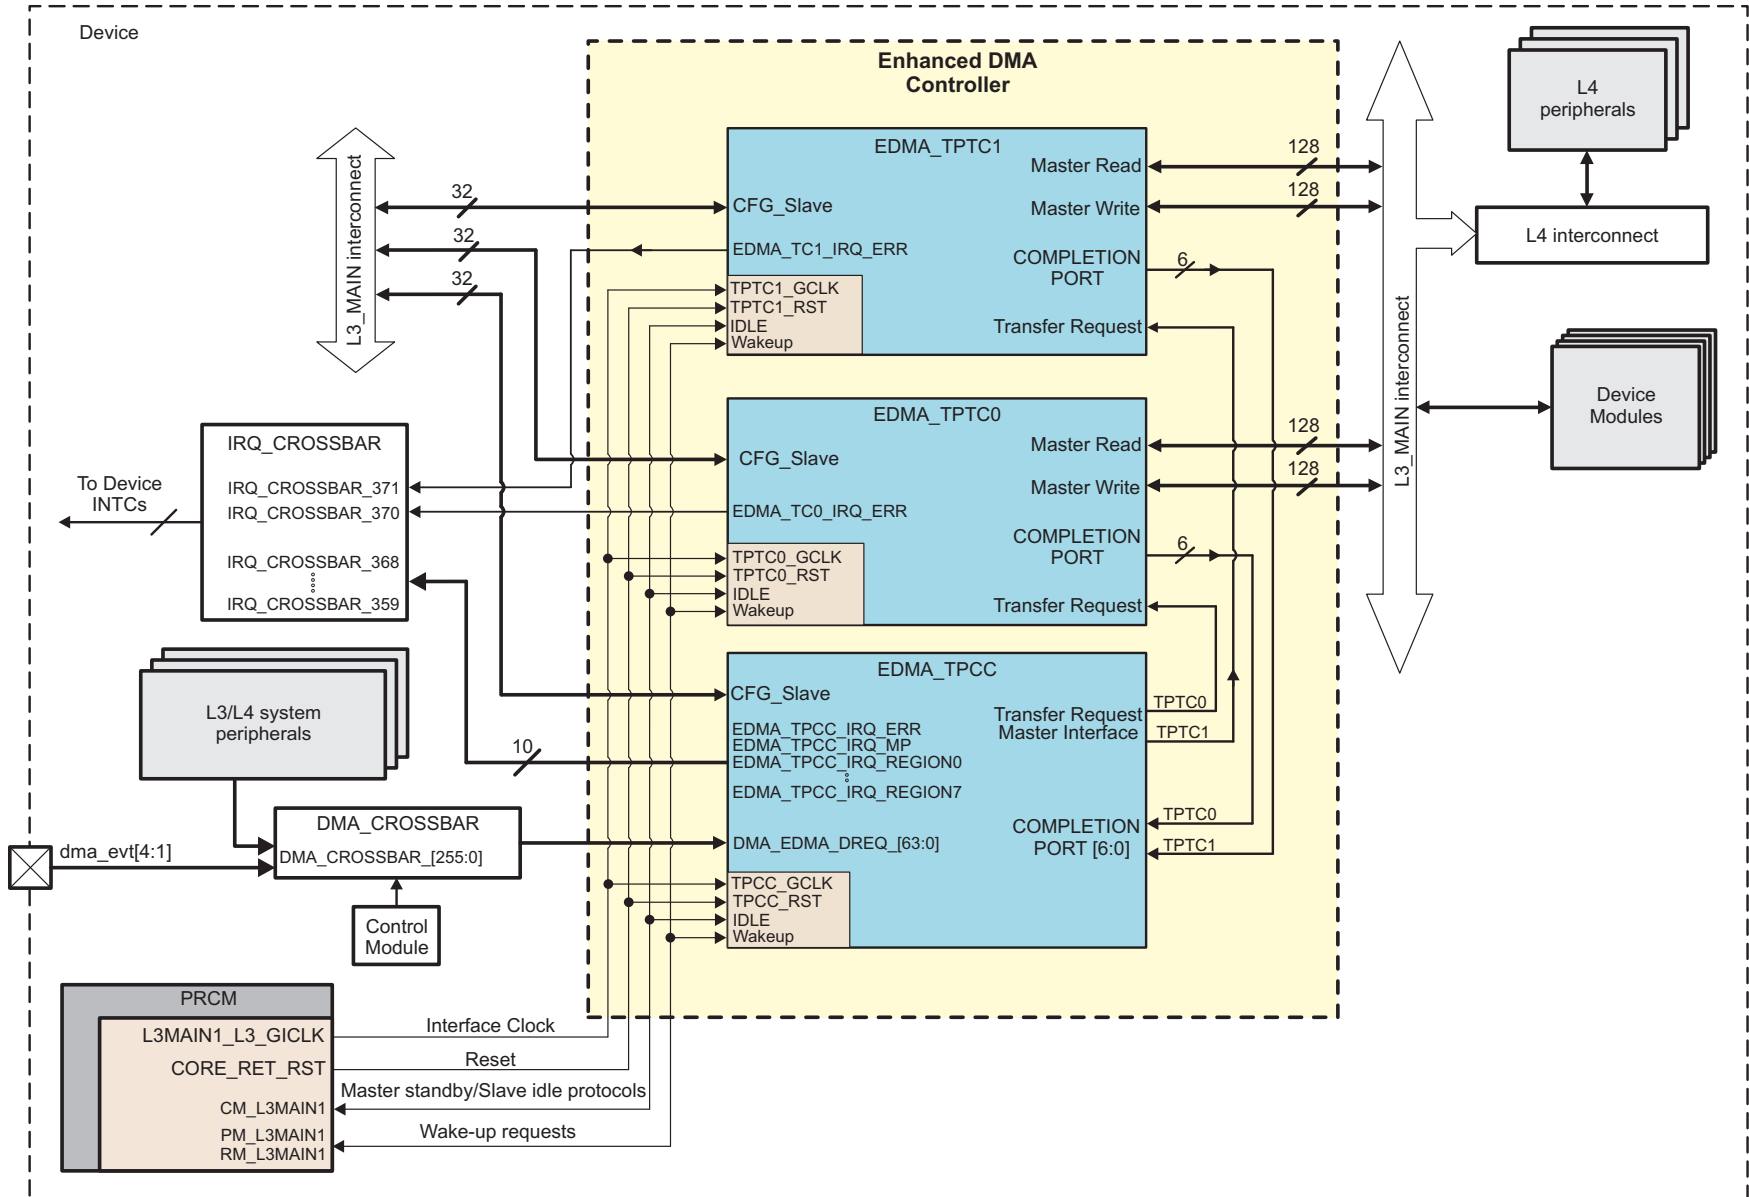

All 64 DMA request lines are transition sensitive.

12.3 EDMA Controller Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

[Figure 12-3](#) shows the EDMA controller integration.

Figure 12-3. EDMA Controller Integration

edma-002

Table 12-4 through Table 12-6 summarize the integration of the module in the device.

Table 12-4. EDMA Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
EDMA_TPCC	PD_COREAON	L3_MAIN
EDMA_TPTC0		
EDMA_TPTC1		

Table 12-5. EDMA Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_GCLK	L3MAIN1_L3_GCLK	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management .
EDMA_TPTC0	EDMA_TPTC0_GCLK			
EDMA_TPTC1	EDMA_TPTC1_GCLK			
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_RST	CORE_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the EDMA controller modules, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, Power, Reset, and Clock Management .
EDMA_TPTC0	EDMA_TPTC0_RST			
EDMA_TPTC1	EDMA_TPTC1_RST			

Table 12-6. EDMA Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR INPUT	Default mapping	Description
EDMA_TPCC	EDMA_TPCC_IRQ_ERR	IRQ_CROSSBAR_359	-	TPCC error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_MP	IRQ_CROSSBAR_360	-	TPCC memory protection interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION0	IRQ_CROSSBAR_361	-	TPCC Region 0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 12-6. EDMA Hardware Requests (continued)

EDMA_TPCC_IRQ_REGION1	IRQ_CROSSBAR_362	-	TPCC Region 1 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION2	IRQ_CROSSBAR_363	-	TPCC Region 2 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION3	IRQ_CROSSBAR_364	-	TPCC Region 3 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION4	IRQ_CROSSBAR_365	-	TPCC Region 4 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION5	IRQ_CROSSBAR_366	-	TPCC Region 5 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION6	IRQ_CROSSBAR_367	-	TPCC Region 6 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION7	IRQ_CROSSBAR_368	-	TPCC Region 7 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPTC0	EDMA_TC0_IRQ_ERR	IRQ_CROSSBAR_370	-	TPTC0 error interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC1	EDMA_TC1_IRQ_ERR	IRQ_CROSSBAR_371	-	TPTC1 error interrupt. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “Default Mapping” column in [Table 12-6 EDMA Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules. For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: [Section 14.4.6.4 IRQ_CROSSBAR Module Functional Description](#) and [Section 14.4.6.5 DMA_CROSSBAR Module Functional Description](#), in [Chapter 14 Control Module](#). For more information about the device interrupt controllers, see [Chapter 13 Interrupt Controllers](#).

NOTE: For a description of the interrupt source, see [Section 12.4.9, EDMA interrupts](#).

12.3.1 DMA Requests to the EDMA Controller

[Table 12-7](#) lists the default DMA sources for the EDMA controller. In addition, the EDMA inputs (DMA_EDMA_DREQ_[63:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in [Table 12-8](#). The CTRL_CORE_DMA_EDMA_DREQ_y_z registers (where y and z are indexes of EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 12-7. EDMA Default Request Mapping

DMA Request Line	DMA CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_0	1	CTRL_CORE_DMA_EDMA_DREQ_0_1 [7:0]	1	Reserved	Reserved
DMA_EDMA_DREQ_1	2	CTRL_CORE_DMA_EDMA_DREQ_0_1 [23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)

12.3.2 Mapping of DMA Requests to DMA_CROSSBAR Inputs

NOTE: The information about the DMA_CROSSBAR module, see in the [Section 14.4.6.5 DMA_CROSSBAR Module Functional Description](#) from the *Control Module* in the device TRM.

[Table 12-8](#) lists the DMA_CROSSBAR inputs request mapping.

NOTE: All DREQs from column “Device Module DREQs” can also be mapped to an input of the device ESM using dedicated DMA_CROSSBAR register. For more information, see *IRQ_CROSSBAR Registers Associated With The Device ESM* in *Control Module*

Table 12-8. Connection of The Device DREQs to The DMA_CROSSBAR Inputs

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_0	Reserved	Reserved
DMA_CROSSBAR_1	Reserved	Reserved
DMA_CROSSBAR_2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_4	GPMC_DREQ	GPMC request from prefetch engine
DMA_CROSSBAR_5	Reserved	Reserved
DMA_CROSSBAR_6	DISPC_DREQ	The line trigger signal to synchronize a memory to memory logical channel in the DMA is generated by the Display Controller IP.
DMA_CROSSBAR_7	CT_TBR_DREQ	DMA request coming from CT_TBR in DEBUGSS (used to be External DMA request 2 - coming from SOC IOs)
DMA_CROSSBAR_8	Reserved	Reserved
DMA_CROSSBAR_9	ISS_DREQ_1	ISS DMA request 1
DMA_CROSSBAR_10	ISS_DREQ_2	ISS DMA request 2
DMA_CROSSBAR_11	Reserved	Reserved

12.4 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller.

12.4.1 Block Diagram

Figure 12-4 shows the functional block diagram of the EDMA controller.

Figure 12-4. EDMA Controller Block Diagram

12.4.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 12-5 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- **Parameter RAM (PaRAM):** The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- **EDMA event and interrupt processing registers:** Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- **Event queues:** Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Memory protection registers:** Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

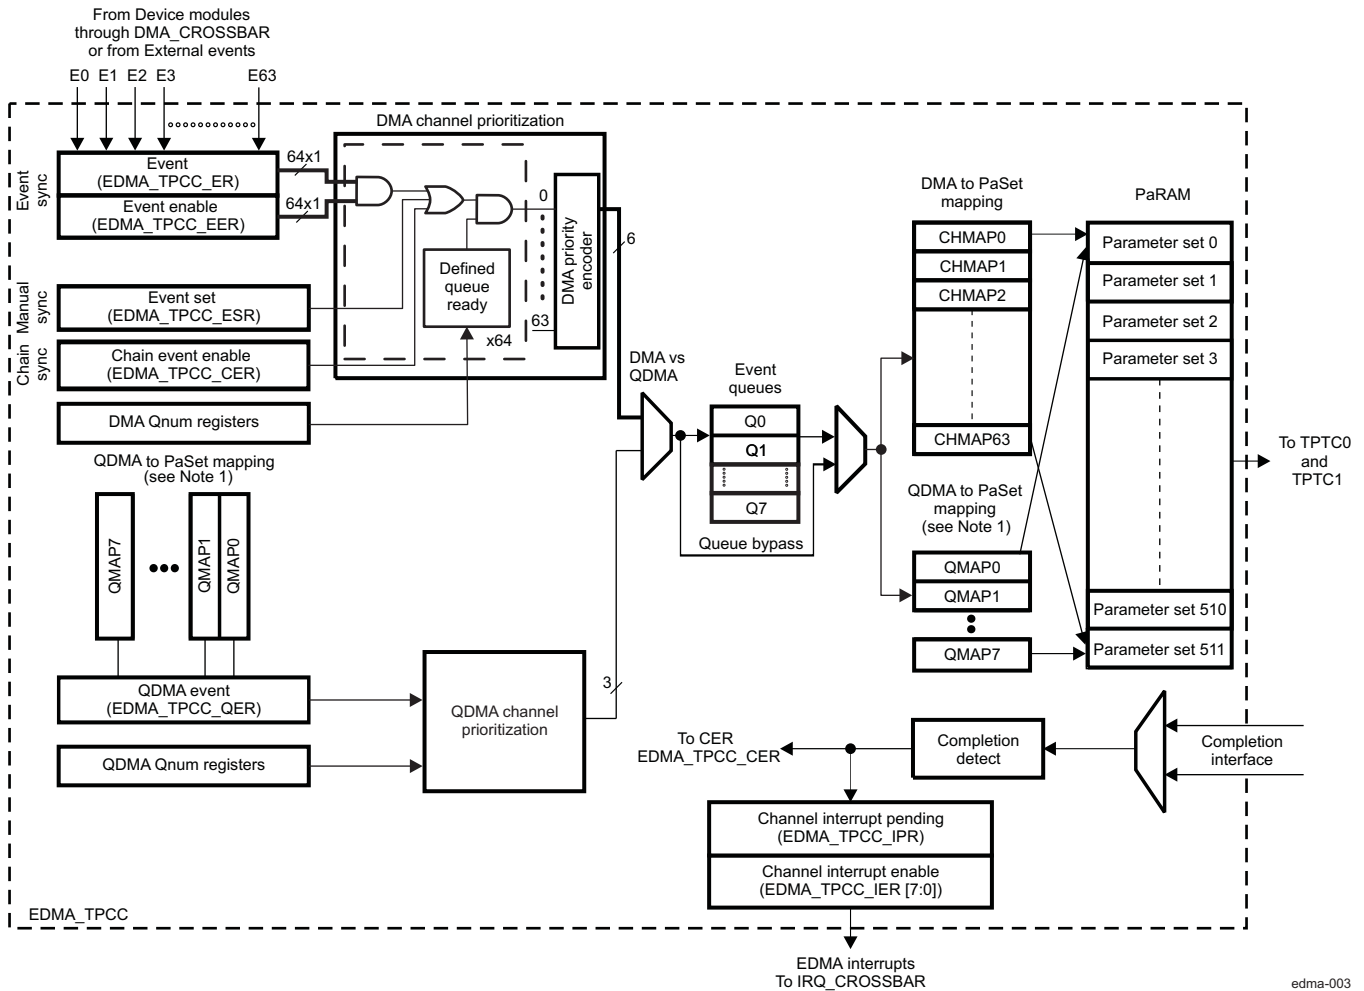

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, DSPs).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 12-5 is a block diagram of the EDMA_TPCC.

Figure 12-5. EDMA Channel Controller Block Diagram

(1) Although it is depicted twice in Figure 12-5, there is only one physical register set for the QDMA to PaRAM set mapping block.

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events (such as McSPI modules TX event and McSPI modules RX event) by the event set registers [EDMA_TPCC_ESR](#) and [EDMA_TPCC_ESRH](#), or through chaining register [EDMA_TPCC_CER](#).
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

edma-003

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaPARAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

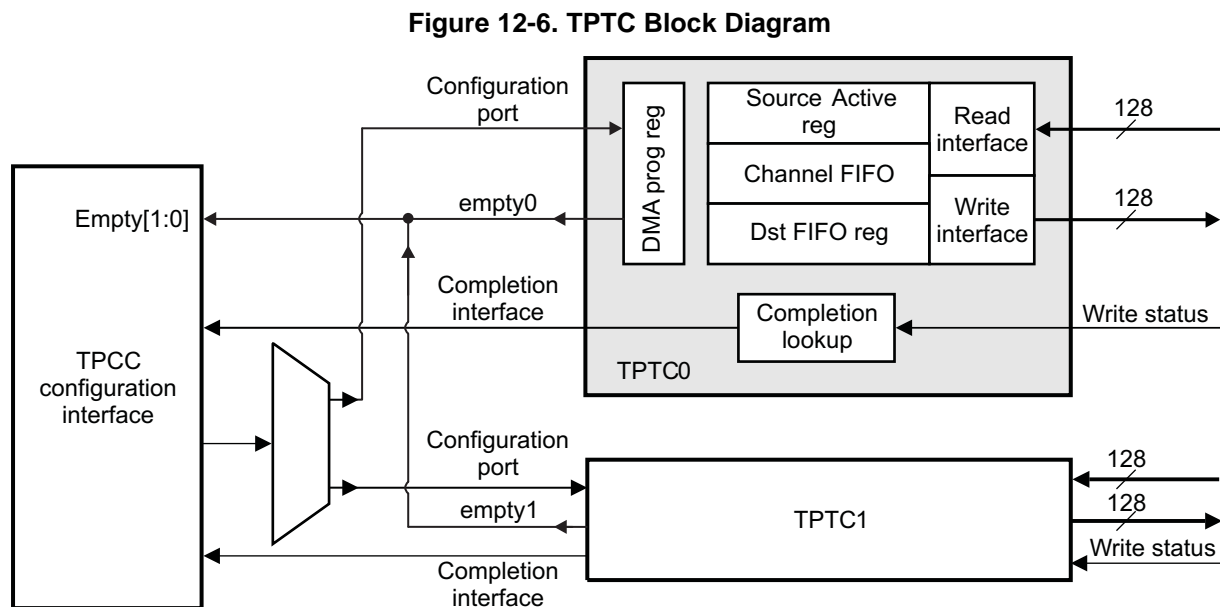

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaPARAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaPARAM entry in anticipation of the next trigger event for that PaPARAM entry.

The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events [EDMA_TPCC_EMR](#) and [EDMA_TPCC_EMRH](#) registers, exceeding event queue thresholds in [EDMA_TPCC_CCERR](#) register, etc.).

12.4.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

[Figure 12-6](#) shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

NOTE: The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- **DMA Program Register Set:** Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- **Source Active Register Set :** Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in

progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

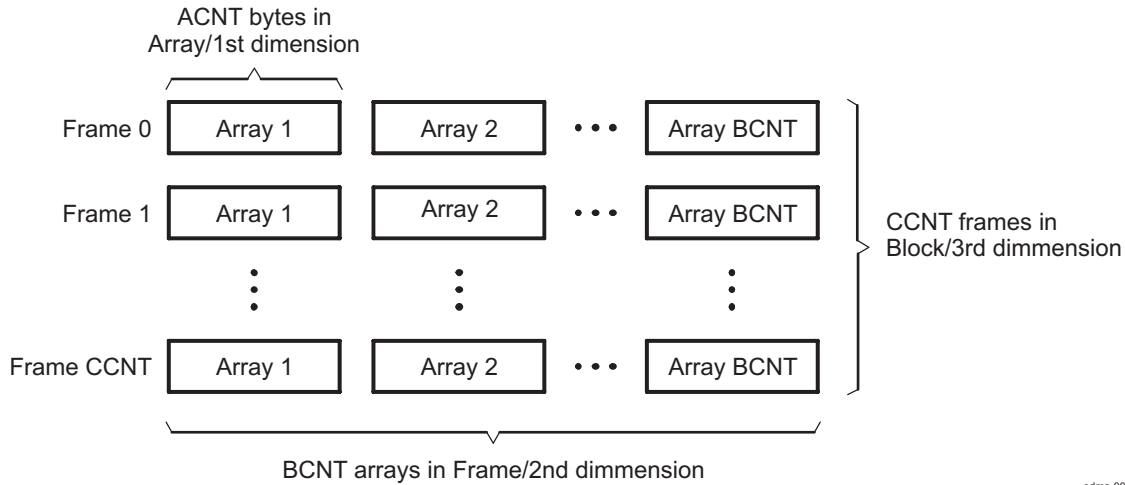

12.4.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 12-7 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

NOTE: The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 12-7. Definition of ACNT, BCNT, and CCNT

edma-007

12.4.2.1 A-Synchronized Transfers

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX and [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX, as shown in [Figure 12-8](#), where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in [EDMA_TPCC_BIDX_n](#) register.

Frames are always separated by [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX and [EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in [Figure 12-8](#), SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

[Figure 12-8](#) shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See [Figure 12-8](#) for details on parameter set updates.

Figure 12-8. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

edma-008

12.4.2.2 AB-Synchronized Transfers

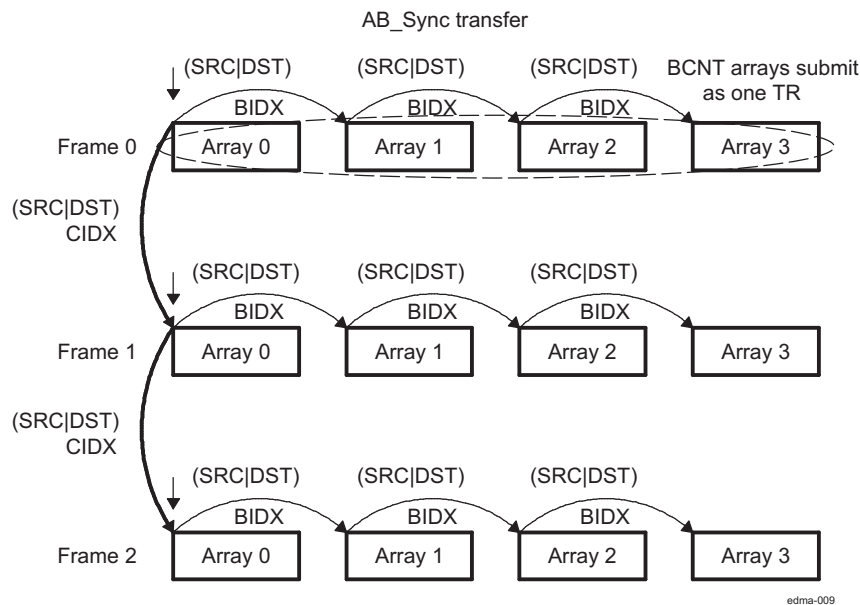

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 12-9. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 12.4.3.6 Parameter Set Updates for details on parameter set updates.

Figure 12-9 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 12-9. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

NOTE: ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

12.4.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels

- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by [EDMA_TPCC_DCHMAPN_m](#) and [EDMA_TPCC_QCHMAPN_j](#) registers.

Table 12-9. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters ⁽¹⁾
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

⁽¹⁾ The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

12.4.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in [Figure 12-10](#) and described in [Table 12-10](#). Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 12-10. PaRAM Set

edma-010

Table 12-10. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h ⁽¹⁾	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n [15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n [31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h ⁽¹⁾	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n [15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n [31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h ⁽¹⁾	LINK	Link Address EDMA_TPCC_LNK_n [15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRL	BCNT Reload EDMA_TPCC_LNK_n [31:16] BCNTRL bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h ⁽¹⁾	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n [15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n [31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n [15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

⁽¹⁾ If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

12.4.3.2 EDMA Channel PaRAM Set Entry Fields

12.4.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the [EDMA_TPCC_OPT_n](#) register description in [Section 12.7.2.2.1, EDMA_TPCC Register Description](#).

12.4.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to [Section 12.4.12.3 Error Generation](#) for additional details.

12.4.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to [Section 12.4.12.3 Error Generation](#) for additional details.

12.4.3.2.4 Count for 1st Dimension (ACNT)

[EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA_TPCC_OPT_n](#).

Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 12.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

12.4.3.2.5 Count for 2nd Dimension (BCNT)

[EDMA_TPCC_ABCNT_n\[15:0\]](#) BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA_TPCC_OPT_n](#).

Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 12.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

12.4.3.2.6 Count for 3rd Dimension (CCNT)

[EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA_TPCC_OPT_n](#).

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 12.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

12.4.3.2.7 BCNT Reload (BCNTRLD)

[EDMA_TPCC_LNK_n\[31:16\]](#) BCNTRLD is a 16-bit unsigned value used to reload the [EDMA_TPCC_ABCNT_n\[15:0\]](#) BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

12.4.3.2.8 Source B Index (SBIDX)

[EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX = FFFFh (−1): the address offset from the beginning of an array to the beginning of the next array in a frame is −1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

12.4.3.2.9 Destination B Index (DBIDX)

[EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to [Section 12.4.3.2.8 Source B Index \(SBIDX\)](#) for examples.

12.4.3.2.10 Source C Index (SCIDX)

[EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 12-8](#)), while the current array in an AB-synchronized transfer is the first array in the frame ([Figure 12-9](#)).

12.4.3.2.11 Destination C Index (DCIDX)

[EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 12-8), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 12-9).

12.4.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter `EDMA_TPCC_LNK_n[15:0]` LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programmed value in the `EDMA_TPCC_LNK_n[15:0]` LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in `EDMA_TPCC_LNK_n[15:0]` LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the `EDMA_TPCC_LNK_n[15:0]` LINK field is set to FFFFh. Also, see Section 12.4.5 *Completion of a DMA Transfer* for details on terminating a transfer.

12.4.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (`EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, and `EDMA_TPCC_CCNT_n[15:0]` CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (`EDMA_TPCC_EMR`, `EDMA_TPCC_EMRH`, or `EDMA_TPCC_QEMR`). This bit remains set in the associated secondary event register (`EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER`).

This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in `EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER` for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

12.4.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (`EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, or `EDMA_TPCC_CCNT_n[15:0]` CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (`EDMA_TPCC_EMR`, `EDMA_TPCC_EMRH`, or `EDMA_TPCC_QEMR`) and the secondary event register (`EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER`) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

12.4.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E_n) in `EDMA_TPCC_EMR` to get set and the E_n bit in `EDMA_TPCC_SER` remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 12-11 summarizes the conditions and effects of null and dummy transfer requests.

Table 12-11. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH , EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

12.4.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT after submission of every transfer request.

Refer to [Table 12-12](#) for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in [Section 12.4.3.7 Linking Transfers](#).

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT, [EDMA_TPCC_LNK_n\[31:16\]](#) BCNTRLD, [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX, [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX, [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX, [EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX, [EDMA_TPCC_OPT_n](#), [EDMA_TPCC_LNK_n\[15:0\]](#)LINK.
- AB-synchronized: [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT, [EDMA_TPCC_LNK_n\[31:16\]](#) BCNTRLD, [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX, [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX, [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX, [EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX, [EDMA_TPCC_OPT_n](#), [EDMA_TPCC_LNK_n\[15:0\]](#)LINK.

NOTE: PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in [Section 12.4.12 EDMA Transfer Controller \(EDMA_TPTC\)](#). For A-synchronized transfers, the EDMA_TPCC always submits a TRP for [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT bytes ([EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT = 1 and [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT bytes of BCNT arrays ([EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT and [EDMA_TPCC_OPT_n\[10:8\]](#) FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX and [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX.

Table 12-12 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 12-12. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_C CNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0] LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0] LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT ⁽¹⁾	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

⁽¹⁾ In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

NOTE: The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

12.4.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field of the current parameter set. Linking only occurs when the [EDMA_TPCC_OPT_n\[3\]](#) STATIC bit is cleared.

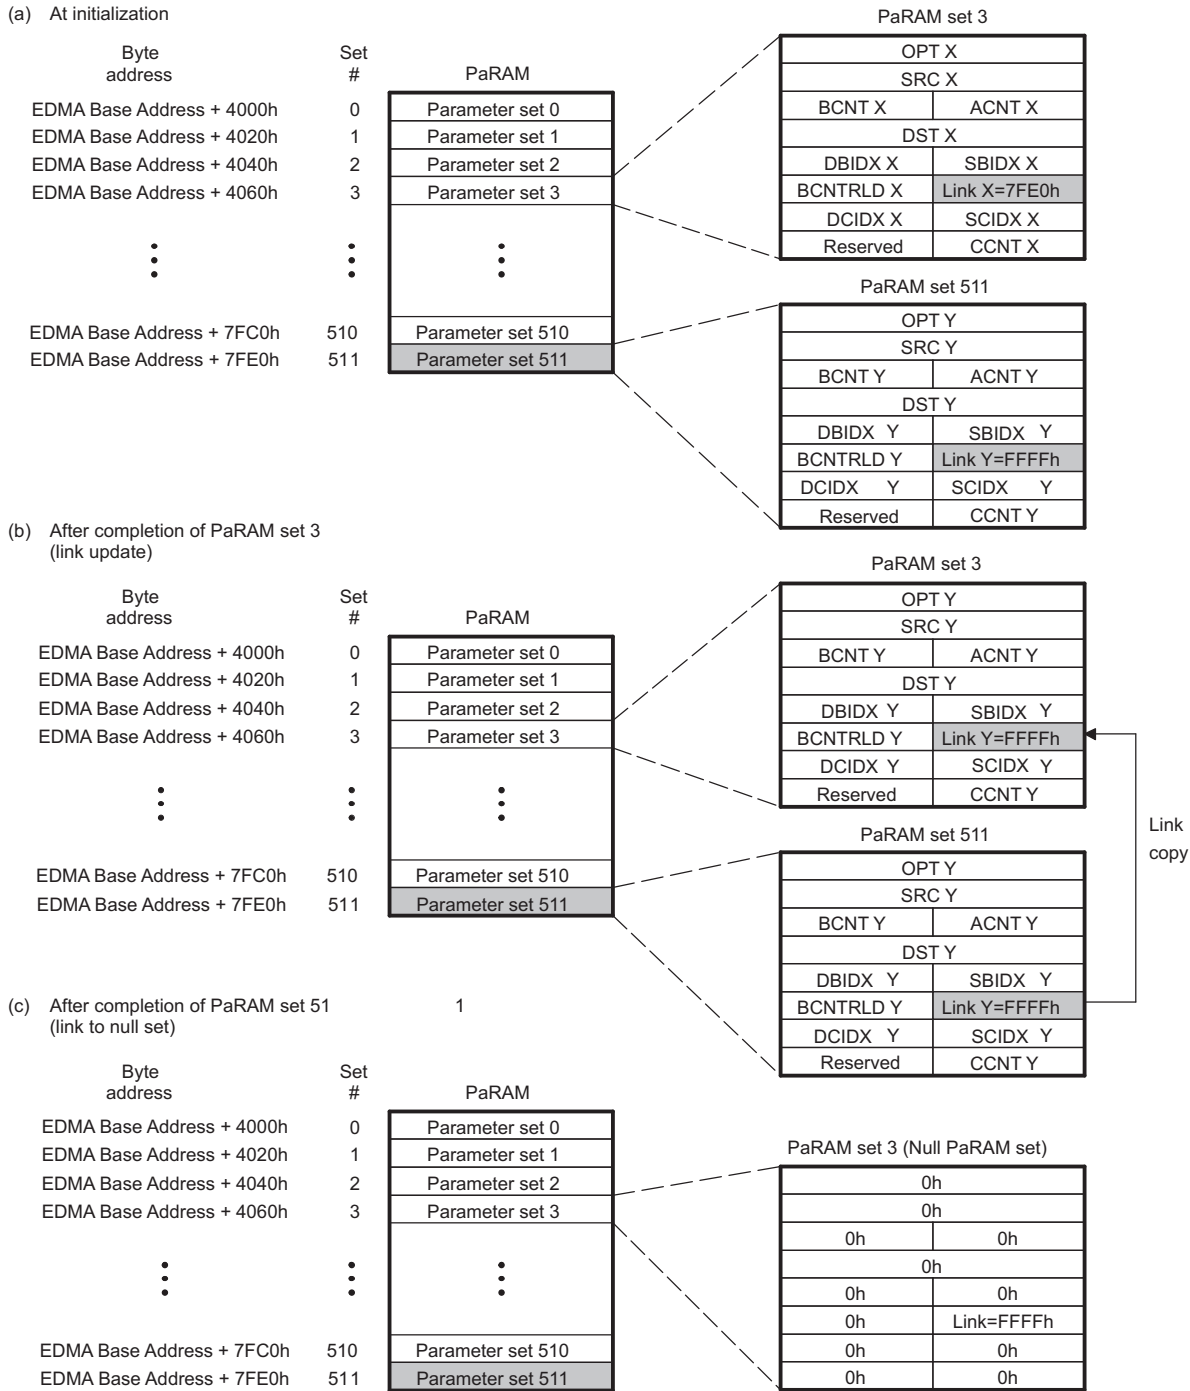

NOTE: It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to [Section 12.4.3.3 Null PaRAM Set](#).

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the [EDMA_TPCC_OPT_n\[3\]](#) STATIC bit and the [EDMA_TPCC_LNK_n\[15:0\]](#) LINK field. In both cases (null or dummy), if the value of [EDMA_TPCC_LNK_n\[15:0\]](#) LINK is FFFFh, then a null PaRAM set (with all 0s and [EDMA_TPCC_LNK_n\[15:0\]](#) LINK set to FFFFh) is written to the current PaRAM set. Similarly, if [EDMA_TPCC_LNK_n\[15:0\]](#) LINK is set to a value other than FFFFh, then the appropriate PaRAM location that [EDMA_TPCC_LNK_n\[15:0\]](#) LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by [EDMA_TPCC_LNK_n\[15:0\]](#) LINK and writes all eight words to the PaRAM set that is associated with the current channel. [Figure 12-11](#) shows an example of a linked transfer.

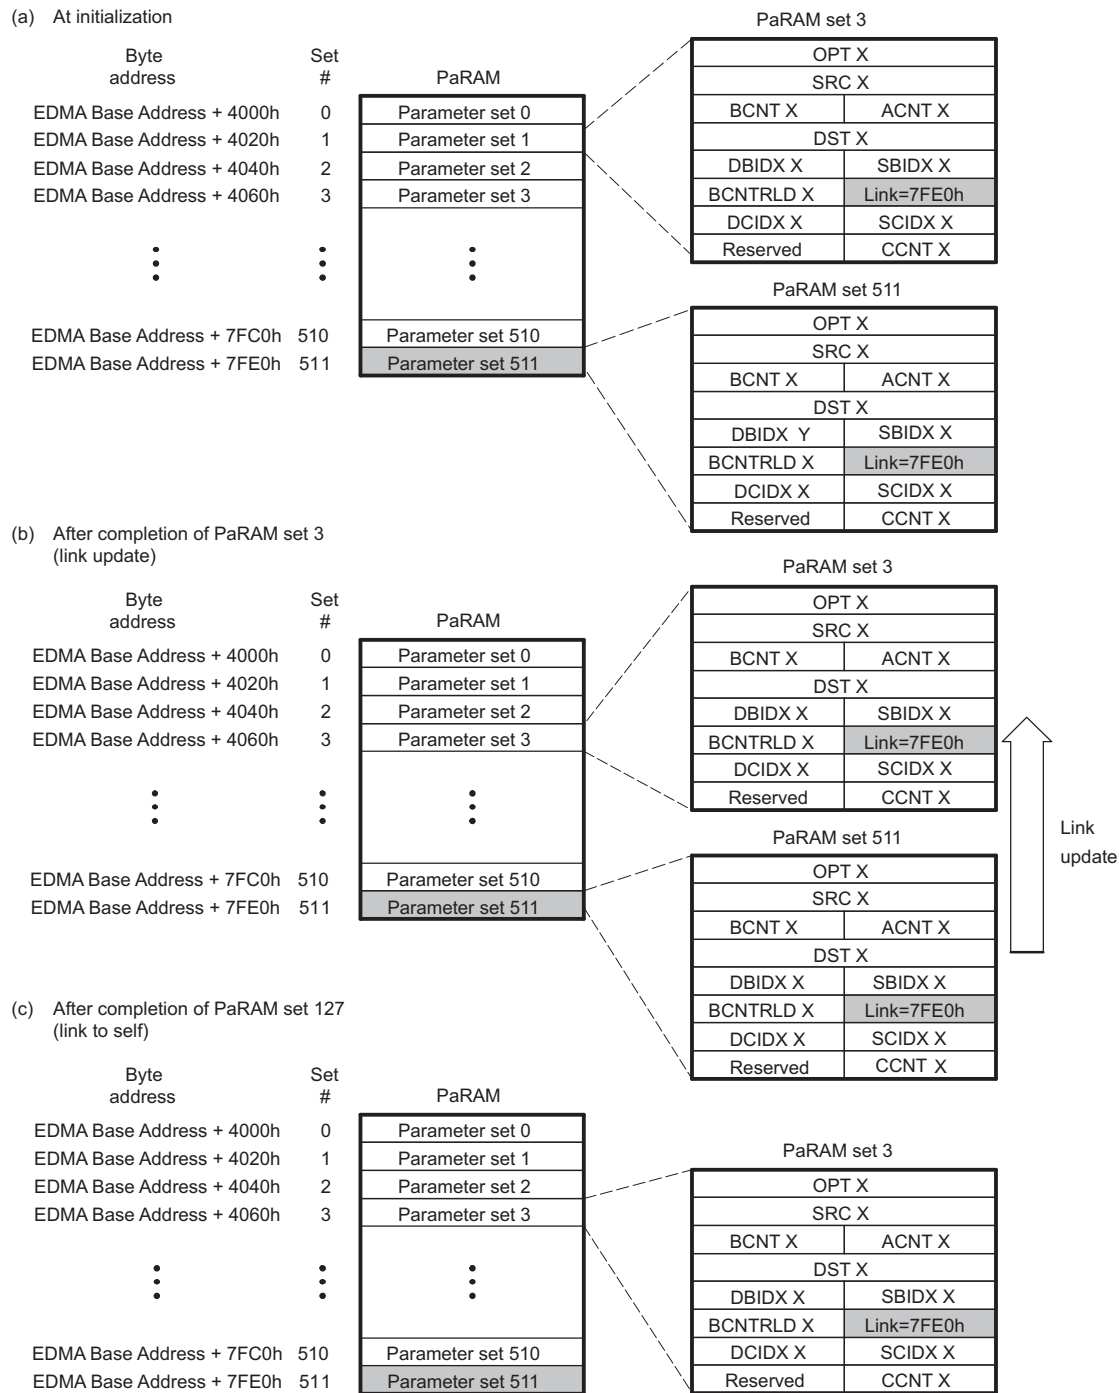

Figure 12-11. Linked Transfer

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to [Section 12.4.6 Event, Channel, and PaRAM Mapping](#)) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by [EDMA_TPCC_QCHMAPN_j](#) register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in [EDMA_TPCC_QER](#) because a write to the trigger word was performed. This feature is used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to [Section 12.4.4.2 QDMA Channels](#).

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 12-12 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

Figure 12-12. Link-to-Self Transfer

edma-012

NOTE: If the in `EDMA_TPCC_OPT_n[3]` STATIC bit is set for a PaRAM set, then link updates are not performed.

12.4.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either `EDMA_TPCC_OPT_n[0]` SAM or `EDMA_TPCC_OPT_n[1]` DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding `EDMA_TPCC_BIDX_n` is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to [Section 12.4.12.3 Error Generation](#).

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (`EDMA_TPCC_OPT_n[0]` SAM / `EDMA_TPCC_OPT_n[1]` DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (`EDMA_TPCC_OPT_n[0]` SAM / `EDMA_TPCC_OPT_n[1]` DAM = 0) by appropriately programming the count and indices values.

12.4.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: `EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, and `EDMA_TPCC_CCNT_n[15:0]` CCNT. An element-indexed transfer is logically achieved by programming `EDMA_TPCC_ABCNT_n[15:0]` ACNT to the size of the element and `EDMA_TPCC_ABCNT_n[31:16]` BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the `EDMA_TPCC_ABCNT_n[15:0]` ACNT = 2 (2 bytes) and `EDMA_TPCC_ABCNT_n[31:16]` BCNT = 256.

12.4.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:** The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (`EDMA_TPCC_ESR` / `EDMA_TPCC_ESRH`).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

12.4.4.1 DMA Channels

12.4.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (`EDMA_TPCC_ER[31:0]` $E_n = 1$). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.

If the corresponding event in the event enable register (`EDMA_TPCC_EER`) is enabled (`EDMA_TPCC_EER[31:0]` $E_n = 1$), then the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the `EDMA_TPCC_ER[31:0]` E_n bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see [Section 12.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding `EDMA_TPCC_ER[31:0] En` bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (`EDMA_TPCC_EMR[31:0] En = 1`) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (`EDMA_TPCC_ER[31:0] En = 1`), regardless of the state of `EDMA_TPCC_EER[31:0] En`. If the event is disabled when an external event is received (`EDMA_TPCC_ER[31:0] En = 1` and `EDMA_TPCC_EER[31:0] En = 0`), the `EDMA_TPCC_ER[31:0] En` bit remains set. If the event is subsequently enabled (`EDMA_TPCC_EER[31:0] En = 1`), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the `EDMA_TPCC_ER[31:0] En` bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (`EDMA_TPCC_ER[31:0] En != 0`), then the second event is registered as a missed event in the corresponding bit of the event missed register (`EDMA_TPCC_EMR[31:0] En = 1`).

12.4.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register `EDMA_TPCC_ESR`. Writing a 1 to an event bit in the `EDMA_TPCC_ESR` results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the `EDMA_TPCC_EER[31:0] En` bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 12.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding `EDMA_TPCC_ER[31:0] En` bit is cleared and simultaneously the corresponding channel bit is set in the event miss register `EDMA_TPCC_EMR[31:0] En = 1` to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register `EDMA_TPCC_ESR[31:0] En = 1` prior to the original being cleared `EDMA_TPCC_ESR[31:0] En = 0`, then the second event is registered as a missed event in the corresponding bit of the event missed register `EDMA_TPCC_EMR[31:0] En = 1`.

12.4.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code `EDMA_TPCC_OPT_n[17:12] TCC` of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register `EDMA_TPCC_CER` to be set (`EDMA_TPCC_CER[31:0] E[TCC] = 1`).

Once a bit is set in `EDMA_TPCC_CER`, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 12.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding `EDMA_TPCC_CER[31:0] En` bit is cleared and simultaneously the corresponding channel bit is set in the event miss register `EDMA_TPCC_EMR[31:0] En = 1` to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (`EDMA_TPCC_CER[31:0] En != 0`), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register `EDMA_TPCC_EMR[31:0] En = 1`.

NOTE: Chained event registers `EDMA_TPCC_CER`, event registers `EDMA_TPCC_ER`, and event set registers `EDMA_TPCC_ESR` operate independently. An event E_n can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

12.4.4.2 QDMA Channels

12.4.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register `EDMA_TPCC_QER[31:0] En = 1`. A bit corresponding to a QDMA channel is set in the QDMA event register `EDMA_TPCC_QER` when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register `EDMA_TPCC_QCHMAPN_j` for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register `EDMA_TPCC_QEER[31:0] En = 1`.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches `EDMA_TPCC_QCHMAPN_j` settings and the corresponding channel is enabled via the QDMA event enable register `EDMA_TPCC_QEER[31:0] En = 1`.

Once a bit is set in `EDMA_TPCC_QER`, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in `EDMA_TPCC_QER[31:0] En = 1` and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register `EDMA_TPCC_QEMR[7:0] En = 1`.

12.4.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

NOTE: The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register `EDMA_TPCC_ESR` to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with `EDMA_TPCC_ABCNT_n[31:0] BCNT = 1` and `EDMA_TPCC_CCNT_n[15:0] CCNT = 1` for A-synchronized transfers, and `EDMA_TPCC_CCNT_n[15:0] CCNT = 1` for AB-synchronized transfers.

Additionally, since linking is also supported (if `EDMA_TPCC_OPT_n[3] STATIC = 0`) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

12.4.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 12-13](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts ([EDMA_TPCC_ABCNT_n\[31:0\]](#) BCNT and/or [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 12-13. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT x CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT x BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or [EDMA_TPCC_OPT_n\[17:12\]](#) TCC along with the other [EDMA_TPCC_OPT_n](#) fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific [EDMA_TPCC_OPT_n\[17:12\]](#) TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register [EDMA_TPCC_CER](#) [TCC] and/or interrupt pending register [EDMA_TPCC_IPR](#) [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set [EDMA_TPCC_OPT_n\[22\]](#) TCCHEN or [EDMA_TPCC_OPT_n\[20\]](#) TCINTEN, for all but the final transfer request (TR) of a parameter set [EDMA_TPCC_OPT_n\[23\]](#) ITCCHEN or [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN), or for all TRs of a parameter set (both). Refer to [Section 12.4.8 Chaining EDMA Channels](#) for details on chaining (intermediate/final chaining) and [Section 12.4.9 EDMA Interrupts](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to [Section 12.4.3.7 Linking Transfers](#) for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#).

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

12.4.5.1 Normal Completion

In normal completion mode [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

12.4.5.2 Early Completion

In early completion mode [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

12.4.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set [Section 12.4.3.4](#) or null set [Section 12.4.3.3](#). In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers [EDMA_TPCC_IPR](#) and [EDMA_TPCC_IPRH](#) or chained event register [EDMA_TPCC_CER](#) and [EDMA_TPCC_CERH](#). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

12.4.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the `dma_evt[4:1]` pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration ([EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT, [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

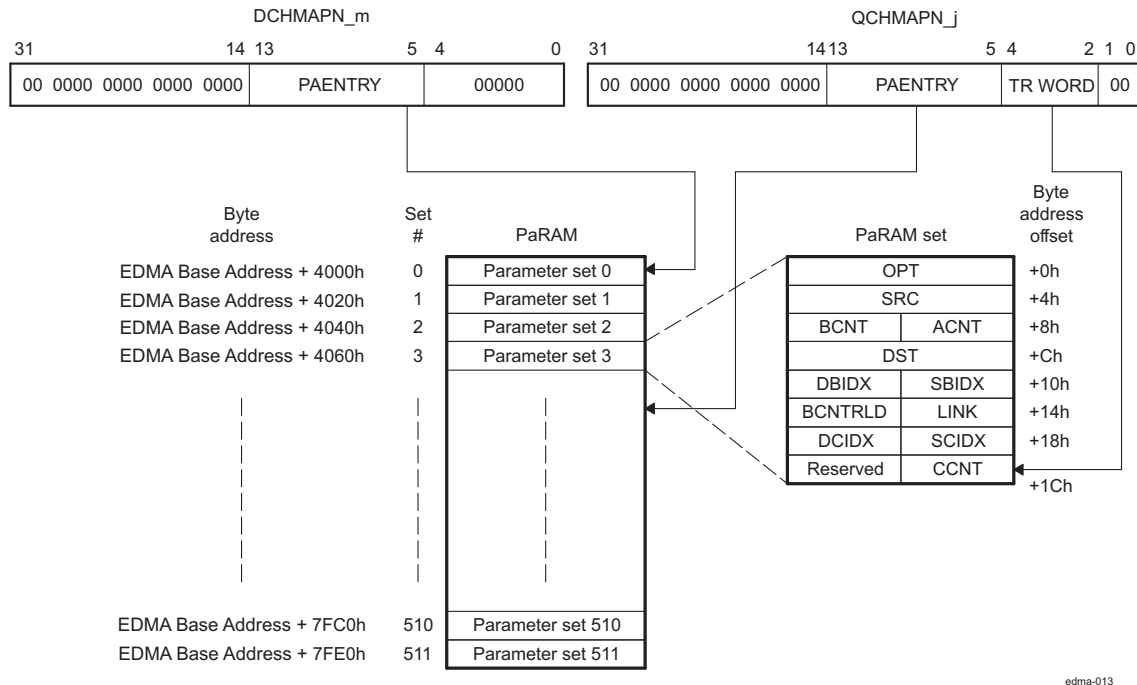

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. The EDMA event crossbar can be used to select which level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in [Section 12.3.1, EDMA Requests to the EDMA Controller](#). The event crossbar mapping is controlled by the device Control Modules registers refer to [Section 14.4.6.4 IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14 Control Module](#).

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

12.4.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see [Table 12-9](#)). The DMA channel mapping registers [EDMA_TPCC_DCHMAPN_m](#) in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. [Figure 12-13](#) illustrates the use of [EDMA_TPCC_DCHMAPN_m](#). There is one [EDMA_TPCC_DCHMAPN_m](#) register per channel.

Figure 12-13. DMA Channel and QDMA Channel to PaRAM Mapping

edma-013

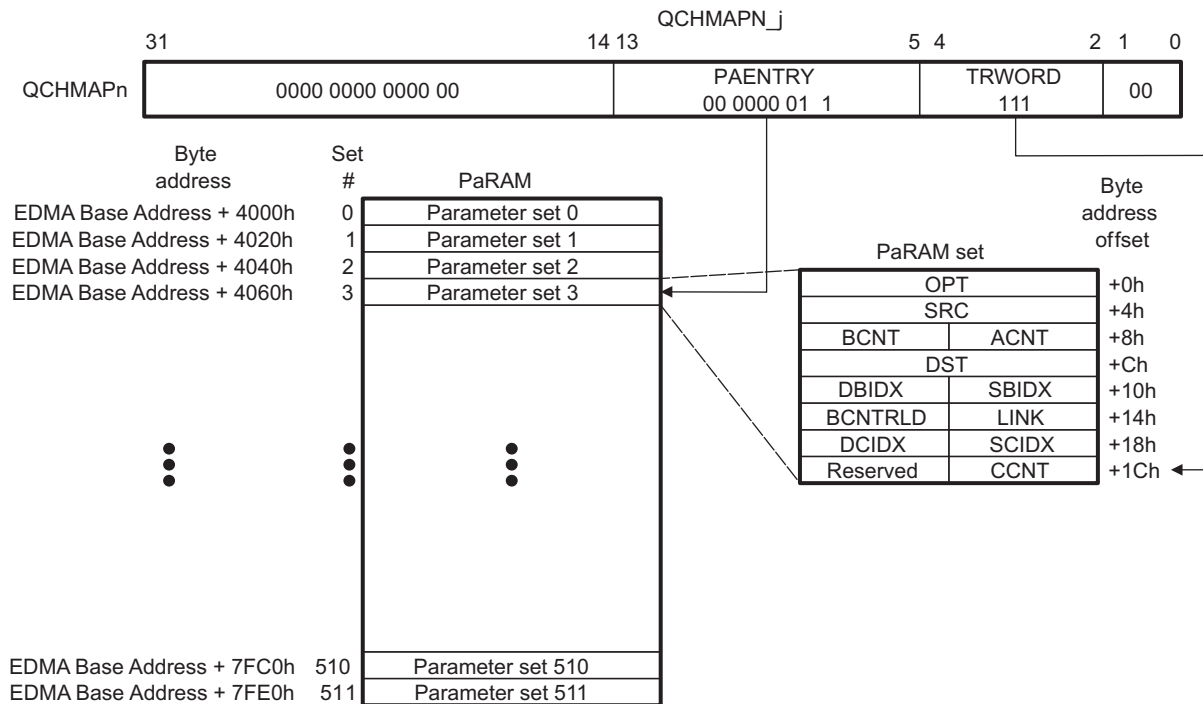

12.4.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register **EDMA_TPCC_QCHMAPN_j** in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. [Figure 12-14](#) illustrates the use of **EDMA_TPCC_QCHMAPN_j**.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by **EDMA_TPCC_QCHMAPN_j** for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

Figure 12-14. QDMA Channel to PaRAM Mapping

edma-014

12.4.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in [Section 12.4.10 Memory Protection](#).

12.4.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow n channel region address range(s). For example, the event enable register [EDMA_TPCC_EER](#) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, ... EDMA Base Address + 2E20h for region 7.

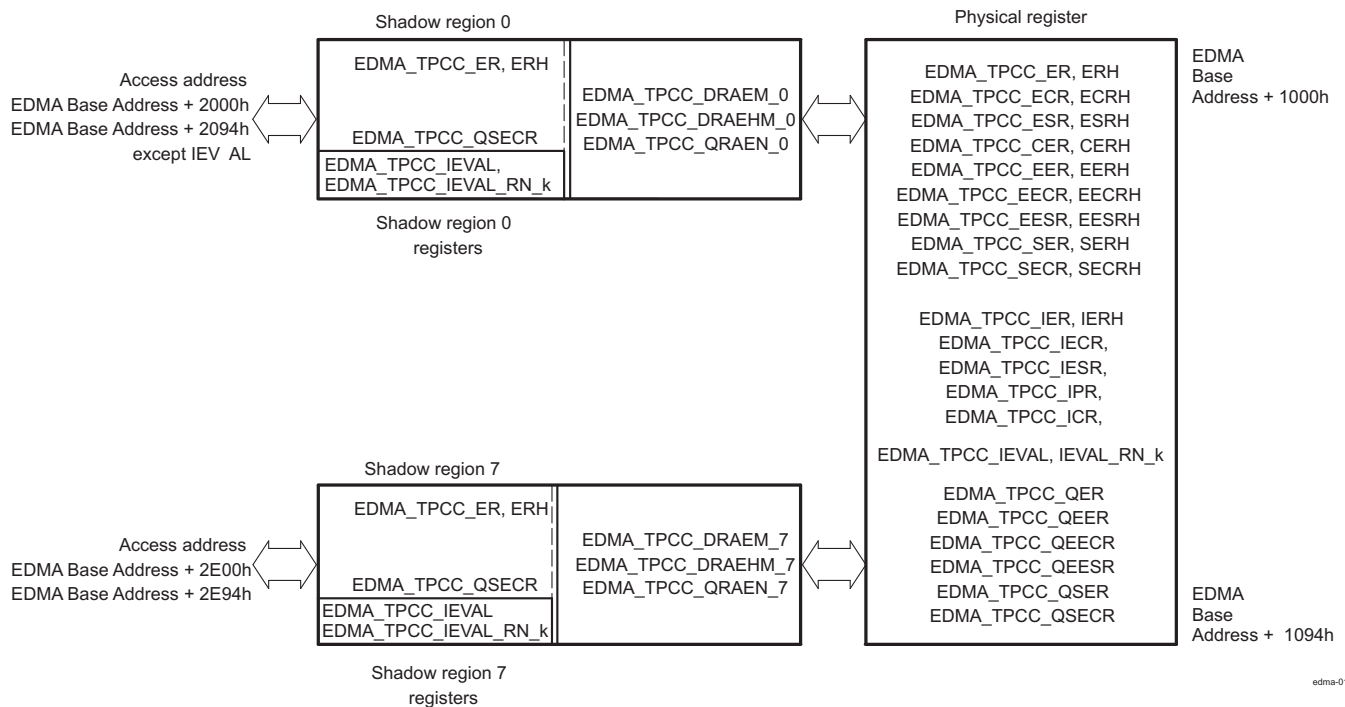

The DMA region access enable registers [EDMA_TPCC_DRAEM_k](#) and the QDMA region access enable registers [EDMA_TPCC_QRAEN_k](#) control the underlying control register bits that are accessible via the shadow region address space (except for [EDMA_TPCC_IEVAL](#) and [EDMA_TPCC_IEVAL_RN_k](#) registers). [Table 12-14](#) lists the registers in the shadow region memory map. Refer to [Table 12-30](#) *EDMA_TPCC register mapping summary* for the complete global and shadow region memory maps.

Figure 12-15. Shadow Region Registers

edma-015

12.4.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- [EDMA_TPCC_DRAEM_k](#) and [EDMA_TPCC_DRAEHM_k](#): One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or [EDMA_TPCC_OPT_n\[17:12\]](#) TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding [EDMA_TPCC_DRAEM_k\[31:0\]](#) / [EDMA_TPCC_DRAEHM_k\[31:0\]](#) bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding [EDMA_TPCC_DRAEM_k\[31:0\]](#) / [EDMA_TPCC_DRAEHM_k\[31:0\]](#) bit forces writes to be discarded and returns a value of 0 for reads.
- [EDMA_TPCC_QRAEN_k](#): One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 [EDMA_TPCC_QEER](#), the corresponding bits in QRAE must be set or writing into [EDMA_TPCC_QEESR](#) there will be no the desired effect.
- [EDMA_TPCC_MPPAN_k](#) and [EDMA_TPCC_MPPAG](#): One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_QRAEN_k](#) registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_QRAEN_k](#) have the associated bit set.

Example 12-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

[EDMA_TPCC_DRAEM_k](#) should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

12.4.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register [EDMA_TPCC_IER](#), DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to [Table 12-6 Hardware Request](#) for more information about EDMA Interrupts.

12.4.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 12.4.3.7 Linking Transfers](#)). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see [Section 12.4.4.1.3 Chain-Triggered Transfer Request](#)).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel m (DMA/QDMA) required to chain to channel n . Channel number n (0-63) needs to be programmed into the `EDMA_TPCC_OPT_n[17:12]` TCC bit-field of channel m channel options parameter (OPT) set.

- If final transfer completion chaining `EDMA_TPCC_OPT_n[22] TCCHEN = 1` is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel m is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining ([EDMA_TPCC_OPT_n\[23\]](#) ITCCHEN = 1) is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining ([EDMA_TPCC_OPT_n\[22\]](#) TCCHEN = 1 and [EDMA_TPCC_OPT_n\[23\]](#) ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 12-15](#) illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT = 3, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT = 4, [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 5, and [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 30.

Table 12-15. Chain Event Triggers

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

12.4.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in [Table 12-16](#). The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 12-16. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1

EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 12-17. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

12.4.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code [EDMA_TPCC_OPT_n\[17:12\]](#) TCC value is directly mapped to the bits of the interrupt pending register [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#).

For example, if [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 10 0001b, [EDMA_TPCC_IPRH\[1\]](#) is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See [Section 12.4.9.1.1 Enabling Transfer Completion Interrupts](#) for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 12-18. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)		EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)		EDMA_TPCC_IPRH Bit Set ⁽¹⁾
0		EDMA_TPCC_IPR[0]	20h		EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1		EDMA_TPCC_IPR[1]	21h		EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h		EDMA_TPCC_IPR[2]	22h		EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h		EDMA_TPCC_IPR[3]	23h		EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h		EDMA_TPCC_IPR[4]	24h		EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	
1Eh		EDMA_TPCC_IPR[30]	3Eh		EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh		EDMA_TPCC_IPR[31]	3Fh		EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

⁽¹⁾ Bit fields [EDMA_TPCC_IPR](#) [32-63] correspond to bits 0 to 31 in [EDMA_TPCC_IPRH](#), respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) and in the corresponding shadow region's DMA region access registers ([EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#)).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt ([EDMA_TPCC_OPT_n\[20\]](#) TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If the intermediate transfer interrupt ([EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts ([EDMA_TPCC_OPT_n\[20\]](#) TCINTEN = 1, and [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 12-19](#) shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with [ABCNT_n\[15:0\]](#) ACNT = 3, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT = 4, [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 5, and [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 30.

Table 12-19. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

12.4.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the [EDMA_TPCC](#). This is in addition to setting up the [EDMA_TPCC_OPT_n\[20\]](#) TCINTEN and [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN bits of the associated PaRAM set.

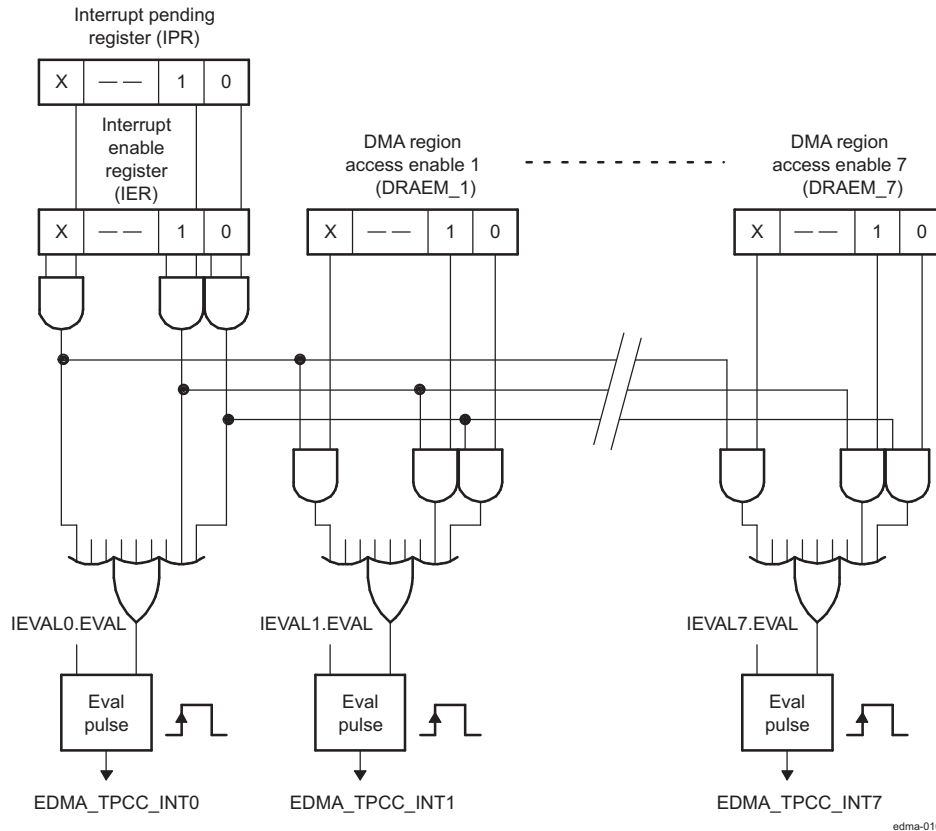

The EDMA channel controller has interrupt enable registers [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) and each bit location in [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) serves as a primary enable for the corresponding interrupt pending registers [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#).

All of the interrupt registers ([EDMA_TPCC_IER](#), [EDMA_TPCC_IESR](#), [EDMA_TPCC_IECR](#), and [EDMA_TPCC_IPR](#)) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) and single set of interrupt enable registers [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#). The programmable DMA region access enable registers [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#), see [Figure 12-16](#)

The region interrupt outputs are gated by [EDMA_TPCC_IER](#) and the specific [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) associated with the region.

[Figure 12-16](#) shows the Interrupt diagram of the EDMA controller.

Figure 12-16. Interrupt Diagram

edma-016

The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: ($EDMA_TPCC_IPR[0] E0 \& EDMA_TPCC_IER[0] E0 \& EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0$) | ($EDMA_TPCC_IPR[1] E1 \& EDMA_TPCC_IER[1] E1 \& EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1$) | ... | ($EDMA_TPCC_IPRH[31] E63 \& EDMA_TPCC_IERH[31] E63 \& EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63$)
- EDMA_TPCC_INT1: ($EDMA_TPCC_IPR[0] E0 \& EDMA_TPCC_IER[0] E0 \& EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0$) | ($EDMA_TPCC_IPR[1] E1 \& EDMA_TPCC_IER[1] E1 \& EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1$) | ... | ($EDMA_TPCC_IPRH[31] E63 \& EDMA_TPCC_IERH[31] E63 \& EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63$)
- EDMA_TPCC_INT2: ($EDMA_TPCC_IPR[0] E0 \& EDMA_TPCC_IER[0] E0 \& EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0$) | ($EDMA_TPCC_IPR[1] E1 \& EDMA_TPCC_IER[1] E1 \& EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1$) | ... | ($EDMA_TPCC_IPRH[31] E63 \& EDMA_TPCC_IERH[31] E63 \& EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63$)....
- Up to EDMA_TPCC_INT7: ($EDMA_TPCC_IPR[0] E0 \& EDMA_TPCC_IER[0] E0 \& EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0$) | ($EDMA_TPCC_IPR[1] E1 \& EDMA_TPCC_IER[1] E1 \& EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1$) | ... | ($EDMA_TPCC_IPRH[31] E63 \& EDMA_TPCC_IERH[31] E63 \& EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63$)

NOTE: The [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the [EDMA_TPCC_OPT_n\[17:12\]](#) TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled ([EDMA_TPCC_OPT_n\[20\]](#) TCINTEN or [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN is set), then based on the TCC value, [EDMA_TPCC_IPRH\[31\]](#) E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to [EDMA_TPCC_IPRH](#) bit that is set upon completion).

12.4.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers ([EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#)) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register ([EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#)). For example, a write of 1 to [EDMA_TPCC_ICR\[0\]](#) E0 clears a pending interrupt in [EDMA_TPCC_IPR\[0\]](#) E0.

If an incoming transfer completion code TCC ([EDMA_TPCC_OPT_n\[17:12\]](#) TCC) gets latched to a bit in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#), then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

12.4.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers ([EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#)), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in [EDMA_TPCC_IPR/EDMA_TPCC_IPRH](#), thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#), thereby resulting in additional interrupts. Each of the bits in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in [Example 12-2](#) and [Example 12-3](#).

The ISR routine in [Example 12-2](#) is more exhaustive and incurs a higher latency.

Example 12-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register [EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#) to clear the corresponding [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) bit(s).
4. Reads [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) again:
 - a. If [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).

Example 12-2. Interrupt Servicing (continued)

- b. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is equal to 0, assure that all of the enabled interrupts are inactive.

NOTE: An event may occur during step 4 while the `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

[Example 12-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 12-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the `EDMA_TPCC_IEVAL[0]` EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`.
3. For the condition that is set in `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`:
 - a. Service interrupt as the application requires.
 - b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to `EDMA_TPCC` after step 2).
4. Reads `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` prior to exiting the ISR:
 - a. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is equal to 0, then exit the ISR.
 - b. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is not equal to 0, then set `EDMA_TPCC_IEVAL` so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

12.4.9.3 Interrupt Evaluation Operations

The `EDMA_TPCC` has interrupt evaluate registers `EDMA_TPCC_IEVAL` that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers `EDMA_TPCC_DRAEM_k` / `EDMA_TPCC_DRAEHM_k`. Writing a 1 to the `EDMA_TPCC_IEVAL[0]` EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via `EDMA_TPCC_IER` / `EDMA_TPCC_IERH`) is still pending `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to [Example 12-3](#) about the use of `EDMA_TPCC_IEVAL` in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register `EDMA_TPCC_EEVAL` exists in the global region. Writing a 1 to the `EDMA_TPCC_EEVAL[0]` EVAL bit causes the pulsing of the error interrupt if any pending errors are in `EDMA_TPCC_EMR` / `EDMA_TPCC_EMRH`, `EDMA_TPCC_QEMR`, or `EDMA_TPCC_CCERR`. See [Section 12.4.9.4 Error Interrupts](#) for additional information regarding error interrupts.

NOTE: While using `EDMA_TPCC_IEVAL` for shadow region completion interrupts, check that the `EDMA_TPCC_IEVAL` operated upon is from that particular shadow region memory map.

12.4.9.4 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers [EDMA_TPCC_EMR](#) / [EDMA_TPCC_EMRH](#).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register [EDMA_TPCC_QEMR](#).
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register [EDMA_TPCC_CCERR](#).
- TCC error: for outstanding transfer requests that are expected to return completion code [EDMA_TPCC_OPT_n\[22\]](#) TCCHEN or [EDMA_TPCC_OPT_n\[23\]](#) TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register [EDMA_TPCC_CCERR](#).

[Figure 12-17](#) illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register [EDMA_TPCC_EEVAL](#) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register [EDMA_TPCC_IEVAL](#). Unlike the [EDMA_TPCC_IEVAL](#) functionality, the [EDMA_TPCC_EEVAL](#) register must be written with '1' after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

12.4.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

12.4.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute [EDMA_TPCC_MPPAN_k](#) registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to [Table 12-30 EDMA_TPCC Registers Mapping Summary](#).

Each of the eight shadow regions has an associated [EDMA_TPCC_MPPAN_k](#) registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register [EDMA_TPCC_MPPAG](#). The [EDMA_TPCC_MPPAG](#) applies to the global region and to the global channel region, except the other [EDMA_TPCC_MPPAN_k](#) registers themselves.

[Table 12-20](#) shows the accesses that are allowed or not allowed to the [EDMA_TPCC_MPPAG](#) and [EDMA_TPCC_MPPAN_k](#). The active memory protection uses the [EDMA_TPCC_OPT_n\[31\]](#) PRIV and [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID attributes of the EDMA peripheral modules. The [EDMA_TPCC_OPT_n\[31\]](#) PRIV is the privilege level (i.e., user vs. supervisor).

The [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 12-20. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

[Table 12-21](#) describes the [EDMA_TPCC_MPPAN_k](#) register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based [EDMA_TPCC_MPPAN_k](#) registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight [EDMA_TPCC_MPPAN_k](#) region registers (MPPAN[0-7]).

Table 12-21. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect ⁽¹⁾	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k . MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

⁽¹⁾ The PARAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register [EDMA_TPCC_EESR](#):

1. The original value of the event enable register [EDMA_TPCC_EER](#) at address offset 0x1020 is 0x0.
2. The [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[7] NS is set to prevent user level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[1] UW = 0, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[2] UR = 0), but it allows supervisor level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[4] SW = 1, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[5] SR = 1) with a privilege ID of 0. ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register [EDMA_TPCC_EESR](#) at address offset 0x2E30.

NOTE: The [EDMA_TPCC_EER](#) is a read-only register and the only way that write to it is by writing to the [EDMA_TPCC_EESR](#). There is only one physical register for [EDMA_TPCC_EER](#), [EDMA_TPCC_EESR](#), etc. and that the shadow regions only provide to the same physical set.

4. Since the [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the [EDMA_TPCC_EER](#) is not written too.

Table 12-22. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR . This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0 X	Memory Protection Filter EDMA_TPCC_MPPAN_k [10] AID0 = 1, EDMA_TPCC_MPPAN_k [1] UW = 0, EDMA_TPCC_MPPAN_k [2] UR = 0, EDMA_TPCC_MPPAN_k [4] SW = 1, EDMA_TPCC_MPPAN_k [5] SR = 1. Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example Access Allowed

Write access to shadow region 7's event enable set register [EDMA_TPCC_EESR](#):

1. The original value of the event enable register [EDMA_TPCC_EER](#) at address offset 0x1020 is 0x0.
2. The [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#) is set to allow user-level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[1] UW = 1, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[2] UR = 1) and supervisor-level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[4] SW = 1, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[5] SR = 1) with a privilege ID of 0. ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register [EDMA_TPCC_EESR](#) at address offset 0x2E30.

NOTE: The [EDMA_TPCC_EER](#) is a read-only register and the only way that write to it is by writing to the [EDMA_TPCC_EESR](#). There is only one physical register for [EDMA_TPCC_EER](#), [EDMA_TPCC_EESR](#), etc. and that the shadow regions only provide to the same physical set.

4. Since the [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#)[1] UW = 1 and [EDMA_TPCC_MPPAN_k](#). [MPPAN_7](#)[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective [EDMA_TPCC_DRAEM_k](#)

register. In this example, the [EDMA_TPCC_DRAEM_k](#). [EDMA_TPCC_DRAEM_7](#) is set of 0x9FF00FC2.

6. The value finally written to [EDMA_TPCC_EER](#) is 0x8BC00102.

Table 12-23. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k , EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k [10] AID = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [1] UW = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [2] UR = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [4] SW = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k , EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	0xBC0 0102	Final value of EER.

12.4.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The [EDMA_TPCC_OPT_n](#)[31] PRIV bit and [EDMA_TPCC_OPT_n](#)[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The [EDMA_TPCC_OPT_n](#)[31] PRIV is the privilege level (i.e., user vs. supervisor). The [EDMA_TPCC_OPT_n](#)[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The [EDMA_TPCC_OPT_n](#)[31] PRIV is 0 for user-level and the CPU has a [EDMA_TPCC_OPT_n](#)[27:24] PRIVID to 0.

The PaRAM set is shown in [Figure 12-18](#).

Figure 12-18. PaPARAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

Figure 12-19. Channel Options Parameter (OPT) Example

(b) Channel Options Parameter (OPT_n) Content

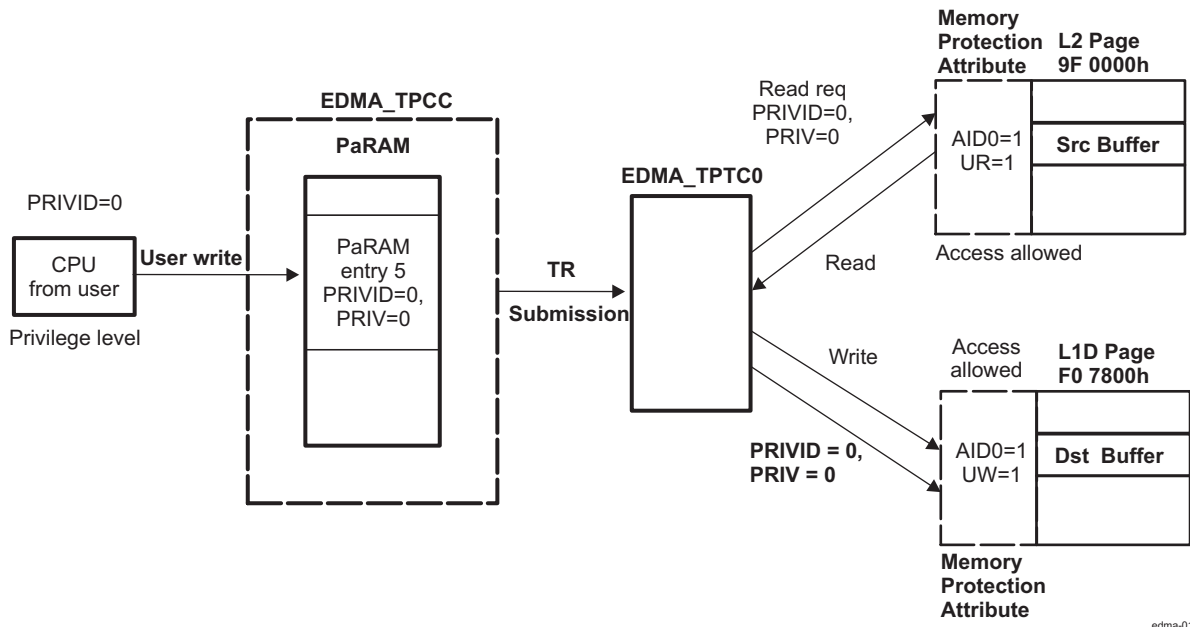

edma-018

The [EDMA_TPCC_OPT_n\[31\]](#) PRIV and [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses [EDMA_TPCC_MPPAN_k\[4\]](#) SW and [EDMA_TPCC_MPPAN_k\[5\]](#) SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses ([EDMA_TPCC_MPPAN_k\[4\]](#) SW, [EDMA_TPCC_MPPAN_k\[5\]](#) SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 12-20 illustrates the propagation of [EDMA_TPCC_OPT_n\[31\]](#) PRIV and [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

Figure 12-20. Proxy Memory Protection Example

edma-019

12.4.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to [Section 12.4.11.4](#) for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers [EDMA_TPCC_Q0E_p](#) and [EDMA_TPCC_Q1E_p](#). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to [Section 12.7.2.2.1 EDMA_TPCC Register Description](#) for [EDMA_TPCC_Q0E_p](#) / [EDMA_TPCC_Q1E_p](#) descriptions of the bit fields.

12.4.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register [EDMA_TPCC_DMAQNUMN_k](#) and the QDMA queue number register [EDMA_TPCC_QDMAQNUM](#). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to [Section 12.4.11.4 System-level Performance Considerations](#).

NOTE: If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

12.4.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register [EDMA_TPCC_QSTATN_i](#) associated with each queue. These along with all of the 16 entries per queue can be read via registers [EDMA_TPCC_QSTATN_i](#) and [Q0E_p / Q1E_p](#), respectively.

These registers provide user visibility.

The event queue entry register ([QxEy Q0E_p / Q1E_p](#)) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register ([QSTATn EDMA_TPCC_QSTATN_i](#)) includes fields for the start pointer [EDMA_TPCC_QSTATN_i\[3:0\] STRTPTR](#) which provides the offset to the head entry of an event. It also includes a field called [EDMA_TPCC_QSTATN_i\[12:8\] NUMVAL](#) that provides the total number of valid entries residing in the event queue at a given instance of time. The [EDMA_TPCC_QSTATN_i\[3:0\] STRTPTR](#) is used to index appropriately into the 16 event entries. [EDMA_TPCC_QSTATN_i\[12:8\] NUMVAL](#) number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

12.4.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programmed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register [EDMA_TPCC_QWMTHRA](#). The maximum queue usage is recorded actively in the watermark [EDMA_TPCC_QSTATN_i\[20:16\] WM](#) field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the [EDMA_TPCC_QSTATN_i\[12:8\] NUMVAL](#) bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the [QTHRXCdn](#) bits in the channel controller error register [EDMA_TPCC_CCERR\[7:0\]](#) and the [EDMA_TPCC_QSTATN_i\[24\] THRXCD](#) bit, where *n* stands for the event queue number. Any bits that are set in [EDMA_TPCC_CCERR](#) also generate an EDMA_TPCC error interrupt.

12.4.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device [IRQ_CROSSBAR](#) are programmed using the Control Module registers. The [EDMA_TPCC_QUEPRI](#) register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to [Section 14.5 Control Module Register Manual](#) in [Chapter 14 Control Module](#) chapter).

12.4.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

12.4.12.1 Architecture Details

12.4.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in [Section 12.4.12.5 EDMA_TPTC Configuration](#).

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT and [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

[Table 12-24](#) lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT array into DBS-sized commands to the source/destination addresses. Each [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension ([EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT == [EDMA_TPCC_BIDX_n](#)) and the ACNT value is a power of 2.

[Table 12-24](#) lists conditions in which the optimizations are performed.

Table 12-24. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

12.4.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 12-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. [EDMA_TPTCn_PCNT\[15:0\]](#) ACNT = 8, [EDMA_TPTCn_PCNT\[31:16\]](#) BCNT = 8, [EDMA_TPTCn_PBIDX\[15:0\]](#) SBIDX = 8, [EDMA_TPTCn_PBIDX\[31:16\]](#) DBIDX = 10, [EDMA_TPTCn_PSRC\[31:0\]](#) SADDR = 64, [EDMA_TPTCn_SADST\[31:0\]](#) DADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to [EDMA_TPTCn_PCNT\[15:0\]](#) ACNT = 64, [EDMA_TPTCn_PCNT\[31:16\]](#) BCNT = 1.

Cmd0 = 64 byte

Write Controller: Because DBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. [EDMA_TPTCn_PCNT\[15:0\]](#) ACNT=128, [EDMA_TPTCn_PCNT\[31:16\]](#) BCNT = 1, [EDMA_TPTCn_PSRC\[31:0\]](#) SADDR = 63, [EDMA_TPTCn_SADST\[31:0\]](#) DADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 63 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 1 byte

12.4.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the [EDMA_TPTCn_RDRATE](#) register. The [EDMA_TPTCn_RDRATE](#) register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The [EDMA_TPTCn_RDRATE\[2:0\]](#) RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

12.4.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

12.4.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.

- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

12.4.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register [EDMA_TPTCn_TCSTAT](#) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The [EDMA_TPTCn_TCSTAT\[1\]](#) SRCACTV bit indicates whether the source active set is active.
- The [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The [EDMA_TPTCn_TCSTAT\[0\]](#) PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

NOTE: If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

12.4.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in [EDMA_TPTCn_TCSTAT](#) that are used during advanced debugging, if necessary. The [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x0 and [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x1 and [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x3 and [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

12.4.12.5 EDMA_TPTC Configuration

[Table 12-25](#) provides the configuration of the individual EDMA transfer controllers present on the device. The DBS for each transfer controller is defined by Control Module register ([CTRL_CORE_CONTROL_IO_1](#)) settings.

Table 12-25. EDMA Transfer Controller Configurations

Name	TC0	TC1
EDMA_TPTCn_TCCFG[2:0] FIFOSIZE	1024 bytes	1024 bytes
EDMA_TPTCn_TCCFG[5:4] BUSWIDTH	16 bytes	16 bytes
EDMA_TPTCn_TCCFG[9:8] DSTREGDEPTH	4 entries	4 entries

Table 12-25. EDMA Transfer Controller Configurations (continued)

Name	TC0	TC1
DBS	Defined by CTRL_CORE_CONTROL_IO_1[9:8] TC0_DEFAULT_BURST_SIZE	Defined by CTRL_CORE_CONTROL_IO_1[13:12] TC1_DEFAULT_BURST_SIZE

12.4.13 Event Dataflow

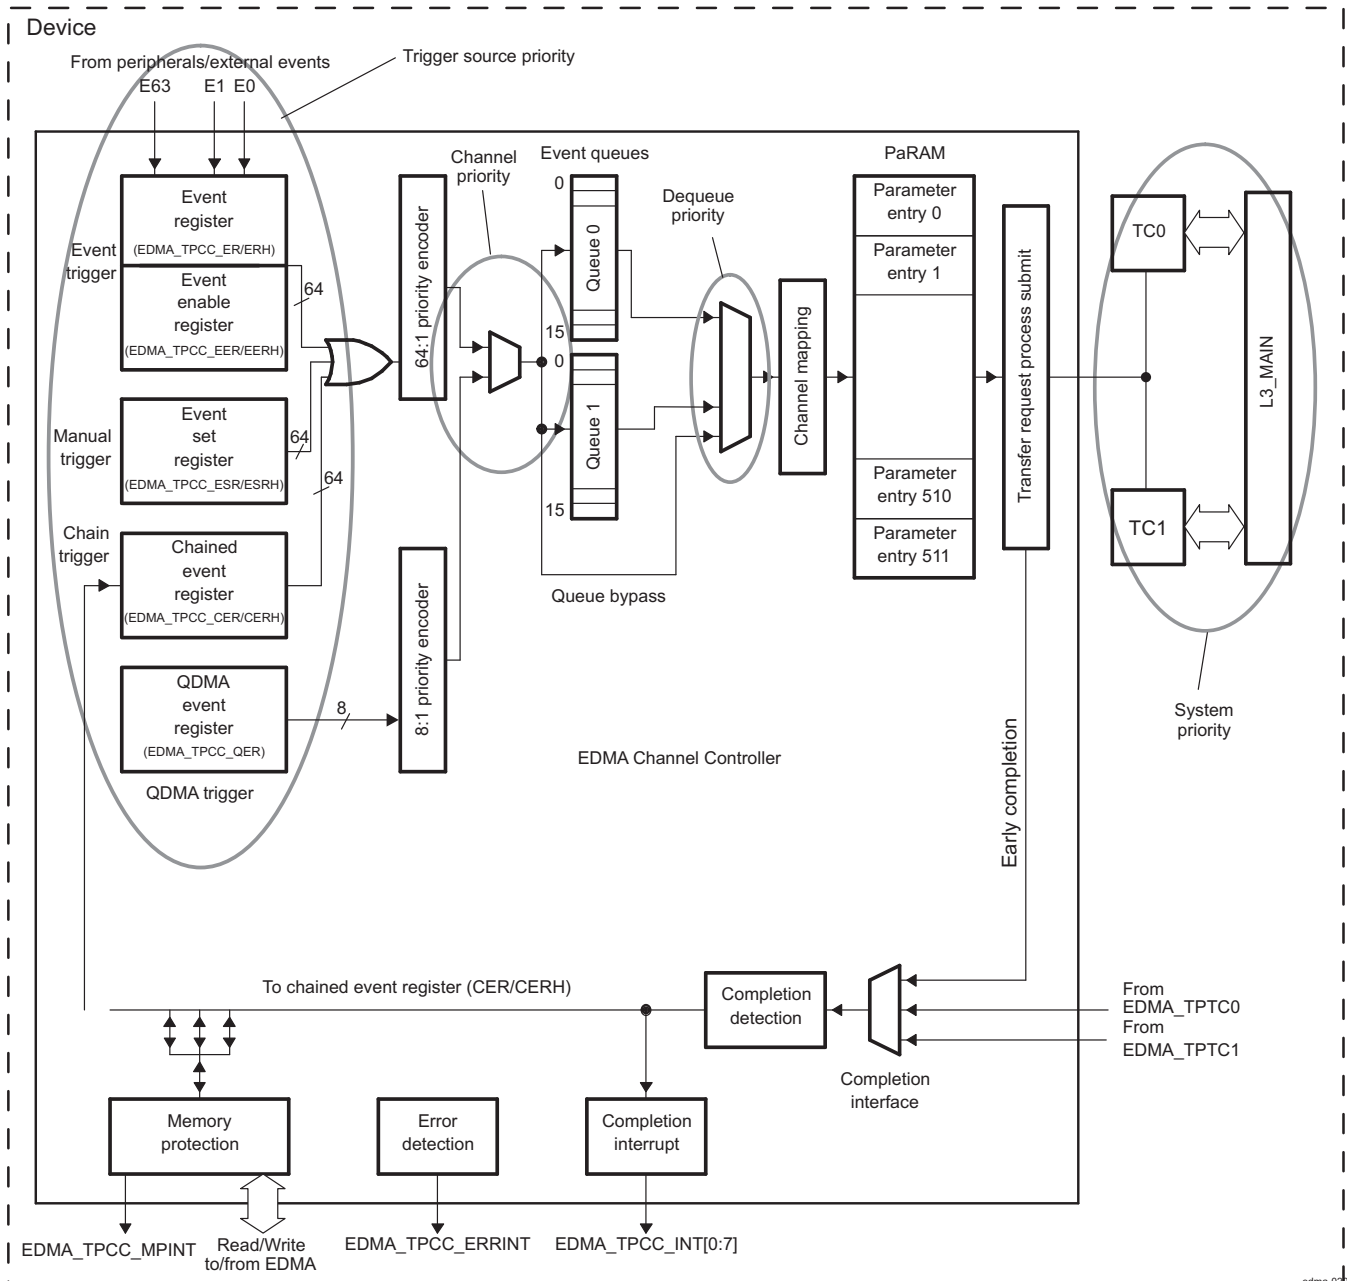

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the [EDMA_TPCC_ER\[31:0\] En](#) / [EDMA_TPCC_ERH\[31:0\] En](#) (or [EDMA_TPCC_CER\[31:0\] En](#) / [EDMA_TPCC_CERH\[31:0\] En](#), [EDMA_TPCC_ESR\[31:0\] En](#) / [EDMA_TPCC_ESRH\[31:0\] En](#), [EDMA_TPCC_QER\[7:0\] En](#)) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the [EDMA_TPCC_SER\[31:0\] En](#) \ [EDMA_TPCC_SERH\[31:0\] En](#) (or [EDMA_TPCC_QSER\[7:0\] En](#)) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the [EDMA_TPCC_ER\[31:0\] En](#) / [EDMA_TPCC_ERH\[31:0\] En](#) (or [EDMA_TPCC_CER\[31:0\] En](#) / [EDMA_TPCC_CERH\[31:0\] En](#), [EDMA_TPCC_ESR\[31:0\] En](#) / [EDMA_TPCC_ESRH\[31:0\] En](#), [EDMA_TPCC_QER\[31:0\] En](#)) bit and the [EDMA_TPCC_SER\[31:0\] En](#) / [EDMA_TPCC_SERH\[31:0\] En](#) bit as soon as it determines the TR is non-null. In the case of a null set, the [EDMA_TPCC_SER\[31:0\] En](#) / [EDMA_TPCC_SERH\[31:0\] En](#) bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register ([EDMA_TPCC_IPR\[31:0\] I\[TCC\]](#) / [EDMA_TPCC_IPRH\[31:0\] I\[TCC\]](#) - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register ([EDMA_TPCC_IPR\[31:0\] I\[TCC\]](#) / [EDMA_TPCC_IPRH\[31:0\] I\[TCC\]](#)) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC_n.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC_n then signals completion status to the EDMA_TPCC.

12.4.14 EDMA controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. [Figure 12-21](#) shows the different places EDMA priorities come into play.

Figure 12-21. EDMA Prioritization

12.4.14.1 Channel Priority

The EDMA event registers `EDMA_TPCC_ER` and `EDMA_TPCC_ERH` capture up to 64 events, the QDMA event register `EDMA_TPCC_QER` captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

12.4.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel ($EDMA_TPCC_ER[31:0] E_n = 1$, $EDMA_TPCC_ESR[31:0] E_n = 1$, $EDMA_TPCC_CER[31:0] E_n = 1$), then the EDMA_TPCC always services these events in the following priority order: event trigger (via $EDMA_TPCC_ER$) is higher priority than chain trigger (via $EDMA_TPCC_CER$) and chain trigger is higher priority than manual trigger (via $EDMA_TPCC_ESR$).

This implies that if for channel 0, both $EDMA_TPCC_ER[0] E_0 = 1$ and $EDMA_TPCC_CER[0] E_0 = 1$ at the same time, then the $EDMA_TPCC_ER[0] E_0$ event is always queued before the $EDMA_TPCC_CER[0] E_0$ event.

12.4.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by $EDMA_TPCC_DMAQNUMN_k$ and $EDMA_TPCC_QDMAQNUM$). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

12.4.15 EDMA Power, Reset and Clock Management

12.4.15.1 Clock and Power Management

The EDMA channel controller and transfer controller are clocked from L3MIAN1_L3_GICLK interface clock. The EDMA system runs at the L3 clock frequency.

The Auto clock gating for the EDMA_TPCC module is controlled by the $EDMA_TPCC_CLKGDIS[0]$ CLKGDIS bit at the module level.

The L3MIAN1_L3_GICLK interface clock to EDMA controller's modules are controlled by the following registers in the PRCM module:

- PRCM.CM_L3MAIN1_TPCC_CLKCTRL - manages EDMA_TPCC module clock.
- PRCM.CM_L3MAIN1_TPTC1_CLKCTRL - manages EDMA_TPTC0 module clock.
- PRCM.CM_L3MAIN1_TPTC2_CLKCTRL - manages EDMA_TPTC1 module clock.

EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 modules have wakeup dependances to several device modules. The wakeup dependency based on EDMA modules service requests are controlled by registers in PRCM module:

- PRCM.PM_L3MAIN1_TPCC_WKDEP - controls wakeup dependency based on TPCC service requests.
- PRCM.PM_L3MAIN1_TPTC1_WKDEP - controls wakeup dependency based on TPTC0 service requests.
- PRCM.PM_L3MAIN1_TPTC2_WKDEP - controls wakeup dependency based on TPTC1 service requests.

The EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the PRCM module. The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 are separate. In general, it should be verified that there are no pending activities in the EDMA controller

NOTE: When EDMA controller modules no longer require the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_L3MAIN1_TPCC_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC1_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the L3MIAN1_L3_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure EDMA modules are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the EDMA modules. For more information, refer to [Chapter 3, Power, Reset, and Clock Management](#).

12.4.15.2 Reset Considerations

A hardware resets the EDMA (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1) and the EDMA configuration registers. The PaRAM memory contents are undefined after device reset and it should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used. The EDMA modules are reset by CORE_RET_RST reset signal from PRCM.

12.4.16 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

12.5 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

12.5.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 12-22.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 12-23 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programmed to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 12-23 shows the parameters Block Move transfer.

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0008h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0001h	0100h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0000h	0000h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- [EDMA_TPCC_OPT_n\[3\]](#) STATIC = 0x1
- [EDMA_TPCC_OPT_n\[20\]](#) TCINTEN = 0x1

12.5.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 x 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 x 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 12-24 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 12-25 shows the parameters for Subframe Extraction transfer.

- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

12.5.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

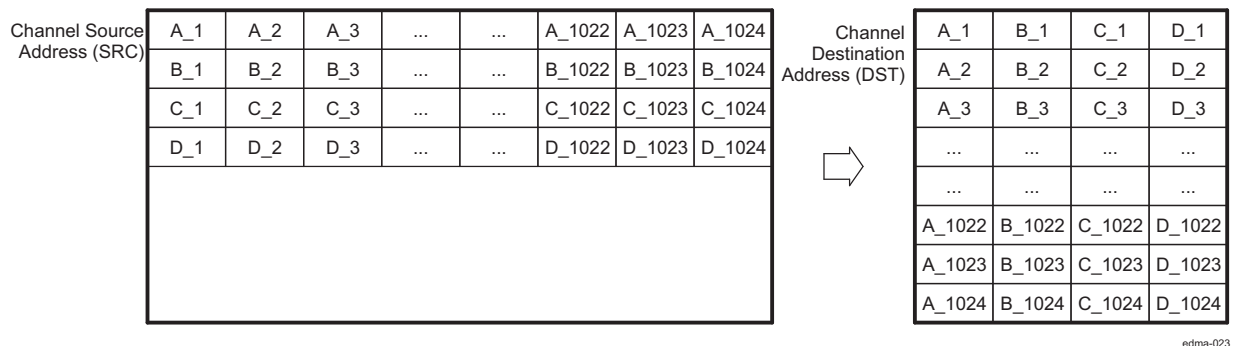

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the `EDMA_TPCC_OPT_n[3]` STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 12-27 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

12.5.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register `EDMA_TPCC_EER`. When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

12.5.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA channel configuration is the same.

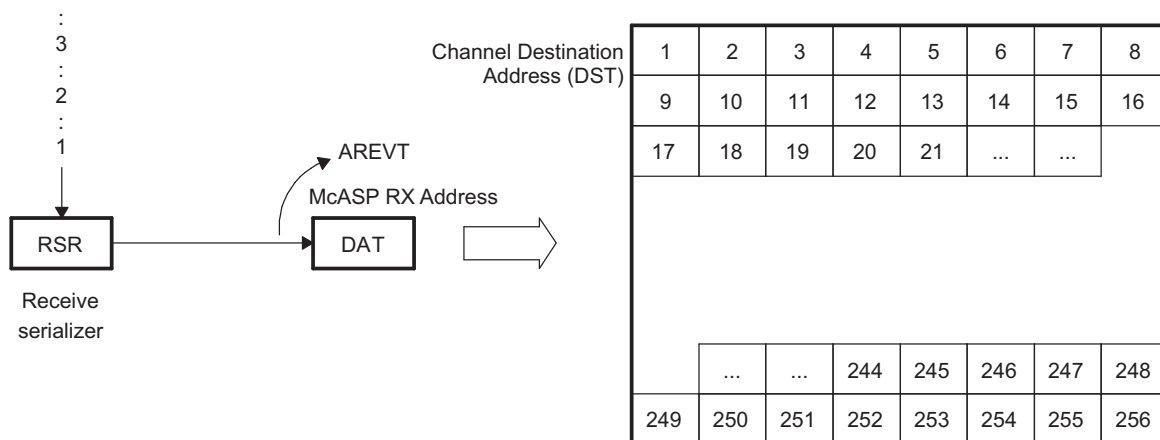

The McASP transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 12-29 shows the parameters for this transfer. The source address of the EDMA channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 0x2 (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 12-28 shows servicing incoming McASP data.

12.5.4.2 Bursting Peripherals

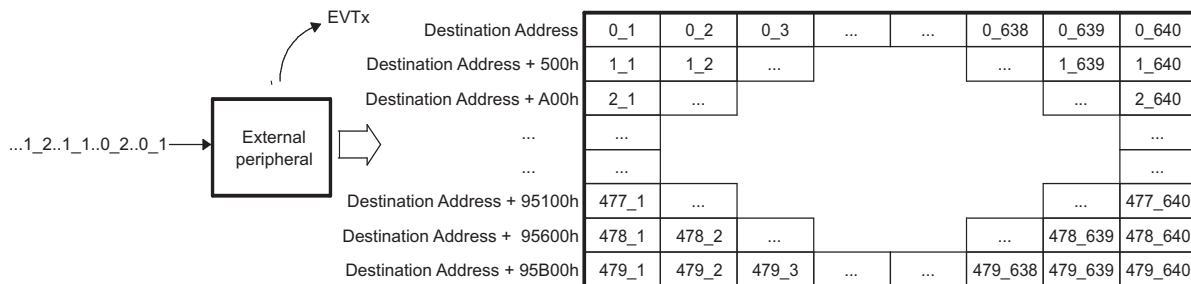

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT_n , channel n must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 12-31 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the $BDIX_n[15:0]$ SBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the $EDMA_TPCC_BIDX_n[31:16]$ DBIDX is set to pixel size, 2 bytes. $EDMA_TPCC_ABCNT_n[15:0]$ ANCT is equal to the pixel size, 2 bytes. $EDMA_TPCC_ABCNT_n[31:16]$ BCNT is set to the number of pixels in an array, 640. $EDMA_TPCC_CCNT_n[15:0]$ CCNT is equal to the total number of arrays in the block, 480. $EDMA_TPCC_CIDX_n[15:0]$ SCIDX is 0 because the source address undergoes no increment. The $EDMA_TPCC_CIDX_n[31:16]$ DCIDX is equal to the difference between the starting addresses of each array. Because one pixel is 16 bits (2 bytes), $EDMA_TPCC_CIDX_n[31:16]$ DCIDX is equal to 640×2 .

Figure 12-30 shows Bursting Peripherals Transfer.

12.5.4.3 Continuous Operation

Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown in Figure 12-32.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, the DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 12-33 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue.

Figure 12-34 shows the reload parameters for the channel.

12.5.4.3.1 Receive Channel

EDMA channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

12.5.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

12.5.4.4 Ping-Pong Buffering

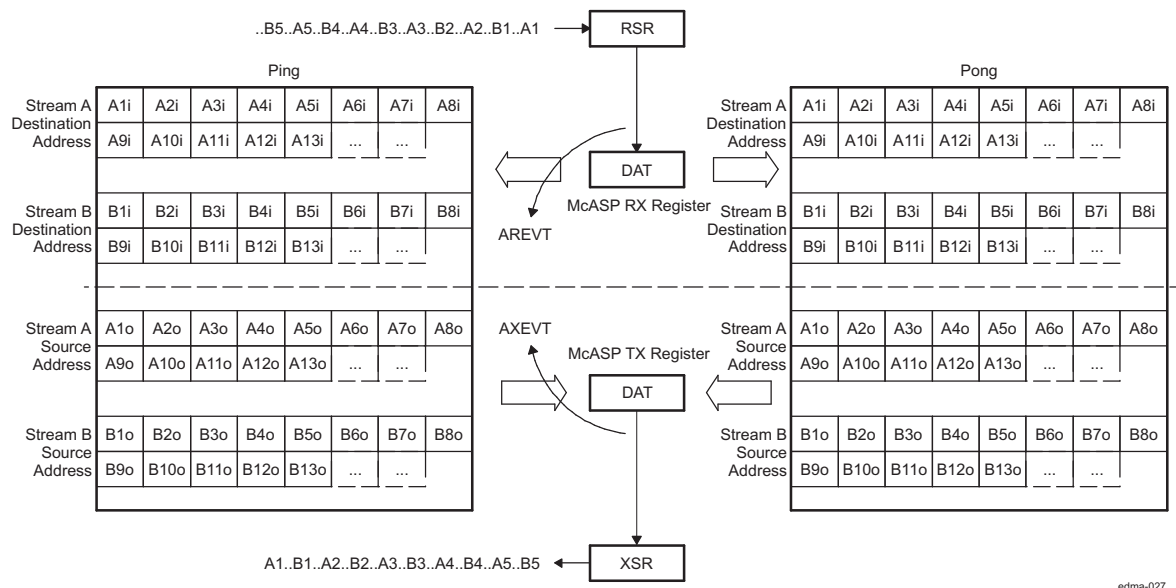

Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 12-35 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaPARAM set for the other and the data transfers continue. Figure 12-36 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 12-37). The link address for the ping set is set to the PaPARAM offset of the pong parameter set (Figure 12-37). The link address for the pong set is set to the PaPARAM offset of the ping parameter set (Figure 12-38). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

Figure 12-35. Ping-Pong Buffering for McASP Data Example

edma-027

12.5.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the EDMA_TPCC_OPT_n[20] TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register

[EDMA_TPCC_IPR](#) is set; when channel 12 empties an output buffer, the E12 bit in [EDMA_TPCC_IPR](#) is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls [EDMA_TPCC_IPR](#) to determine when to switch. The EDMA and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA to complete.

12.5.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

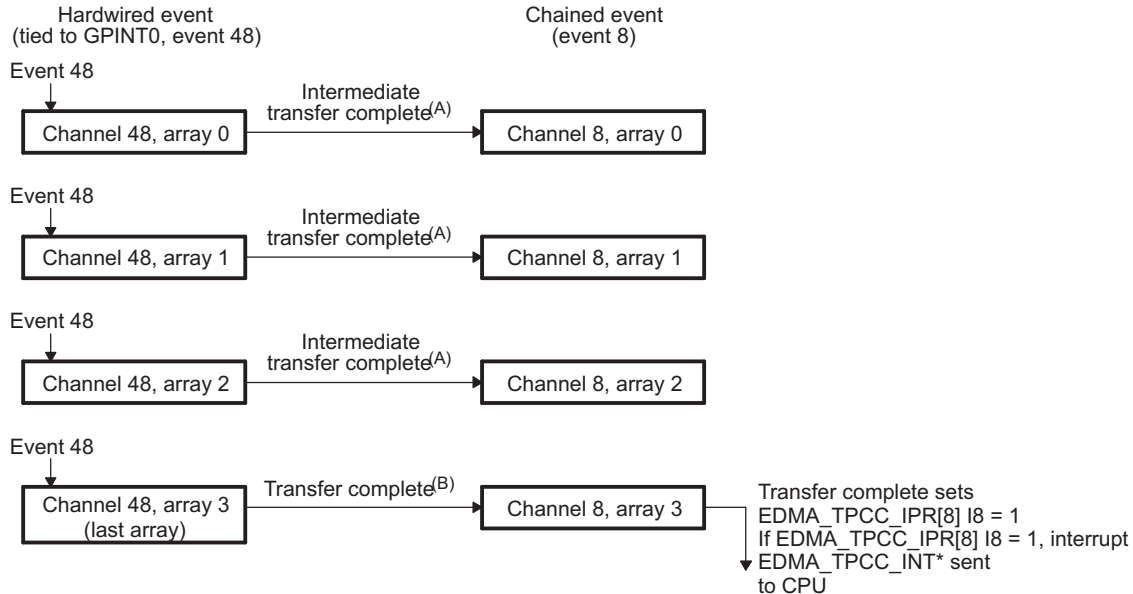

12.5.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event.

For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). [Figure 12-39](#) shows the EDMA setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register [EDMA_TPCC_CER](#) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in [EDMA_TPCC_CER](#) (specified by [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE: TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE: TCC) in the interrupt pending register [EDMA_TPCC_IPR](#), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register [EDMA_TPCC_IER](#) is set.

[Figure 12-39](#) shows the Intermediate Transfer Completion Chaining Example.

Figure 12-39. Intermediate Transfer Completion Chaining Example

Notes: (A) Intermediate transfer complete chaining synchronizes event 8
EDMA_TPCC_OPT_n[23] ITCCHEN = 1, TCC = 01000b, and sets EDMA_TPCC_CER[8] E8 = 1
(B) Transfer complete chaining synchronizes event 8
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[17:12] TCC = 01000b and sets EDMA_TPCC_CER[8] E8 = 1

edma-028

12.5.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

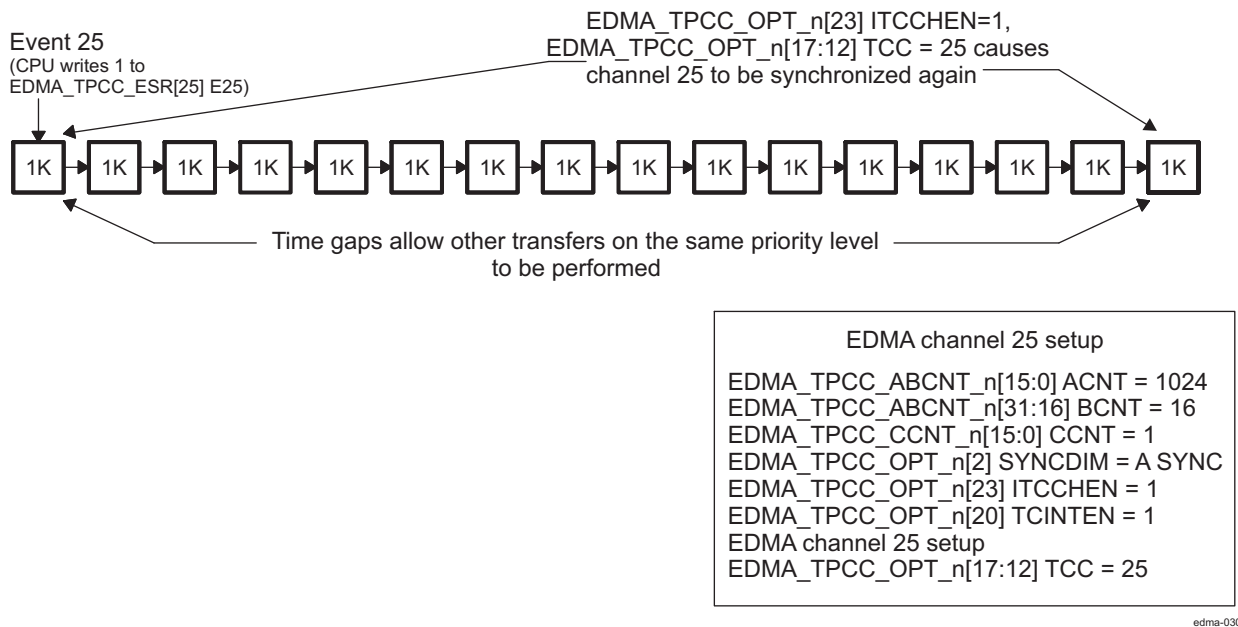

Another feature of intermediate transfer chaining EDMA_TPCC_OPT_n[23] ITCCHEN is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 12-40 shows the EDMA setup and illustration of an example single large block transfer.

Figure 12-40. Single Large Block Transfer Example

The intermediate transfer chaining enable [EDMA_TPCC_OPT_n\[23\] ITCCHEN](#) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The [EDMA_TPCC_OPT_n\[17:12\] TCC](#) field in the channel options parameter (OPT) is set to the same value as the channel number and [EDMA_TPCC_OPT_n\[23\] ITCCHEN](#) are set. In this example, EDMA channel 25 is used and [EDMA_TPCC_OPT_n\[17:12\] TCC](#) is also set to 25. The [EDMA_TPCC_OPT_n\[20\] TCINTEN](#) may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA transfer by writing to the appropriate bit of the event set register [EDMA_TPCC_ESR\[25\] E25](#). The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the [EDMA_TPCC_OPT_n\[17:12\] TCC](#) field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. [Figure 12-41](#) shows the EDMA setup and illustration of the broken up smaller packet transfers.

Figure 12-41. Smaller Packet Data Transfers Example

12.5.5 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

Step 1. Initiating a DMA/QDMA channel

1. Determine the type of channel (QDMA or DMA) to be used.
2. Channel mapping
 - i. If using a QDMA channel, program the [EDMA_TPCC_QCHMAPN_j](#) with the parameter set number to which the channel maps and the trigger word.
 - ii. If using a DMA channel, program the [EDMA_TPCC_DCHMAPN_m](#) with the parameter set number to which the channel maps.
3. If the channel is being used in the context of a shadow region, ensure the [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 12.4.7.1](#).)
4. Determine the type of triggering used.
 - i. If external events are used for triggering (DMA channels), enable the respective event in [EDMA_TPCC_EER](#) / [EDMA_TPCC_EERH](#) by writing into [EDMA_TPCC_EESR](#) / [EDMA_TPCC_EESRH](#).
 - ii. If QDMA Channel is used, enable the channel in [EDMA_TPCC_QEER](#) by writing into [EDMA_TPCC_QEESR](#).
5. Queue setup
 - i. If a QDMA channel is used, set up the [EDMA_TPCC_QDMAQNUM](#) to map the channel to the respective event queue.
 - ii. If a DMA channel is used, set up the [EDMA_TPCC_DMAQNUMN_k](#) to map the event to the respective event queue.

Step 2. Parameter set setup

1. Program the PaRAM set number associated with the channel. Note that

NOTE: If it is a QDMA channel, the PaPARAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

Step 3. Interrupt setup

1. Enable the interrupt in the [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) by writing into [EDMA_TPCC_IESR](#) / [EDMA_TPCC_IESRH](#).
2. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
3. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
4. Set up the interrupt controller properly to receive the expected EDMA interrupt.

Step 4. Initiate transfer

1. This step is highly dependent on the event trigger source:
 - i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the [EDMA_TPCC_ER](#) transfer.
 - ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
 - iii. Manually triggered transfers will be initiated by writes to the Event Set Registers [EDMA_TPCC_ESR](#) / [EDMA_TPCC_ESRH](#).
 - iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

1. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#). The set bits must be cleared in the [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) by writing to corresponding bit in [EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#).
2. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#). Again, the set bits in the [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) must be manually cleared via [EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#) before the next set of transfers is performed for the same transfer completion code values.

12.6 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

12.6.1 EDMA Debug Checklist

Table 12-26 provides some common issues and their probable causes and resolutions.

Table 12-26. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH , check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH . Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER . 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER . This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] En and EDMA_TPCC_EMR[31:0] En set, preventing further event prioritization. Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	Check the following: 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 12.4.9.1.2 Clearing Transfer Completion Interrupts for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).

12.6.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers.
 For example, the Event Register ([EDMA_TPCC_ER](#) / [EDMA_TPCC_ERH](#)) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers ([EDMA_TPCC_ECR](#) / [EDMA_TPCC_ECRH](#)). Similarly, the Event Enable Register ([EDMA_TPCC_EER](#) / [EDMA_TPCC_EERH](#)) bits can only be set with writing of 0x1 to the Event Enable Set Registers ([EDMA_TPCC_EESR](#) / [EDMA_TPCC_EESRH](#)) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register ([EDMA_TPCC_EEER](#) / [EDMA_TPCC_EEERH](#)).
2. Writes to the shadow region memory maps are governed by region access registers ([EDMA_TPCC_DRAE](#) / [EDMA_TPCC_DRAEHM_k](#) / [EDMA_TPCC_QRAEN_k](#)). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers ([EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#)) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.
 For example, if [EDMA_TPCC_DRAEM_k.DRAEM_0\[0\]](#) E0 and [EDMA_TPCC_DRAEM_k.DRAEM_1\[0\]](#) E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.
 However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

12.7 EDMA Register Manual

12.7.1 EDMA Instance Summary

Table 12-27 shows the L3_MAIN base address and address space for the EDMA module instances.

Table 12-27. EDMA Instance Summary

Module Name	Base Address	Size
SYS_EDMA_TPCC	0x4330 0000	1 MB
SYS_EDMA_TPTC0	0x4340 0000	1 MB
SYS_EDMA_TPTC1	0x4350 0000	1 MB

12.7.2 EDMA Registers

12.7.2.1 EDMA Register Summary

Table 12-30 through Table 12-39 summarize the EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 registers.

NOTE: All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see Section 12.1.2, *EDMA Controllers Configuration*).

Table 12-66. EDMA_TPCC_QEMR (continued)

Description	QDMA Event Missed Register: The QDMA Event Missed register is set if 2 QDMA events are detected without the first event being cleared or if a Null TR is serviced. If any bit in the EDMA_TPCC_QEMR register is set (and all errors (including EDMA_TPCC_EMR / EDMA_TPCC_CCERR) were previously clear), then an error will be signaled with TPCC error interrupt.

Table 12-110. EDMA_TPCC_ER (continued)

Description	Event Register: If EDMA_TPCC_ER .En bit is set and the EDMA_TPCC_EER .En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER .En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER .En bit. EDMA_TPCC_ER .En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER .En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.

Table 12-126. EDMA_TPCC_EER

Address Offset	0x0000 1020	Instance	SYS_EDMA_TPCC
Physical Address	0x4330 1020 0x40D1 1020 0x4151 1020 0x01D1 1020 0x420A 1020		DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Enable Register: Enables DMA transfers for EDMA_TPCC_ER .En pending events. EDMA_TPCC_ER .En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (EDMA_TPCC_CER) or Event Set Register (EDMA_TPCC_ESR). Note that if a bit is set in EDMA_TPCC_ER .En while EDMA_TPCC_EER .En is disabled, no action is taken. If EDMA_TPCC_EER .En is enabled at a later point (and EDMA_TPCC_ER .En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync'. EDMA_TPCC_EER .En is not directly writeable. Events can be enabled via writes to EDMA_TPCC_EESR and can be disabled via writes to EDMA_TPCC_EECR register. EDMA_TPCC_EER .En = 0: EDMA_TPCC_ER .En is not enabled to trigger DMA transfers. EDMA_TPCC_EER .En = 1: EDMA_TPCC_ER .En is enabled to trigger DMA transfers.

Address Offset	0x0000 1080	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Physical Address	0x4330 1080 0x40D1 1080 0x4151 1080 0x01D1 1080 0x420A 1080		
Description	<p>QDMA Event Register: If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.</p>

Table 12-180. EDMA_TPCC_ER_RN_k

Address Offset	0x0000 2000 + (0x200 * k)		
Physical Address	0x4330 2000 + (0x200 * k) 0x40D1 2000 + (0x200 * k) 0x4151 2000 + (0x200 * k) 0x01D1 2000 + (0x200 * k) 0x420A 2000 + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Register If EDMA_TPCC_ER .En bit is set and the EDMA_TPCC_EER .En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER .En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER .En bit. EDMA_TPCC_ER .En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER .En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.

Table 12-192. EDMA_TPCC_CER_RN_k

Address Offset	0x0000 2018 + (0x200 * k)		
Physical Address	0x4330 2018 + (0x200 * k) 0x40D1 2018 + (0x200 * k) 0x4151 2018 + (0x200 * k) 0x01D1 2018 + (0x200 * k) 0x420A 2018 + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Chained Event Register If EDMA_TPCC_CER.En bit is set (regardless of state of EDMA_TPCC_EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CER.En cannot be set or cleared via software.

Table 12-194. EDMA_TPCC_CERH_RN_k

Address Offset	0x0000 201C + (0x200 * k)		
Physical Address	0x4330 201C + (0x200 * k) 0x40D1 201C + (0x200 * k) 0x4151 201C + (0x200 * k) 0x01D1 201C + (0x200 * k) 0x420A 201C + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Chained Event Register (High Part) If EDMA_TPCC_CERH.En bit is set (regardless of state of EDMA_TPCC_EERH.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CERH.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CERH.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CERH.En cannot be set or cleared via software.

Table 12-196. EDMA_TPCC_EER_RN_k

Address Offset	0x0000 2020 + (0x200 * k)		
Physical Address	0x4330 2020 + (0x200 * k) 0x40D1 2020 + (0x200 * k) 0x4151 2020 + (0x200 * k) 0x01D1 2020 + (0x200 * k) 0x420A 2020 + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Enable Register Enables DMA transfers for EDMA_TPCC_ER .En pending events. EDMA_TPCC_ER .En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (EDMA_TPCC_CER) or Event Set Register (EDMA_TPCC_ESR). NOTE: If a bit is set in EDMA_TPCC_ER.En while EDMA_TPCC_EER.En is disabled, no action is taken. If EDMA_TPCC_EER .En is enabled at a later point (and EDMA_TPCC_ER .En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EDMA_TPCC_EER .En is not directly writeable. Events can be enabled via writes to EDMA_TPCC_EESR and can be disabled via writes to EDMA_TPCC_EEER register. EDMA_TPCC_EER .En = 0: EDMA_TPCC_ER .En is not enabled to trigger DMA transfers. EDMA_TPCC_EER .En = 1: EDMA_TPCC_ER .En is enabled to trigger DMA transfers.

Table 12-238. EDMA_TPCC_QER_RN_k

Address Offset	0x0000 2080 + (0x200 * k)		
Physical Address	0x4330 2080 + (0x200 * k) 0x40D1 2080 + (0x200 * k) 0x4151 2080 + (0x200 * k) 0x01D1 2080 + (0x200 * k) 0x420A 2080 + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	QDMA Event Register If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

21	ITCINTEN	Intermediate transfer completion interrupt enable 0x0: Intermediate transfer complete interrupt is disabled. 0x1: Intermediate transfer complete interrupt is enabled (corresponding EDMA_TPCC_IER[TCC] bit must be set to 1 to generate interrupt)	RW	0x0
20	TCINTEN	Transfer complete interrupt enable 0x0: Transfer complete interrupt is disabled. 0x1: Transfer complete interrupt is enabled (corresponding EDMA_TPCC_IER[TCC] bit must be set to 1 to generate interrupt)	RW	0x0
19	WIMODE	Backward compatibility mode 0x0: Normal operation 0x1: WI Backwards Compatibility mode, forces BCNT to be adjusted by '1' upon TR submission (0 means 1, 1 means 2, ...) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)	RW	0x0
18	RESERVED	Reserved	R	0x0
17:12	TCC	Transfer Complete Code The 6-bit code is used to set the relevant bit in EDMA_TPCC_CER (bit EDMA_TPCC_CER[TCC]) for chaining or in EDMA_TPCC_IER (bit EDMA_TPCC_IER[TCC]) for interrupts.	RW	0x0
11	TCCMODE	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0x0: Normal Completion. A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral) 0x1: Early Completion, A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally.	RW	0x0
10:8	FWID	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.	RW	0x0
7:4	RESERVED	Reserved	R	0x0
3	STATIC	Static Entry 0x0: Entry is updated as normal 0x1: Entry is static, Count and Address updates are not updated after TRP is submitted. Linking is not performed.	RW	0x0
2	SYNCDIM	Transfer Synchronization Dimension: 0x0: A-Sync, Each event triggers the transfer of ACNT elements. 0x1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements.	RW	0x0
1	DAM	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0x0: INCR, Dst addressing within an array increments. Dst is not a FIFO. 0x1: FIFO, Dst addressing within an array wraps around upon reaching FIFO width.	RW	0x0
0	SAM	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0x0: INCR, Src addressing within an array increments. Source is not a FIFO. 0x1: FIFO, Src addressing within an array wraps around upon reaching FIFO width.	RW	0x0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	BCNT: Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set, then the programmed BCNT value will be incremented by '1' before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFF means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	ACNT	<p>ACNT: number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00' by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.</p>	RW	0x0

Description	Link and Reload parameters		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not thus BCNTRLD is a don't care field.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	LINK	<p>Link Address:</p> <p>The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NUL PaRAM link field.</p>	RW	0x0

RESERVED																			DFSTRPTR			RESERVED			ACTV			RESERVED	DSTACTV				RESERVED	WSACTV	SRCACTV	PROGBUSY

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	R Return 0's	0x0
12:11	DFSTRPTR	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO, in units of *entries*. Legal values = 0x0 to 0x3	R	0x0
10:9	RESERVED	Reserved	R Return 0's	0x0
8	ACTV	Channel Active Channel Active is a logical-OR of each of the *BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. 0x0: Channel is idle 0x1: Channel is busy	R	0x1
7	RESERVED	Reserved	R Return 0's	0x0
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter.	R	0x0
3	RESERVED	Reserved	R Return 0's	0x0
2	WSACTV	Write Status Active 0x0: Write status is not pending. Write status has been received for all previously issued write commands. 0x1: Write Status is pending. Write status has not been received for all previously issued write commands.	R	0x0
1	SRCACTV	Source Active State 0x0: Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). 0x1: Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0x0

Bits	Field Name	Description	Type	Reset
0	PROGBUSY	Program Register Set Busy 0x0: Program set idle and is available for programming. 0x1: Program set busy. User should poll for PROGBUSY equal to '0' prior to re-programming the Program Register set.	R	0x0

RESERVED														TCCHEN	TCINTEN	RESERVED	TCC				RESERVED				STAT						

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R Return 0's	0x0
17	TCCHEN	Contains the EDMA_TPCC_OPT_n[17] TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
16	TCINTEN	Contains the EDMA_TPCC_OPT_n[16] TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
15:14	RESERVED	Reserved	R Return 0's	0x0
13:8	TCC	Transfer Complete Code: Contains the EDMA_TPCC_OPT_n[13:8] TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
7:4	RESERVED	Reserved	R Return 0's	0x0
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec and is summarized here: 0xF =	R	0x0

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

Topic	Page
13.1 Interrupt Controllers Overview	4715
13.2 Interrupt Controllers Environment	4717
13.3 Interrupt Controllers Integration	4718
13.4 Interrupt Controllers Functional Description	4744

13.1 Interrupt Controllers Overview

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The DSP (x2), IPU, and EVE subsystems are capable of servicing these interrupts via their integrated interrupt controllers. In addition, each processor's interrupt controller is preceded by an Interrupt Controller Crossbar (IRQ_CROSSBAR) that provides flexibility in mapping the device interrupts to processor interrupt inputs. For more information about IRQ crossbar, see [Chapter 14, Control Module](#).

C66x DSP Subsystem Interrupt Controller (DSPx_INTC, where x = 1, 2)

There are two Digital Signal Processing (DSP) subsystems in the device - DSP1, and DSP2. Each DSP subsystem integrates an interrupt controller - DSPx_INTC, which interfaces the system events to the C66x core interrupt and exceptions inputs. It combines up to 128 interrupts into 12 prioritized interrupts presented to the C66x CPU.

For detailed information about this module, see [Chapter 4, DSP Subsystem](#).

Dual Cortex-M4 IPU Subsystem Interrupt Controller (IPU_Cx_INTC, where x = 1, 2)

There is one Image Processing Unit (IPU) subsystem in the device. The IPU subsystem integrates two Arm® Cortex-M4 cores.

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M4. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:

- 96 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to Arm *Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

EVE Subsystem Interrupt Controller (EVE_INTC)

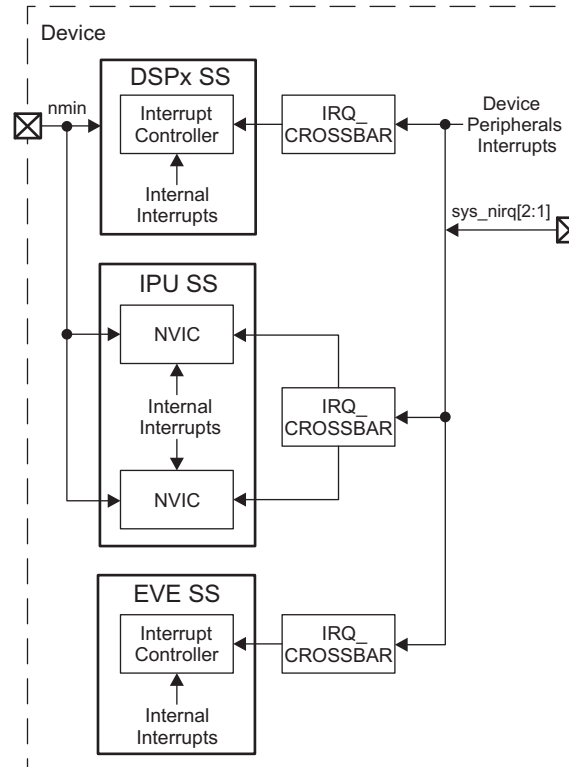

There is one Embedded Video Engine (EVE) subsystems in the device. The EVE subsystem integrates an interrupt controller - EVE_INTC, which handles incoming interrupts, merging them with internal interrupt sources to drive ARP32's interrupt inputs. It also allows ARP32 to generate outgoing interrupts or events to synchronize with other system processors and EDMA.

The EVE_INTC supports up to 32 active-high level interrupt inputs. Its architecture allows both hardware and software prioritization.

For detailed information about this module, see [Section 6.1, Embedded Vision Engine](#).

[Figure 13-1](#) shows the top-level block diagram of the interrupt controllers in this device.

Figure 13-1. Interrupt Controllers in the Device

13.2 Interrupt Controllers Environment

Figure 13-2 shows the relationship between the device INTCs and external interrupts.

Figure 13-2. Interrupts From External Devices

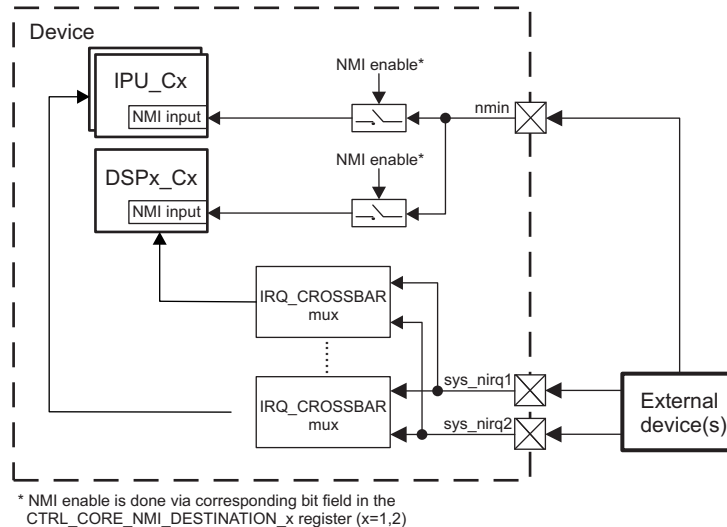

Table 13-1 describes the signals that can be used by external devices to generate interrupts to the device INTCs.

Table 13-1. Interrupts From External Devices

Device Pin	I/O ⁽¹⁾	Description
sys_nirq1	I	External devices can use these pins to generate a system wake-up interrupt event to any device INTC. The user must take care to configure the corresponding IRQ_CROSSBAR properly (via Control Module).
sys_nirq2	I	
nmin	I	External device can use this pin to generate a non-maskable interrupt (NMI) event to the following device processors: - IPU_C0, IPU_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU_C0 and IPU_C1. - DSP1, DSP2. Upon enable (via Control Module), the NMI is routed directly to the NMI input of C66x CPU.
		The Control Module registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are used to route the NMI signal to the corresponding device processor subsystems as follows: <ul style="list-style-type: none"> • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1[7:0] IPU_C1 enables NMI mapping to IPU_C1; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[31:24] IPU_C0 enables NMI mapping to IPU_C0; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[23:16] DSP2 enables NMI mapping to DSP2; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[15:8] DSP1 enables NMI mapping to DSP1; For more information about CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 registers, see Chapter 14, Control Module.

⁽¹⁾ I = Input, O = Output

NOTE: External devices can also use the GPIO modules to generate an interrupt to the device INTCs. For more information, see Chapter 21, General-Purpose Interface.

13.3 Interrupt Controllers Integration

Table 13-2 through Table 13-5 present the default interrupt mapping of the device INTCs. The mapping of device interrupts to IRQ_CROSSBAR inputs is presented in Table 13-6.

NOTE: All device interrupts (external to the DSP [x2], IPU, and EVE subsystems) are active-high, level-sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs. With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

13.3.1 Interrupt Requests to DSP1_INTC

Table 13-2 lists the default interrupt sources for the DSP1_INTC. In addition, interrupts DSP1_IRQ_32 through DSP1_IRQ_95 can alternatively be sourced through the DSP1's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in Table 13-6. The CTRL_CORE_DSP1_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-2. DSP1_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP1_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt
DSP1_IRQ_2	N/A	N/A	N/A	CGEM_IRQ_2	CGEM Internal Interrupt
DSP1_IRQ_3	N/A	N/A	N/A	CGEM_IRQ_3	CGEM Internal Interrupt
DSP1_IRQ_4	N/A	N/A	N/A	CGEM_IRQ_4	CGEM Internal Interrupt
DSP1_IRQ_5	N/A	N/A	N/A	CGEM_IRQ_5	CGEM Internal Interrupt
DSP1_IRQ_6	N/A	N/A	N/A	CGEM_IRQ_6	CGEM Internal Interrupt
DSP1_IRQ_7	N/A	N/A	N/A	CGEM_IRQ_7	CGEM Internal Interrupt
DSP1_IRQ_8	N/A	N/A	N/A	CGEM_IRQ_8	CGEM Internal Interrupt
DSP1_IRQ_9	N/A	N/A	N/A	CGEM_IRQ_9	CGEM Internal Interrupt
DSP1_IRQ_10	N/A	N/A	N/A	CGEM_IRQ_10	CGEM Internal Interrupt
DSP1_IRQ_11	N/A	N/A	N/A	CGEM_IRQ_11	CGEM Internal Interrupt
DSP1_IRQ_12	N/A	N/A	N/A	CGEM_IRQ_12	CGEM Internal Interrupt
DSP1_IRQ_13	N/A	N/A	N/A	CGEM_IRQ_13	CGEM Internal Interrupt
DSP1_IRQ_14	N/A	N/A	N/A	CGEM_IRQ_14	CGEM Internal Interrupt
DSP1_IRQ_15	N/A	N/A	N/A	CGEM_IRQ_15	CGEM Internal Interrupt
DSP1_IRQ_16	N/A	N/A	N/A	TPCC_INTG	EDMA CC global interrupt
DSP1_IRQ_17	N/A	N/A	N/A	TPCC_INT0	EDMA CC region0 interrupt
DSP1_IRQ_18	N/A	N/A	N/A	TPCC_INT1	EDMA CC region1 interrupt
DSP1_IRQ_19	N/A	N/A	N/A	TPCC_INT2	EDMA CC region2 interrupt
DSP1_IRQ_20	N/A	N/A	N/A	TPCC_INT3	EDMA CC region3 interrupt
DSP1_IRQ_21	N/A	N/A	N/A	FW0_FUNC_ERROR	Firewall0 func access error
DSP1_IRQ_22	N/A	N/A	N/A	FW0_DEBUG_ERROR	Firewall0 debug access error
DSP1_IRQ_23	N/A	N/A	N/A	FW1_FUNC_ERROR	Firewall1 func access error
DSP1_IRQ_24	N/A	N/A	N/A	FW1_DEBUG_ERROR	Firewall1 debug access error
DSP1_IRQ_25	N/A	N/A	N/A	MMU0_INT	DSP MMU0 Interrupt
DSP1_IRQ_26	N/A	N/A	N/A	MMU1_INT	DSP MMU1 Interrupt
DSP1_IRQ_27	N/A	N/A	N/A	TPCC_ERRINT	EDMA CC error interrupt
DSP1_IRQ_28	N/A	N/A	N/A	TPTC_ERRINT0	EDMA TC0 error interrupt
DSP1_IRQ_29	N/A	N/A	N/A	TPTC_ERRINT1	EDMA TC1 error interrupt
DSP1_IRQ_30	N/A	N/A	N/A	NOC_ERRINT	Interconnect error interrupt
DSP1_IRQ_31	NA	N/A	N/A	EDMA_WAKE_INT	EDMA wakeup interrupt

Table 13-2. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_32	1	CTRL_CORE_DSP1_IRQ_32_33[8:0]	1	ELM_IRQ	Error location process completion interrupt
DSP1_IRQ_33	2	CTRL_CORE_DSP1_IRQ_32_33[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
DSP1_IRQ_34	3	CTRL_CORE_DSP1_IRQ_34_35[8:0]	3	CTRL_MODULE_CORE_IRQ_SE C_EVTS	Combined firewall error interrupt. For more information, see Section 14.4.6.13.2 .
DSP1_IRQ_35	4	CTRL_CORE_DSP1_IRQ_34_35[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
DSP1_IRQ_36	5	CTRL_CORE_DSP1_IRQ_36_37[8:0]	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
DSP1_IRQ_37	6	CTRL_CORE_DSP1_IRQ_36_37[24:16]	6	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_38	7	CTRL_CORE_DSP1_IRQ_38_39[8:0]	7	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_39	8	CTRL_CORE_DSP1_IRQ_38_39[24:16]	8	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_40	9	CTRL_CORE_DSP1_IRQ_40_41[8:0]	9	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_41	10	CTRL_CORE_DSP1_IRQ_40_41[24:16]	10	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_42	11	CTRL_CORE_DSP1_IRQ_42_43[8:0]	11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN statistic collector alarm interrupt
DSP1_IRQ_43	12	CTRL_CORE_DSP1_IRQ_42_43[24:16]	12	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_44	13	CTRL_CORE_DSP1_IRQ_44_45[8:0]	13	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_45	14	CTRL_CORE_DSP1_IRQ_44_45[24:16]	14	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_46	15	CTRL_CORE_DSP1_IRQ_46_47[8:0]	15	GPMC_IRQ	GPMC interrupt
DSP1_IRQ_47	16	CTRL_CORE_DSP1_IRQ_46_47[24:16]	16	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_48	17	CTRL_CORE_DSP1_IRQ_48_49[8:0]	17	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_49	18	CTRL_CORE_DSP1_IRQ_48_49[24:16]	18	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_50	19	CTRL_CORE_DSP1_IRQ_50_51[8:0]	19	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_51	20	CTRL_CORE_DSP1_IRQ_50_51[24:16]	20	DISPC_IRQ	Display controller interrupt
DSP1_IRQ_52	21	CTRL_CORE_DSP1_IRQ_52_53[8:0]	21	MAILBOX1_IRQ_USER0	Mailbox 1 user 0 interrupt
DSP1_IRQ_53	22	CTRL_CORE_DSP1_IRQ_52_53[24:16]	22	Reserved	Reserved by default but can be remapped to a valid interrupt source

Table 13-2. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_54	23	CTRL_CORE_DSP1_IRQ_54_55 [8:0]	23	DSP1_IRQ_MMU0	DSP1 MMU0 interrupt

DSP1_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP1_IRQ_127	N/A	N/A	N/A	CGEM_IRQ_47	CGEM Internal Interrupt

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-2](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP1_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP1_INTC inputs. For example, the DSP1_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP1_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP1_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP1_INTC input line and therefore, the user cannot change its default mapping.

13.3.2 Interrupt Requests to DSP2_INTC

[Table 13-3](#) lists the default interrupt sources for the DSP2_INTC. In addition, interrupts DSP2_IRQ_32 through DSP2_IRQ_95 can alternatively be sourced through the DSP2's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in [Table 13-6](#). The DSP2_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-3. DSP2_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP2_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt
DSP2_IRQ_2	N/A	N/A	N/A	CGEM_IRQ_2	CGEM Internal Interrupt
DSP2_IRQ_3	N/A	N/A	N/A	CGEM_IRQ_3	CGEM Internal Interrupt

DSP2_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP2_IRQ_127	N/A	N/A	N/A	CGEM_IRQ_47	CGEM Internal Interrupt

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-3](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP2_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP2_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP2_INTC inputs. For example, the DSP2_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP2_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP2_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP2 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP2_INTC input line and therefore, the user cannot change its default mapping.

13.3.3 Interrupt Requests to IPU_Cx_INTC

[Table 13-4](#) lists the default interrupt sources for the IPU_Cx_INTC. In addition, device interrupts IPU_IRQ_23 through IPU_IRQ_79 can alternatively be sourced through the IPU's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in [Table 13-6](#). The CTRL_CORE_IPU_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-4. IPU_Cx_INTC Default Interrupt Mapping

IRQ Input Line ⁽¹⁾	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table

⁽¹⁾ This column shows the number of the corresponding exception type.

Table 13-4. IPU_Cx_INTC Default Interrupt Mapping (continued)

IRQ Input Line ⁽¹⁾	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI input (interrupt from nmin device pad)
IPU_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error
IPU_IRQ_7	N/A	N/A	N/A	Reserved	Reserved

IPU_IRQ_80	N/A	N/A	N/A	L1TAG_ECC_SEC_IRQ	SEC interrupt for L1-Tag
IPU_IRQ_81	N/A	N/A	N/A	L1TAG_ECC_DED_IRQ	DED interrupt for L1-Tag
IPU_IRQ_82	N/A	N/A	N/A	L1DATA_ECC_SEC_IRQ	SEC interrupt for L1-Data
IPU_IRQ_83	N/A	N/A	N/A	L1DATA_ECC_DED_IRQ	DED interrupt for L1-Data
IPU_IRQ_84	N/A	N/A	N/A	L2_RAM_ECC_SEC_IRQ	SEC interrupt for L2-RAM
IPU_IRQ_85	N/A	N/A	N/A	L2_RAM_ECC_DED_IRQ	DED interrupt for L2-RAM

NOTE: Exceptions/interrupts IPU_IRQ_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU_IRQ_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU_IRQ_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU_IRQ_79 (exception #79).

For more information about Cortex-M4 exception types, refer to Arm *Cortex™-M4 Devices Generic User Guide* (available at <http://infocenter.arm.com/help/index.jsp>).

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-4](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU1_Cx_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_IPU1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to IPU1_Cx_INTC inputs. For example, the IPU1_IRQ_23_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU1_IRQ_23 line. The reset value of this bit field is 0x14, meaning that DISPC_IRQ would be mapped to IPU1_IRQ_23 by default because it is connected to the IRQ_CROSSBAR_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated IPU1_Cx_INTC input line and therefore, the user cannot change its default mapping.

The CTRL_CORE_IPU1_IRQ_y_z registers control the IRQ_CROSSBAR settings for both NVICs in the IPU1 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU1.

13.3.4 Interrupt Requests to EVE_INTC1

[Table 13-5](#) lists the default interrupt sources for the EVE_INTC1. In addition, device interrupts EVE_IRQ_0 through EVE_IRQ_7 can alternatively be sourced through the EVE's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in [Table 13-6](#). The CTRL_CORE_EVE_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-5. EVE_INTC1 Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE_IRQ_0	1	CTRL_CORE_EVE_IRQ_0_1 [8:0]	1	ELM_IRQ	Error location process completion interrupt
EVE_IRQ_1	2	CTRL_CORE_EVE_IRQ_0_1 [24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
EVE_IRQ_2	3	CTRL_CORE_EVE_IRQ_2_3 [8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see Section 14.4.6.13.2 .
EVE_IRQ_3	4	CTRL_CORE_EVE_IRQ_2_3 [24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
EVE_IRQ_4	5	CTRL_CORE_EVE_IRQ_4_5 [8:0]	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
EVE_IRQ_5	6	CTRL_CORE_EVE_IRQ_4_5 [24:16]	6	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_6	7	CTRL_CORE_EVE_IRQ_6_7 [8:0]	7	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_7	8	CTRL_CORE_EVE_IRQ_6_7 [24:16]	8	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_8	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_9	N/A	N/A	N/A	Reserved	Reserved

EVE_IRQ_26	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_27	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_28	N/A	N/A	N/A	EVE_MBX2_INT0	EVE Mailbox 2 Interrupt 0
EVE_IRQ_29	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_30	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_31	N/A	N/A	N/A	Reserved	Reserved

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-5](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding EVE_INTC1 input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_EVE1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to EVE_INTC1 inputs. For example, the EVE1_IRQ_0_1[8:0] bit field is used to configure which device interrupt would be mapped to the EVE1_IRQ_0 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to EVE1_IRQ_0 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the EVE1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated EVE_INTC1 input line and therefore, the user cannot change its default mapping.

13.3.5 Mapping of Device Interrupts to IRQ_CROSSBAR Inputs

[Table 13-6](#) shows the individual connection between all module IRQs and all IRQ_CROSSBAR inputs.

Table 13-6. Connection of Device IRQs to IRQ_CROSSBAR Inputs

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_0	Reserved	Reserved	Reserved
IRQ_CROSSBAR_1	ELM_IRQ	ELM	Error location process completion interrupt
IRQ_CROSSBAR_2	EXT_SYS_IRQ_1	External system	External interrupt (active low) via sys_nirq1 pin
IRQ_CROSSBAR_3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	CTRL_MODULE_CORE	Combined firewall error interrupt. For more information, see Section 14.4.6.13.2
IRQ_CROSSBAR_4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	L3_MAIN debug error
IRQ_CROSSBAR_5	L3_MAIN_IRQ_APP_ERR	L3_MAIN	L3_MAIN application or non-attributable error

13.4 Interrupt Controllers Functional Description

For detailed information about each device INTC (including functional description and registers descriptions), see the TRM chapters and Arm documents referenced in [Section 13.1](#), *Interrupt Controllers Overview*.

Control Module

This chapter describes the system control module for the device.

Topic	Page
14.1 Control Module Overview	4746
14.2 Control Module Environment.....	4748
14.3 Control Module Integration	4749
14.4 Control Module Functional Description	4751
14.5 Control Module Register Manual.....	4779

14.1 Control Module Overview

The control module is composed of two submodules, the CTRL_MODULE_CORE submodule and the CTRL_MODULE_WKUP submodule. These two submodules represent a set of registers which are used to control the device I/O ports and also various kinds of settings related to the different modules available in this device.

The CTRL_MODULE_CORE submodule has registers for the following features:

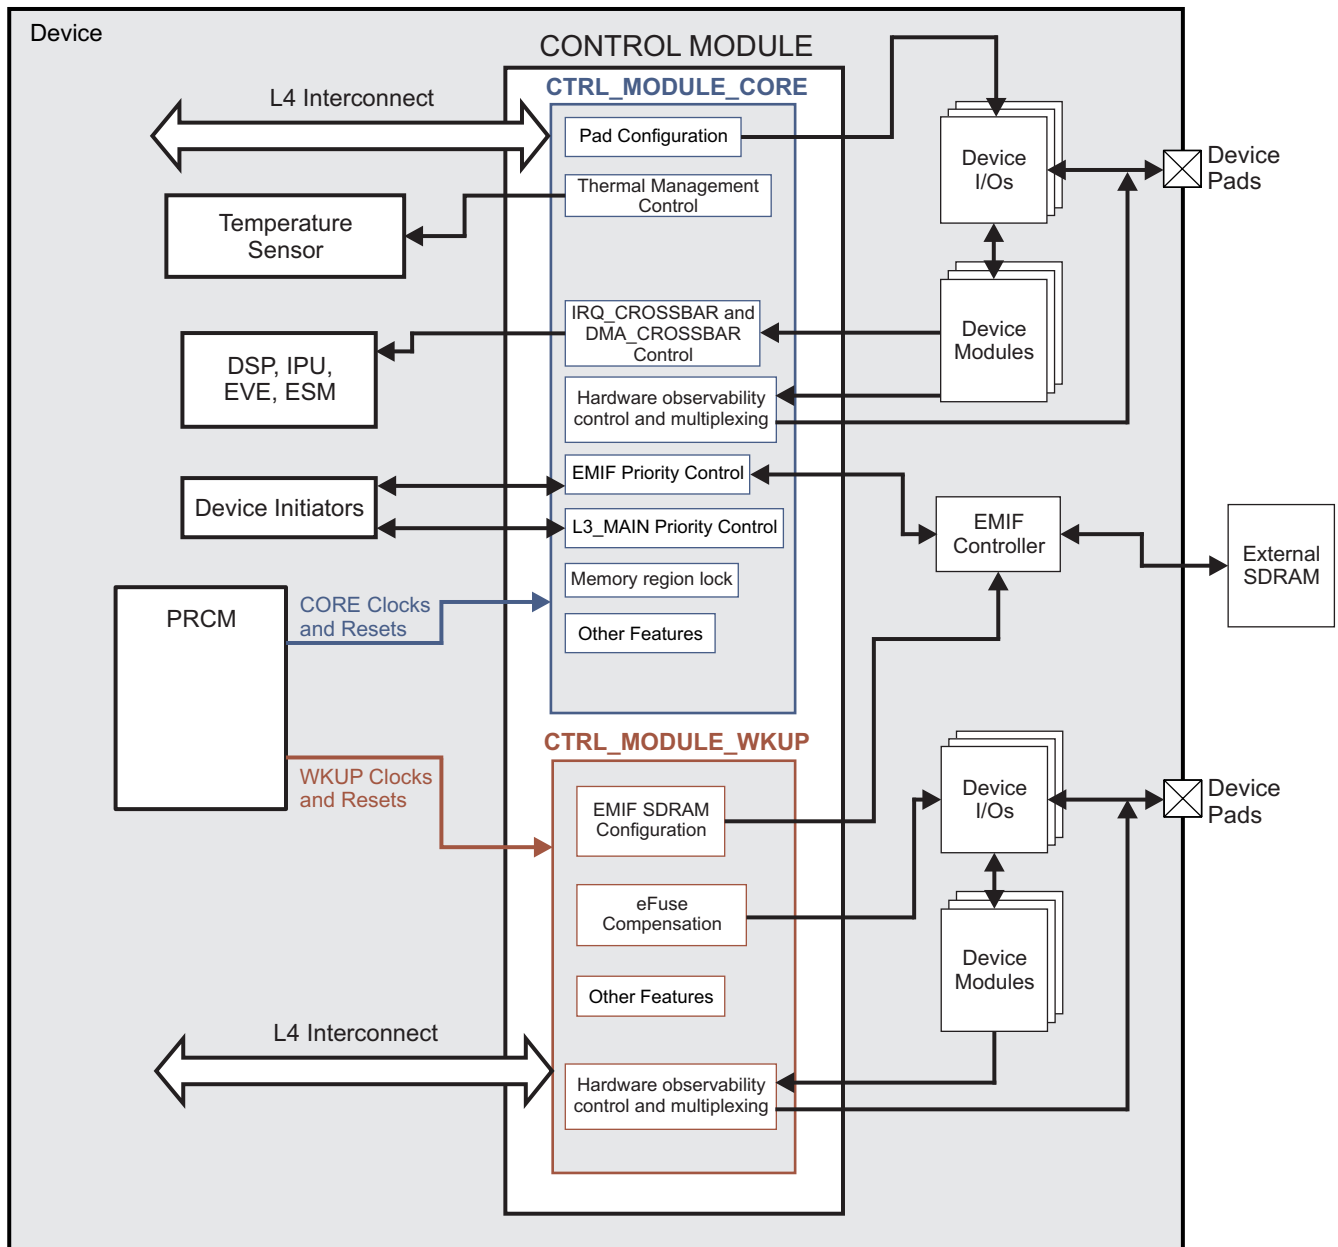

- Pad configuration with following controls:
 - Pad I/O multiplexing
 - Pad pull-up and pull-down configuration
 - Pad input buffer enabling
 - Pad slew rate control
- Device thermal management control and status registers
- IRQ_CROSSBAR and DMA_CROSSBAR control
- Control the priority of initiator accesses to the external SDRAM
- Control the priority of initiators connected to L3_MAIN interconnect
- Memory region lock registers
- Mapping of the device non-maskable interrupt (NMI) to respective cores
- Controls for the LPDDR2/DDR2/DDR3 I/O Cells
- Controls for the LPDDR2/DDR2/DDR3 associated vref-generation cells
- AVS Class 0 associated registers
- Status of the system boot settings
- Firewalls error status
- Settings related to different peripheral modules
- Hardware observability control and multiplexing
- Registers related to PRCM and PLL control
- Registers related to the boot ROM
- Other functions

The CTRL_MODULE_WKUP submodule has registers for the following features:

- Basic EMIF configuration settings
- XTAL Oscillator control
- Efuse I/O compensation
- Hardware observability control and multiplexing
- Other functions

[Figure 14-1](#) represents an overview block diagram of the control module.

Figure 14-1. Control Module Overview Block Diagram

ctrlmod-001

14.2 Control Module Environment

Figure 14-2 shows the control module environment.

Figure 14-2. Control Module Environment

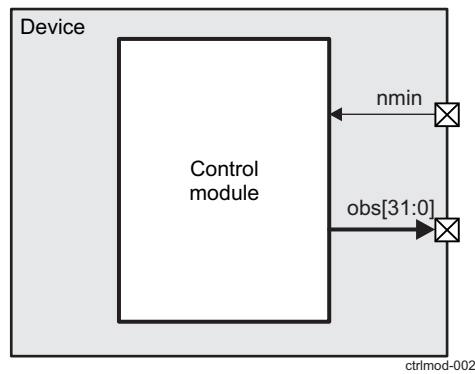

Table 14-1 shows the NMI input and observability output signals.

Table 14-1. Control Module I/O Signals Description

Signal	I/O ⁽¹⁾	Description
nmin	I	External non-maskable interrupt signal ⁽²⁾
obs[31:0]	O	32 hardware observability signals ⁽³⁾

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

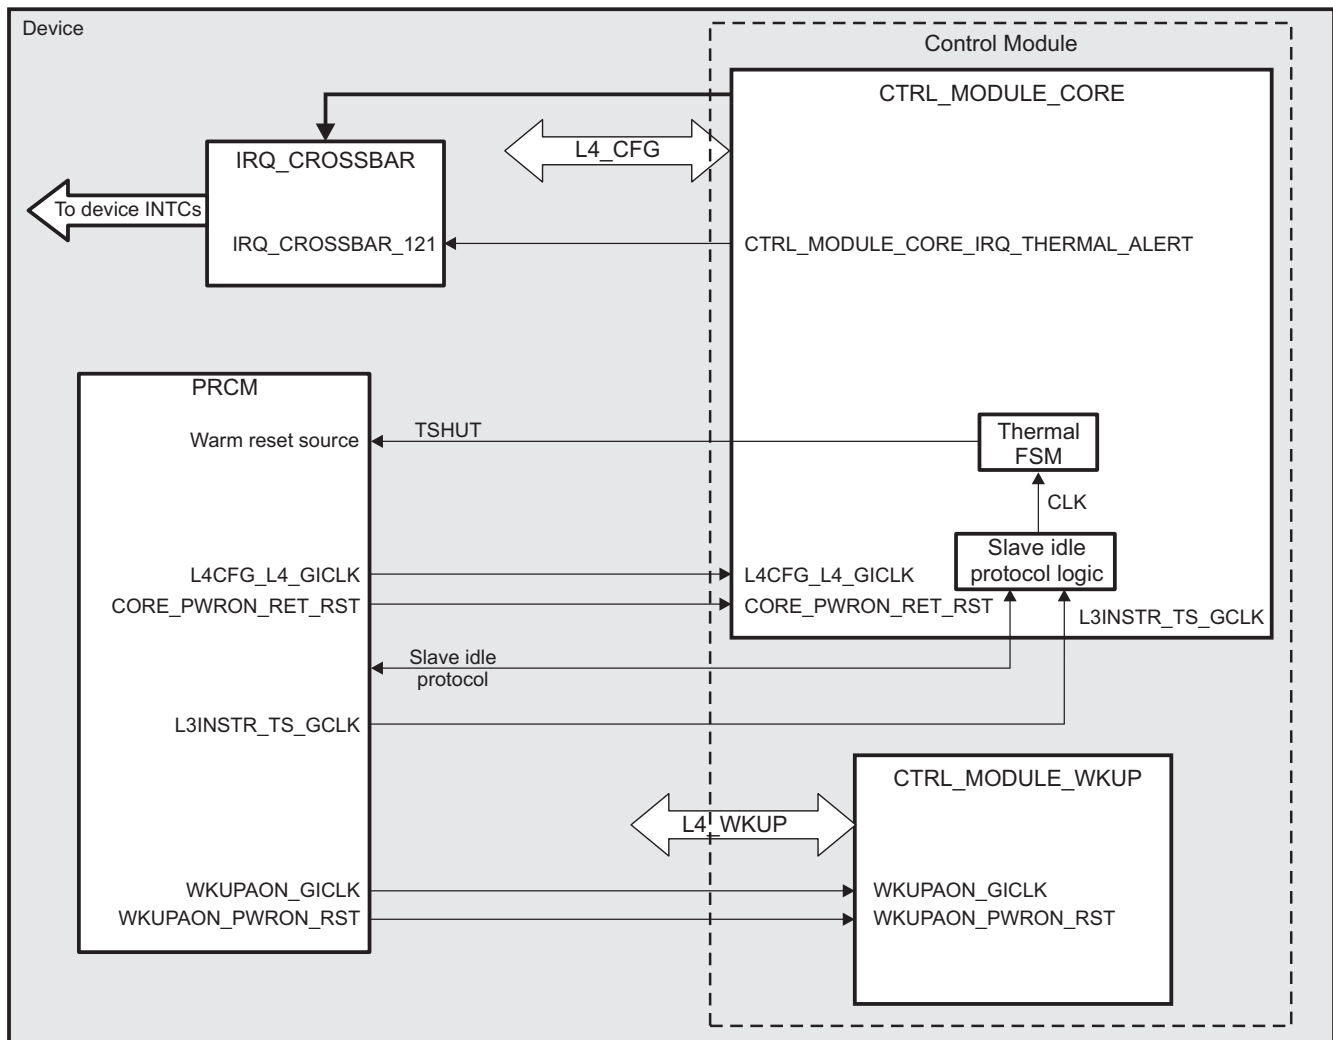

⁽²⁾ For more information, see [Section 14.4.6.9, NMI Mapping to respective cores](#)

⁽³⁾ For more information, see [Section 14.4.6.14, Hardware Observability Related Registers](#)

14.3 Control Module Integration

Figure 14-3 shows the integration of the control module in the device.

Figure 14-3. Control Module Integration

ctrlmod-003

Table 14-2 through Table 14-4 summarize the integration of the Control Module in the device.

Table 14-2. Control Module Integration Attributes

Submodule	Attributes	
	Power Domain	Interconnect
CTRL_MODULE_CORE	PD_COREAON	L4_CFG
CTRL_MODULE_WKUP	PD_WKUPAON	L4_WKUP

Table 14-3. Control Module Clocks and Resets

Clocks				
Submodule	Destination Signal Name	Source Signal Name	Source	Description

Table 14-3. Control Module Clocks and Resets (continued)

CTRL_MODULE_CORE E	L4CFG_L4_GICKL	L4CFG_L4_GICKL	PRCM	Interface clock to the CTRL_MODULE_CORE submodule
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Functional clock for the thermal FSM instantiated in the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP P	WKUPAON_GICKL	WKUPAON_GICKL	PRCM	Interface clock to the CTRL_MODULE_WKUP submodule
Resets				
CTRL_MODULE_CORE E	CORE_PWRON_RST	CORE_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP P	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the CTRL_MODULE_WKUP submodule

Table 14-4. Control Module Hardware Requests

Submodule	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
CTRL_MODULE_CORE E	CTRL_MODULE_CORE_IRQ_THERMAL_ALERT	IRQ_CROSSBAR_121	-	Thermal alert interrupt signal generated when the thermal sensor goes over the temperature threshold value. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “Default Mapping” column in [Table 14-4 Control Module Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

The integration of the control module is the following:

- No wake-up request generation
- No DMA request generation
- No master standby protocol with the PRCM
- Slave idle protocol, between the CTRL_MODULE_CORE submodule and the PRCM, related only to the L3INSTR_TS_GCLK
- One interrupt request to the IRQ_CROSSBAR module
- One (thermal shutdown) TSHUT signal used as PRCM warm reset source
- Two clocks and one reset signal to the CTRL_MODULE_CORE submodule
- One clock and one reset signal to the CTRL_MODULE_WKUP submodule

14.4 Control Module Functional Description

14.4.1 Control Module Clock Configuration

There is no software control over the L4CFG_L4_GICLK and WKUPAON_GICLK clocks neither in the control module nor in the PRCM module. The L4CFG_L4_GICLK clock is automatically gated when there is no access to the CTRL_MODULE_CORE registers and the WKUPAON_GICLK is automatically gated when there is no access to the CTRL_MODULE_WKUP registers. There are clock activity status bits for these two clocks in the PRCM module.

The L3INSTR_TS_GCLK is controlled by the [CTRL_CORE_BANDGAP_MASK_1](#)[31:30] SIDLEMODE bit field. For more information, see [Section 14.4.6.3.5](#).

The L3INSTR_TS_GCLK has also the following software controls located in the PRCM module:

- Status: see [Chapter 3, Power, Reset, and Clock Management](#)
- Divider ratio: see [Chapter 3, Power, Reset, and Clock Management](#)

14.4.2 Control Module Resets

The control module is not sensitive to software reset. It does not respond to global warm reset too. The control module can be reset only by the internal POR (global cold reset).

Despite the previously stated that control module is not sensitive to global warm reset the following registers are exception of this rule and are sensitive to global warm reset:

- All CTRL_CORE_PAD_x registers
- [CTRL_CORE_IPU_WAKEUP](#)
- [CTRL_CORE_TESOC_LAST_RESET_INDICATOR](#) (SR2.0 Only)
- [CTRL_CORE_ROM_AUXBOOT0](#) (SR2.0 Only)
- [CTRL_CORE_ROM_AUXBOOT1](#) (SR2.0 Only)

All other control module registers are sensitive only to global cold reset.

The PRCM provides the CORE_PWRON_RET_RST POR signal to the CTRL_MODULE_CORE and the WKUPAON_PWRON_RST POR signal to the CTRL_MODULE_WKUP. For more information, see [Section 3.5.5, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

14.4.3 Control Module Power Management

14.4.3.1 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support master standby or slave idle protocols for handshaking with the PRCM. Only the thermal FSM supports slave idle protocol used to control its functional clock, that is the L3INSTR_TS_GCLK clock.

14.4.4 Hardware Requests

The control module does not generate DMA and wake-up requests. The CTRL_MODULE_CORE submodule generates only one IRQ to the IRQ_CROSSBAR module. This is the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT interrupt. For more information, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#).

14.4.5 Control Module Initialization

The control module responds to the internal POR. During device initialization, only modules used at boot time are associated with the pads. Other module inputs are internally tied and output buffers are turned off. After POR, software must set the pad configuration registers to appropriate values according to the desired device configuration.

The [CTRL_CORE_BOOTSTRAP](#)[15:0] bit field reflects the state of the sysboot[15:0] pads captured at POR in the PRCM module.

14.4.6 Functional Description Of The Various Register Types In CTRL_MODULE_CORE Submodule

The following sections describe the purpose of the various kinds of registers and register groups which reside in the CTRL_MODULE_CORE submodule.

14.4.6.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is associated only with one pad. The name of each register is formed by the corresponding pad name and the prefix "CTRL_CORE_PAD_". Almost all pad configuration registers have same bits. In some of these registers certain bits cannot be present. Figure 14-4 shows the general case in which all the pad configuration register bits are present. Table 14-5 describes these bits.

After POR, software must set the pad configuration registers to appropriate values depending on the desired device configuration.

Figure 14-4. Pad Configuration Register Bits

ctrlmod-005

Table 14-5. Description Of The Pad Configuration Register Bits

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
SLEWCONTROL	Fast slew is selected	Slow slew is selected	Selects the slew rate for a given pad. The slew rate should be set to the value specified in the device Data Manual for a given mode of operation.
INPUTENABLE	Receive mode is disabled. The pad is configured in output mode only.	Receive mode is enabled. The pad is configured in bidirectional mode.	Enables the input buffer of a given I/O
PULLTYPESELECT	Weak pull-down resistor is selected	Weak pull-up resistor is selected	Weak pull-up or weak pull-down resistor selection for a given pad
PULLUDENABLE	Weak pull-up/pull-down resistor is enabled	Weak pull-up/pull-down resistor is disabled	Enables weak pull-up/pull-down feature of a given pad
MUXMODE	This bit field selects one of maximum sixteen possible functions to be available on the corresponding pad. Mostly, only several functions are available.		

When MUXMODE is set to 0x0 the function mapped to the pad corresponds to the name of the pad. In other words, pad names are signal names available when MUXMODE = 0x0.

By default the MUXMODE bit field of most device pads is set to 0xF, which means that there are no signals routed to these pads and the pads are in Hi-Z. The only exception are the sysboot signals available on several pads when MUXMODE = 0xF.

Only MUXMODE values which correspond to defined functions should be used.

NOTE: The default SLEWCONTROL settings in each pad configuration register must be used to guarantee timings, unless specific instructions otherwise are given in the individual timing sub-sections of the device Data Manual. The only exception is when the MUXMODE is configured to select a vout*_ * signal. In this case the corresponding SLEWCONTROL bit must be configured to slow slew instead of the default fast slew.

NOTE: When an external pull resistor is desired, the internal pull resistors must be disabled by software because they are enabled by default.

NOTE: For information about the signals available on each pad, see the *Multiplexing Characteristics* table in the device Data Manual.

NOTE: GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

The following signals require CTRL_CORE_PAD_x to be programmed with INPUTENABLE=1 for retiming purposes:

- mmc_clk
- gpmc_clk
- i2cj_scl where j=1-2
- spim_sclk where m=1-4
- mcasp1_aclkx, mcasp1_ahclkx, and mcasp1_aclkr
- SR2.0 Only: mcasp2_aclkx, mcasp2_ahclkx, mcasp2_aclkr, mcasp3_aclkx, mcasp3_ahclkx, and mcasp3_aclkr

SR2.0 Only:

Except the maximum 16 possible combinations through the MUXMODE bit fields using the bits within [CTRL_CORE_SMA_SW_14](#) and [CTRL_CORE_SMA_SW_15](#) registers an additional signal can be mapped to several device pads. In other words, for these pads there are up to 17 possible signal combinations although not all of them are really implemented. These registers control McASP2 and McASP3 signal multiplexing. If a bit is set to 0x1, function 17 is selected for the corresponding pad. In that case the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF. If a bit is set to 0x0, function 17 is not selected.

14.4.6.2 Pull Selection

There is no automatic gating control to ensure that internal weak pull-up or pull-down resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it to avoid unnecessary consumption.

[Table 14-6](#) describes the software controls available for pad internal pull-up and pull-down resistors in the control module pad configuration registers.

Table 14-6. Pull Selection

PULL		Pad Behavior
PULLTYPESELECT	PULLUDENABLE	
0	1	Pull-down selected but not activated
0	0	Pull-down selected and activated
1	1	Pull-up selected but not activated
1	0	Pull-up selected and activated

14.4.6.3 Thermal Management Related Registers

There is one temperature sensor on the device die. It is part of a VBGAPTS cell. This cell has a 10-bit ADC. The ADC converts the temperature values into digital output values proportional to the temperature measured. The VBGAPTS cell is controlled by a dedicated FSM referred to as thermal FSM. The registers associated with this FSM reside in the CTRL_MODULE_CORE submodule. The FSM is clocked by the L3INSTR_TS_GCLK clock. The PRCM module controls this clock through the slave idle protocol.

The device thermal management related registers can be split into the following classes:

- Temperature sensor control registers
- Registers for the thermal alert comparator block
- Temperature timestamp registers
- Other registers used for:
 - controlling the FIFO
 - controlling the clock provided to the thermal FSM

Figure 14-5 shows the block diagram of the device thermal management.

Figure 14-5. Thermal Management Functional Block Diagram

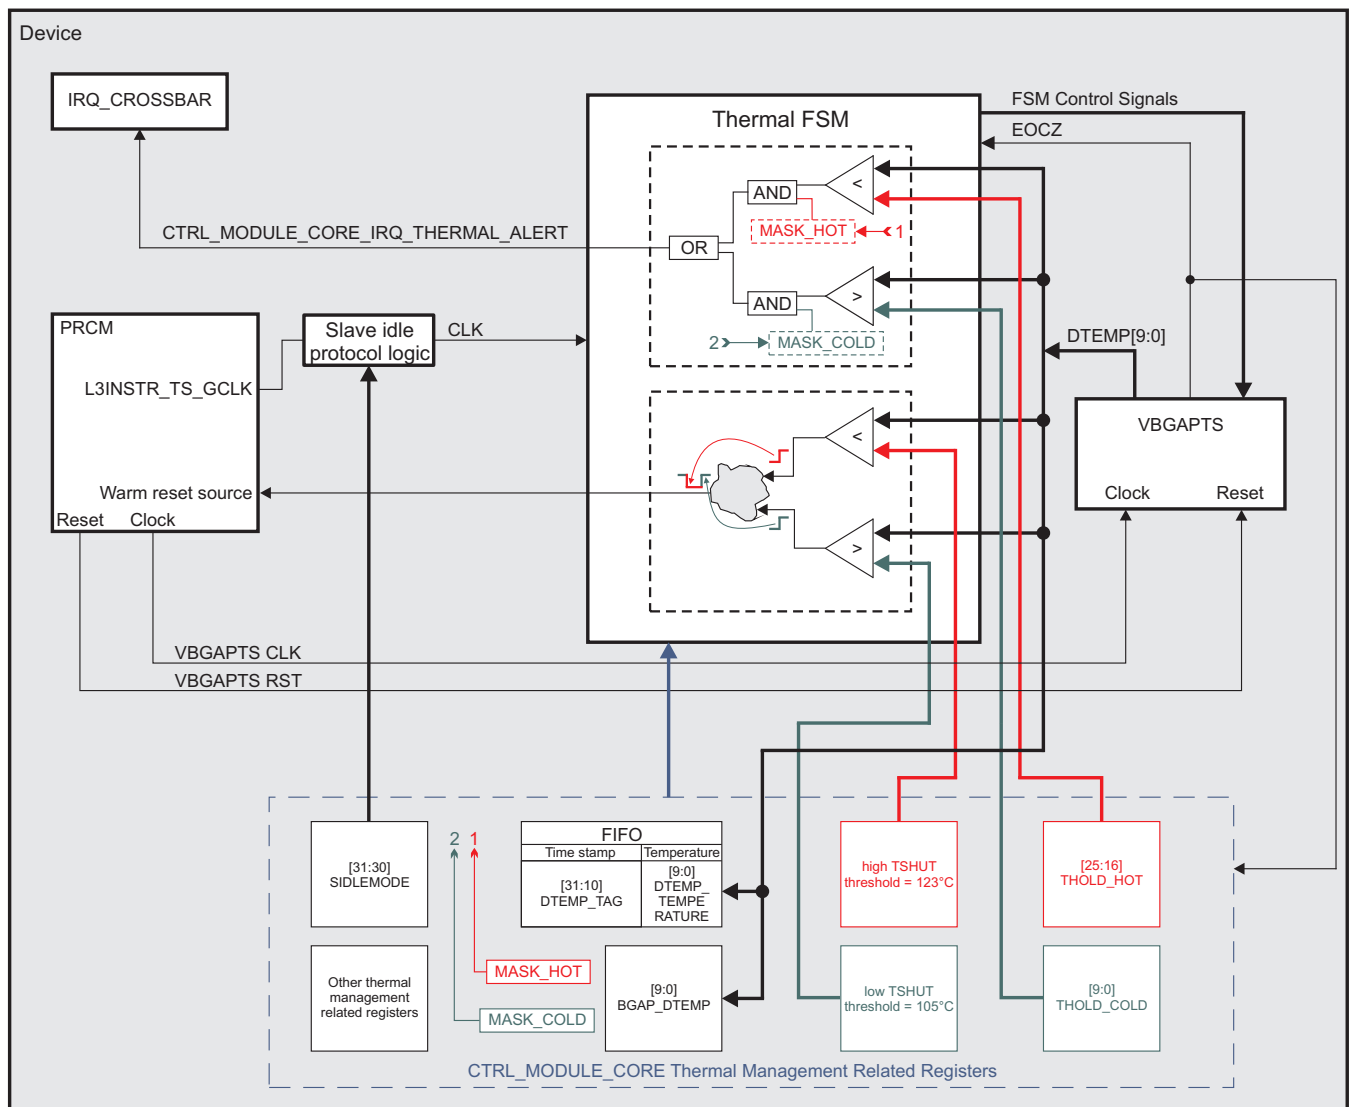

Table 14-7 describes the signals related to the device thermal management logic.

Table 14-7. Thermal Management Signals Description

Signal	I/O ⁽¹⁾	Description
EOCZ	O	End of conversion signal. When low, this signal indicates that the value of DTEMP[9:0] is valid.

⁽¹⁾ I = Input; O = Output

Table 14-7. Thermal Management Signals Description (continued)

Signal	I/O ⁽¹⁾	Description
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
VBGAPTS CLK	I	Functional clock from the WKUPAON power domain used by the temperature sensor during temperature conversion.
THERMAL ALERT	O	This is an output signal from the thermal FSM mapped as an interrupt request to the IRQ_CROSSBAR module. Software uses this interrupt to implement the device thermal management policy.
TSHUT	O	This is an output signal from the thermal FSM mapped to the PRCM and is used as a warm reset signal. This overheat protection signal is high during normal operation and go low during thermal shutdown event.

The ADC values which correspond to the current temperature are listed in [Table 14-10](#).

14.4.6.3.1 Temperature Sensor Control Registers

The VBGAPTS cell works in continuous conversion mode controlled by the thermal FSM. This means that the temperature is measured at regular time intervals. The start of temperature measurement is initiated automatically by the thermal FSM after it goes out of reset state. To control the main delay between two measurements the [CTRL_CORE_BANDGAP_MASK_1\[29:27\]](#) COUNTER_DELAY bit field is used. After this delay expires the FSM automatically starts a temperature conversion.

The conversion is complete when the [CTRL_CORE_TEMP_SENSOR_CORE\[10\]](#) BGAP_EOCZ_CORE status bits is set to 0x0. After this the valid temperature is written automatically in the [CTRL_CORE_TEMP_SENSOR_CORE\[9:0\]](#) BGAP_DTEMP_CORE bit field, and then software is able to read it. After writing the valid temperature value the FSM waits one clock cycle and start another conversion cycle.

14.4.6.3.2 Registers For The Thermal Alert Comparator Block

There is a comparator block responsible for the thermal alert function of the CTRL_MODULE_CORE thermal management logic. This comparator block is composed of two comparators. One dedicated to low temperature threshold and the other one to high temperature threshold. Software can configure the low temperature threshold through the [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[9:0\]](#) THOLD_COLD_CORE bit field and high temperature threshold through the [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[25:16\]](#) THOLD_HOT_CORE bit field. The values which have to be loaded in these bit fields are the same as those listed in [Table 14-10](#). For example, to set the high temperature threshold value to 120°C, the THOLD_HOT_CORE filed must be loaded with value of 931 (0x3A3).

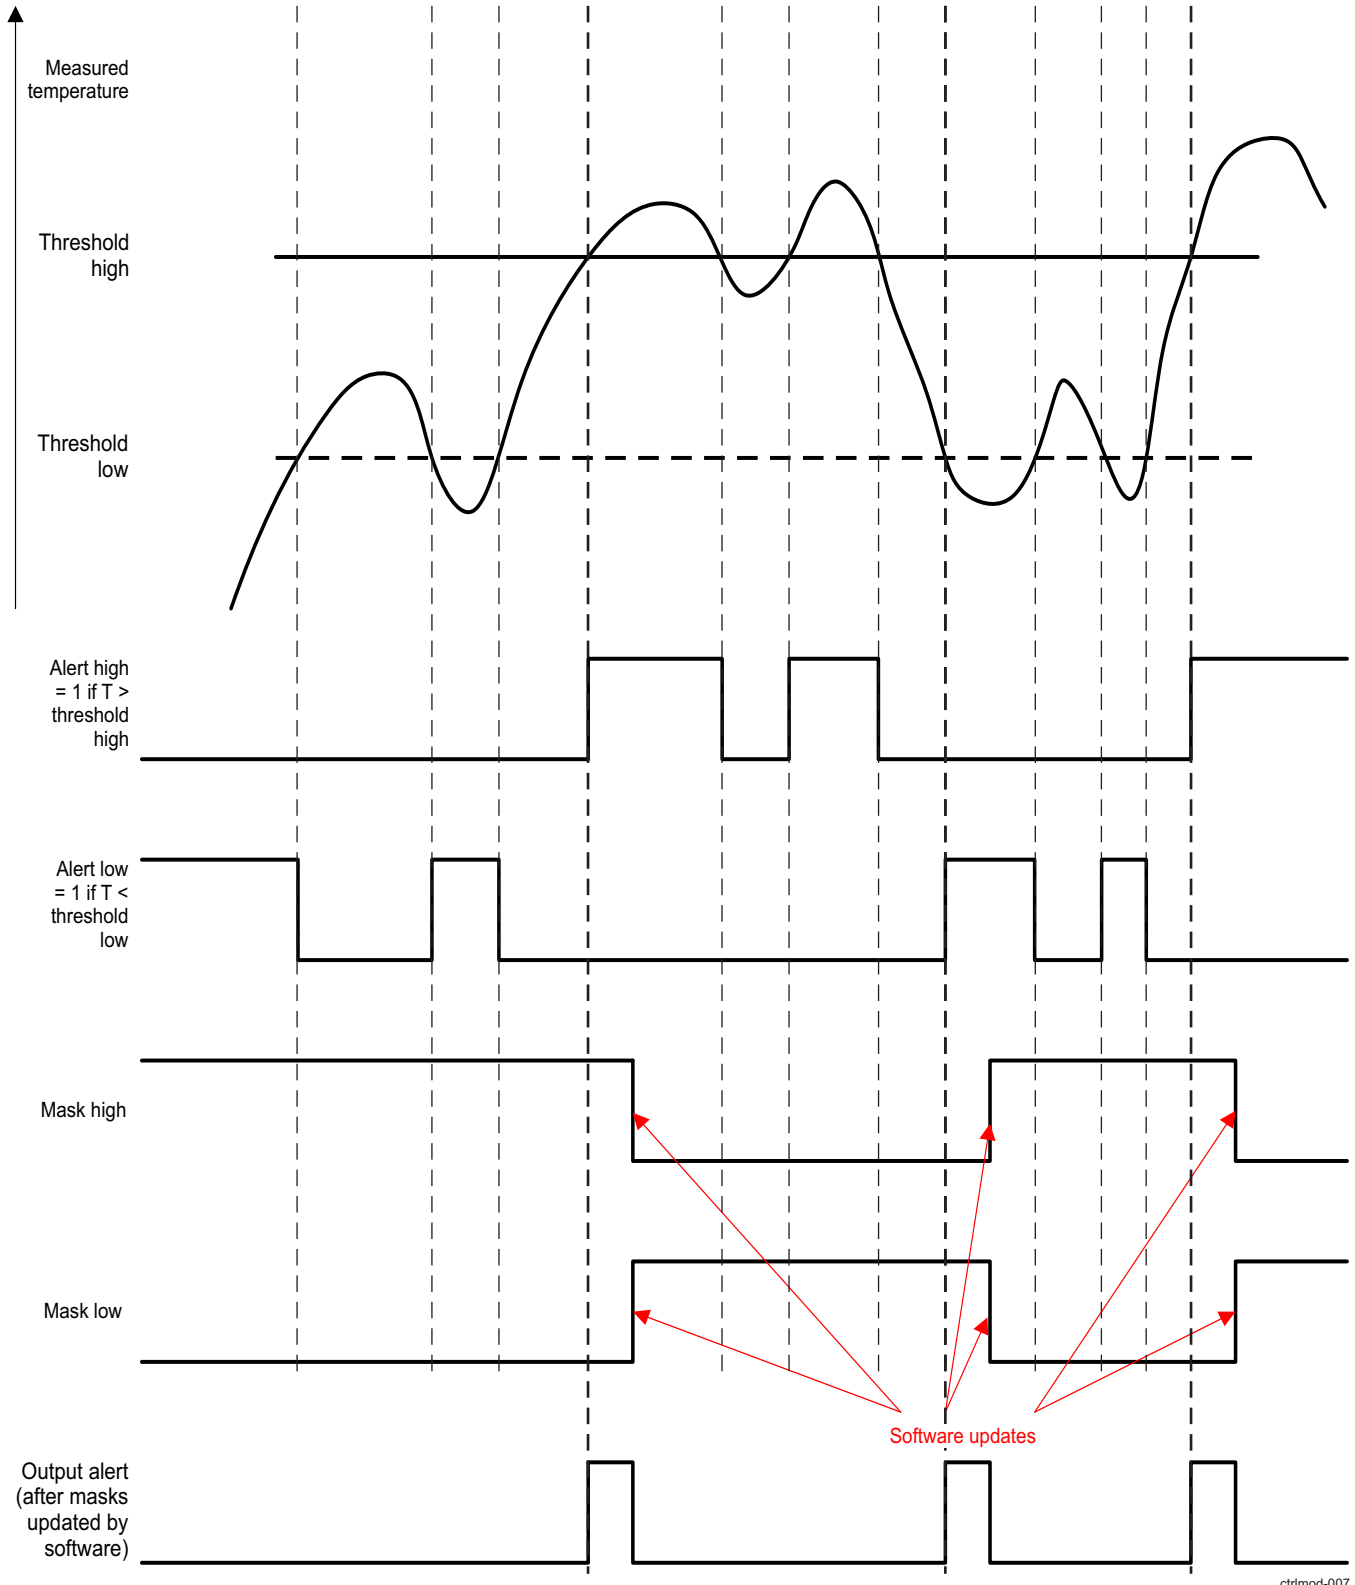

The thermal alert logic provides also a capability to mask the outputs of the comparators associated with low and high temperature thresholds. The low temperature threshold comparator output can be masked by setting to 0x0 the [CTRL_CORE_BANDGAP_MASK_1\[4\]](#) MASK_COLD_CORE bit. The high temperature threshold comparator output can be masked by setting to 0x0 the [CTRL_CORE_BANDGAP_MASK_1\[5\]](#) MASK_HOT_CORE bit.

The masked low and high temperature threshold outputs are ORed (see [Figure 14-5](#)) in the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal, which delivers an interrupt to the IRQ_CROSSBAR_121 input line of the IRQ_CROSSBAR module. Software can use this interrupt to implement the device thermal management policy. The CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is also routed to the [CTRL_CORE_BANDGAP_STATUS_1\[31\]](#) ALERT bit. Value of 0x1 indicates that the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is asserted.

The [CTRL_CORE_BANDGAP_STATUS_1\[4\]](#) COLD_CORE bit indicates the non masked (raw) comparator output for the low temperature threshold. The [CTRL_CORE_BANDGAP_STATUS_1\[5\]](#) HOT_CORE bit indicates the non masked (raw) comparator output for the high temperature threshold.

[Figure 14-6](#) shows the behavior of the thermal alert logic.

Figure 14-6. Behavior Of The Thermal Alert Logic

ctrlmod-007

14.4.6.3.3 Thermal Shutdown Comparator Block

There is also a comparator block responsible for the thermal shutdown (TSHUT) function of the CTRL_MODULE_CORE thermal management logic. This comparator block is also composed of two comparators. One dedicated to low TSHUT threshold and the other one to high TSHUT threshold. The comparator outputs for the low and high TSHUT thresholds are connected to a logic which then generates a single TSHUT signal tied to the PRCM and used as warm reset source. For details, see [Figure 14-5](#).

The values of the low and high TSHUT thresholds are fixed and can be neither overridden nor read by software. The value for the high TSHUT threshold is 123°C (assuming +/-2C temperature sensor accuracy) and for the low TSHUT threshold it is 105°C.

When the high TSHUT threshold is reached, the TSHUT output is activated. To deactivate the TSHUT output, the temperature must go below the value of the low TSHUT threshold.

The TSHUT signal is used as an overheat protection. [Figure 14-7](#) shows the behavior of the TSHUT logic.

Figure 14-7. Behavior Of The Thermal Shutdown Logic

ctrlmod-008

14.4.6.3.4 Temperature Timestamp Registers

Each time when the CTRL_CORE_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit field is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is registered too. This FIFO is used to store a brief history for the last few temperature measurements and is also dedicated to temperature timestamping. The FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements. The FIFO is composed of the following registers:

- CTRL_CORE_DTEMP_CORE_0
- CTRL_CORE_DTEMP_CORE_1
- CTRL_CORE_DTEMP_CORE_2
- CTRL_CORE_DTEMP_CORE_3

- [CTRL_CORE_DTEMP_CORE_4](#)

Table 14-8 describes the FIFO.

Table 14-8. FIFO Description

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10]	Description	First FIFO field (10 Bits) – Temperature Bits [9:0]	Description
Level 1	DTEMP_TAG_CORE_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_CORE_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_CORE_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_CORE_0 – 1)	DTEMP_TEMPERATURE_CORE_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_CORE_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_CORE_0 – 2)	DTEMP_TEMPERATURE_CORE_2	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_1
Level 4	DTEMP_TAG_CORE_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_CORE_0 – 3)	DTEMP_TEMPERATURE_CORE_3	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_2
Level 5	DTEMP_TAG_CORE_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_CORE_0 – 4)	DTEMP_TEMPERATURE_CORE_4	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_3 (the oldest sample)

NOTE: DTEMP_TAG_CORE_4 increments its value with one after each fifth temperature measurement.

DTEMP_TAG_CORE_3 increments its value with one after each fourth temperature measurement.

DTEMP_TAG_CORE_2 increments its value with one after each third temperature measurement.

DTEMP_TAG_CORE_1 increments its value with one after each second temperature measurement.

DTEMP_TAG_CORE_0 increments its value with one after each temperature measurement.

14.4.6.3.5 Other Thermal Management Related Registers

- **Controlling the FIFO:**

Software can stop the FIFO to update with new temperature and timestamp values when setting to 0x1 the [CTRL_CORE_BANDGAP_MASK_1](#)[23] FREEZE_CORE bit. This bit is automatically cleared by hardware after the FIFO has been cleared.

The FIFO is cleared by setting to 0x1 the [CTRL_CORE_BANDGAP_MASK_1](#)[20] CLEAR_CORE bit. This bit is automatically set by hardware to 0x0 after the FIFO clearing procedure completes.

- **Controlling the clock provided to the thermal FSM:**

The thermal FSM complies with the PRCM slave idle protocol. Its functional clock (L3INSTR_TS_GCLK) is automatically gated by PRCM depending on the value of the [CTRL_CORE_BANDGAP_MASK_1](#)[31:30] SIDLEMODE bit field. L3INSTR_TS_GCLK clock is also enabled automatically by the PRCM module.

14.4.6.3.6 Summary Of The Thermal Management Related Registers

Table 14-9 summarizes all the thermal management related registers.

Table 14-9. Summary Of The Thermal Management Related Registers

Register Name	Description	Access
CTRL_CORE_TEMP_SENSOR_CORE	Temperature sensor control register	RW
CTRL_CORE_BANDGAP_THRESHOLD_CORE	Register for the thermal alert comparator	RW
CTRL_CORE_BANDGAP_TSHUT_CORE	Register for the thermal shutdown comparator	RW
CTRL_CORE_DTEMP_CORE_0	Temperature timestamp registers	RO
CTRL_CORE_DTEMP_CORE_1		
CTRL_CORE_DTEMP_CORE_2		
CTRL_CORE_DTEMP_CORE_3		
CTRL_CORE_DTEMP_CORE_4		
CTRL_CORE_BANDGAP_STATUS_1	Register with status bits for the non masked comparator outputs and the thermal alert signal.	RO
CTRL_CORE_BANDGAP_MASK_1	Register used to mask the comparator outputs for the low and high thermal alert thresholds. This register is also used to control the FIFO and the clock provided to the thermal FSM.	RW

14.4.6.3.7 ADC Values Versus Temperature

Table 14-10 provides all valid ADC values corresponding to the measured temperature which should be read from the [CTRL_CORE_TEMP_SENSOR_CORE\[9:0\]](#) BGAP_DTEMP_CORE bit field. Table 14-10 also provides the values for the low and high temperature thresholds which are configurable through the [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[9:0\]](#) THOLD_COLD_CORE and [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[25:16\]](#) THOLD_HOT_CORE bit fields.

Table 14-10. ADC Values Versus Temperature

ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature

14.4.6.4 IRQ_CROSSBAR Module Functional Description

There is an IRQ_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The IRQ_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device interrupt sources. The IRQs from all the device modules are connected to the IRQ_CROSSBAR inputs. Each module IRQ is connected only to one crossbar input. Each output of the IRQ_CROSSBAR module is connected only to one interrupt line of certain interrupt controller (INTC). Thus, the device IRQs are mapped to the device INTCs through the

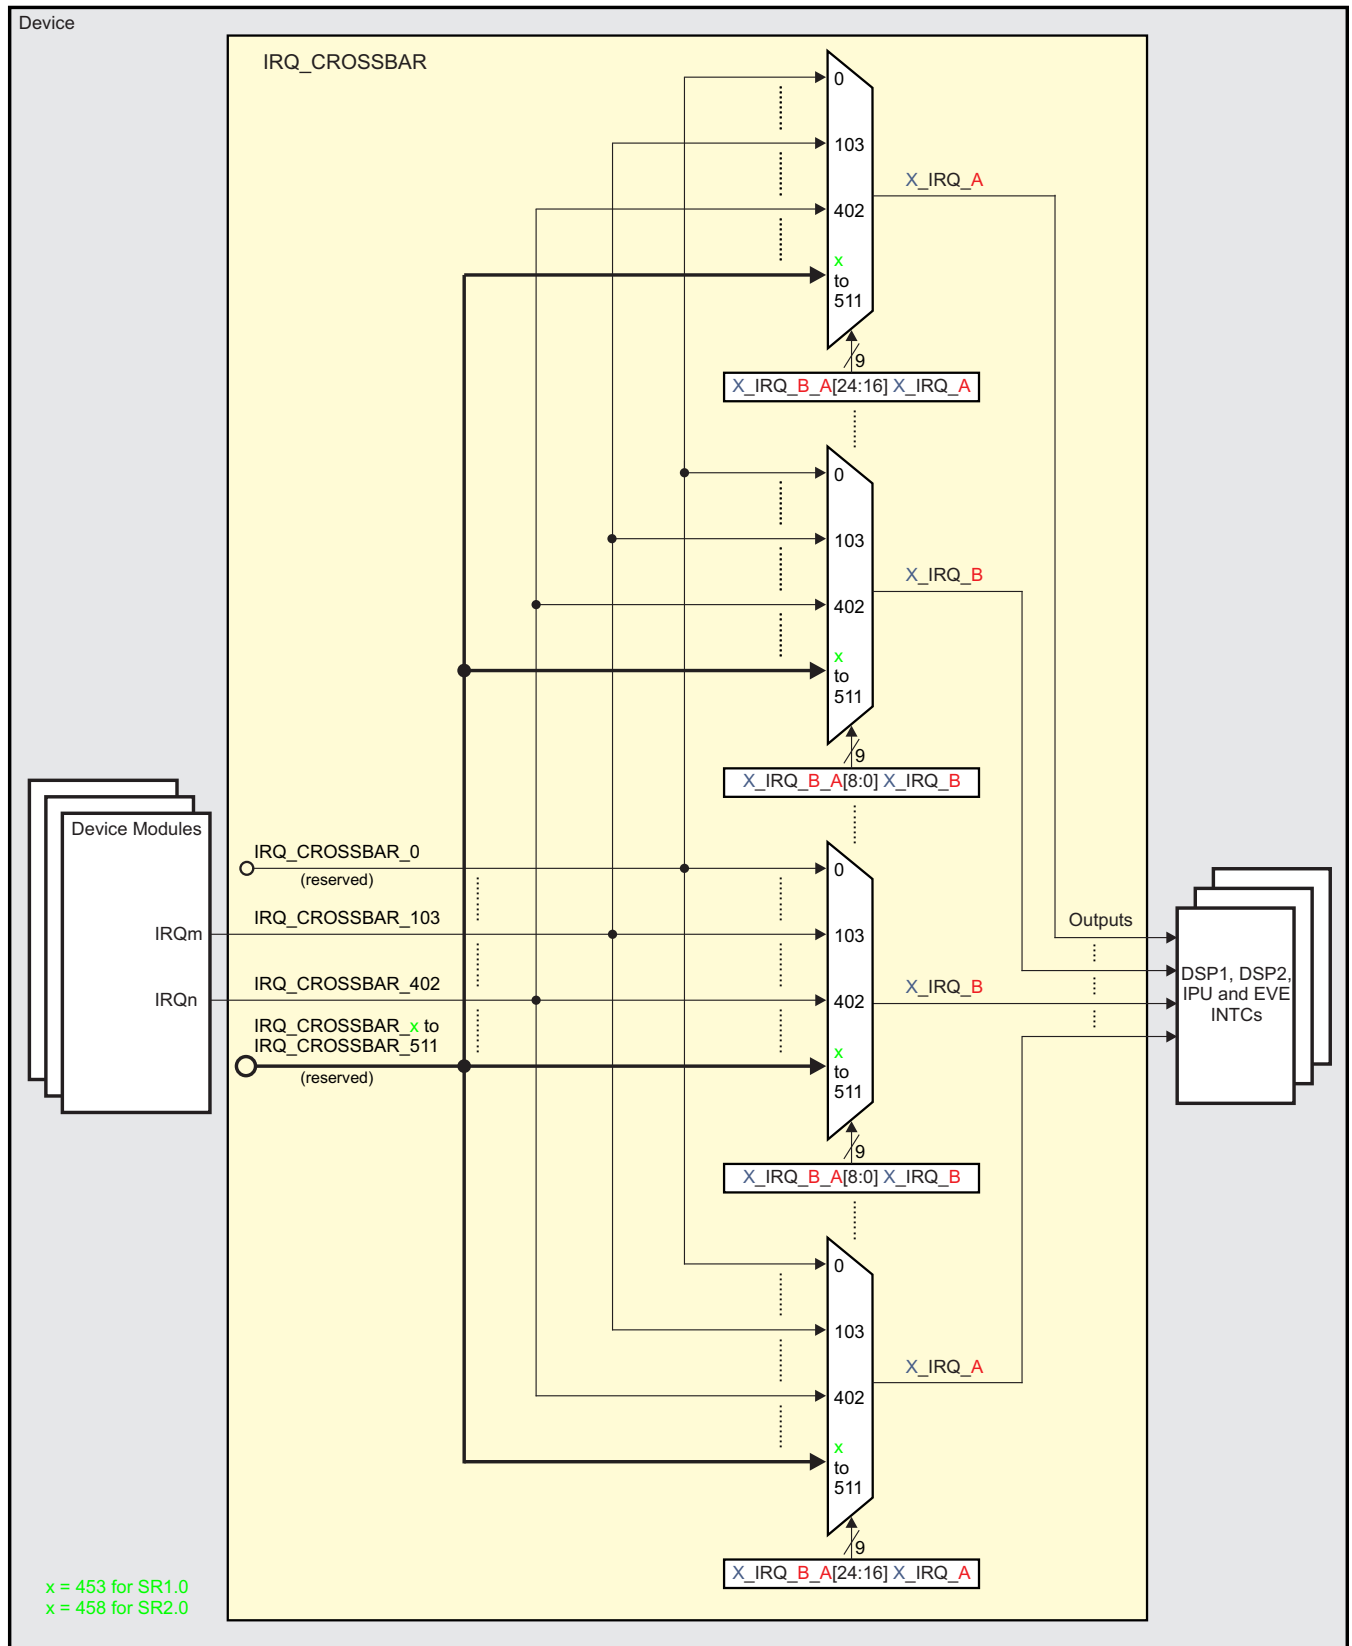

IRQ_CROSSBAR. Some of these IRQs are mapped by default to certain interrupt lines of one of the device INTCs, but there are IRQs which are not mapped by default to any interrupt line of any device INTC. All IRQs, connected to the IRQ_CROSSBAR inputs, can be remapped to other interrupt lines of the different device INTCs through the CTRL_CORE_X_IRQ_B_A registers. Each of these registers has a structure described in [Table 14-11](#).

Table 14-11. Generic Description of the CTRL_CORE_X_IRQ_B_A IRQ_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:25	RESERVED		R	
24:16	X_IRQ_A	Selects an interrupt source signal for the X_IRQ_A INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_A INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_A INTC line 0x-: 0x67: Maps IRQ_CROSSBAR input 103 to X_IRQ_A INTC line 0x-: 0x1C5 to 0x1FF: Reserved	RW	X is summarization. It is equal to: <ul style="list-style-type: none"> • DSP1 • DSP2 • IPU • EVE X shows the module name to which interrupt controller all inputs of the IRQ_CROSSBAR module can be mapped to. A is also summarization. It shows the number of the line for the corresponding INTC. A is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module. For more details, see Table 14-12 .
15:9	RESERVED		R	
8:0	X_IRQ_B	Selects an interrupt source signal for the X_IRQ_B INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_B INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_B INTC line 0x-: 0x67: Maps IRQ_CROSSBAR input 103 to X_IRQ_B INTC line 0x-: 0x1C5 to 0x1FF: Reserved	RW	B is summarization. It shows the number of the line for the corresponding INTC. B is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module.

Figure 14-8 represents the way in which the IRQ_CROSSBAR module works. It shows the device modules and their IRQs connected to the IRQ_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device INTCs.

Figure 14-8. IRQ_CROSSBAR Module Functional Diagram

ctrlmod-010

Each IRQ_CROSSBAR control register has two 9-bit fields. Each 9-bit field is associated only with one interrupt line. Through this 9-bit field any of the IRQs connected to the IRQ_CROSSBAR inputs can be mapped to the INTC line associated with this 9-bit field. For example, the register [CTRL_CORE_DSP1_IRQ_56_57](#) is associated with DSP1_IRQ_56 and DSP1_IRQ_57. The 9-bit field [CTRL_CORE_DSP1_IRQ_56_57\[24:16\]](#) DSP1_IRQ_57 is associated only with DSP1_IRQ_57 interrupt line of the DSP1 INTC. Setting this bit field to any other value different than its reset value will map another module IRQ to the DSP1_IRQ_57 interrupt line. The default (reset) value of this bit field is 0x1A which corresponds to IRQ_CROSSBAR_26 input. The GPIO3_IRQ_1 is connected to this cross-bar input. Setting another register to 0x1A will cause the GPIO3_IRQ_1 to be mapped to another INTC line. For example, if the [CTRL_CORE_DSP1_IRQ_40_41\[8:0\]](#) DSP1_IRQ_40 is set to 0x1A the GPIO3_IRQ_1 will be mapped to the DSP1_IRQ_40 interrupt line. The same logic also applies to the other interrupt lines of the device INTCs.

In addition, not all of the interrupt lines of a given INTC are controlled by the IRQ_CROSSBAR registers. This means, that there are interrupt lines which are not connected to any IRQ_CROSSBAR output and thus only one IRQ is connected to these interrupt lines. In the most common case these lines are used by interrupt sources internal or specific for the corresponding module, which has an INTC.

[Table 14-12](#) shows which lines of each INTC are associated with the IRQ_CROSSBAR control registers. The rest of the INTC lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 14-12. Interrupt Lines Associated With The IRQ_CROSSBAR Control Registers

DSP INTC Lines	IPU INTC Lines	EVE INTC Lines
DSP1_IRQ_32 to DSP1_IRQ_95, DSP2_IRQ_32 to DSP2_IRQ_95	IPU_IRQ_23 to IPU_IRQ_80	EVE_IRQ_0 to EVE_IRQ_7

The individual connection between all module IRQs and all IRQ_CROSSBAR inputs is shown in [Section 13.3.5, Mapping of Device Interrupts to IRQ_CROSSBAR Inputs](#) of [Chapter 13, Interrupt Controllers](#).

In addition, there are three IRQ_CROSSBAR registers associated with three channels of the device ESM. The registers are the following:

- [CTRL_CORE_ESM_GROUP1_0](#)
- [CTRL_CORE_ESM_GROUP1_1](#)
- [CTRL_CORE_ESM_GROUP1_2](#)

These three registers follow the same logic as previously described. For example, using the [CTRL_CORE_ESM_GROUP1_0\[8:0\]](#) ESM_GROUP1_0_IRQ_0 bit field any of the device interrupts connected to an IRQ_CROSSBAR input can be mapped to channel ESM_GROUP1_0.

14.4.6.5 DMA_CROSSBAR Module Functional Description

There is a DMA_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The DMA_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device DMA request (DREQ) source signals. The DREQs from all the device modules are connected to the DMA_CROSSBAR inputs. Each DREQ signal is connected only to one DMA cross-bar input. Each output of the DMA_CROSSBAR module is connected only to one input line of the device DMA modules. The DMAs associated with the DMA_CROSSBAR are the following:

- DMA_EDMA
- DMA_DSP1_EDMA
- DMA_DSP2_EDMA

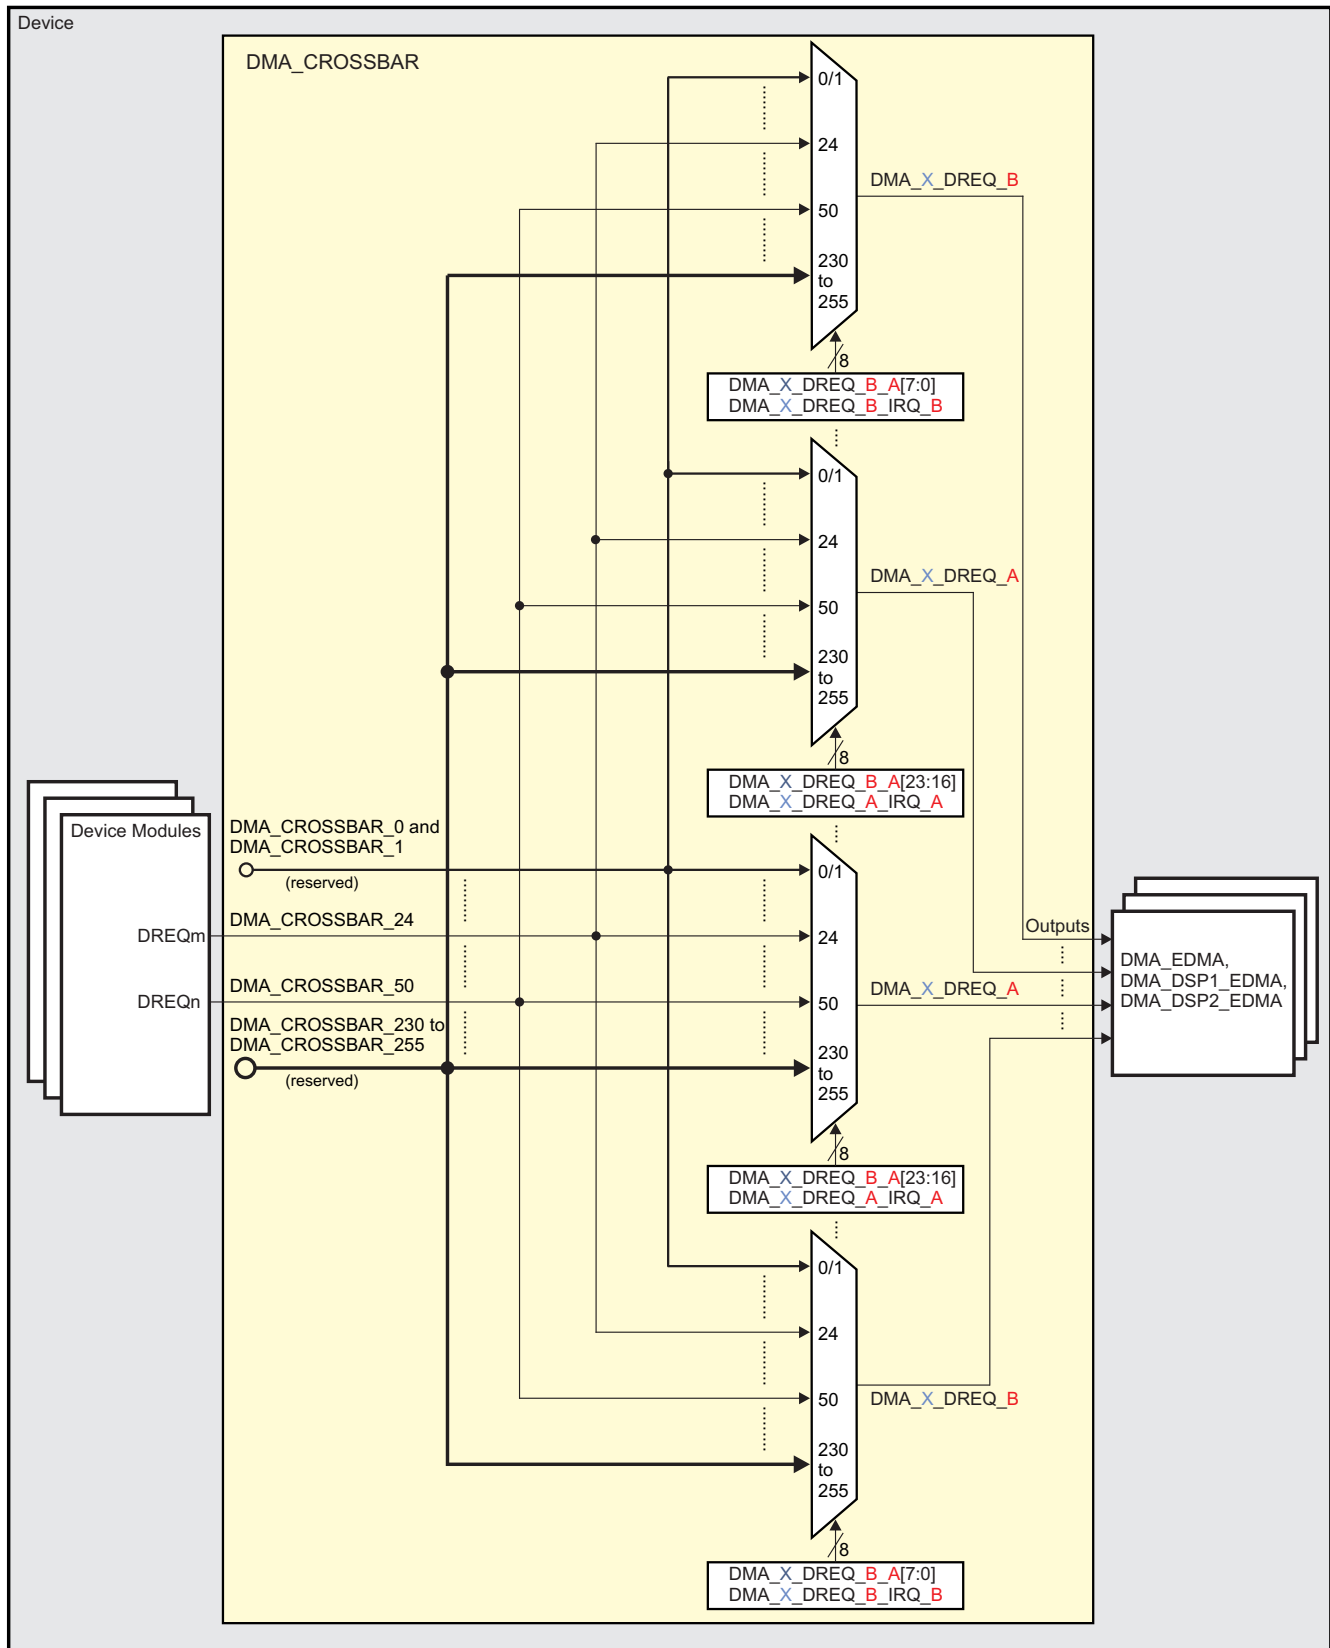

All DREQs, connected to the DMA_CROSSBAR inputs, can be remapped to other lines of the these DMA modules through the CTRL_CORE_DMA_X_DREQ_B_A registers. Each of these registers has a structure described in [Table 14-13](#).

Table 14-13. Generic Description of the CTRL_CORE_DMA_X_DREQ_B_A DMA_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:24	RESERVED		R	
23:16	DMA_X_DREQ_A_IRQ_A	Selects a DMA request source signal for the DMA_X_DREQ_A_IRQ_A DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_A_IRQ_A DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: 0xE6 to 0xFF: Reserved	RW	X is summarization. It is equal to: <ul style="list-style-type: none"> • EDMA • DSP1_EDMA • DSP2_EDMA X shows to which DMA all inputs of the DMA_CROSSBAR module can be mapped to. A is also summarization. It shows the number of the DREQ line for the corresponding DMA module. A is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 14-14 .
15:8	RESERVED		R	
7:0	DMA_X_DREQ_B_IRQ_B	Selects a DMA request source signal for the DMA_X_DREQ_B_IRQ_B DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_B_IRQ_B DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: 0xE6 to 0xFF: Reserved	RW	B is also summarization. It shows the number of the DREQ line for the corresponding DMA module. B is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 14-14 .

Figure 14-9 represents the way in which the DMA_CROSSBAR module works. It shows the device modules and their DREQs connected to the DMA_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device DMA modules.

Figure 14-9. DMA_CROSSBAR Module Functional Diagram

ctrlmod-011

Each DMA_CROSSBAR control register has two 8-bit fields. Each 8-bit field is associated only with one line of certain DMA module. Through this 8-bit field any of the DREQs connected to the DMA_CROSSBAR inputs can be mapped to the DMA line associated with this 8-bit field. For example, the register [CTRL_CORE_DMA_EDMA_DREQ_48_49](#) is associated with DMA_EDMA_DREQ_48 and DMA_EDMA_DREQ_49 lines. The 8-bit field [CTRL_CORE_DMA_EDMA_DREQ_48_49\[7:0\]](#) DMA_EDMA_DREQ_48_IRQ_48 is associated only with DMA_EDMA_DREQ_48 line of the DMA_EDMA module. Setting this bit field to any other value different than its reset value will map another DREQ from the device modules to the DMA_EDMA_DREQ_48 line. The default (reset) value of this bit field is 0x31 which corresponds to the DMA_CROSSBAR_49 input. The UART1_DREQ_TX is connected to this crossbar input. Setting another register to 0x31 will cause the UART1_DREQ_TX to be mapped to another DMA line. For example, if the [CTRL_CORE_DMA_EDMA_DREQ_40_41\[23:16\]](#) DMA_EDMA_DREQ_41_IRQ_41 is set to 0x31 the UART1_DREQ_TX will be mapped to the DMA_EDMA_DREQ_41 line. The same logic also applies to the other lines of the device DMAs.

[Table 14-14](#) shows which lines of each DMA are associated with the DMA_CROSSBAR control registers. The rest of the lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 14-14. DREQ Lines Associated With The DMA_CROSSBAR Control Registers

DMA_EDMA DREQ Lines	DMA_DSP1_EDMA DREQ Lines	DMA_DSP2_EDMA DREQ Lines
DMA_EDMA_DREQ_0 to DMA_EDMA_DREQ_63	DMA_DSP1_DREQ_0 to DMA_DSP1_DREQ_19	DMA_DSP2_DREQ_0 to DMA_DSP2_DREQ_19

The individual connection between all module DREQs and all DMA_CROSSBAR inputs is shown in , *Mapping of DMA Requests to DMA_CROSSBAR Inputs* of [Chapter 12, Enhanced DMA Controllers](#).

In addition, the [CTRL_CORE_ESM_GROUP1_3](#) register can be used to map any of the device DREQs connected to a DMA_CROSSBAR input to channel ESM_GROUP1_3 of the device ESM. The same logic as previously described applies when configuring this register.

14.4.6.6 SDRAM Initiator Priority Registers

The [CTRL_CORE_EMIF_INITIATOR_PRIORITY_1](#) to [CTRL_CORE_EMIF_INITIATOR_PRIORITY_8](#) registers are intended to control the priority of each initiator accessing the EMIF controller. Each 3-bit field in these registers is associated only with one initiator. Setting this bit field to 0x0 means that the corresponding initiator has a highest priority over the others and setting it to 0x7 is for lowest priority. This is useful in case of concurrent access to the external SDRAM from several initiators.

14.4.6.7 L3_MAIN Initiator Priority Registers

The [CTRL_CORE_L3_INITIATOR_PRESSURE_1](#) register is used for controlling the priority of certain initiators on the L3_MAIN. Each 2-bit field in this register is associated only with one initiator. Setting this bit field to 0x3 means that the traffic of this initiator has highest priority over the other traffics. A value of 0x0 is for lowest priority. This register provides a dynamic priority escalation for the following L3_MAIN initiators:

- DSP1
- DSP2

14.4.6.8 Memory Region Lock Registers

There are five registers used to lock different memory regions of CTRL_MODULE_CORE memory mapped space. A memory region is locked, means that all write accesses to this region are ignored. Writing a value unique for each register will lock certain memory region and writing another unique value results in unlocking of the same region. These five registers can lock the entire memory space of the CTRL_MODULE_CORE submodule. [Table 14-15](#) gives more details.

Table 14-15. Memory Region Lock Registers

Register	Memory Space to Lock	Groups of Registers Associated With This Memory Region	Lock/Unlock (register reset value)
CTRL_CORE_MMR_LOCK_1	Region from 0x0000 0100 to 0x0000 079F and from 0x0000 1A00 to 0x0000 1FFF	Thermal management related registers, EMIF initiator priority, L3_MAIN initiator pressure (priority) and other registers	locked
CTRL_CORE_MMR_LOCK_2	Region from 0x0000 07A0 to 0x0000 0D9F	IRQ_CROSSBAR and DMA_CROSSBAR registers	locked
CTRL_CORE_MMR_LOCK_3	Region from 0x0000 0DA0 to 0x0000 0FFF	A few registers associated with device I/Os	locked
CTRL_CORE_MMR_LOCK_4	Region from 0x0000 1000 to 0x0000 13FF	Hardware observability related registers	locked
CTRL_CORE_MMR_LOCK_5	Region from 0x0000 1400 to 0x0000 19FF	Pad configuration registers	locked

NOTE: By default the entire CTRL_MODULE_CORE memory space is locked but the ROM code unlocks it by writing corresponding unlock values to all CTRL_CORE_MMR_LOCK_x registers.

14.4.6.9 NMI Mapping To Respective Cores

Two registers [CTRL_CORE_NMI_DESTINATION_1](#) and [CTRL_CORE_NMI_DESTINATION_2](#) are intended to map the external non-maskable interrupt (NMI) to certain of the device host processors. Writing 0x1 into a bit field of these registers enables the NMI to be mapped to the corresponding processor associated with this bit field. Writing 0x0 disables the NMI mapping to this processor.

14.4.6.10 Software Controls for the LPDDR2/DDR2/DDR3 I/O Cells

There are two types of I/O cells associated with the LPDDR2/DDR2/DDR3 interface. These are single-ended and differential I/O cells.

These I/O cells have the following software controls which reside in registers of the CTRL_MODULE_CORE:

- Output impedance controls - I[2:0]
- Slew rate controls - SR[2:0]
- Weak driver controls - WD[1:0]

The I and SR controls apply when the I/Os operate as outputs. The WD controls apply when the I/Os operate as both inputs or outputs.

The bits I[2:0] are used for programming the desired impedance value of the output buffer. [Table 14-16](#) describes the I[2:0] controls which are valid for pull-up and pull-down outputs.

Table 14-16. Output Impedance Controls - I[2:0]

I[2]	I[1]	I[0]	Drive Setting Name	Output Impedance
0	0	0	Imp80	80 Ohms
0	0	1	Imp60	60 Ohms
0	1	0	Imp48	48 Ohms
0	1	1	Imp40	40 Ohms
1	0	0	Imp34	34 Ohms
1	0	1	Reserved	Reserved
1	1	0	Reserved	Reserved
1	1	1	Reserved	Reserved

To achieve optimal noise/slew trade-off the slew rate of the output signal can also be programmed using the slew rate control bits SR[2:0] shown in [Table 14-17](#). These SR settings do not affect the DC drive strength of the output buffer. They only control its turn-on time.

Table 14-17. Slew Rate Controls - SR[2:0]

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...		
...		
1	1	1	slowest	

Weak pull-up, pull-down or keeper option for device LPDDR2/DDR2/DDR3 pads is enabled through the WD[1:0] bits. The weak pull-up or pull-down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. [Table 14-18](#) describes the WD controls. They are used for avoiding floating pads on the LPDDR2/DDR2/DDR3 interface.

Table 14-18. Weak Driver Controls - WD[1:0]

WD[1]	WD[0]	Single-Ended Operation	Differential Pair Operation	
			padp	padn
0	0	Pull logic disabled	Pull logic disabled	Pull logic disabled
0	1	Weak pullup enabled	Weak pullup enabled	Weak pulldown enabled
1	0	Weak pulldown enabled	Weak pulldown enabled	Weak pullup enabled
1	1	Weak keeper enabled	Weak keeper enabled	Weak keeper enabled

NOTE: To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

It must be taken into account that the I, SR and WD software controls apply for several pads combined in groups, and not for a single pad. For example, writing 0x1 to the [CTRL_CORE_CONTROL_DDR3CH1_0\[17:16\]](#) DDR3CH1_PART5A_WD bit field enables the weak pull-up resistors for all pads in the PART5A group. These are the ddr1_a[15:0] pads. [Table 14-19](#) shows the I, SR and WD controls for the different LPDDR2/DDR2/DDR3 pad groups.

Table 14-19. Software Group Controls for the LPDDR2/DDR2/DDR3 Pads

LPDDR2/DDR2/DDR3 Interface I/O Group Controls	Group Name	EMIF Pads in a Group

14.4.6.11 Reference Voltage for the Device LPDDR2/DDR2/DDR3 Receivers

The device LPDDR2/DDR2/DDR3 input buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from LPDDR2/DDR2/DDR3 memory and negative terminal connected to a source of reference voltage.

To work properly, a reference voltage must be provided to the device LPDDR2/DDR2/DDR3 input buffers. There are two Vref-generation cells in the device intended to supply this internal reference voltage.

[Figure 14-10](#) shows the Vref-generation cells in the device.

Figure 14-10. Vref-Generation Cells and Their Controls

ctrlmod-004

The control bits for the Vref-generation cells reside in the [CTRL_CORE_CONTROL_DDRIO_0](#) register. There are VREF_x_TAP[1:0] control bits which set the output drive capability of the Vref cells. [Table 14-20](#) lists the possible options for selection of load current sourced from the output of each Vref-generation cell.

Table 14-20. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2- μ A load current
0	1	4- μ A load current
1	0	8- μ A load current
1	1	32- μ A load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to each Vref-generation cell are available and configurable through the VREF_x_CCAP[1:0] control bits in the [CTRL_CORE_CONTROL_DDRIO_0](#) register as specified in [Table 14-21](#).

Table 14-21. Vref Cell Coupling Capacitor Selection

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground. ⁽¹⁾
1	0	One capacitor connected between Vbias and Vdds. ⁽²⁾
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds.

⁽¹⁾ Vbias is the output of the Vref-generation cell which provides the reference voltage.

⁽²⁾ Vdds is the power supply voltage of the Vref-generation cell.

The Vref-generation cells can be enabled by setting to 0x1 the VREF_x_EN bits in the [CTRL_CORE_CONTROL_DDRIO_0](#) register. These cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF_x_EN bits.

[Table 14-22](#) shows the Vref-generation cells control bits and the LPDDR2/DDR2/DDR3 pads used as receivers to which the corresponding Vref cell supplies reference voltage.

Table 14-22. Controls for the Vref-Generation Cells Versus LPDDR2/DDR2/DDR3 Receiver Pads

Vref-generation Cell Control Bits	LPDDR2/DDR2/DDR3 Vref Cell Associated Pads Used as Receivers
CTRL_CORE_CONTROL_DDRIO_0 [19] DDRCH1_VREF_DQ0_INT_CCAP0	ddr1_d[7:0], ddr1_d[15:8]

14.4.6.12 AVS Class 0 Associated Registers

AVS Class 0 attempts to normalize the power consumption across all devices by lowering the operating voltage of certain voltage rails. This procedure of lowering the voltage should be performed in the boot loader after ROM code. The new voltage to be set for each AVS Class 0 supported voltage rail should be read from the eFuse using dedicated registers. Then the power supply output voltage is adjusted to this new voltage value.

The following voltage rails support AVS Class 0:

- vdd_dspeve
- vdd

NOTE: For descriptions of the voltage rails previously listed see the "Power Supply Signal Descriptions" table in the device Data Manual.

[Table 14-23](#) shows all registers associated with AVS Class 0. The corresponding AVS Class 0 voltage value can be read from the 12 LSbits of each of the listed registers. They contain the voltage value in hex format. To find the actual value in mV a conversion from hex to decimal value is needed. For example, if the value read from [CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2](#)[11:0] STD_FUSE_OPP_VMIN_CORE_2 is 0x041F, then this corresponds to 1055 mV.

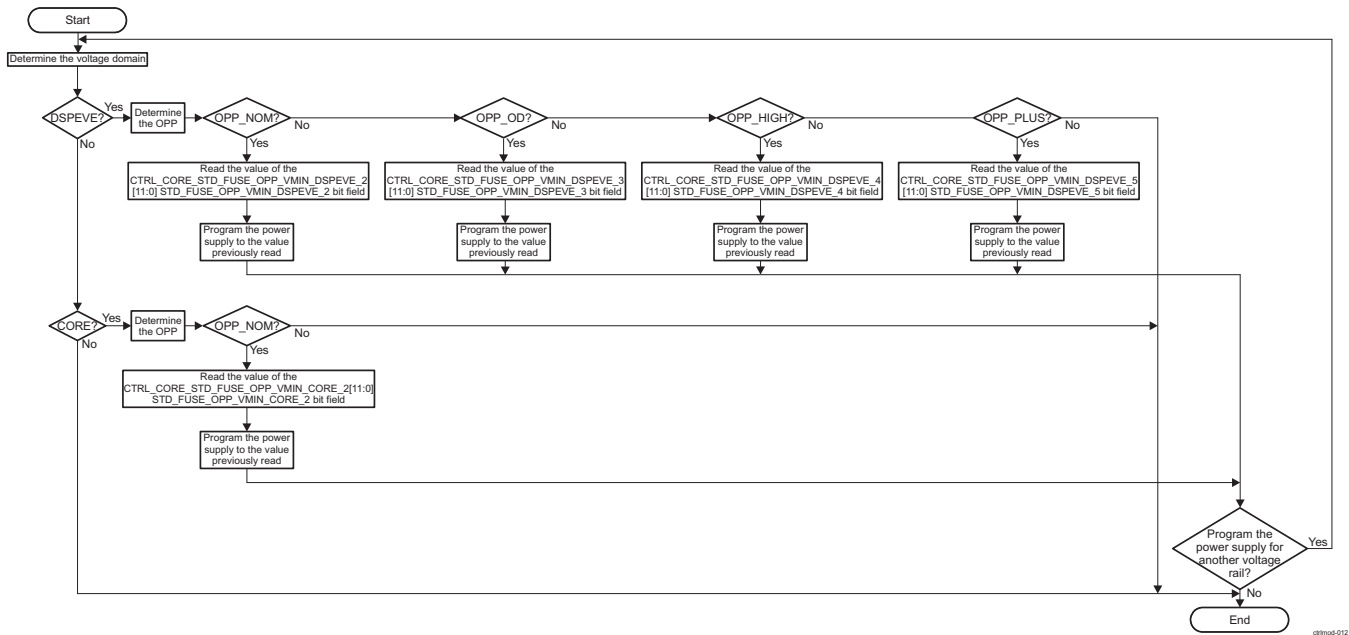

Table 14-23. Registers Associated With AVS Class 0 Voltage

Physical Address	Bit Field Containing the AVS Class 0 Voltage Value	Voltage Rail	Supported OPP
0x4A00 25E0	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_2 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_2	vdd_dspeve	OPP_NOM
0x4A00 25E4	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_3 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_3		OPP_OD
0x4A00 25E8	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_4 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_4		OPP_HIGH
0x4A00 25D8	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_5 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_5		OPP_PLUS
0x4A00 25F4	CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2 [11:0] STD_FUSE_OPP_VMIN_CORE_2	vdd	OPP_NOM

NOTE: Some of the OPPs listed in [Table 14-23](#) may not be supported for some devices. In these cases the voltage values in the corresponding AVS Class 0 registers can be disregarded. For more information about the supported OPPs, see the "Operating Performance Points" section of the device Data Manual.

In some cases, the AVS Class 0 voltage that is read from the `CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y` registers has a value between two incremental voltage steps of the power supply. If such a case occurs, the higher voltage value should be selected.

[Figure 14-11](#) shows a general example of how AVS Class 0 should be performed.

Figure 14-11. AVS Class 0 Procedure

14.4.6.13 Registers For Other Miscellaneous Functions

14.4.6.13.1 System Boot Status Settings

The `CTRL_CORE_BOOTSTRAP` register is a status register which indicates the state of the sysboot0 through sysboot15 input signals. Their purpose is to select the boot interface, the device source clock configuration and also other boot related settings.

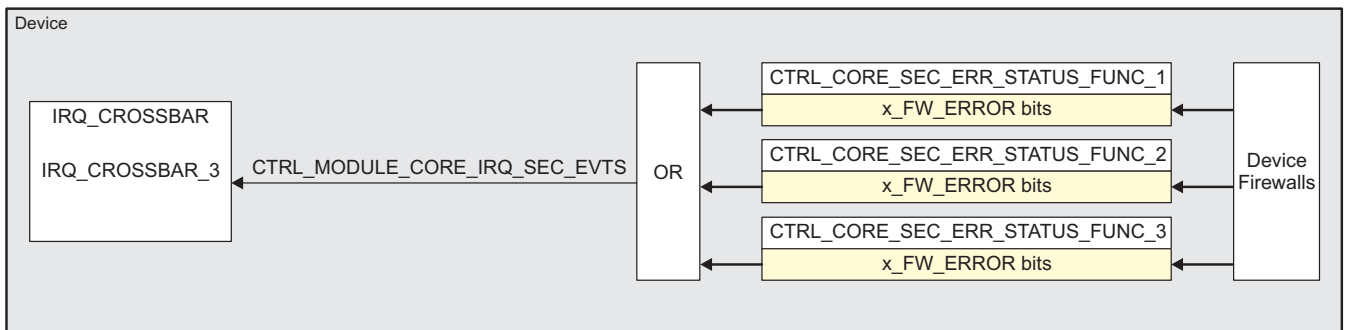

NOTE: For proper device operation, sysboot15 must be tied to vdd and sysboot14 must be tied to vss.

14.4.6.13.2 Firewall Error Status Registers

There are several status registers which show when there is a firewall error. The [CTRL_CORE_SEC_ERR_STATUS_FUNC_1](#), [CTRL_CORE_SEC_ERR_STATUS_FUNC_2](#) and [CTRL_CORE_SEC_ERR_STATUS_FUNC_3](#) registers are used in device normal operation mode. The x_FW_ERROR bits from these three registers are combined into a single interrupt signal sent to the IRQ_CROSSBAR module as shown in [Figure 14-12](#). The [CTRL_CORE_SEC_ERR_STATUS_DEBUG_1](#), [CTRL_CORE_SEC_ERR_STATUS_DEBUG_2](#) and [CTRL_CORE_SEC_ERR_STATUS_DEBUG_3](#) registers are used when the device is in debug mode. These registers have same bits as in the [CTRL_CORE_SEC_ERR_STATUS_FUNC_1](#), [CTRL_CORE_SEC_ERR_STATUS_FUNC_2](#) and [CTRL_CORE_SEC_ERR_STATUS_FUNC_3](#) registers.

All bits in these registers are cleared when the [ERROR_LOG_k](#) and [L4_IA_ERROR_LOG_L](#) registers are cleared.

Figure 14-12. Combined Firewall Error Interrupt

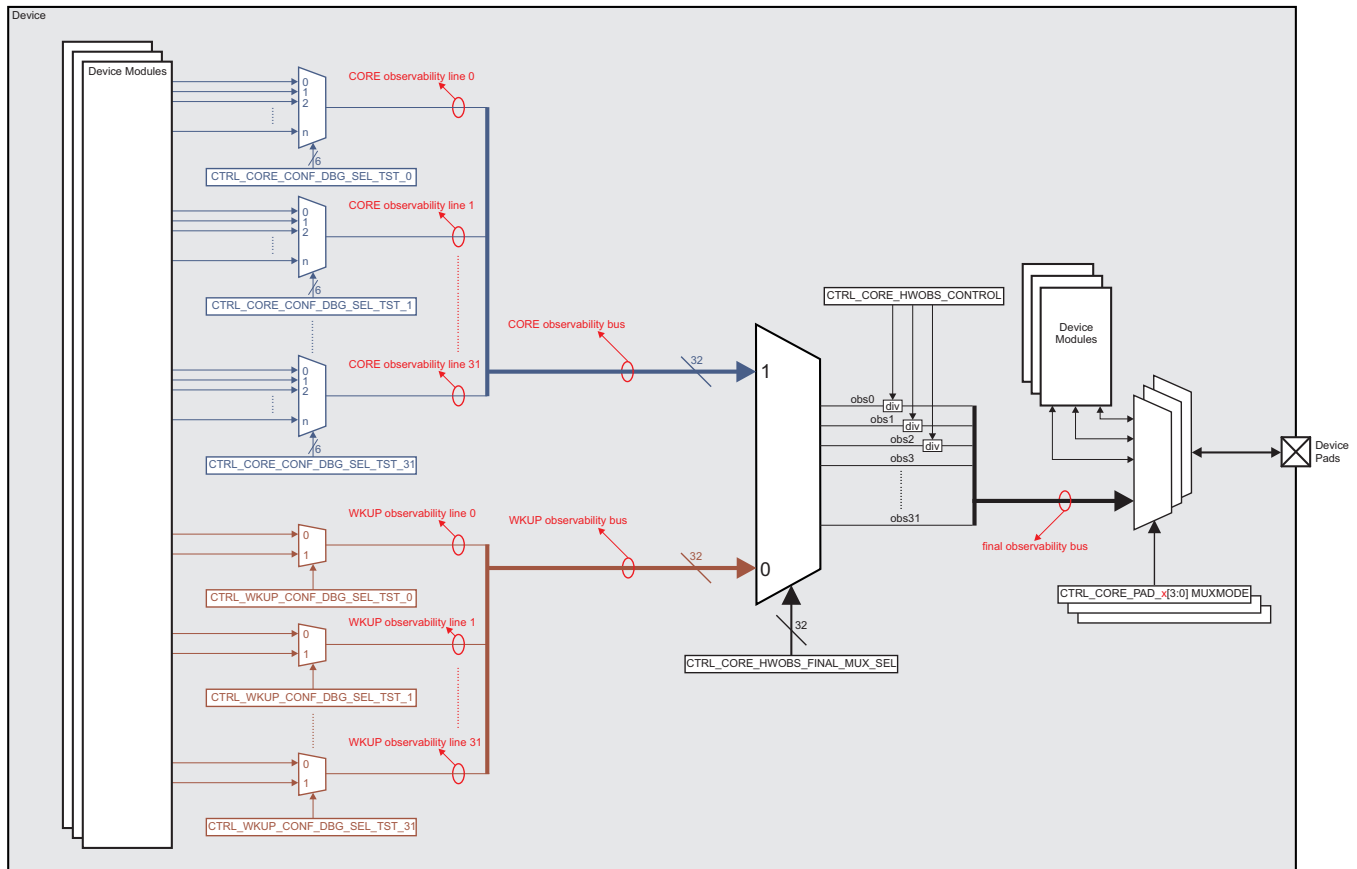

ctrlmod-018

14.4.6.13.3 Settings Related To Different Peripheral Modules

The [CTRL_CORE_CONTROL_IO_1](#) and [CTRL_CORE_CONTROL_IO_2](#) registers have controls for specific settings of several device peripheral modules. For more information, see the bit field descriptions.

14.4.6.14 Hardware Observability Related Registers

There is a set of registers which are associated with the device observability logic. Using these registers a desired module signal can be mapped to dedicated-for-observation pad and then this signal can be observed. [Figure 14-13](#) shows the device observability logic.

Figure 14-13. Hardware Observability Logic

As can be seen on [Figure 14-13](#) there are two 32-bit wide observability buses. One associated with signals in CORE and one with signals in WKUP power domain. The multiplexing of the CORE observable signals is controlled by [CTRL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CTRL_CORE_CONF_DEBUG_SEL_TST_31](#) registers. The multiplexing of the WKUP observable signals is controlled by [CTRL_WKUP_CONF_DEBUG_SEL_TST_0](#) through [CTRL_WKUP_CONF_DEBUG_SEL_TST_31](#) registers. Each of these registers is associated with one observability line. For example, the [CTRL_CORE_CONF_DEBUG_SEL_TST_0](#) register selects one of N observability signals to be mapped to CORE observability line 0.

The [CTRL_CORE_HWOBS_FINAL_MUX_SEL](#) register is used to control the final multiplexer which selects CORE or WKUP observable signals to be mapped to the final observability bus. This bus is composed of obs0 through obs31 lines. Each bit in the [CTRL_CORE_HWOBS_FINAL_MUX_SEL](#) register is associated with one of these lines. A value of 0x0 selects a WKUP observable signal and 0x1 select CORE observable signal.

Optionally, the frequency of obs0, obs1 and obs2 lines can be divided through the bit fields HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1 and HWOBS_CLKDIV_SEL_2 from register [CTRL_CORE_HWOBS_CONTROL](#). This register provides also an option to force all 32 signals (obs0 through obs31) of the observability bus to 0 or to 1 setting to 0x1 bit HWOBS_ALL_ZERO_MODE or bit HWOBS_ALL_ONE_MODE, respectively.

14.4.7 Functional Description Of The Various Register Types In CTRL_MODULE_WKUP Submodule

The following sections describe the purpose of the registers which reside in the CTRL_MODULE_WKUP submodule.

14.4.7.1 Registers For Basic EMIF configuration

The [CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG](#) register has bits which determine the basic settings of the EMIF controller. These are, for example, settings like CAS write latency, SDRAM drive strength, SDRAM termination resistor values, SDRAM type and others. The [CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG](#) bit field values are exported upon POR to the EMIF.EMIF_SDRAM_CONFIG register.

The [CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT](#) register is associated with DDR PHY controls, ODT values for device DDR I/Os, some leveling related parameters and others.

TSHUT_MUXCTRL_CORE	RESERVED								TSHUT_HOT_CORE								RESERVED								TSHUT_COLD_CORE							

Bits	Field Name	Description	Type	Reset
31	TSHUT_MUXCTRL_COR E	Writing a '1' to this field allows SW to override the TSHUT_HOT and TSHUT_COLD values that are set by default in efuse.	RW	0x0
30:26	RESERVED		R	0x0
25:16	TSHUT_HOT_CORE	Controls the TSHUT_HOT reset threshold, which protects the device from thermal runaway and potential device damage. The register defaults to 123°C. Software override of this register value is not recommended, and should only be done with extreme caution as damage to the device can occur above the default setting.	RW	0x0
15:10	RESERVED		R	0x0
9:0	TSHUT_COLD_CORE	Controls the TSHUT_COLD reset threshold, which is the limit where the TSHUT comparator releases the device from reset after cooling from a TSHUT condition. The register defaults to 105°C. Software override of this register value is not recommended, and should only be done with extreme caution.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27:24	IPU_LAST_RESET_INDICATOR	IPU reset indicator. IPU writes into this bit field when it initiates self-test. IPU reads this bit field after coming up from reset after field-test and understands that the reset was due to TESOC. Software can choose to do partial boot using this indicator. For details on TESOC, refer to Tester On Chip (TESOC) in the device Safety Subsystem.	RW	0x0
23:20	RESERVED		R	0x0
19:16	DSP1_LAST_RESET_INDICATOR	DSP1 reset indicator. DSP1 writes into this bit field when it initiates self-test. DSP1 reads this bit field after coming up from reset after field-test and understands that the reset was due to TESOC. Software can choose to do partial boot using this indicator. For details on TESOC, refer to Tester On Chip (TESOC) in the device Safety Subsystem.	RW	0x0
15:12	RESERVED		R	0x0
11:8	DSP2_LAST_RESET_INDICATOR	DSP2 reset indicator. DSP2 writes into this bit field when it initiates self-test. DSP2 reads this bit field after coming up from reset after field-test and understands that the reset was due to TESOC. Software can choose to do partial boot using this indicator. For details on TESOC, refer to Tester On Chip (TESOC) in the device Safety Subsystem.	RW	0x0
7:4	RESERVED		R	0x0
3:0	EVE_LAST_RESET_INDICATOR	EVE reset indicator. EVE writes into this bit field when it initiates self-test. EVE reads this bit field after coming up from reset after field-test and understands that the reset was due to TESOC. Software can choose to do partial boot using this indicator. For details on TESOC, refer to Tester On Chip (TESOC) in the device Safety Subsystem.	RW	0x0

Bits	Field Name	Description	Type	Reset
31	MCASP_MODE_17_VOUT1_D22_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d22 not selected 0x1: mcasep2_axr4 selected on pad vout1_d22 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
30	MCASP_MODE_17_VOUT1_D21_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d21 not selected 0x1: mcasep2_axr3 selected on pad vout1_d21 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
29	MCASP_MODE_17_VOUT1_D20_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d20 not selected 0x1: mcasep2_axr2 selected on pad vout1_d20 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
28	MCASP_MODE_17_VOUT1_D19_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d19 not selected 0x1: mcasep2_axr1 selected on pad vout1_d19 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
27	MCASP_MODE_17_VOUT1_D18_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d18 not selected 0x1: mcasep2_axr0 selected on pad vout1_d18 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0

Bits	Field Name	Description	Type	Reset
26	MCASP_MODE_17_VOUT1_D17_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d17 not selected 0x1: mcasep2_fsr selected on pad vout1_d17 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
25	MCASP_MODE_17_VOUT1_D16_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d16 not selected 0x1: This option is not supported and must not be used. NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
24	MCASP_MODE_17_VOUT1_D15_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d15 not selected 0x1: mcasep2_fsx selected on pad vout1_d15 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
23	MCASP_MODE_17_VOUT1_D14_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d14 not selected 0x1: mcasep2_aclkx selected on pad vout1_d14 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
22	MCASP_MODE_17_VOUT1_D13_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vout1_d13 not selected 0x1: mcasep2_aclkr selected on pad vout1_d13 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
21	MCASP_MODE_17_GPMC_AD7_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad7 not selected 0x1: mcasep2_ahclkx selected on pad gpmc_ad7 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
20	MCASP_MODE_17_VIN1A_D5_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_d5 not selected 0x1: mcasep3_ahclkx selected on pad vin1a_d5 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
19	MCASP_MODE_17_VIN1A_D4_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_d4 not selected 0x1: mcasep3_axr5 selected on pad vin1a_d4 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0

Bits	Field Name	Description	Type	Reset
18	MCASP_MODE_17_VIN1A_D3_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_d3 not selected 0x1: mcasep3_axr4 selected on pad vin1a_d3 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
17	MCASP_MODE_17_VIN1A_D2_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_d2 not selected 0x1: mcasep3_axr3 selected on pad vin1a_d2 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
16	MCASP_MODE_17_VIN1A_D1_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_d1 not selected 0x1: mcasep3_axr2 selected on pad vin1a_d1 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
15	MCASP_MODE_17_VIN1A_D0_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_d0 not selected 0x1: mcasep3_axr1 selected on pad vin1a_d0 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
14	MCASP_MODE_17_VIN1A_VSYNC0_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_vsync0 not selected 0x1: mcasep3_axr0 selected on pad vin1a_vsync0 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
13	MCASP_MODE_17_VIN1A_HSYNC0_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_hsync0 not selected 0x1: mcasep3_fsr selected on pad vin1a_hsync0 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
12	MCASP_MODE_17_VIN1A_FLD0_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_fld0 not selected 0x1: mcasep3_aclr selected on pad vin1a_fld0 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
11	MCASP_MODE_17_VIN1A_DE0_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_de0 not selected 0x1: This option is not supported and must not be used. NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0

Bits	Field Name	Description	Type	Reset
10	MCASP_MODE_17_VIN1A_CLK0_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad vin1a_clk0 not selected 0x1: mcasep3_aclcx selected on pad vin1a_clk0 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
9	MCASP_MODE_17_GPMC_AD15_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad15 not selected 0x1: mcasep2_axr5 selected on pad gpmc_ad15 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
8	MCASP_MODE_17_GPMC_AD14_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad14 not selected 0x1: mcasep2_axr4 selected on pad gpmc_ad14 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
7	MCASP_MODE_17_GPMC_AD13_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad13 not selected 0x1: mcasep2_axr3 selected on pad gpmc_ad13 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
6	MCASP_MODE_17_GPMC_AD12_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad12 not selected 0x1: mcasep2_axr2 selected on pad gpmc_ad12 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
5	MCASP_MODE_17_GPMC_AD11_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad11 not selected 0x1: mcasep2_axr1 selected on pad gpmc_ad11 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
4	MCASP_MODE_17_GPMC_AD10_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad10 not selected 0x1: mcasep2_axr0 selected on pad gpmc_ad10 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
3	MCASP_MODE_17_GPMC_AD9_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad9 not selected 0x1: mcasep2_fsr selected on pad gpmc_ad9 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0

Bits	Field Name	Description	Type	Reset
2	MCASP_MODE_17_GPMC_AD8_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad8 not selected 0x1: mcasep2_aclkr selected on pad gpmc_ad8 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
1	MCASP_MODE_17_GPMC_AD6_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad6 not selected 0x1: mcasep2_fsx selected on pad gpmc_ad6 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0
0	MCASP_MODE_17_GPMC_AD5_MUX_CONTROL_0	SR2.0 Only: 0x0: Function 17 for pad gpmc_ad5 not selected 0x1: mcasep2_aclkx selected on pad gpmc_ad5 as function 17 NOTE: When this bit is set to 0x1, the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF.	RW	0x0

Table 14-983. CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG

Address Offset	0x0000 0110
Physical Address	0x4AE0 C110
Instance	CTRL_MODULE_WKUP
Description	EMIF1 SDRAM configuration register. Its values are exported to EMIF_SDRAM_CONFIG register at POR. For bit field descriptions see EMIF_SDRAM_CONFIG register in Section 11.2, EMIF Controller , in Chapter 11, Memory Subsystem . Write to this register is allowed if the CTRL_WKUP_SEC_CTRL[4] SECURE_EMIF_CONFIG_RO_EN bit is set to 0x0 (default).
Type	RW

Description	SLICE register for emif1 and emif2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0										
RESERVED								EMIF1_NARROW_ONLY		EMIF1_EN_ECC		EMIF1_REG_PHY_NUM_OF_SAMPLES				EMIF1_REG_PHY_SEL_LOGIC		EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP				EMIF1_REG_PHY_OUTPUT_STATUS_SELECT				RESERVED		EMIF1_SDRAM_DISABLE_RESET		EMIF1_PHY_RD_LOCAL_ODT		RESERVED		EMIF1_DFI_CLOCK_PHASE_CTRL		EMIF1_EN_SLICE_2		EMIF1_EN_SLICE_1		EMIF1_EN_SLICE_0	

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17	EMIF1_NARROW_ONLY	EMIF1 operates in narrow mode, to allow for data macros to be powered down to save power 0x0 = narrow mode disabled 0x1 = narrow mode enabled	RW	0x0
16	EMIF1_EN_ECC	EMIF1 ECC enable 0x0 = ECC is disabled 0x1 = ECC is enabled	RW	0x0
15:14	EMIF1_REG_PHY_NUM_OF_SAMPLES	Controls the number of DQ samples required for read leveling. The recommended setting for full leveling is 0x3 (128 samples) and for incremental leveling is 0x0 (4 samples). 0x0 = 4 samples 0x1 = 8 samples. 0x2 = 16 samples 0x3 = 128 samples	RW	0x0
13	EMIF1_REG_PHY_SEL_LOGIC	Selects an algorithm for read leveling. The use of algorithm 1 (set by default) is recommended. 0x0 = Algorithm 1 is used 0x1 = Algorithm 2 is used	RW	0x0
12	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	Analysis method of DQ bits during read leveling. 0x0: if the DRAM provides a read response on only one DQ bit (this can be any bit, since in this mode all 8 DQ bits are OR-ed together). This is the default setting and works with all memory types (memories send responses on all DQ bits or on a single DQ bit). 0x1: if the DRAM provides a read response on all DQ bits.	RW	0x0
11:9	EMIF1_REG_PHY_OUTPUT_STATUS_SELECT	Selects the status to be observed on the outputs of the DDR PHYs through CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT_1 register. 0x0 = selects phy_reg_rdlvl_start_ratio[7:0] 0x1 = selects phy_reg_rdlvl_start_ratio[15:8] 0x2 = selects phy_reg_rdlvl_end_ratio[7:0] 0x3 = selects phy_reg_rdlvl_end_ratio[15:8]	RW	0x0

Bits	Field Name	Description	Type	Reset
8	RESERVED		R	0x1
7	EMIF1_SDRAM_DISABLERESET	DDR3 SDRAM reset disable. 0x0 = DDR3 SDRAM reset signal is enabled. It can be asserted by EMIF 0x1 = DDR3 SDRAM reset signal is disabled. It is forbidden to EMIF to assert it.	RW	0x0
6:5	EMIF1_PHY_RD_LOCAL_ODT	Control of ODT (on – die termination) settings for the device DDR I/Os. ODT is enabled only during read operations when termination is required. 0x0 = ODT disabled 0x1= 60 Ohms 0x2 = 80 Ohms 0x3 =120 Ohms	RW	0x0
4	RESERVED		RW	0x0
3	EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF_FICLK clock phase control (shifting by 180°). For normal operation this bit must always be set to 0x0 (disabled).	RW	0x0
2	EMIF1_EN_SLICE_2	Enable command PHY 2. When using DDR3 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used.	RW	0x1
1	EMIF1_EN_SLICE_1	Enable command PHY 1. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1
0	EMIF1_EN_SLICE_0	Enable command PHY 0. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1

15.5 Mailbox Register Manual.....	5177

15.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

The device implements the following mailbox types:

- System mailbox:
 - Number of instances: 2
 - Used for communication between: DSP1, DSP2, and IPU subsystems
 - Reference names: MAILBOX1, MAILBOX2
- EVE mailbox:
 - Number of instances: 2
 - Used for communication between: EVE local user (ARP32) and three external users (DSP1, DSP2, and IPU) – EVE_MBOX0 and EVE_MBOX1 are dedicated for this communication
 - Reference names: EVE_MBOX0, EVE_MBOX1

Each mailbox module supports the following features:

- Parameters configurable at design time (see [Table 15-1](#)):
 - Number of users
 - Number of mailbox message queues
 - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

[Table 15-1](#) shows the configuration of the mailbox modules in the device.

Table 15-1. Mailbox Configuration in the Device

Module Parameters	Mailbox Type		
	System Mailbox		EVE Mailbox (0, 1)
	MAILBOX1	MAILBOX2	
Number of users	3	4	4
Number of mailbox message queues	8	12	16
Number of messages (FIFO depth) for each message queue	4		4

15.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

15.2.1 System MAILBOX Integration

[Figure 15-1](#) and [Figure 15-2](#) show the MAILBOX1 and MAILBOX2 integration, respectively.

Figure 15-1. MAILBOX1 Integration

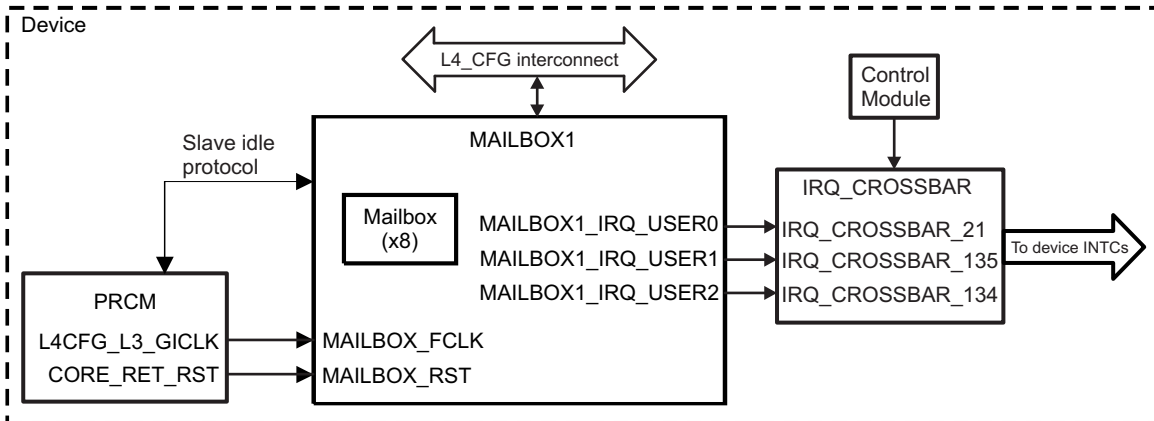

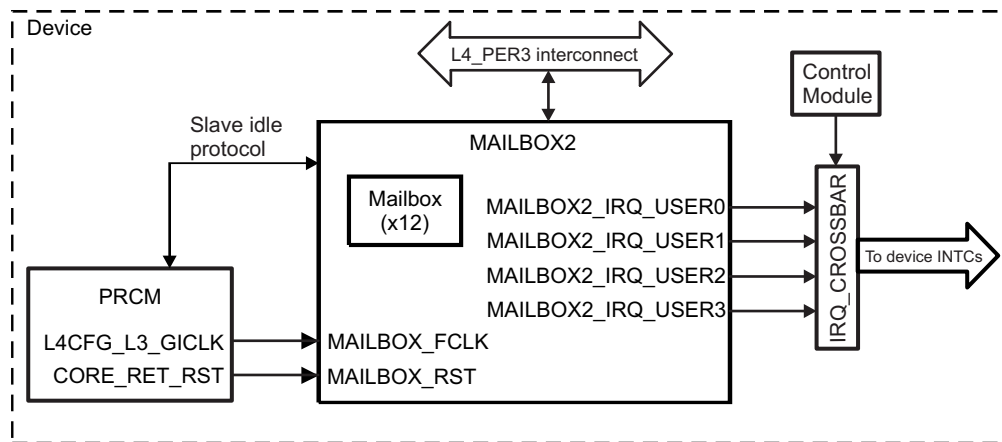

Figure 15-2. MAILBOX2 Integration

NOTE: For more information about the Slave idle protocol, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-2 through Table 15-4 summarize the MAILBOX1/2 integration in the device.

Table 15-2. MAILBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MAILBOX1	PD_COREAON	N/A	L4_CFG
MAILBOX2	PD_COREAON	N/A	L4_PER3

Table 15-3. MAILBOX Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MAILBOX	MAILBOX_FCLK	L4CFG_L3_GICLK	PRCM	MAILBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

Table 15-3. MAILBOX Clocks and Resets (continued)

MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	MAILBOX hardware reset. This reset is asynchronously applied to the MAILBOX registers.
---------	-------------	--------------	------	--

Table 15-4. MAILBOX Hardware Requests

Interrupt Requests							
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description			
MAILBOX1	MAILBOX1_IRQ_USER0	IRQ_CROSSBAR_21	DSP1_IRQ_52; DSP2_IRQ_52;	MAILBOX1 request.	user	0	interrupt
	MAILBOX1_IRQ_USER1	IRQ_CROSSBAR_135	–	MAILBOX1 request.	user	1	interrupt
	MAILBOX1_IRQ_USER2	IRQ_CROSSBAR_134	IPU_IRQ_50;	MAILBOX1 request.	user	2	interrupt
MAILBOX2	MAILBOX2_IRQ_USER0	IRQ_CROSSBAR_237	–	MAILBOX2 request.	user	0	interrupt
	MAILBOX2_IRQ_USER1	IRQ_CROSSBAR_238	–	MAILBOX2 request.	user	1	interrupt
	MAILBOX2_IRQ_USER2	IRQ_CROSSBAR_239	–	MAILBOX2 request.	user	2	interrupt
	MAILBOX2_IRQ_USER3	IRQ_CROSSBAR_240	–	MAILBOX2 request.	user	3	interrupt

No DMA Requests

NOTE: The “Default Mapping” column in [Table 15-4](#) and [Table 15-7](#) shows the default mapping of module interrupts. These interrupts can also be mapped to other input lines of each device interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see [Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For information about interrupt source description, see [Section 15.3.4, Mailbox Interrupt Requests](#).

15.2.2 EVE Mailbox Integration

Figure 15-3 shows the EVE_MBOX integration.

Figure 15-3. EVE_MBOX Integration

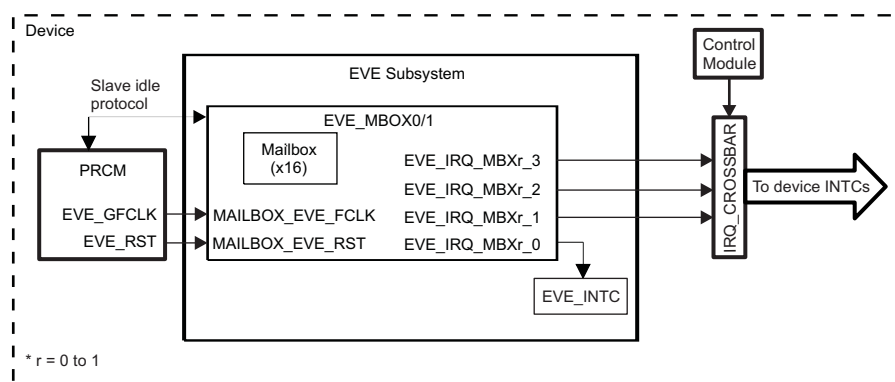

Table 15-5 through Table 15-7 summarize the EVE_MBOX integration in the device.

Table 15-5. EVE_MBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
EVE_MBOX	PD_EVE	N/A	EVE local interconnect

Table 15-6. EVE_MBOX Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EVE_MBOX	MAILBOX_EVE_FCLK	EVE_GFCLK	PRCM	EVE_MBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EVE_MBOX	MAILBOX_EVE_RST	EVE_RST	PRCM	EVE_MBOX hardware reset. This reset is asynchronously applied to the EVE_MBOX registers.

Table 15-7. EVE_MBOX Hardware Requests

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
EVE_MBOX0	EVE1_IRQ_MBX0_USER0	TBD	–	EVE_MBOX0 user 0 interrupt request.
	EVE1_IRQ_MBX0_USER1	IRQ_CROSSBAR_284	–	EVE_MBOX0 user 1 interrupt request.
	EVE1_IRQ_MBX0_USER2	IRQ_CROSSBAR_285	–	EVE_MBOX0 user 2 interrupt request.
	EVE1_IRQ_MBX0_USER3	IRQ_CROSSBAR_286	–	EVE_MBOX0 user 3 interrupt request.
EVE_MBOX1	EVE1_IRQ_MBX1_USER0	TBD	–	EVE_MBOX1 user 0 interrupt request.
	EVE1_IRQ_MBX1_USER1	IRQ_CROSSBAR_287	–	EVE_MBOX1 user 1 interrupt request.
	EVE1_IRQ_MBX1_USER2	IRQ_CROSSBAR_288	–	EVE_MBOX1 user 2 interrupt request.
	EVE1_IRQ_MBX1_USER3	IRQ_CROSSBAR_289	–	EVE_MBOX1 user 3 interrupt request.

No DMA Requests

15.3 Mailbox Functional Description

NOTE: The functionality of all mailbox instances in the device is the same and is described in this section.

NOTE: In this chapter, u is the user number and m is the mailbox number as follows:

- For MAILBOX1: $u = 0$ to 2 and $m = 0$ to 7;
- For MAILBOX2: $u = 0$ to 3 and $m = 0$ to 11;
- For EVE_MBOX: $u = 0$ to 3 and $m = 0$ to 15;

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the [MAILBOX_IRQENABLE_SET_u](#) (or [MAILBOX_IRQENABLE_CLR_u](#)) register.

[Table 15-8](#) shows the potential users of the mailbox modules in the device.

Table 15-8. Mailbox Users in the Device

Mailbox Type		Users			
		User 0	User 1	User 2	User 3
System Mailbox	MAILBOX1	Any of: DSP1, DSP2, and IPU ⁽¹⁾			–
	MAILBOX2	Any of: DSP1, DSP2, and IPU ⁽¹⁾			
EVE Mailbox	EVE_MBOX0, EVE_MBOX1	TBD	Any of: DSP1, DSP2, and IPU ⁽¹⁾		

⁽¹⁾ It is software responsibility to select a user by mapping (via [IRQ_CROSSBAR](#)) the corresponding mailbox interrupt to the interrupt controller of the appropriate processor subsystem.

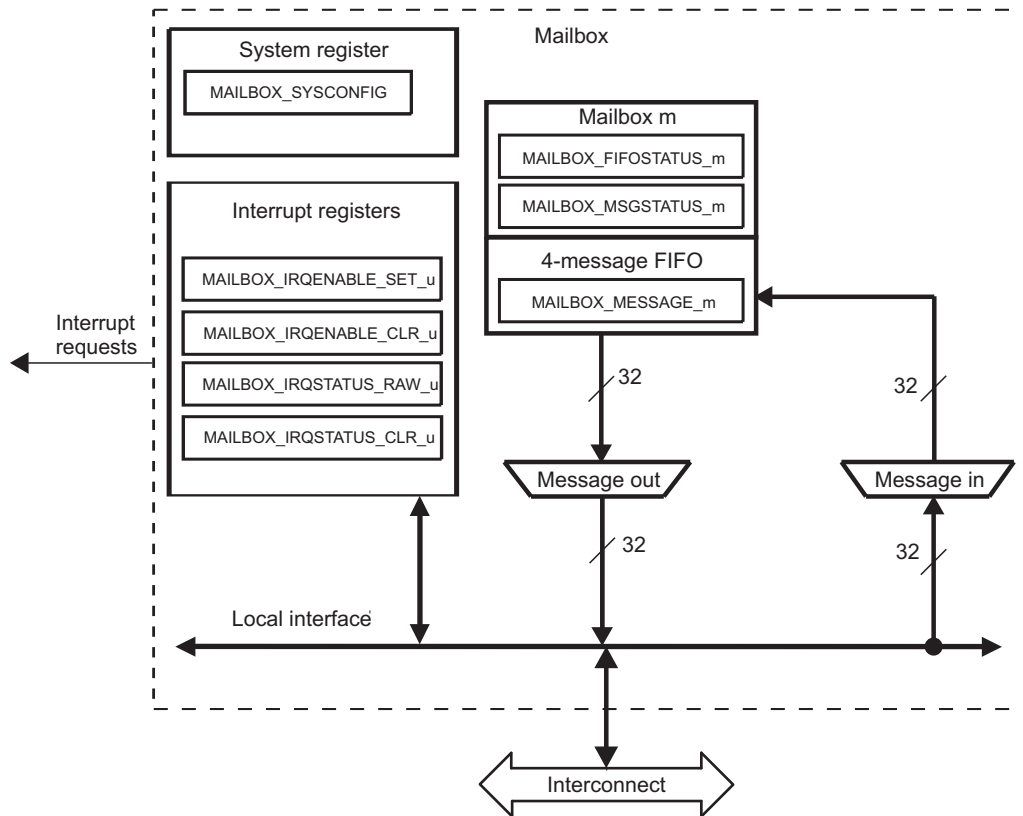

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each [MAILBOX_IRQSTATUS_RAW_u](#)/[MAILBOX_IRQSTATUS_CLR_u](#) interrupt status register corresponds to a particular user.

15.3.1 Mailbox Block Diagram

Figure 15-4 shows the mailbox block diagram.

Figure 15-4. Mailbox Block Diagram

15.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the `MAILBOX_SYSCONFIG[0]` SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the `MAILBOX_SYSCONFIG[0]` SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

15.3.3 Mailbox Power Management

Table 15-9 describes power-management features available for the mailbox module.

Table 15-9. Local Power Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	<code>MAILBOX_SYSCONFIG[3:2]</code> SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

The mailbox module can be configured using the [MAILBOX_SYSCONFIG\[3:2\]](#) SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

15.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

[Table 15-10](#) lists the event flags, and their mask, that can cause module interrupts.

Table 15-10. Interrupt Events

Non-Maskable Event Flag ⁽¹⁾	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQSTATUS_CLR_u[0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQENABLE_CLR_u[0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQENABLE_SET_u[0+m*2] NEWMSGSTATUSUUM Bm	Mailbox <i>m</i> receives a new message.
MAILBOX_IRQSTATUS_RAW_u[1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQSTATUS_CLR_u[1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQENABLE_CLR_u[1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQENABLE_SET_u[1+m*2] NOTFULLSTATUSUUM Bm	Mailbox <i>m</i> message queue is not full.

⁽¹⁾ [MAILBOX_IRQSTATUS_RAW_u](#) register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register.

Writing a logical 1 in a bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register will also clear to 0 the corresponding bit in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the [MAILBOX_IRQENABLE_SET_u](#) register. Events are reported in the appropriate [MAILBOX_IRQSTATUS_CLR_u](#) and [MAILBOX_IRQSTATUS_RAW_u](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MAILBOX_IRQENABLE_CLR_u](#) register. Events are only reported in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

In case of the [MAILBOX_IRQSTATUS_RAW_u](#) register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

15.3.5 Mailbox Assignment

15.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register. The receiver reads the [MAILBOX_MESSAGE_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the [MAILBOX_FIFOSTATUS_m](#) and/or [MAILBOX_MSGSTATUS_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the [MAILBOX_FIFOSTATUS_m](#) or [MAILBOX_MSGSTATUS_m](#) registers
- Write the message to the corresponding [MAILBOX_MESSAGE_m](#) register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate [MAILBOX_IRQENABLE_SET_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the [MAILBOX_IRQSTATUS_CLR_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the [MAILBOX_IRQSTATUS_CLR_u](#) register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

15.3.6 Sending and Receiving Messages

15.3.6.1 Description

When a 32-bit message is written to the [MAILBOX_MESSAGE_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the [MAILBOX_FIFOSTATUS_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the [MAILBOX_MESSAGE_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the [MAILBOX_MESSAGE_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the [MAILBOX_MSGSTATUS_m](#) register.

15.3.7 16-Bit Register Access

15.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the [MAILBOX_MESSAGE_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the [MAILBOX_MESSAGE_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

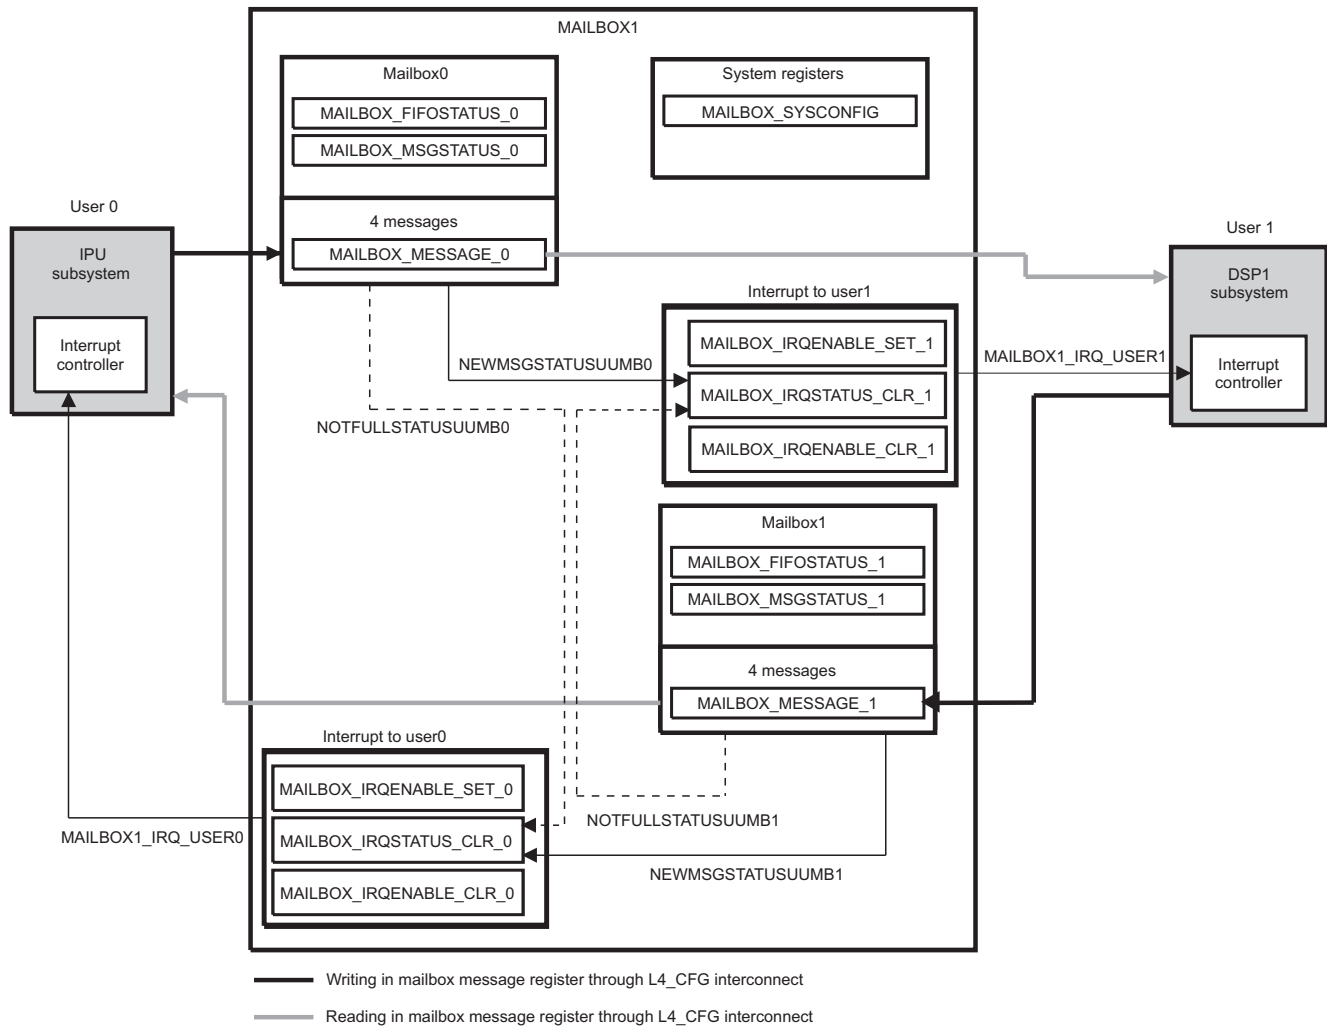

CAUTION

When using 16-bit accesses to the [MAILBOX_MESSAGE_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the [MAILBOX_MSGSTATUS_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a [MAILBOX_MESSAGE_m](#) are accessed.

15.3.8 Example of Communication

Figure 15-5 shows an example of communication between IPU and DSP1 subsystems.

Figure 15-5. Example of Communication

15.4 Mailbox Programming Guide

15.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

15.4.1.1 Global Initialization

15.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 15.2, Mailbox Integration](#), for further information.

Table 15-11. Global Initialization of Surrounding Modules for MAILBOX

Surrounding Modules	Comments
PRCM	MAILBOX functional/interface clock must be enabled.
Interrupt Controllers	IPU, or DSP1, or DSP2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

Table 15-12. Global Initialization of Surrounding Modules for EVE_MBOX

Surrounding Modules	Comments
PRCM	EVE_MBOX functional/interface clock must be enabled.
Interrupt Controllers	IPU, or DSP1, or DSP2, or EVE interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

15.4.1.1.2 Mailbox Global Initialization

15.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 15-13. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2] SIDLEMODE	0x-

15.4.1.2 Mailbox Operational Modes Configuration

15.4.1.2.1 Mailbox Processing modes

15.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 15-14. Sending a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

15.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 15-15. Sending a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 15.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

15.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 15-16. Receiving a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

15.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 15-17. Receiving a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 15.4.1.3.2 for interrupt handling in receiving mode		

15.4.1.3 Mailbox Events Servicing

15.4.1.3.1 Events Servicing in Sending Mode

Table 15-18 describes the events servicing in sending mode.

Table 15-18. Events Servicing in Sending Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

15.4.1.3.2 Events Servicing in Receiving Mode

Table 15-19 describes the events servicing in receiving mode.

Table 15-19. Events Servicing in Receiving Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
ENDIF

Memory Management Units

This chapter describes the memory management units (MMUs) in the device.

Topic	Page
16.1 MMU Overview.....	5201
16.2 MMU Integration	5203
16.3 MMU Functional Description	5205
16.4 MMU Low-level Programming Models.....	5217
16.5 MMU Register Manual.....	5221

16.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include:

- Translation of initiator internal (virtual) addresses to physical addresses (that is, virtual memory management)
- Preventing an initiator from making accesses to unmapped pages of the system memory

This device includes the following MMUs:

- One top-level (system) MMU, dedicated to EDMA Transfer Controller 0 (TC0), and EDMA Transfer Controller 1 (TC1):
- Two MMUs inside each of the DSP1, and DSP2 subsystems:
 - DSP1 subsystem: DSP1_MMU0, and DSP1_MMU1
 - DSP2 subsystem: DSP2_MMU0, and DSP2_MMU1
- Two MMUs inside the EVE subsystem: EVE_MMU0, and EVE_MMU1
- Two MMUs inside the IPU subsystem:
 - L1 unicache MMU – IPU_UNICACHE_MMU
 - L2 MMU – IPU_MMU

NOTE: This chapter provides a detailed description of the following MMUs:

- System MMU
- DSP MMUs
- EVE MMUs
- IPU L2 MMU

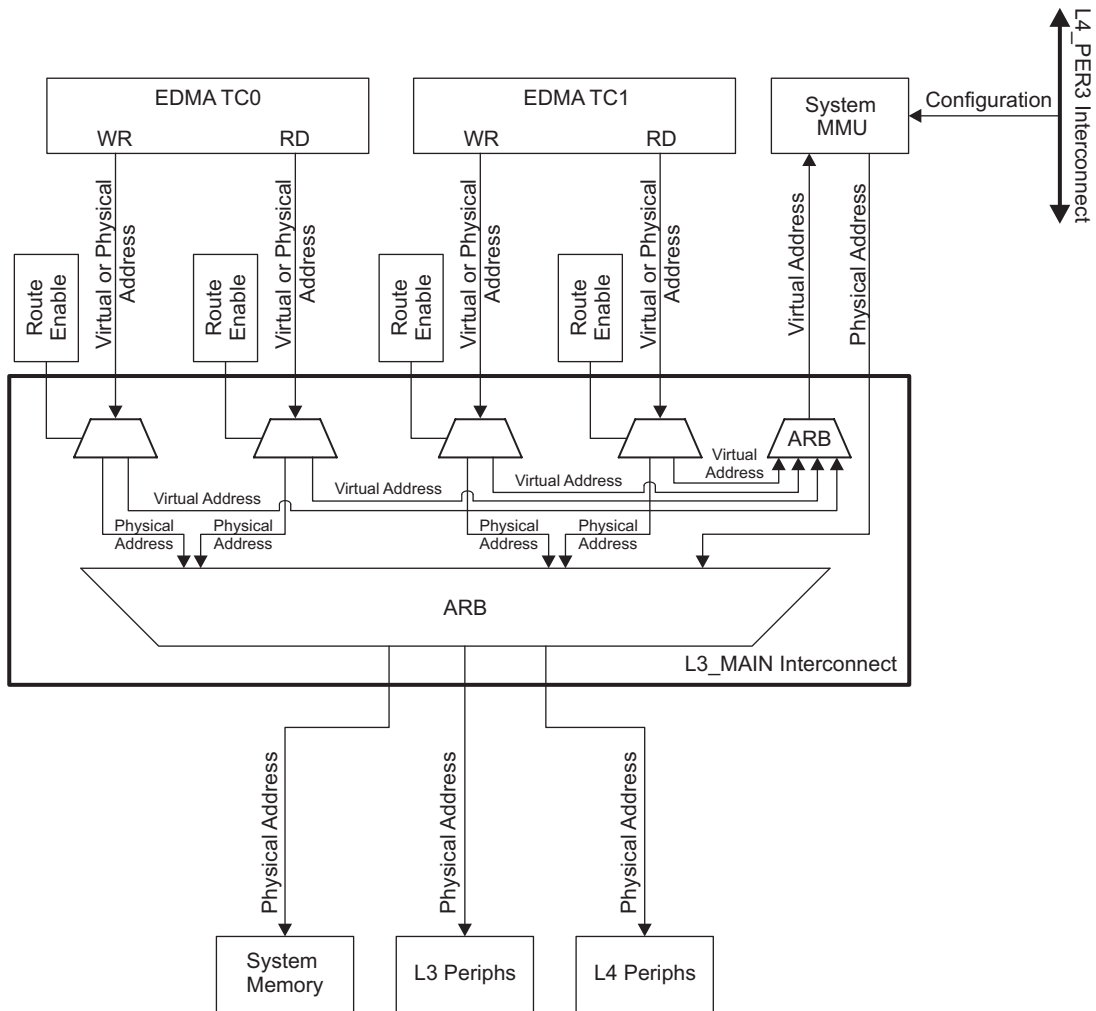

System MMUs, DSP MMUs and EVE MMUs are fully identical from functional perspective. IPU L2 MMU is different in that it does not support “bypass” functionality.

For more information about IPU unicache MMU, see [Chapter 5, Dual Cortex-M4 IPU Subsystem](#).

[Figure 16-1](#) shows an overview of system MMU. In summary, requests initiated by a given requestor (EDMA TC0 or TC1 [both read and write ports]) can optionally be routed through the system MMU. Each requestor’s use (or not) of the MMU is independently controllable via the Control Module CTRL_CORE_SMA_SW_7 register bitfields. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3_MAIN interconnect to the MMU and will again go through the L3_MAIN interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3_MAIN interconnect to the requested physical address, thus minimizing bus request latency.

Figure 16-1. System MMU1 Overview

16.2 MMU Integration

This section describes the system MMUs integration in the device, including information about clocks, resets, and hardware requests. For more information about DSP, EVE, and IPU MMUs integration, refer to their respective chapters.

Figure 16-2 shows system MMU integration.

Figure 16-2. System MMU1 Integration

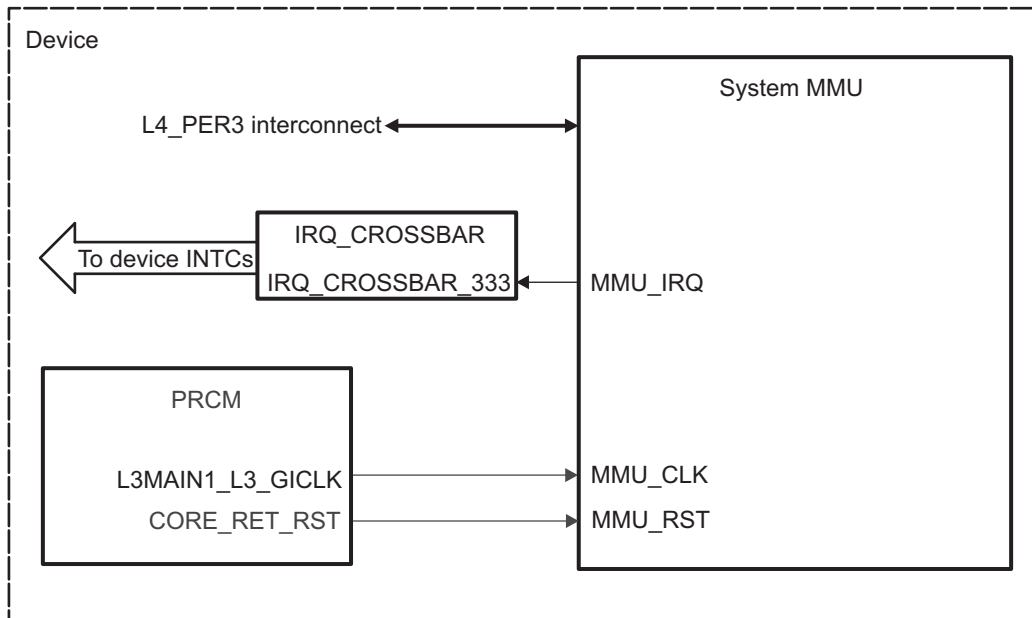

Table 16-1 through Table 16-3 summarize the system MMU integration.

Table 16-1. MMU Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
System MMU	PD_COREAON	L4_PER3

Table 16-2. MMU Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
System MMU	MMU_CLK	L3MAIN1_L3_GICKL	PRCM	System MMU interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
System MMU	MMU_RST	CORE_RET_RST	PRCM	System MMU hardware reset. This reset is asynchronously applied to the MMU internal registers.

Table 16-3. MMU Hardware Requests

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
System MMU	MMU_IRQ	IRQ_CROSSBAR_333	–	System MMU interrupt.

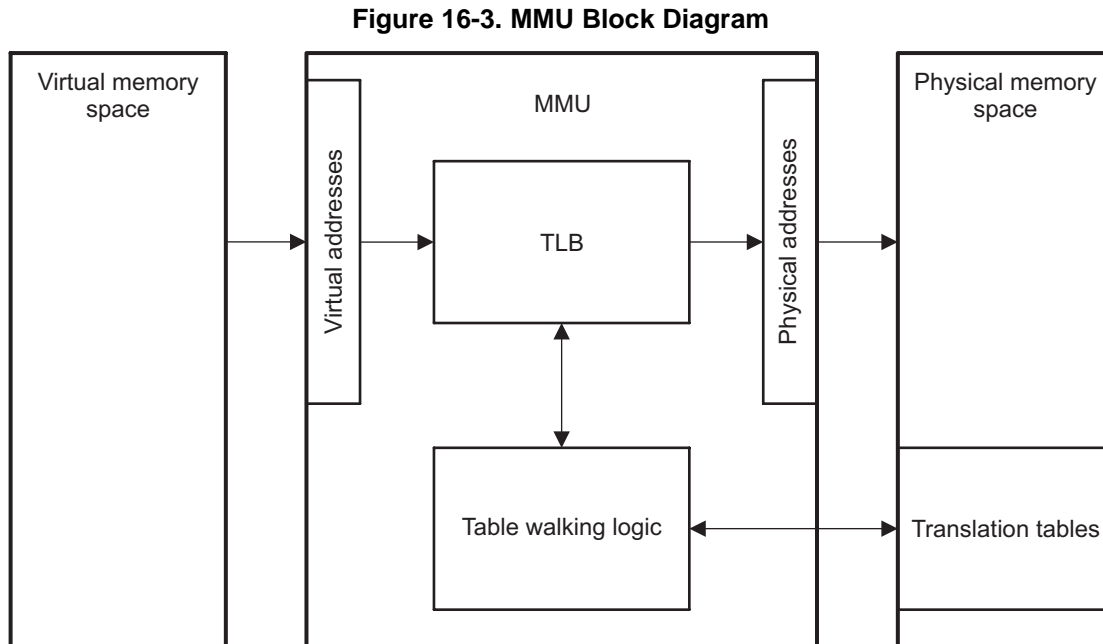

No DMA Requests

NOTE: For a description of the interrupt sources, see [Section 16.3.4, MMU Interrupt Requests](#).

16.3 MMU Functional Description

16.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. [Figure 16-3](#) shows the MMU block diagram.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 16.3.1.2, Translation Tables](#).

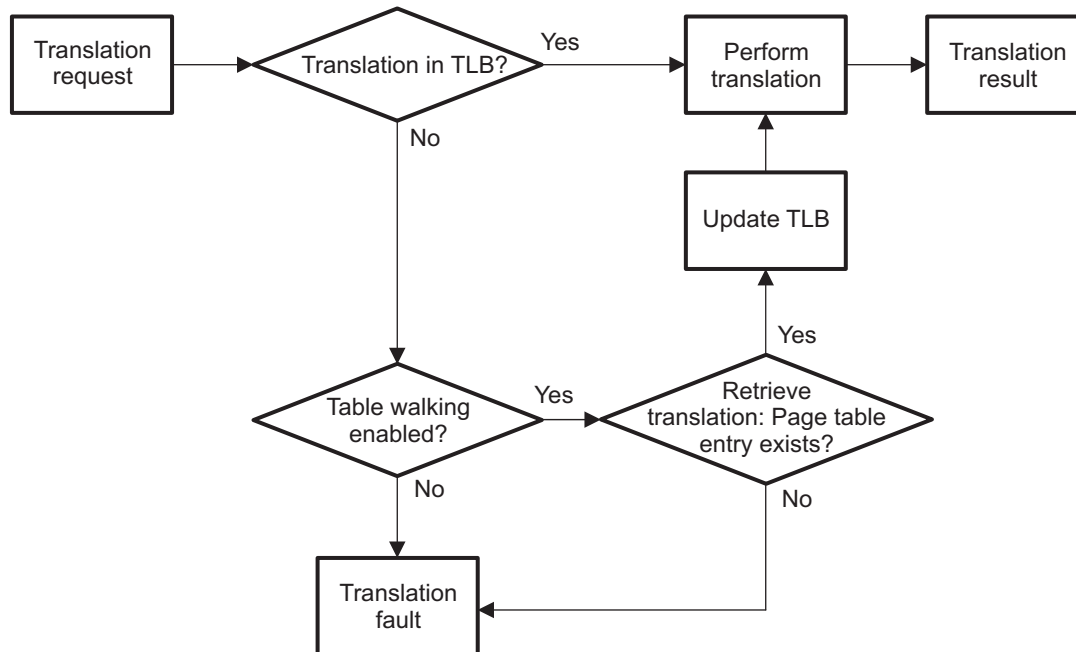

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

16.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 16-4](#) summarizes the process.

Figure 16-4. Translation Process

16.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

16.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4-KiB and 64-KiB pages, a 1-MiB section, and a 16-MiB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4 KiB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4 KiB memory pages with one translation table would require one million entries to span the entire 4-GiB address range. The table itself would be 32 MiB, a size that is not feasible.

However, using bigger pages reduces the flexibility of typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1 MiB memory regions.

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1 MiB (section) or 16 MiB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1-MiB page of memory. These pages can be either 64 KiB (large page) or 4

KiB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. Figure 16-5 shows the hierarchy.

Figure 16-5. Translation Hierarchy

The structure of the first and second-level translation tables and their entries are described in more detail in Section 16.3.1.2.2, *First-Level Translation Table*, and Section 16.3.1.2.3, *Two-Level Translation*.

16.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1-MiB sections. To describe a 4-GiB address range requires 4096 32-bit entries (so-called first-level descriptors).

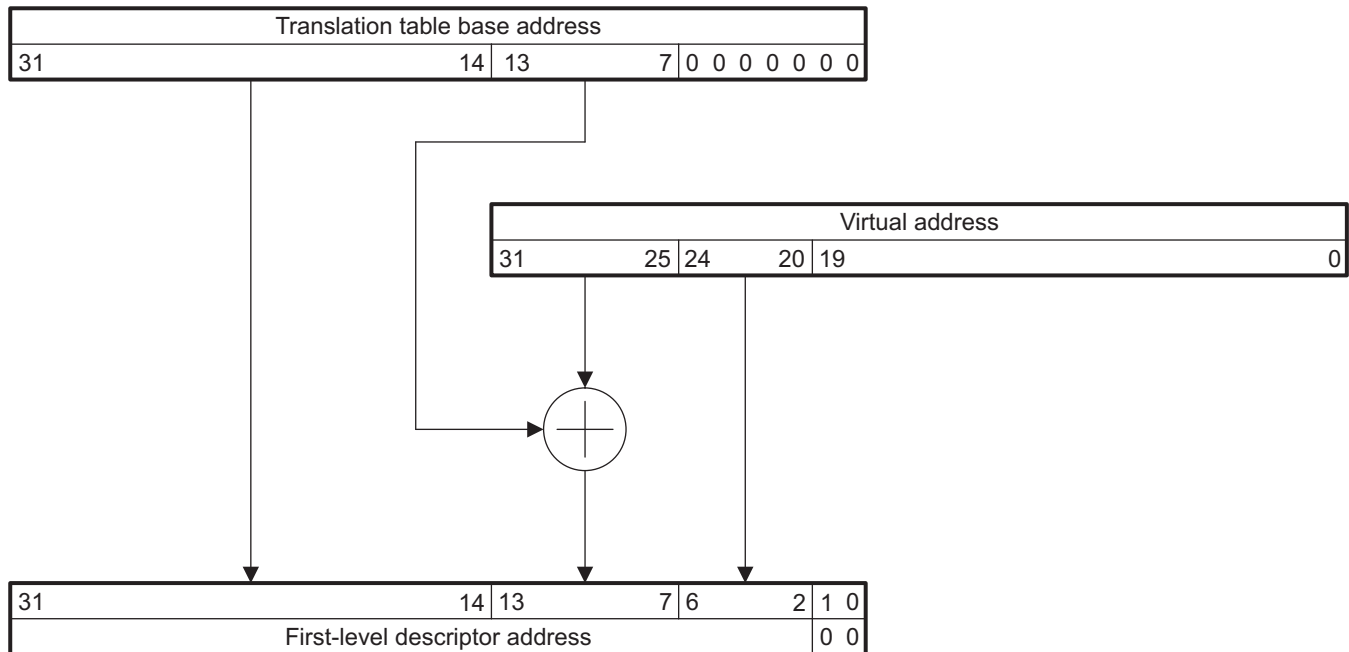

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. Figure 16-6 shows this mechanism.

Figure 16-6. First-level Descriptor Address Calculation

To summarize, the translation table base and the translation table index together define the first-level descriptor address. Figure 16-7 outlines the precise mechanism used to calculate this address.

Figure 16-7. Detailed First-Level Descriptor Address Calculation

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is $0x8000:0000 + (0x123 \ll 2) = 0x8000:048C$.

16.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1-MiB or 16-MiB sections or provides a pointer to a second-level translation table for 4 KiB or 64 KiB pages. [Table 16-4](#) shows the first-level descriptor format.

Table 16-4. First-Level Descriptor Format

First-Level Descriptor Format									
31:24	23:20	19	18	17:10	9:2	1	0		
X							0	0	Fault
Second-Level Translation Table Base Address					X	0	1	Page	
Section Base Address		X	0	X		1	0	Section	
Supersection Base Address		X		1	X		1	0	Supersection
X							1	1	Fault

X = Don't care. Set to 0 for future compatibility.

16.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1 MiB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

16.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1-MiB section or a 16-MiB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1 MiB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

16.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 16-8 summarizes the address translation process for a section.

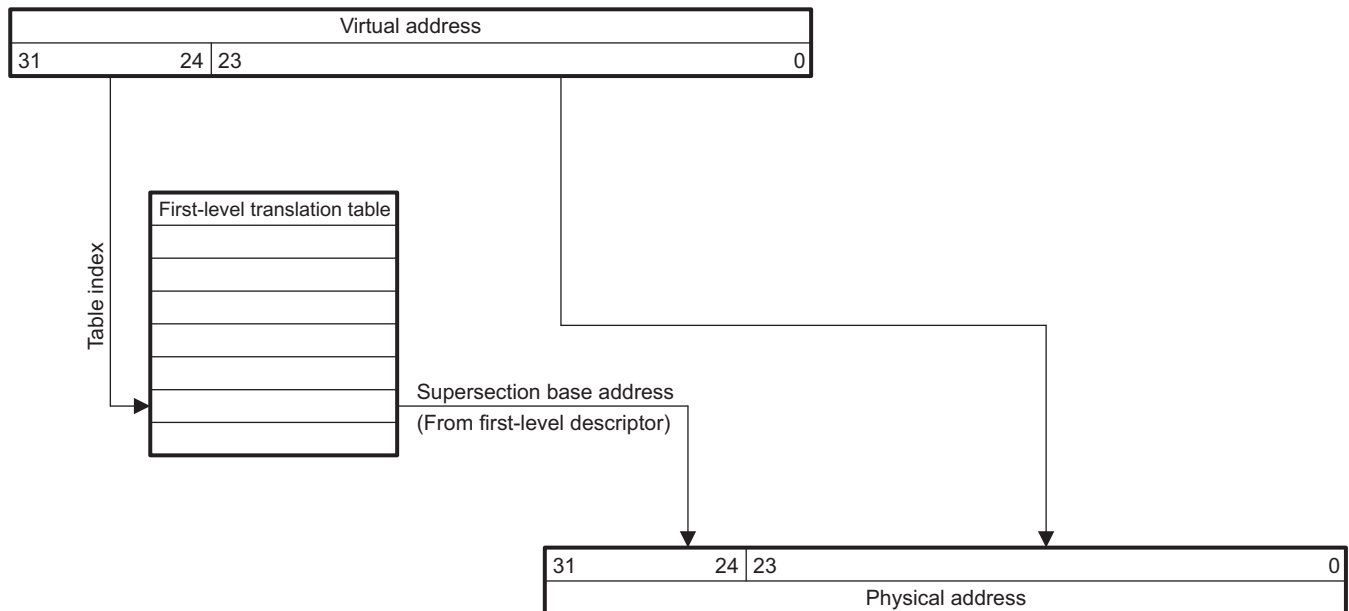

Figure 16-8. Section Translation Summary

16.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 16-9 shows the translation mechanism for a supersection.

Figure 16-9. Supersection Translation Summary

16.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1 MiB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. [Figure 16-10](#) shows this indexing mechanism.

Figure 16-10. Two-Level Translation

Each second-level translation table describes the translation of 1 MiB of address space in pages of 64 KiB (large page) or 4 KiB (small page). It consists of 256 second-level descriptors describing 4 KiB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

16.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 16-5 shows the format of second-level descriptors.

Table 16-5. Second-Level Descriptor Format

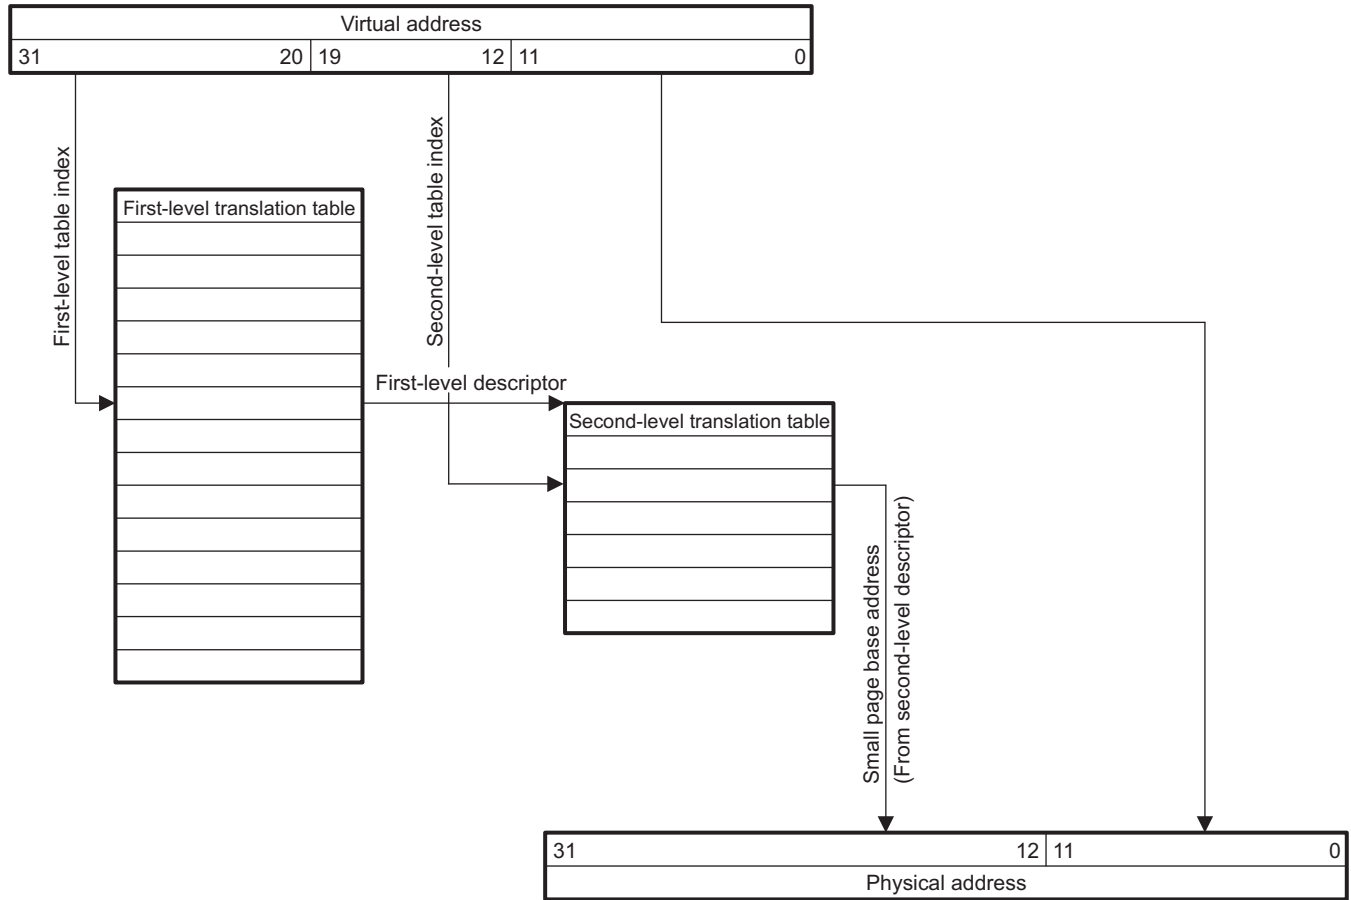

Second-Level Descriptor Format					
31:16	15:12	11:2	1	0	
X				0	0
Large Page Base Address		X		0	1
Small Page Base Address		X		1	X
					Fault
					Large Page
					Small Page

X = Don't care. Set to 0 for future compatibility.

16.3.1.2.3.2 Small Page Translation Summary

Figure 16-11 summarizes the translation process for small pages.

Figure 16-11. Small Page Translation Summary

16.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 16-12.

Figure 16-12. Large Page Translation Summary

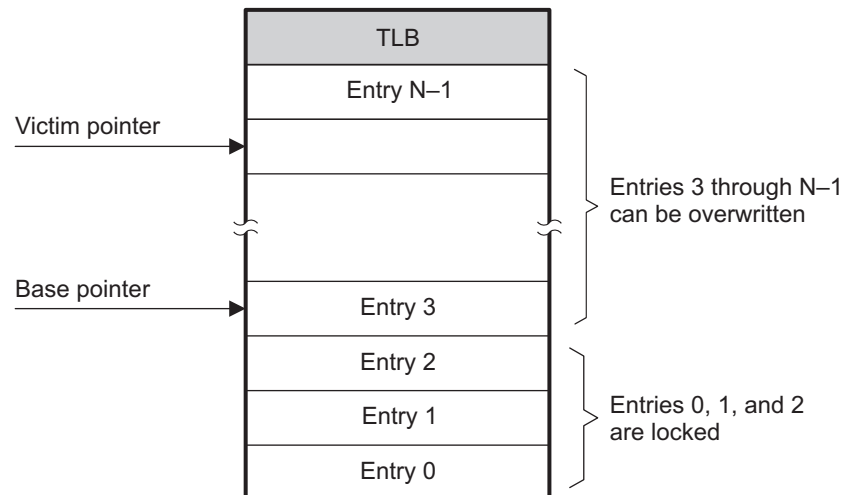

16.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where $n < Total\ Number\ N\ of\ TLB\ Entries$, can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 16-13 shows an example of the TLB with N TLB entries (ranging from 0 to $N-1$). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry $N-1$) always remains unprotected.

Figure 16-13. TLB Entry Lock Mechanism

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

16.3.1.3.1 TLB Entry Format

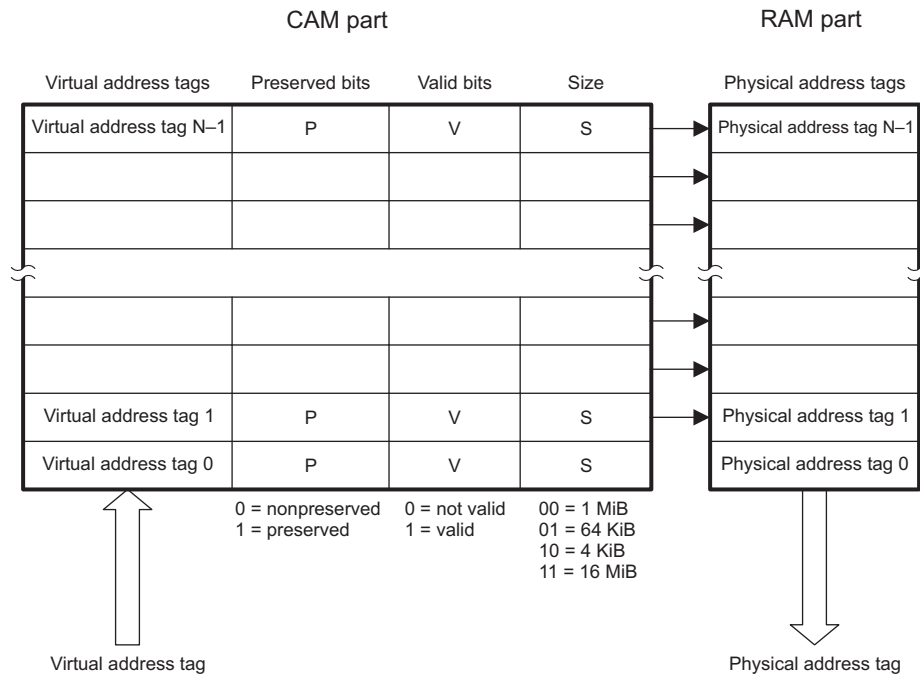

TLB entries consist of two parts:

- The Content Addressable Memory (CAM) part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU_CAM](#) register table for more details.
- The Random Addressable Memory (RAM) part contains the address translation that belongs to the virtual address tag. See the [MMU_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [MMU_GFLUSH\[0\]](#) GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. [Section 16.3.1.2.2, First-Level Translation Table](#) describes the procedure to delete TLB entries.

[Figure 16-15](#) shows the TLB entry structure.

Figure 16-14. TLB Entry Structure

16.3.1.4 No Translation (Bypass) Regions

The MMU provides support for up to four user programmable regions where there is no address translation. Any access to a region specified by the MMU_BYPASS_REGIONx_ADDR and MMU_BYPASS_REGIONx_SIZE registers (where x = 1 to 4) will have no virtual to physical address translation.

16.3.2 MMU Software Reset

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

16.3.3 MMU Power Management

Table 16-6 describes the power-management features available for the MMU modules.

Table 16-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bit field is read only.

16.3.4 MMU Interrupt Requests

Table 16-7. MMU Events

Event Flag	Event Mask	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Error due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Error due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS	Error due to unrecoverable TLB miss during debug (hardware TWL disabled)
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Error due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Error due to unrecoverable TLB miss (hardware TWL disabled)

16.3.5 MMU Error Handling

Table 16-8 summarizes the intended operation for real and potential error conditions.

Table 16-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.
7	Interrupt is not enabled and a fault/miss happens during translation.	If MMU_GPR[0] FAULT_INTR_DIS = 1 : Error response is sent back. If MMU_GPR[0] FAULT_INTR_DIS = 0 : <ul style="list-style-type: none"> Mreqdebug = 1 (debug access) : Error response is sent back Mreqdebug = 0 (application access) : Error response is not sent. MMU is waiting for TLB to be updated through config port. But since the interrupt is not asserted, system does not know there was a fault. This results in deadlock. Software must take care of this by enabling interrupts.

16.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

16.4.1 Global Initialization

16.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see [Section 16.2, MMU Module Integration](#).

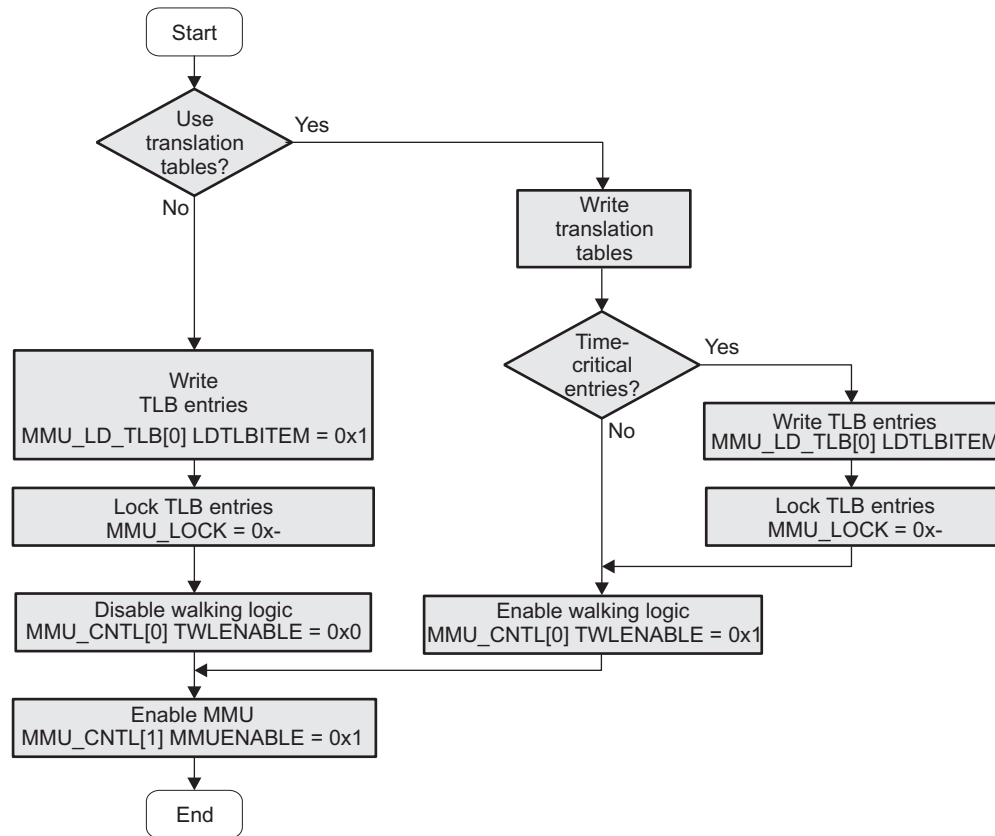

Table 16-9. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Enable MMU interface/functional clock.
(optional) Interrupt controller(s)	Configure device interrupt controller(s) to enable the interrupts from MMU.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

16.4.1.2 MMU Global Initialization

16.4.1.2.1 Main Sequence - MMU Global Initialization

[Figure 16-15](#) shows the procedure to initialize the MMU after a power-on or software reset.

Figure 16-15. MMU Global Initialization

16.4.1.2.2 Subsequence - Configure a TLB entry

Table 16-10. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

16.4.1.3 Operational Modes Configuration

16.4.1.3.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 16-11. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 16-10	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

16.4.1.3.2 Main Sequence - Protecting TLB Entries

The first n TLB entries (with $n <$ total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 16-12. Protecting TLB Entries

Step	Register/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

16.4.1.3.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 16-13. Deleting TLB Entries

Step	Register / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

16.4.1.3.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 16-14. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	

Table 16-14. Read TLB Entries (continued)

Step	Register / Bit Field / Programming Model	Value
Read CAM parts of the TLB entry	MMU_READ_CAM	

16.5 MMU Register Manual

16.5.1 MMU Instance Summary

Table 16-15. MMU Instance Summary

Module Name	Base Address (L3/L4 Access)	Base Address (CPU Private Access)	Size
System MMU	0x4881 C000	–	176 Bytes

Table 16-23. MMU_SYSCONFIG

Address Offset	0x0000 0010	Instance	See Table 16-15
Physical Address	See Section 16.5.2.1		
Description	This register controls the various parameters of the OCP interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY		RESERVED		IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE							

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x000000
9:8	CLOCKACTIVITY	Clock activity during wake-up mode 0x0: Functional and OCP clocks can be switched off	R	0x0
7:5	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
4:3	IDLEMODE	Idle mode 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved. Do not use	RW	0x0
2	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0 Write 0x0: No functional effect Write 0x1: The module is reset	W	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity	RW	0x0

Spinlock

This chapter describes the Spinlock module of the device.

Topic	Page
17.1 Spinlock Overview	5244
17.2 Spinlock Integration	5245
17.3 Spinlock Functional Description	5246
17.4 Spinlock Programming Guide.....	5248
17.5 Spinlock Register Manual	5251

17.1 Spinlock Overview

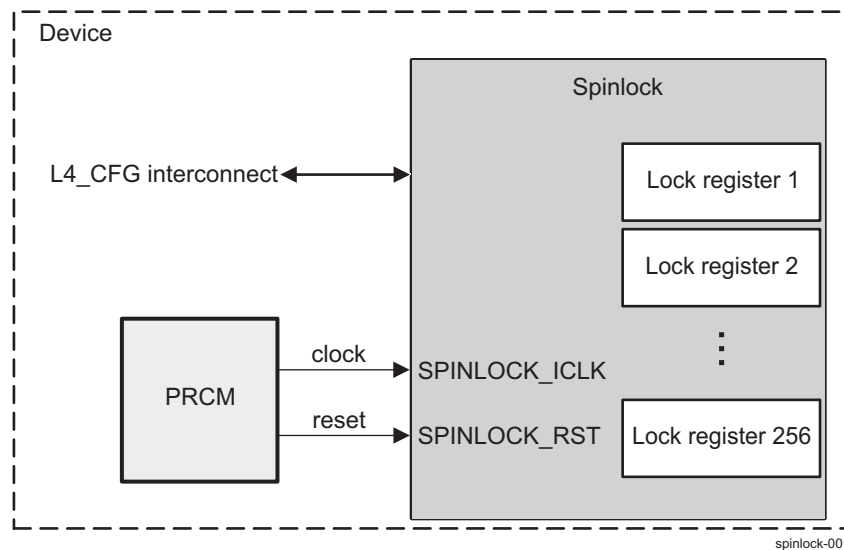

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Digital signal processor (DSP) subsystems – DSP1 and DSP2
- Dual Cortex-M4 image processing unit (IPU) subsystem – IPU

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 17-1 shows an overview of the Spinlock module.

Figure 17-1. Spinlock Overview

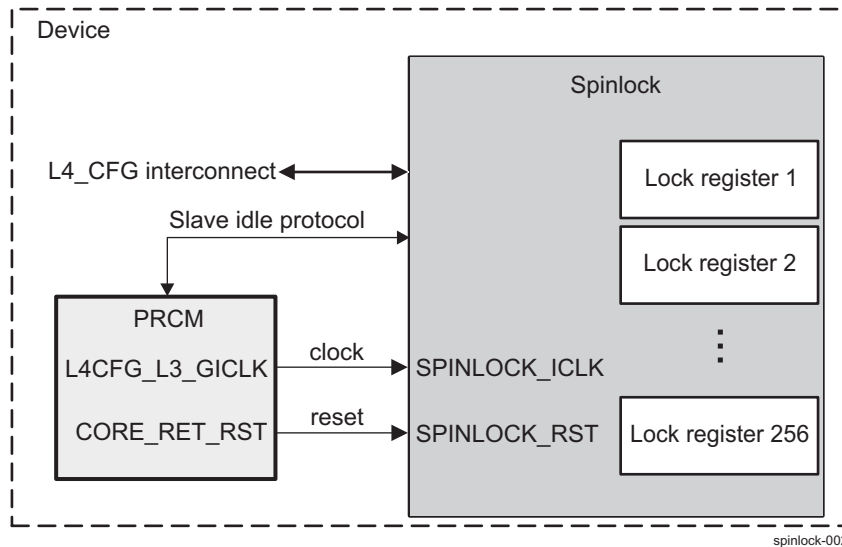

17.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 17-2 shows the Spinlock integration.

Figure 17-2. Spinlock Integration

NOTE: For more information about the Slave idle protocol and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 17-1](#) and [Table 17-2](#) summarize the integration of the module in the device.

Table 17-1. Spinlock Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_COREAON	L4_CFG

Table 17-2. Spinlock Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_ICLK	L4CFG_L3_GICLK	PRCM	Spinlock interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

NOTE: The Spinlock module does not support any interrupt and DMA requests.

17.3 Spinlock Functional Description

17.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the `SPINLOCK_SYSCONFIG[1]` `SOFTRESET` bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The `SPINLOCK_SYSTATUS[0]` `RESETDONE` bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

17.3.2 Spinlock Power Management

Table 17-3 describes power-management features available to the Spinlock module.

Table 17-3. Spinlock Local Power Management Features

Feature	Registers	Description
Clock auto gating	<code>SPINLOCK_SYSCONFIG[0]</code> <code>AUTOGATING</code> bit	This bit indicates that the Spinlock module uses an automatic internal interface clock gating strategy, based on interface activity.
Global wake-up enable	<code>SPINLOCK_SYSCONFIG[2]</code> <code>ENAWAKEUP</code> bit	This bit indicates that the wake-up generation feature (at Spinlock module level) is disabled.
Slave idle modes	<code>SPINLOCK_SYSCONFIG[4:3]</code> <code>SIDLEMODE</code> bit field	This bit field indicates that the Spinlock module uses smart-idle mode.

NOTE: All Spinlock local power management features are non-configurable – that is, their respective bit fields are read-only and only show the actual hardware implementation.

For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#). For descriptions of `EnaWakeUp`, and `IdleMode` features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

17.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

17.3.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the `SPINLOCK_LOCK_REG_i[0]` TAKEN bit. There are two states: Taken (`SPINLOCK_LOCK_REG_i[0]` TAKEN = 1) or Not Taken (`SPINLOCK_LOCK_REG_i[0]` TAKEN = 0).

When the status of lock *i* (where *i* = 0 to 255) is Not Taken (free), a read from the `SPINLOCK_LOCK_REG_i` register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

A write to the `SPINLOCK_LOCK_REG_i` register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION
Only 32-bit reads and writes are supported.

Figure 17-3 shows the `SPINLOCK_LOCK_REG_i` register state diagram.

Figure 17-3. Lock Register State Diagram

NOTE:

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

17.4 Spinlock Programming Guide

17.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

17.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 17-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see Section 3.6.4.11, CD_L4_CFG Clock Domain , in Chapter 3, Power, Reset, and Clock Management .
Interconnect	For more information about the L4_CFG interconnect configuration, see Section 10.3, L4 Interconnects .

17.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

17.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the [SPINLOCK_LOCK_REG_i](#) registers at system startup to insure that all locks are initialized to Not Taken.

Table 17-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 == 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 256 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i = 0 to 255)	0x0
END		

17.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the [SPINLOCK_LOCK_REG_i\[0\] TAKEN](#) bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. [Figure 17-4](#) shows the described above procedure.

18.1 Timers Overview	5256
18.2 General-Purpose Timers	5257
18.3 32-kHz Synchronized Timer (COUNTER_32K)	5303

18.1 Timers Overview

The device includes several types of timers used by the system software, including eight general-purpose (GP) timers, and a 32-kHz synchronized timer (COUNTER_32K). [Figure 18-1](#) shows a high-level block diagram of the device timers.

Figure 18-1. Timers Overview

timers-001

The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. The eight GP timers, which are useful as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

18.2 General-Purpose Timers

18.2.1 General-Purpose Timers Overview

The device has eight GP timers: TIMER1 through TIMER8.

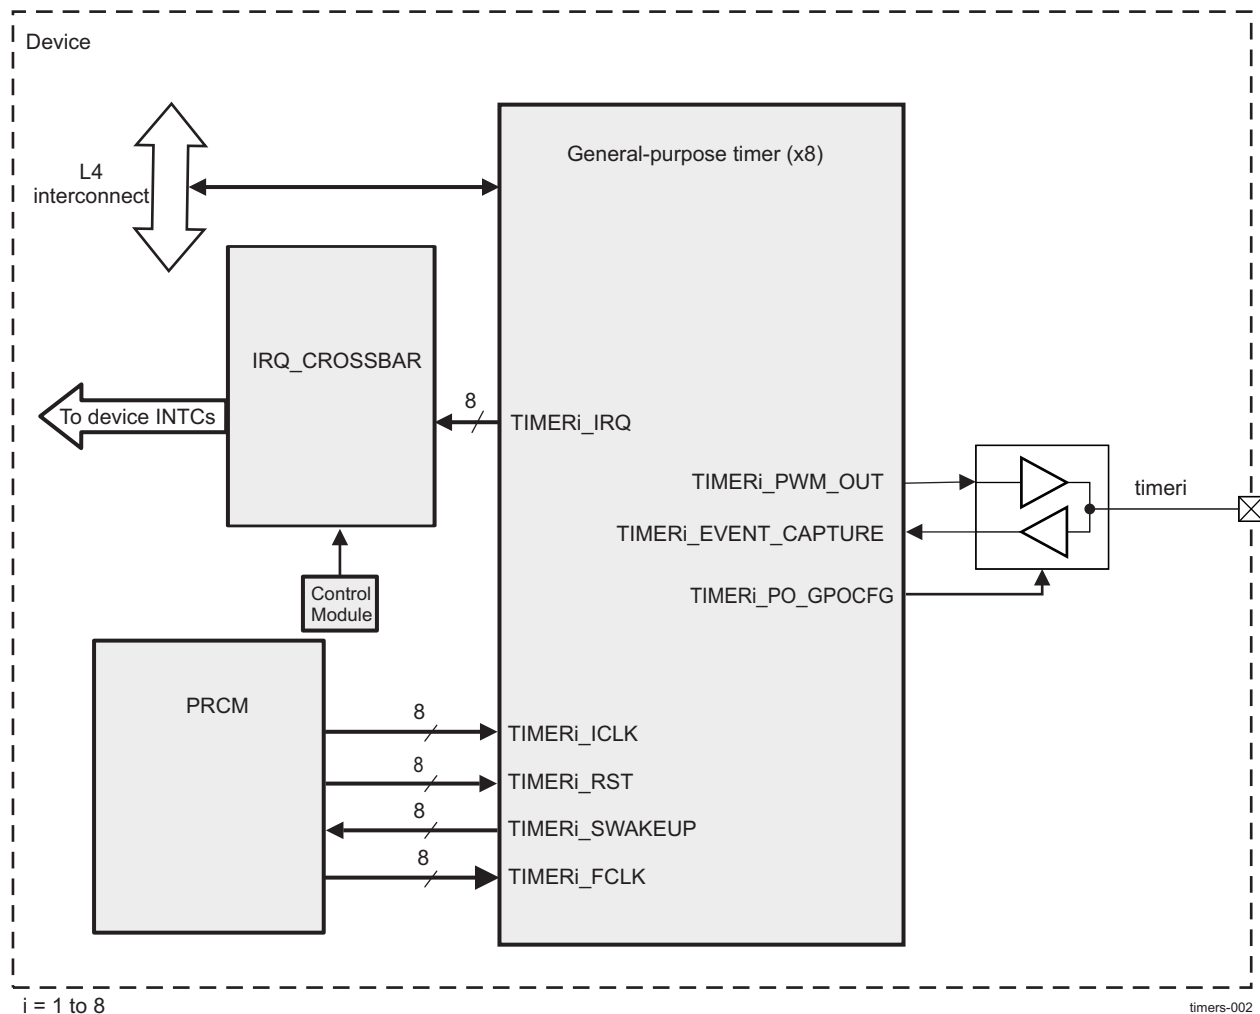

- TIMER1 (1-ms tick) includes a specific function to generate accurate tick interrupts to the operating system and it belongs to the PD_WKUPAON domain.
- TIMER2 through TIMER8 belong to the PD_COREAON module.

Each timer can be clocked from the system clock (19.2, 20, or 27 MHz) or the 32-kHz clock. Select the clock source at the power, reset, and clock management (PRCM) module level.

Each timer provides an interrupt through the device IRQ_CROSSBAR.

Each timer is connected to an external pin by their PWM output or their event capture input pin (for external timer triggering). Figure 18-2 shows an overview of the GP timers.

Figure 18-2. GP Timers Overview

18.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- Level 4 (L4) slave interface support:
 - 32-bit data bus width

- 32- or 16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start and stop mode
- Programmable divider clock source (2^n , where $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the `TIMERi_GPO_CFG` signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32.768-Hz functional clock generated (only TIMER1)

18.2.2 GP Timer Environment

18.2.2.1 GP Timer External System Interface

Each timer can send or receive stimulus to and from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count.

Figure 18-3 shows the external system interface for the GP timers, and Table 18-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the timer_i (where i = 1 to 8) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the timer_i I/O pads, see Section 14.4.6.1, Pad Configuration Registers.

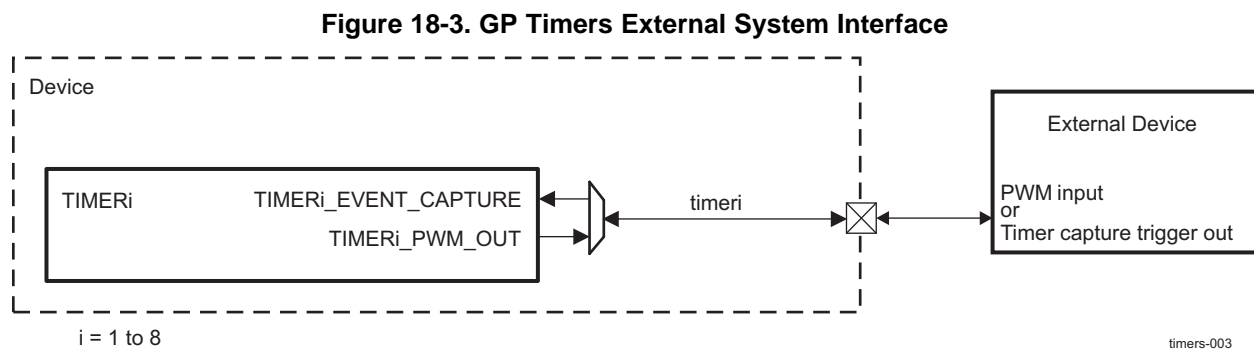

Table 18-1. Input/Output Description

Pin Name	Type ⁽¹⁾	Reset Value	Signal Name	Description
timer1	I/O	0	TIMER1_PI_EVENT_CAPTURE TIMER1_PWM_OUT	TIMER1 trigger input/ PWM output
timer2	I/O	0	TIMER2_PI_EVENT_CAPTURE TIMER2_PWM_OUT	TIMER2 trigger input/ PWM output
timer3	I/O	0	TIMER3_PI_EVENT_CAPTURE TIMER3_PWM_OUT	TIMER3 trigger input/ PWM output
timer4	I/O	0	TIMER4_PI_EVENT_CAPTURE TIMER4_PWM_OUT	TIMER4 trigger input/ PWM output
timer5	I/O	0	TIMER5_PI_EVENT_CAPTURE TIMER5_PWM_OUT	TIMER5 trigger input/ PWM output
timer6	I/O	0	TIMER6_PI_EVENT_CAPTURE TIMER6_PWM_OUT	TIMER6 trigger input/ PWM output
timer7	I/O	0	TIMER7_PI_EVENT_CAPTURE TIMER7_PWM_OUT	TIMER7 trigger input/ PWM output
timer8	I/O	0	TIMER8_PI_EVENT_CAPTURE TIMER8_PWM_OUT	TIMER8 trigger input/ PWM output

⁽¹⁾ When configured for that function; I = Input, O = Output

NOTE: Each TIMER_i_PO_GPOCFG signal is used to as an output enable to control the function of the TIMER_i pin (where i = 1 to 8) as the PWM output (PO_GPOCFG = 0) or capture input (PO_GPOCFG = 1).

18.2.3 GP Timer Integration

Figure 18-4 shows the integration of the GP timer in the device.

Figure 18-4. GP Timer Integration

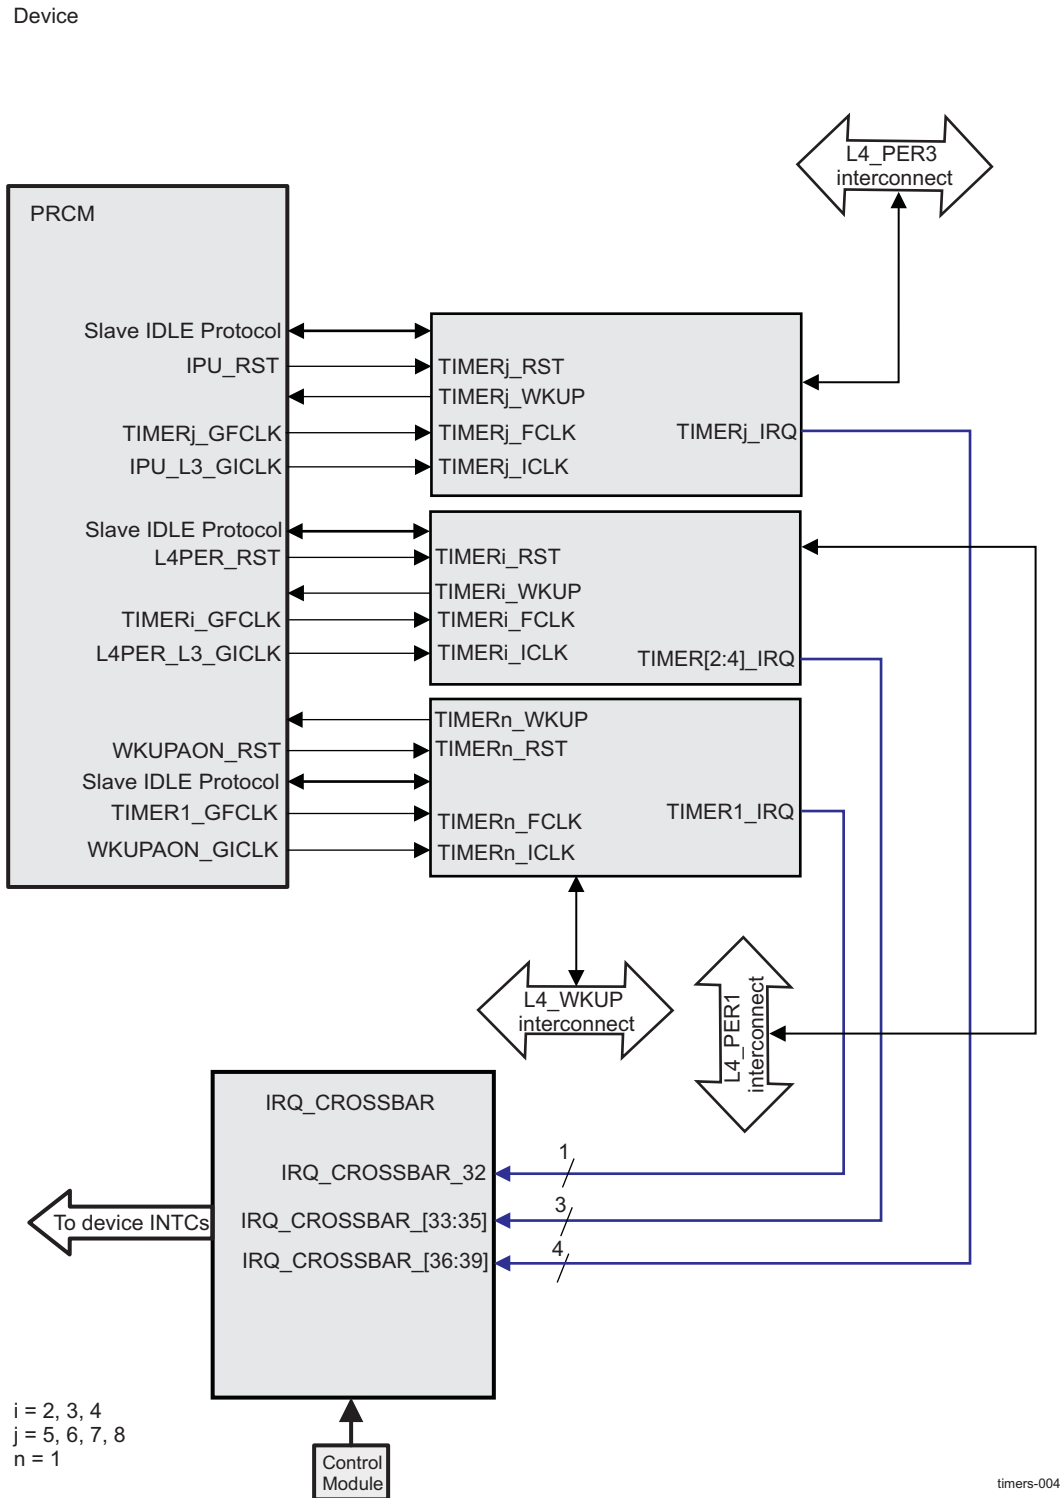

Table 18-2 through Table 18-4 summarize the integration of the module in the device.

Table 18-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
TIMER1	PD_WKUPAON	Yes	L4_WKUP
TIMER2	PD_COREAON	Yes	L4_PER1
TIMER3	PD_COREAON	Yes	L4_PER1
TIMER4	PD_COREAON	Yes	L4_PER1
TIMER5	PD_COREAON	Yes	L4_PER3
TIMER6	PD_COREAON	Yes	L4_PER3
TIMER7	PD_COREAON	Yes	L4_PER3
TIMER8	PD_COREAON	Yes	L4_PER3

Table 18-3. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
TIMER1	TIMER1_FCLK	TIMER1_GFCLK	PRCM	TIMER1 functional clock
	TIMER1_ICLK	WKUPAON_GICLK	PRCM	TIMER1 interface clock
TIMER2	TIMER2_FCLK	TIMER2_GFCLK	PRCM	TIMER2 functional clock

TIMER6	TIMER6_IRQ	IRQ_CROSSBAR_37	DSP1_IRQ_68 DSP2_IRQ_68	TIMER6 interrupt
TIMER7	TIMER7_IRQ	IRQ_CROSSBAR_38	DSP1_IRQ_69 DSP2_IRQ_69	TIMER7 interrupt
TIMER8	TIMER8_IRQ	IRQ_CROSSBAR_39	DSP1_IRQ_70 DSP2_IRQ_70	TIMER8 interrupt
No DMA Requests				

NOTE: The Default Mapping column in [Table 18-4](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For the description of the interrupt source, see [Section 18.2.4.5, GP Timer Interrupt](#).

18.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the [IRQSTATUS_SET](#) and [IRQSTATUS_CLR](#) registers for the interrupt features, and a dedicated bit of the [IRQWAKEEN](#) register for the wake-up of TIMER1. In addition, a mechanism implemented in these timers generate an accurate tick interrupt.

For all other internal interrupts, the source can be independently enabled and disabled through the [IRQENABLE_SET](#) and [IRQENABLE_CLR](#) registers.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

The input clock source is selected in the registers in the PRCM configuration (see [Section 18.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

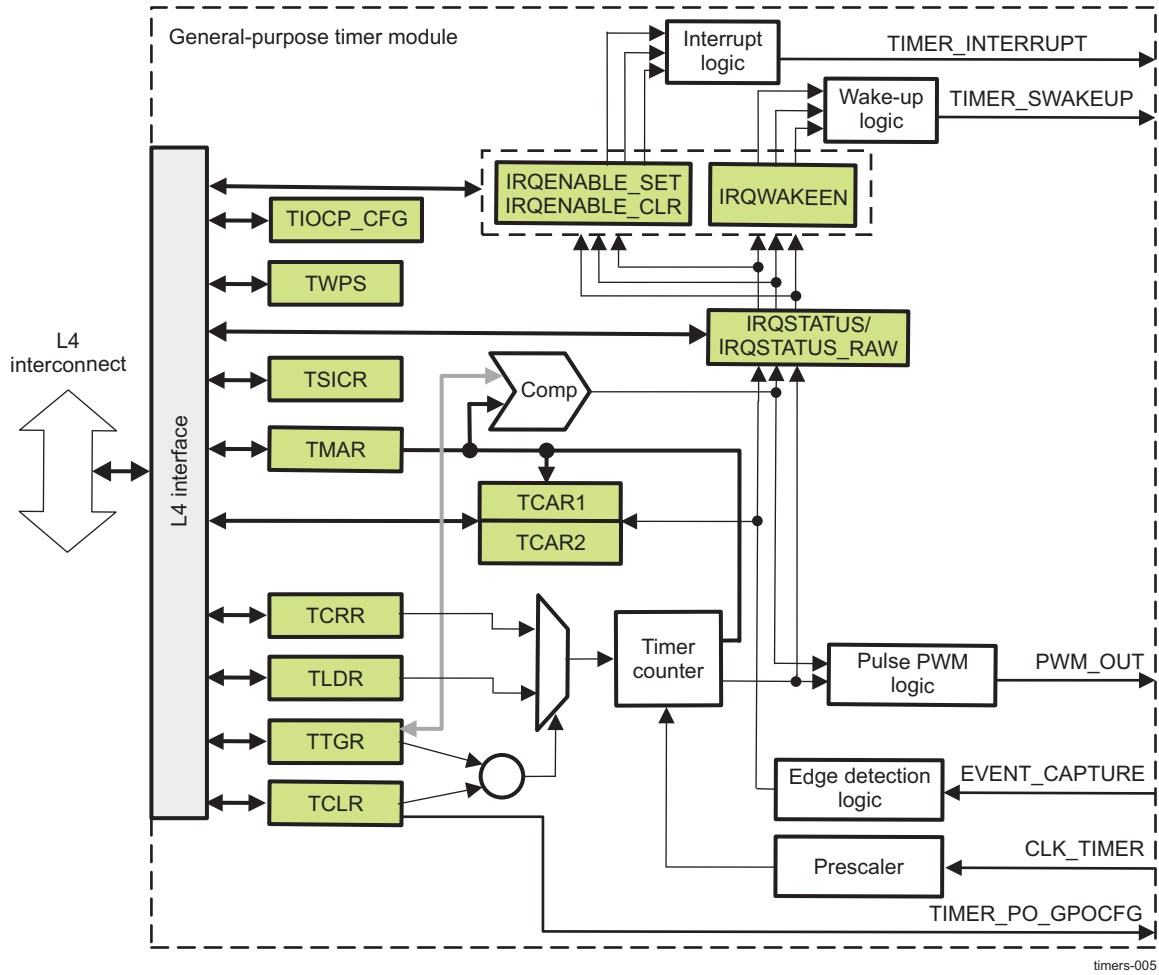

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

18.2.4.1 GP Timer Block Diagram

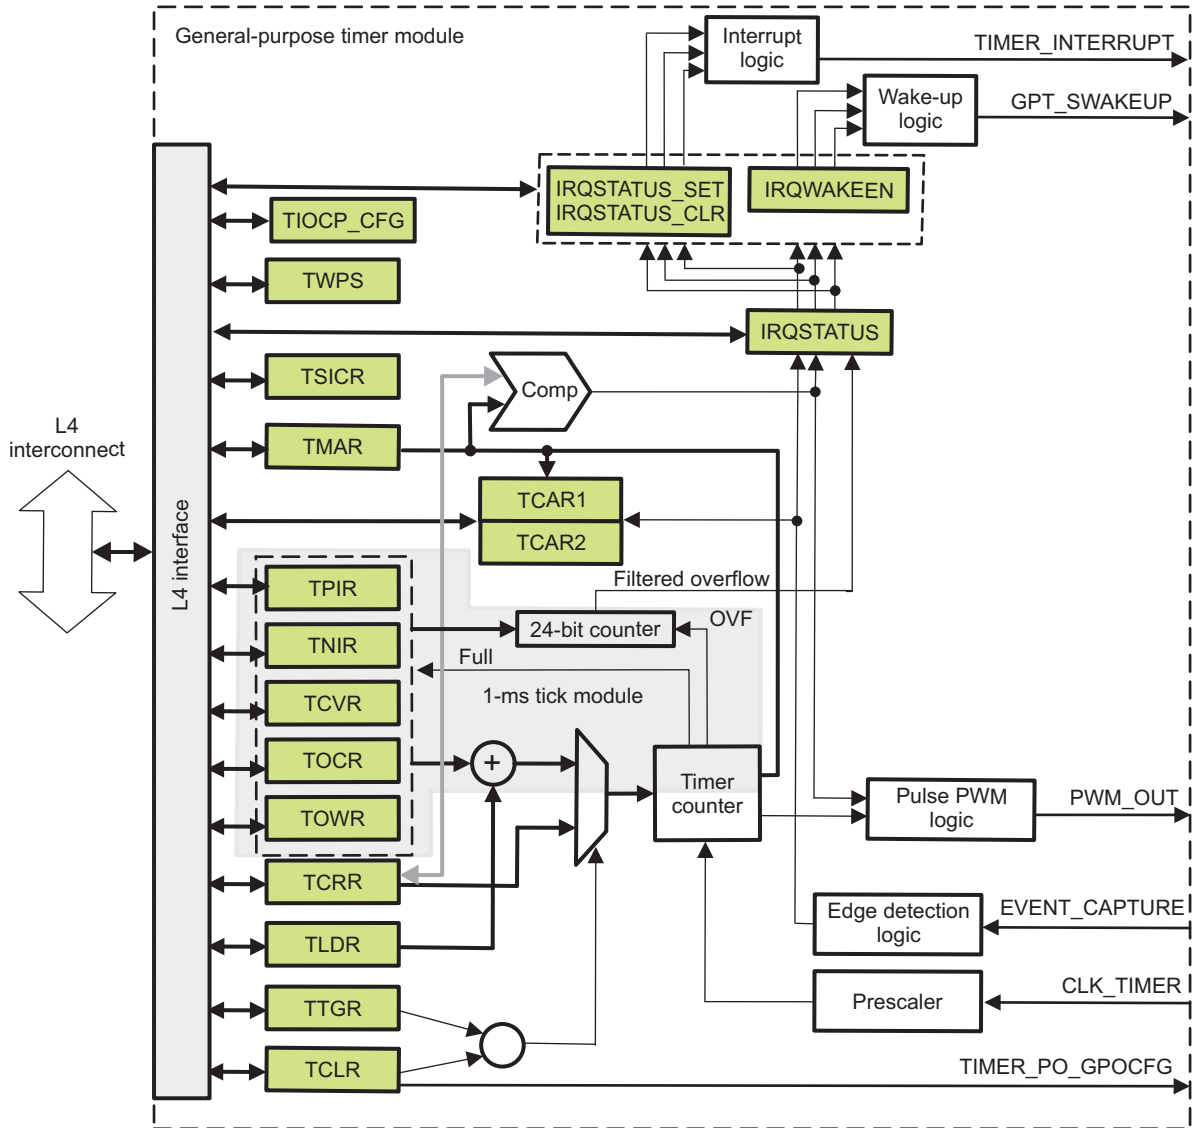

[Figure 18-5](#) is a block diagram of the common GP timers, and [Figure 18-6](#) is a block diagram of the GP timers with a 1-ms tick generation module.

Figure 18-5. Block Diagram of TIMER2 Through TIMER8

timers-005

Figure 18-6. Block Diagram of TIMER1

timers-006

18.2.4.2 TIMER1 Power Management

At the PRCM module level, when all conditions to shut off the functional or interface output clocks in the PRCM module are met (see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the `TIOCP_CFG[3:2]` IDLEMODE bit field.

[Table 18-5](#) lists the IDLEMODE settings and the related acknowledgment modes.

Table 18-5. IDLEMODE Settings

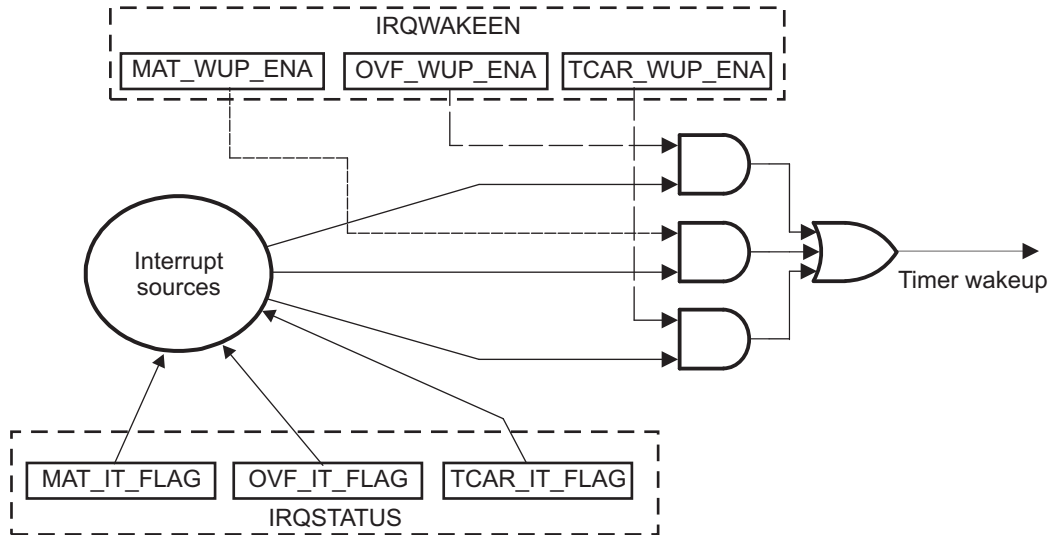

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. No-idle mode is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

18.2.4.2.1 Wake-Up Capability

If the `TIOCP_CFG[3:2]` IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode.

[Figure 18-7](#) shows the wake-up request generation. For more information about the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset and Clock Management](#).

Figure 18-7. Wake-Up Request Generation

timers-007

For TIMER1 the timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (TCRR), a timer match (the compare result of TCRR and TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

18.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the functional or interface output clocks of the PRCM module are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 18-6 lists the IDLEMODE settings and the related acknowledgment modes.

Table 18-6. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. INo-idle mode is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

Table 18-6. IDLEMODE Settings (continued)

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

18.2.4.3.1 Wake-Up Capability

If the `TIOCP_CFG[3:2]` IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode. This wake-up request is sent only if the `IRQWAKEEN[2:0]` bit field enables the timer wake-up capability.

Figure 18-8 shows the wake-up request generation. For more information about the GP timer clock control, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Figure 18-8. Wake-Up Request Generation

timers-008

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (`IRQSTATUS`). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

18.2.4.4 Software Reset

Two bits can generate a software reset of the GP timer:

- `TIOCP_CFG[0]` SOFTRESET
- `TSICR[1]` SFT

For both bits, all read accesses return 0.

The `TIOCP_CFG[0]` SOFTRESET bit allows resetting of the functional and interface domains. The `TSICR[1]` SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the `TIOCP_CFG[0]` SOFTRESET bit. This bit monitors the internal reset status.

18.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (`IRQSTATUS_SET` for `TIMER1` and `IRQENABLE_SET` for other timers) and disabled in the interrupt-disable register (`IRQSTATUS_CLR` for `TIMER1` and `IRQENABLE_CLR` for other timers). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (`IRQSTATUS`).

18.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the `TCLR[0]` ST bit). The timer counter register (`TCRR`) can be loaded when stopped or on-the-fly (while counting). `TCRR` can be loaded directly by a `TCRR` write access with a new timer value. `TCRR` can also be loaded with the value held in the timer load register (`TLDR`) by a trigger register (`TTGR`) write access. The loading of `TCRR` is done regardless of the written value of `TTGR`. The value of `TCRR` can be read when stopped or captured on-the-fly by a `TCRR` read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the `TCLR[1]` AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the `TCLR[1]` AR bit is set to 1), `TCRR` is reloaded with the value of `TLDR` after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFF FFFF) in the `TLDR` register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the `IRQSTATUS_SET[1]` OVF_EN_FLAG bit is set to 1 for `TIMER1/2/10` and the `IRQENABLE_SET[1]` OVF_EN_FLAG bit is set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in the `TCLR[12]` PT bit through the `TCLR[11:10]` (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The `TCLR[12]` PT bit selects pulse/toggle modulation (the `TCLR[11:10]` TRG bit field selects trigger mode).

Figure 18-9 shows the `TCRR` timing value.

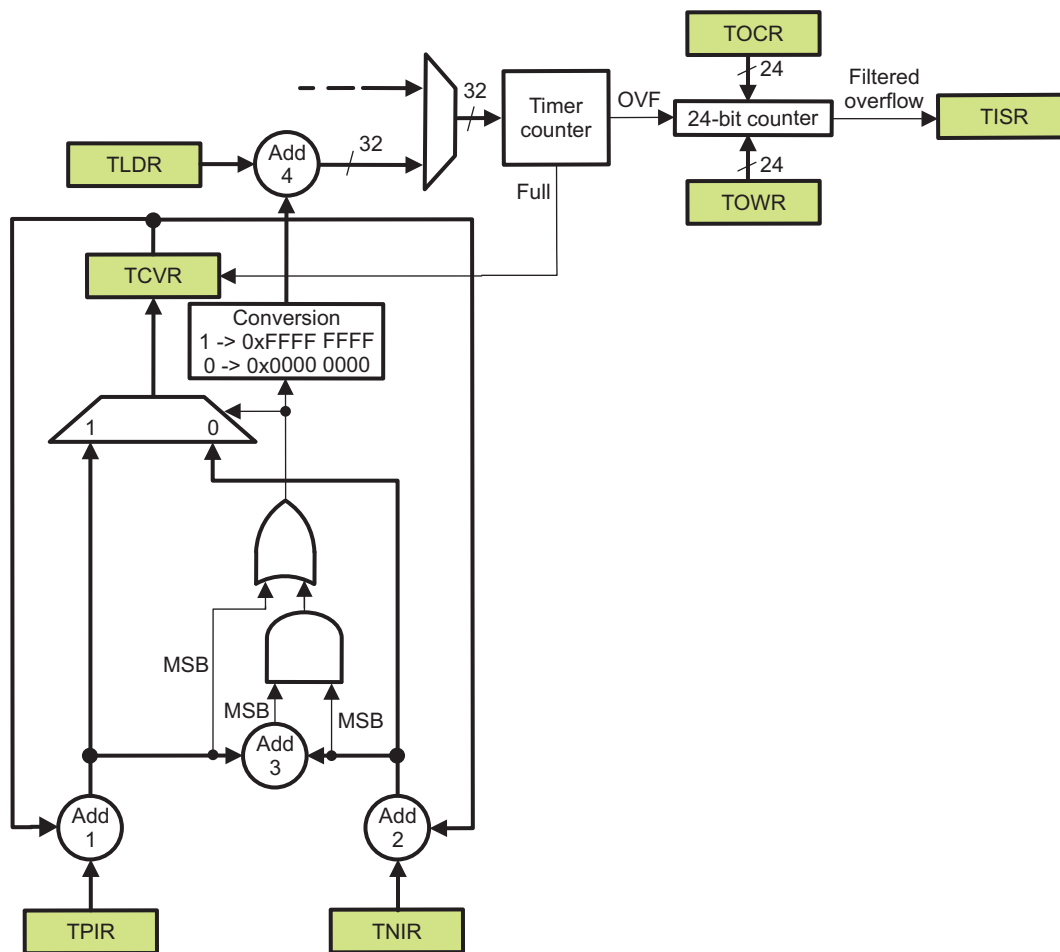

18.2.4.6.1 1-ms Tick Generation (Only TIMER1)

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See [Figure 18-10](#).

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the **TPIR**[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (the **TNIR**[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 18-10. Block Diagram of the 1-ms Tick Module

timers-010

The **TPIR**, **TNIR**, and **TCVR** registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the **TCRR**[31:0] TIMER_COUNTER bit field) is the value of the **TLDR**[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of **TLDR**[31:0] LOAD_VALUE -1 (period greater than 1 ms).

[Table 18-7](#) lists the value loaded in the **TCRR** according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

Table 18-7. Value Loaded in TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of TCRR Register
0	0	0	TLDR[31:0] LOAD_VALUE bit field
0	0	1	TLDR[31:0] LOAD_VALUE bit field
0	1	0	TLDR[31:0] LOAD_VALUE bit field
0	1	1	TLDR[31:0] LOAD_VALUE -1
1	0	0	N/A
1	0	1	N/A
1	1	0	TLDR[31:0] LOAD_VALUE -1
1	1	1	TLDR[31:0] LOAD_VALUE -1

The values of the **TPIR** and **TNIR** registers are calculated using the following formulas:

- Positive increment value = $((\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value = $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

NOTE: F_{clk} clock frequency (kHz)

T_{tick} tick period (ms)

The timer overflow counter register (**TOCR**) and the timer overflow wrapping register (**TOWR**) are used to filter interrupts. When the timer overflows, it increments the 24-bit **TOCR**. When the values in the 24-bit **TOCR** match the values in the 24-bit **TOWR** and the timer overflow is asserted, the **TOCR** is reset and an interrupt is generated to the **IRQSTATUS** register.

NOTE: **TOWR** must to be set to requested value. For example, if no interrupt needs to be masked, **TOWR** must be set to 0; if one interrupt must be masked, **TOWR** must be set to 1; if two interrupts must be masked **TOWR** must be set to 2, and so on.

It is important to remember that it is not possible to mask the FFFFFFF interrupt.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of **TIMER1** remain unchanged.

For 1-ms tick with a 32.768-Hz clock:

- **TPIR**[31:0] POSITIVE_INC_VALUE = 232,000
- **TNIR**[31:0] NEGATIVE_INC_VALUE = -768,000
- **TLDR**[31:0] LOAD_VALUE = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the **TPIR**, **TNIR**, and **TLDR** registers.

By default, the **TPIR**, **TNIR**, **TCVR**, **TOCR**, and **TOWR** registers and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

18.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (**EVENT_CAPTURE**), the timer value in the **TCRR** can be captured and saved in the **TCAR1** or **TCAR2** register function of the mode selected in the **TCLR**[13] **CAPT_MODE** bit. The edge detection circuitry monitors transitions on the input pin (**EVENT_CAPTURE**).

The rising edge, falling edge, or both, can be selected in the **TCLR**[9:8] **TCM** bit field to trigger the timer counter capture. The module sets the **IRQSTATUS**[2] **TCAR_IT_FLAG** bit when an active edge is detected, and at the same time, the counter value **TCRR** is stored in timer capture register **TCAR1** or **TCAR2**, as follows:

- If the **TCLR[13] CAPT_MODE** bit is 0, on the first enabled capture event, the value of the counter register is saved in the **TCAR1** register, and the next events are ignored (no update on the **TCAR1** register and no interrupt triggering) until the detection logic is reset or the **IRQSTATUS[2] TCAR_IT_FLAG** is cleared by writing 1 to it.
- If the **TCLR[13] CAPT_MODE** bit is 1, on the first enabled capture event, the value of the counter register is saved in the **TCAR1** register, and on the second enabled capture event, the value of the counter register is saved in the **TCAR2** register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on **TCAR1/TCAR2** and no interrupt triggering) until the detection logic is reset or the **IRQSTATUS[2] TCAR_IT_FLAG** bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the **EVENT_CAPTURE** input pin.

The edge detection logic is reset (a new capture pin is enabled) when the active capture interrupt is served. The **IRQSTATUS[2] TCAR_IT_FLAG** bit is cleared by writing 1 to it or when the edge detection mode bits (the **TCLR[9:8] TCM** bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (**EVENT_CAPTURE**). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the **IRQSTATUS_SET[2] TCAR_EN_FLAG** bit (for **TIMER1**) or in the **IRQENABLE_SET[2] TCAR_EN_FLAG** bit (for other timers). See the examples in [Figure 18-11](#) and [Figure 18-12](#).

In [Figure 18-11](#), the value of the **TCLR[9:8] TCM** bit field is 0b01, and the **TCLR[13] CAPT_MODE** bit is 0. Only the rising edge of **EVENT_CAPTURE** triggers a capture in the **TCAR1** and **TCAR2** registers, and only the **TCAR1** register updates.

Figure 18-11. Capture Wave Example for **TCLR[13] CAPT_MODE = 0**

In [Figure 18-12](#), the value of the **TCLR[9:8] TCM** bit field is 0b01, and the **TCLR[13] CAPT_MODE** bit is 1. Only the rising edge of **EVENT_CAPTURE** triggers a capture in the **TCAR1** register on the first enabled event, and the **TCAR2** register updates on the second enabled event.

Figure 18-12. Capture Wave Example for TCLR[13] CAPT_MODE = 1

18.2.4.8 Compare Mode Functionality

When the **TCLR[6]** CE bit of the compare-enable register is set to 1, the timer value (the **TCRR[31:0]** TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register (**TMAR**). The value of the **TMAR[31:0]** COMPARE_VALUE bit field can be loaded at any time (timer counting or stopped). When the values of the **TCRR** and the **TMAR** registers match, an interrupt is issued, if the **IRQSTATUS_SET[0]** MAT_EN_FLAG bit (for TIMER1), or the **IRQENABLE_SET[0]** MAT_EN_FLAG bit (for other timers) is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the **TMAR** before setting the **TCLR[6]** CE bit.

The dedicated output pin (timer PWM) can be programmed in the **TCLR[12]** PT bit through the **TCLR[11:10]** TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

18.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the **TCLR[5]** PRE bit is set. The **TCLR[4:2]** PTV bit field sets the 2ⁿ division ratio (the prescaler value is 2^(PTV + 1)). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 18-8 lists the prescaler/timer reload values versus contexts.

Table 18-8. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	TLDR[31:0]
TCRR write	Reset	TCRR[31:0]
TTGR write	Reset	TLDR[31:0]
Stop	Reset	Frozen

18.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The **TCLR[11:10]** TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

NOTE: In toggle mode, when **TCLR[11:10]** TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first, it does not toggle the PWM line (see [Figure 18-14](#)).

The **TCLR[7]** SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the **TCLR[11:10]** TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In [Figure 18-13](#), the internal overflow pulse is set each time the (0xFFFF FFFF – **TLDR**[31:0] **LOAD_VALUE** + 1) value is reached, and the internal match pulse is set when the counter reaches the value of **TMAR**. Depending on the value of the **TCLR[12]** PT bit and **TCLR[11:10]** TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The **TLDR** and **TMAR** must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the **TMAR** and the value in the **TLDR** must be at least two units. When match event is used, the compare mode **TCLR[6]** CE bit must be set.

In [Figure 18-13](#), the **TCLR[7]** SCPWM bit is set to 0. In [Figure 18-14](#), the **TCLR[7]** SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (**TCLR[7]** SCPWM bit).

Figure 18-13. Timing Diagram of PWM With **TCLR[7] SCPWM Bit = 0**

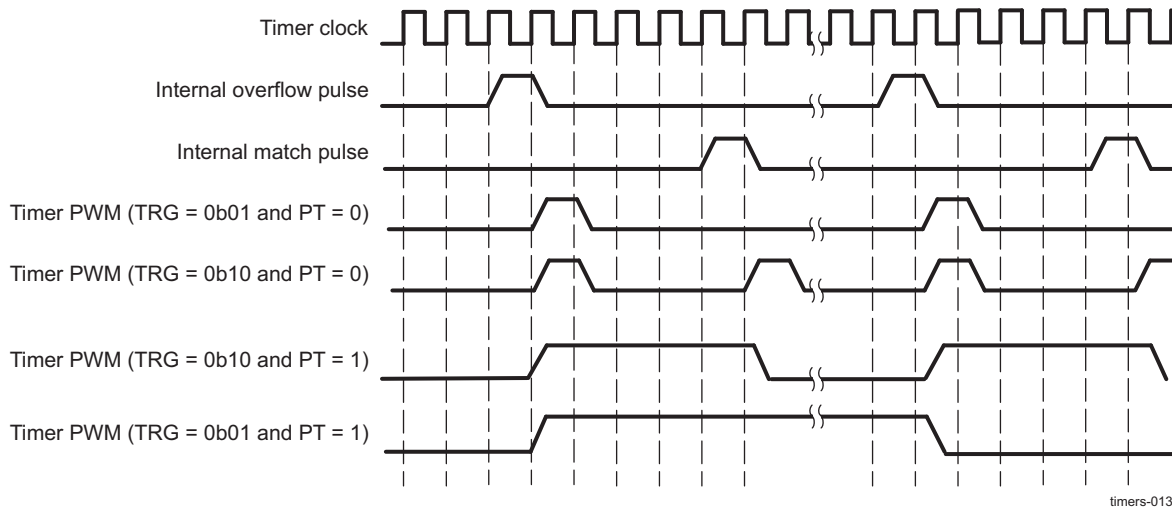

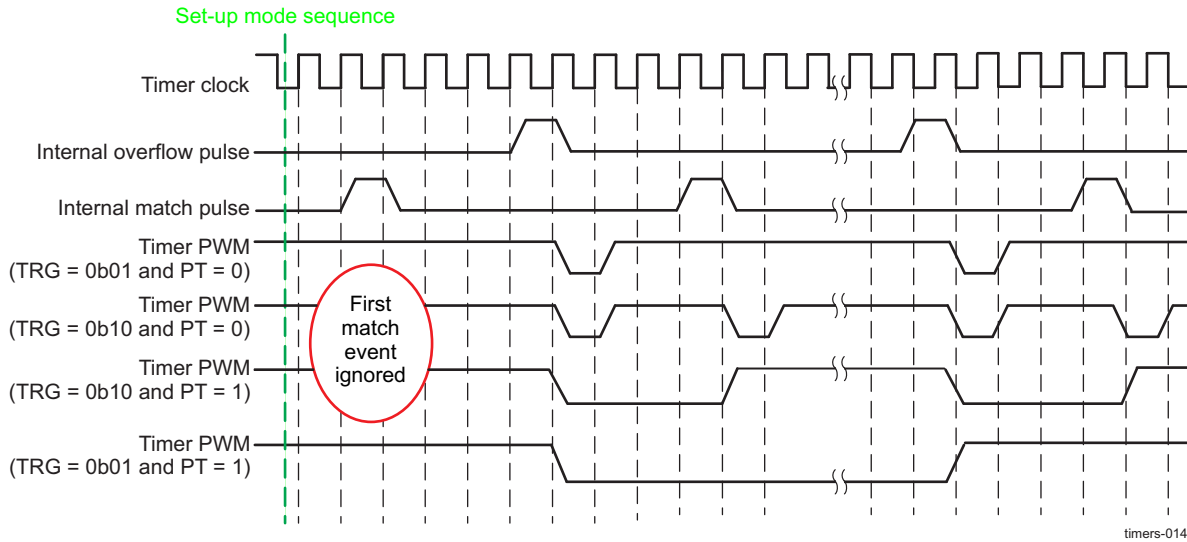

Figure 18-14. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 1

18.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the [TCLR\[5\]](#) PRE bit and the [TCLR\[4:2\]](#) PTV bit field)
- Value loaded into the [TLDR](#)

[Table 18-9](#) lists the prescaler clock ratio values.

Table 18-9. Prescaler Clock Ratio Values

TCLR[5] PRE	TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$OVF_Rate = (0xFFFF\ FFFF - TLDR + 1) \times (\text{timer-functional clock period}) \times PS$$

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = 2^(PTV + 1) if prescaler is enabled, or PS = 1 if prescaler is disabled.

NOTE: Internal resynchronization causes any write to the [TCLR\[1\]](#) ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write_TIMER_TCLR_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the [TCLR\[1\]](#) ST bit.

NOTE:

- In non-PWM mode, **TLDR** must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, **TLDR** must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the **TCLR**[5] PRE bit set to 0, the timer output period is as listed in [Table 18-10](#).

Table 18-10. Value and Corresponding Interrupt Period

TLDR [31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 μ s
0xFFFF FFFE	62.5 μ s

18.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the **TIOCP_CFG**[1] **EMUFREE** bit.

If the **TIOCP_CFG**[1] **EMUFREE** bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the **TIOCP_CFG**[1] **EMUFREE** bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (timerx_pwm_evt, where x = [8:11]) is internally synchronized on two timer-clock rising edges.

18.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the OCP interface with 16- or 32-bit access (read/write).

Any 16-bit write access must be least significant bit (LSB) first, and the second write access must be most significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- **TIDR** (all GP timers)
- **TIOCP_CFG** (all GP timers)
- **IRQSTATUS_SET** (GP timer 1)
- **IRQSTATUS_RAW** (all GP timers)
- **IRQSTATUS** (all GP timers)
- **IRQENABLE_SET** (all GP timers except 1)
- **IRQENABLE_CLR** (all GP timers except 1)
- **IRQSTATUS_SET** (GP timer 1)
- **IRQSTATUS_CLR** (GP timer 1)
- **IRQWAKEEN** (all GP timers)
- **TSICR** (all GP timers)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- **TCLR** (all GP timers)
- **TCRR** (all GP timers)
- **TLDR** (all GP timers)
- **TTGR** (all GP timers)
- **TMAR** (all GP timers)

- [TPIR](#) (GP timer 1)
- [TNIR](#) (GP timer 1)
- [TCVR](#) (GP timer 1)
- [TOCR](#) (GP timer 1)
- [TOWR](#) (GP timer 1)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- [TIDR](#)
- [TIOCP_CFG](#)
- [IRQSTATUS](#)
- [IRQSTATUS_RAW](#)
- [IRQENABLE_SET](#)
- [IRQENABLE_CLR](#)
- [IRQSTATUS_SET](#)
- [IRQSTATUS_CLR](#)
- [IRQWAKEEN](#)
- [TWPS](#)
- [TSICR](#)

18.2.4.13.1 Writing to Timer Registers

The host uses the OCP interface to write to the following registers synchronously with the timer interface clock:

- [TLDR](#)
- [TCRR](#)
- [TCLR](#)
- [TIOCP_CFG](#)
- [IRQSTATUS](#)
- [IRQENABLE_SET](#)
- [IRQENABLE_CLR](#)
- [IRQWAKEEN](#)
- [TTGR](#)
- [TSICR](#)
- [TMAR](#)

TIMER1 also has the following registers:

- [IRQSTATUS_SET](#)
- [IRQSTATUS_CLR](#)
- [TPIR](#)
- [TNIR](#)
- [TCVR](#)
- [TOCR](#)
- [TOWR](#)

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

18.2.4.13.1.1 Write Posting Synchronization Mode

This mode is used if the [TSICR\[2\]](#) POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (**TCLR**, **TCRR**, **TLDR**, **TTGR**, **TMAR**, and **TPIR**, **TNIR**, **TCVR**, **TOCR**, and **TOWR** for TIMER1). Therefore, the write transaction is immediately acknowledged on the open-core protocol (OCP) interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, the timer write-posted status (**TWPS**) register provides a status bit. In this mode, software must check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the OCP clock. Consequently, any read access to **TCRR** does not add any resynchronization latency; the current value is always available.

NOTE: Because the overflow IRQ is generated when the value of **TCRR** reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of $(1 \times PS \times \text{timer-functional clock period})$ before any read access to **TCRR** to ensure a correct reading of its content.

NOTE: If the **TTGR** register is written during posted write to **TCRR**, the value written to **TCRR** will be discarded.

If a posted write to **TCVR** is started, the user must not write to **TPIR** or **TNIR** before the **TCVR** write is finished, because the value of **TCVR** is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range: $\text{freq}(\text{timer clock}) < \text{freq}(\text{OCP interface clock}) / 4$.

18.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the **TSICR**[2] POSTED bit is set to 0 (default value). It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the OCP interface frequency and the timer clock frequency.

18.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (**TCRR**, **TCAR1**, and **TCAR2**) captures the current timer counter value. This must be followed by reading the 16 MSBs. The synchronization schemes for read posted and read non-posted transactions are the same as the corresponded write transactions described before.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The **TCRR** is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the **TCAR1** and **TCAR2** registers as they can be changed due to internal processes too. DSP 16 bit accesses can be interleaved with MCU 32 bit accesses.

NOTE: The counter value of GPTimer5/6/7/8 should be read with a delay of 10 L4_PER clock cycles when the functional clock source is 32kHz and the IPU CD is in the hardware Auto state.

NOTE: The counter value of GPTimer5/6/7/8 can be read without any delay when the functional clock source is 32kHz and the IPU CD is in software Wakeup mode.

18.2.4.13.2.1 Read Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency are. The recommended functional frequency range is $\text{freq}(\text{timer}) < \text{freq}(\text{OCP}) / 4$.

Read posted mode is used if **TSICR**[2] POSTED = 0x1 or **TSICR**[3] READ_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

18.2.4.13.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is $\text{freq}(\text{timer}) \geq \text{freq}(\text{OCP}) / 4$.

Read non-posted mode is used if **TSICR**[2] POSTED = 0x0 and **TSICR**[3] READ_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the OCP interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

18.2.4.14 Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are TCLR, TLDR, TCRR, TTGR, TMAR, TPIR, TNIR, TCVR, TOCR, and TOWR. For read operation, the registers affected by this selection are: TCRR, TCAR1, TCAR2, TCVR, and TOWR.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, IRQSTATUS, IRQSTATUS_SET, IRQWAKEEN, TWPS, and TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one OCP clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in **TSICR**[2] POSTED bit. The **TSICR**[3] READ_MODE defines how the read operation is performed when the module is configured in non-posted mode (see **TSICR**). The following cases are possible:

- **TSICR**[2] POSTED = 0x1 and **TSICR**[3] READ_MODE = x (don't care): read and write operations are expected in posted mode.
- **TSICR**[2] POSTED = 0x0 and **TSICR**[3] READ_MODE = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- **TSICR**[2] POSTED = 0x0 and **TSICR**[3] READ_MODE = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

18.2.5 GP Timer Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

18.2.5.1 Global Initialization

18.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see [Section 18.2.3, GP Timers Integration](#), and [Section 18.2.2, GP Timers Environment](#). [Table 18-11](#) summarizes the surrounding modules.

Table 18-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, Module-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management .
Control module	The module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 14.4.6.1 Pad Configuration Registers , in Chapter 14, Control Module .
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be done to enable the interrupts from the GP timer module. See Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description .

18.2.5.1.2 GP Timer Module Global Initialization

18.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

[Table 18-12](#) identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

Table 18-12. GP Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIOCP_CFG[3:2] IDLEMODE	0x-
Enable wake-up interrupt events.	IRQWAKEEN[2:0]	0x-
Select posted mode.	TSICR[2] POSTED	0x-

18.2.5.2 Operational Mode Configuration

18.2.5.2.1 GP Timer Mode

18.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

[Table 18-13](#) lists the steps in the GP timer mode configuration.

Table 18-13. GP Timer Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1

Table 18-13. GP Timer Mode Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Enable overflow interrupt.	IRQSTATUS_SET[1] OVF_EN_FLAG ⁽¹⁾ or IRQENABLE_SET[1] OVF_EN_FLAG ⁽²⁾	0x1
Load timer counter value.	TCRR	0x-
Load timer load value.	TLDR	0x-
Start the timer.	TCLR[0] ST	0x1

⁽¹⁾ Applies only to TIMER1

⁽²⁾ Applies to TIMER3 through TIMER8

18.2.5.2.2 GP Timer Compare Mode

18.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

Table 18-14 lists the steps in the GP timer compare mode configuration.

Table 18-14. GP Timer Compare Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Enable match interrupt.	IRQSTATUS_SET[0] MAT_EN_FLAG ⁽¹⁾ or IRQENABLE_SET[0] MAT_EN_FLAG ⁽²⁾	0x1
Load timer counter value.	TCRR	0x-
Load timer compare value.	TMAR	0x-
Enable compare mode.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

⁽¹⁾ Applies only to TIMER1

⁽²⁾ Applies to TIMER3 through TIMER8

18.2.5.2.3 GP Timer Capture Mode

18.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

Table 18-15 lists the steps in the GP timer capture mode configuration.

Table 18-15. GP Timer Capture Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 18.2.5.2.3.2.	
Enable capture interrupt.	IRQENABLE_SET[2] TCAR_EN_FLAG ⁽¹⁾ or IRQSTATUS_SET[2] TCAR_EN_FLAG ⁽²⁾	0x1
Start the timer.	TCLR[0] ST	0x1
Detect event.	See Section 18.2.5.2.3.3.	

⁽¹⁾ Applies only to TIMER3 through TIMER8

⁽²⁾ Applies only to TIMER1

18.2.5.2.3.2 Subsequence – Initialize Capture Mode

Table 18-16 lists the steps to initialize capture mode.

Table 18-16. Initialize Capture Mode

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select TIMER _i (where i = 2 to 8). Capture input at device pin timer _i .	TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TCLR[9:8] TCM	0x-

18.2.5.2.3.3 Subsequence – Detect Event

Table 18-17 lists the steps in detecting an event.

Table 18-17. Detect Event

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TCAR1 and/or TCAR2	
Clear capture interrupt request.	IRQSTATUS[2] TCAR_IT_FLAG	0x1

18.2.5.2.4 GP Timer PWM Mode

18.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 18-18 lists the steps in the GP timer PWM mode configuration.

Table 18-18. GP Timer PWM Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select trigger output mode.	TCLR[11:10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TCLR[12] PT	0x-
Select TIMER _i (where i = 2 to 11 and 13 to 16) PWM output at device pin timer _i .	TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TCLR[7] SCPWM	0x-
Load timer load value.	TLDR	0x-
Load timer compare value.	TMAR	0x-
Enable compare.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

18.2.6 GP Timer Register Manual

18.2.6.1 GP Timer Instance Summary

[Table 18-19](#) lists the base address and block size for the GP timer module instances.

Table 18-19. GP Timer Instance Summary

Module Name	Base Address L4_PER1 Interconnect	Base Address L4_PER3 Interconnect	Base Address L4_WKUP Interconnect	Size
TIMER2	0x4803 2000	–	–	92 Bytes
TIMER3	0x4803 4000	–	–	92 Bytes
TIMER4	0x4803 6000	–	–	92 Bytes

TIMER1	--	–	0x4AE1 8000	112 Bytes

18.2.6.2 GP Timer Registers

18.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

[Table 18-20](#) through [Table 18-22](#) provide the register summary and associated offset addresses for the 8 GP timer internal registers.

Table 18-20. TIMER1 Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	TIMER1 Physical Address L4_WKUP Interconnect
TIDR	RO	32	0x0000 0000	0x4AE1 8000

18.2.6.2.2 GP Timer Register Description

Table 18-23 through Table 18-69 describe the individual GP timer registers.

Table 18-23. TIDR

Address Offset	0x0000 0000		
Physical Address	See Table 18-20 Table 18-21 Table 18-22	Instance	See Table 18-19
Description	This read-only register contains the revision number of the module. A write to this register has no effect. This register is used by software to track features, bugs, and compatibility.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31: 0	REVISION	IP Revision	R	0x- ⁽¹⁾

Table 18-25. TIOCP_CFG

Address Offset	0x0000 0010		
Physical Address	See Table 18-20 Table 18-21 Table 18-22	Instance	See Table 18-19
Description	This register controls the various parameters of the L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IDLEMODE		EMUFREE		SOFTRESET											

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x00000000
3:2	IDLEMODE	Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module <i>swake-up</i> output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset 0x0: Read 0: reset done, no pending action Write 0: No action 0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

Table 18-27. IRQ_EOI

Address Offset	0x0000 0020
Physical Address	See Table 18-20 Table 18-21 Table 18-22 Instance See Table 18-19
Description	Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if a new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																	LINE_NUMBER														

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	LINE_NUMBER	Write the number of the interrupt line to apply a SW EOI to it. Note that there is only a single line (i.e. number 0). Read : Read always returns 0 Write 0 : SW EOI on interrupt line Write 1 : No action	RW	0x0

Table 18-39. TCLR

Address Offset	0x0000 0038		
Physical Address	See Table 18-20 Table 18-21 Table 18-22	Instance	See Table 18-19
Description	This register controls optional features specific to the timer functionality.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GPO_CFG	CAPT_MODE	PT	TRG	TCM	SCPWM	CE	PRE	PTV	AR	ST					

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the PO_GPOCFG output. For specific use of the GPO_CFG bit, see Section 18.2.2.1 , <i>GP Timer External System Interface</i> . 0x0: PO_GPOCFG drives 0. 0x1: PO_GPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1 . 0x1: Capture on second event: Capture the second enabled capture event in TCAR1 and the second enabled capture event in TCAR2 .	RW	0
12	PT	Pulse or toggle mode on TIMERi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on TIMERi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode on TIMERi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of TIMERi_EVENT_CAPTURE pin 0x2: Capture on falling edges of TIMERi_EVENT_CAPTURE pin 0x3: Capture on both edges of TIMERi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the TIMERi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the TIMERi_PWM_out output pin and select negative pulse for pulse mode.	RW	0

Bits	Field Name	Description	Type	Reset
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

18.3 32-kHz Synchronized Timer (COUNTER_32K)

18.3.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer (COUNTER_32K) is a 32-bit counter clocked by the falling edge of the 32-kHz system clock.

Figure 18-15 is the block diagram of the 32-kHz synchronized timer.

Figure 18-15. 32-kHz Synchronized Timer Block Diagram

18.3.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface (OCP) support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 16-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

18.3.2 32-kHz Synchronized Timer Integration

The synchronized timer is accessible only through the L4_WKUP interface.

Table 18-71 through Table 18-73 summarize the integration of the module in the device.

Table 18-71. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
COUNTER_32K	PD_WKUPAON	No	L4_WKUP

Table 18-72. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

COUNTER_32K	COUNTER_32K_ICLK	WKUPAON_GICLK	PRCM	COUNTER_32K interface clock
Resets				
COUNTER_32K	COUNTER_32K_NRESPWRON	WKUPAON_SYS_PWRON_RST	PRM	Reset to COUNTER_32K. Reset all internal logic, running on COUNTER_32K_FCLK
COUNTER_32K	COUNTER_32K_OCPRESETN	WKUPAON_RST	PRM	Reset to COUNTER_32K. Reset all L4 interface logic, running on COUNTER_32K_ICLK.

Table 18-73. Hardware Requests

No Interrupt Requests
No DMA Requests

18.3.3 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (COUNTER_32K_NRESPWRON). When COUNTER_32K_NRESPWRON is released (on the rising edge of COUNTER_32K_FCLK), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz COUNTER_32K_FCLK clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay.

Figure 18-16 shows the reset synchronization timing diagram.

Figure 18-16. Reset Resynchronization Timing Diagram

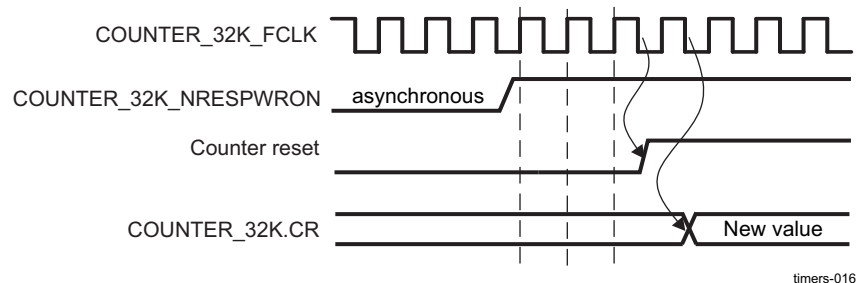

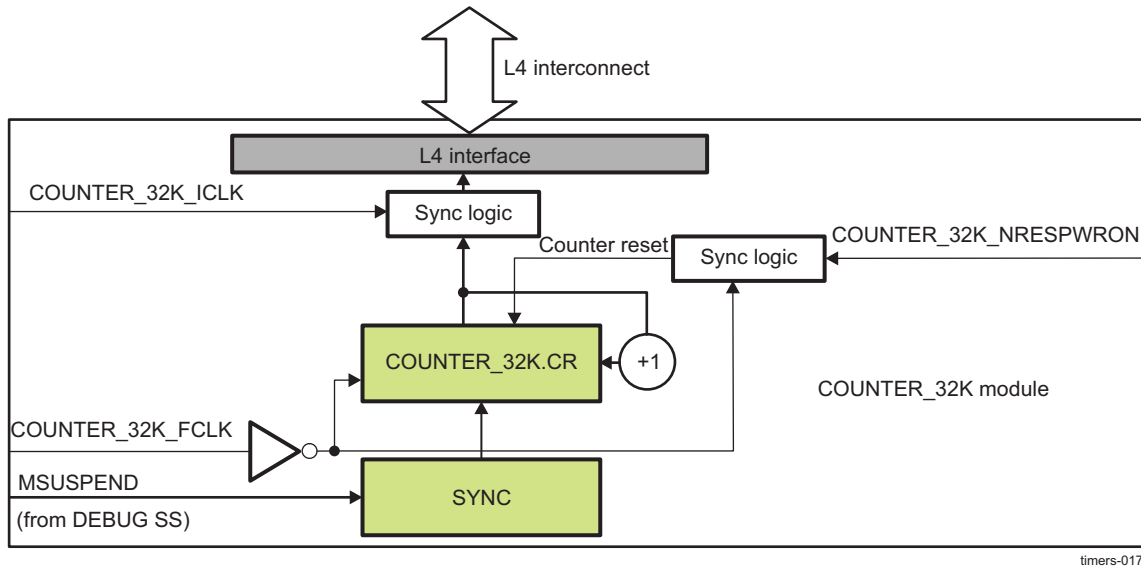

Figure 18-17 is the block diagram of the synchronized timer.

Figure 18-17. COUNTER_32K Block Diagram

The sync logic ensures the correctness of the read transaction by synchronizing the counter register read access on COUNTER_32K_ICLK, because the COUNTER_32K_ICLK clock signal is completely asynchronous with COUNTER_32K_FCLK. The COUNTER_32K_NRESPWRON input resets the counter register (CR). The inverted COUNTER_32K_FCLK clocks the counter register CR.

The counting is temporally stopped when MSUSPEND control signal (coming from DEBUG SS) is asserted.

18.3.3.1 Reading the 32-kHz Synchronized Timer

The counter register (CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. The value of the counter is read through the L4 interconnect slave interface. Internal synchronization logic allows the reading of the counter value with COUNTER_32K_ICLK while the counter is running. The time latency to read the synchronized counter register is one COUNTER_32K_ICLK clock period.

The user can select between two synchronization schemes by setting SYSCONFIG[0]SYNCSMODE bit.

- SYSCONFIG[0]SYNCSMODE = 0x0 - default. In this mode COUNTER_32K timer uses Gray encode/decode scheme. When the L4 interface sends a LSB16 read request command, the 32 bit coded value is registered directly to the interface domain. Due to the characteristics of this encoding if a read command arrives during a count up event either the old or the new value of CR is captured, not a transient value. The captured value will be decoded and send on the SDATA bus. The MSB16 read command reads upper 16 bits of the 32 bit value of counter register captured during the last LSB16 read access.
- SYSCONFIG[0]SYNCSMODE = 0x1 - legacy synchronization scheme. In this mode the value of the CR is synchronized to the OCP domain at every count up event. This synchronization is possible because the COUNTER_32K_ICLK is much faster that the 32KHz clock (COUNTER_32K_FCLK). The drawback of this method is that if the interface clock is switched back after wake up from idle mode, the synchronized value will be updated only at the next count up event , until then it will be incorrect.

18.3.4 COUNTER_32K Timer Register Manual

Table 18-74 lists the base address and block size for the 32-kHz synchronized timer. It is memory-mapped to the L4 peripheral bus memory space.

Table 18-74. COUNTER_32KTimer Instance Summary

Module Name	Module Base Address	Size

18.3.4.1 COUNTER_32K Timer Register Mapping Summary

CAUTION

The 32-kHz synchronized timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 18-75 lists the 32-kHz synchronized timer registers. Table 18-76 through Table 18-80 describe the register bits.

19.8 Gigabit Ethernet Switch (GMAC_SW)	5905

19.1 Multimaster I²C Controller

This section describes the two inter-integrated circuit (I²C) controller modules in the device.

NOTE: The device I²C controllers do not support high-speed (HS) mode. See the Device Data Manual for details.

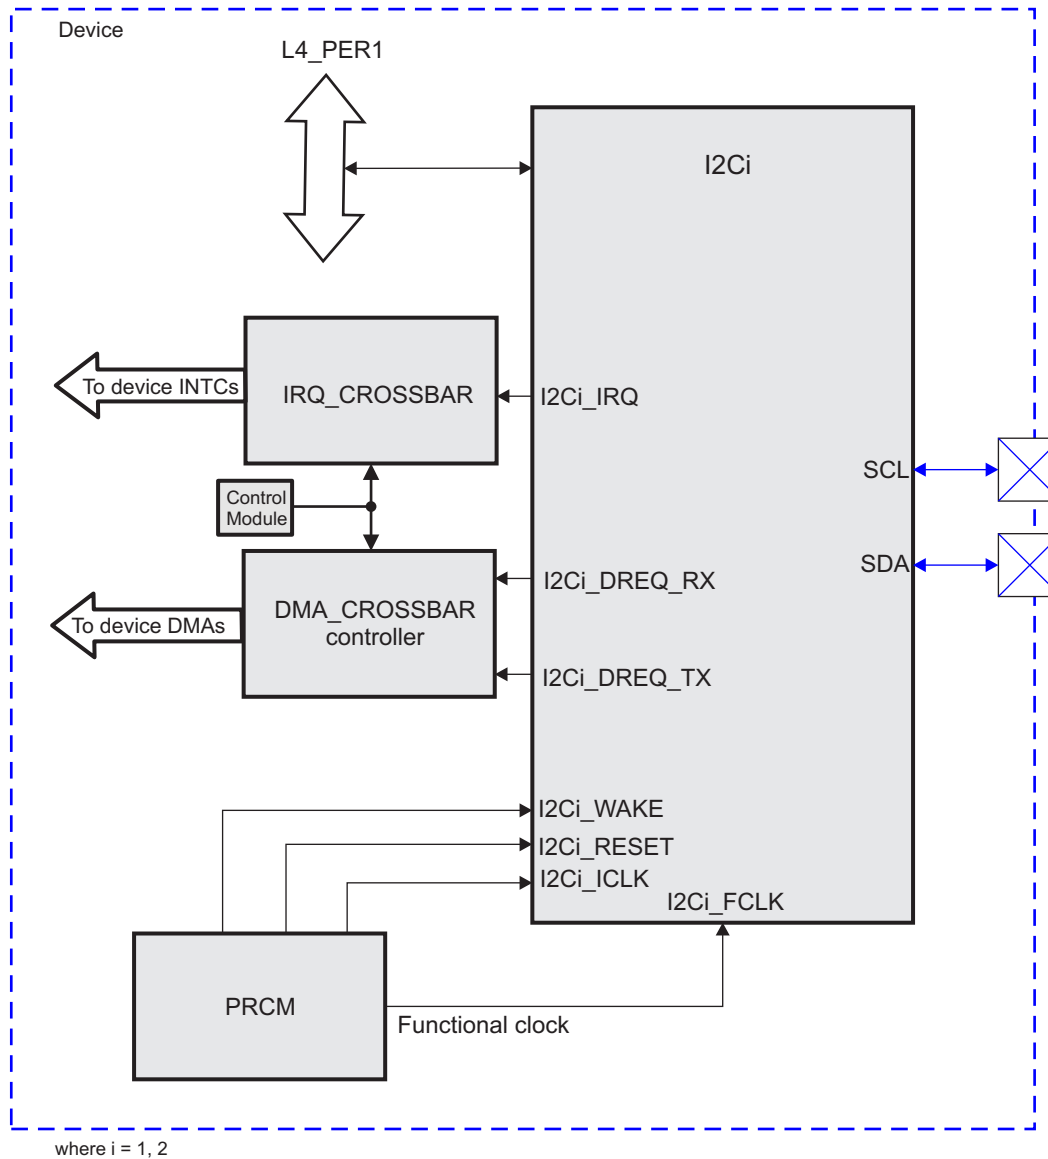

19.1.1 I²C Overview

The device contains two multimaster inter-integrated circuit (I²C) controllers (I²C_{*i*} modules, where $i = 1, 2$) each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

Each multimaster I²C controller can be configured to act like a slave or master I²C-compatible device.

[Figure 19-1](#) shows the I²C.

Figure 19-1. I²C Controllers

I2C-001

The multimaster I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports a standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFOs (16 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation

- 8-bit-wide data access
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability

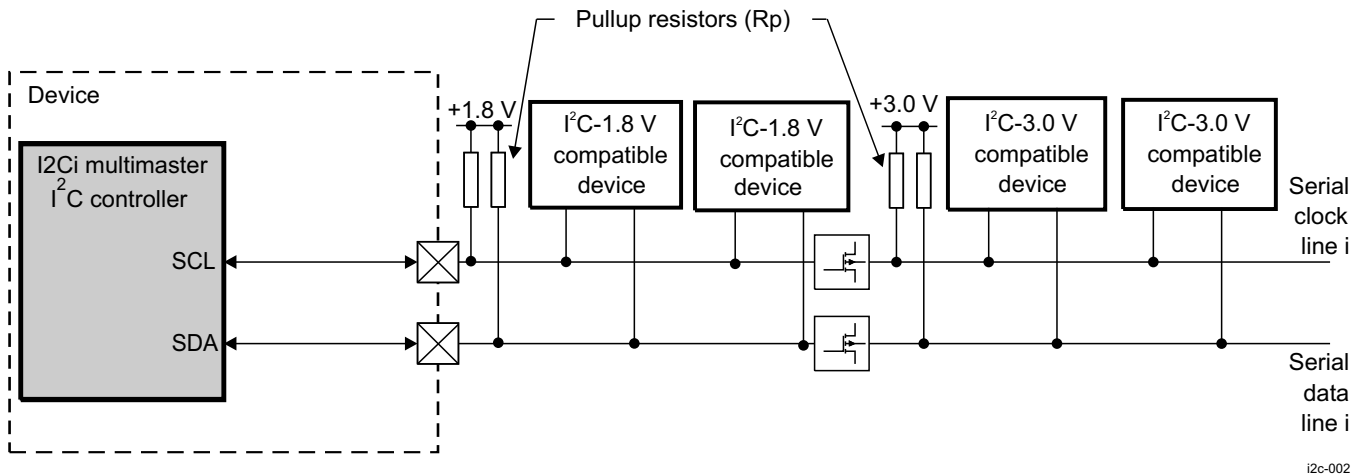

19.1.2 I²C Environment

This section describes the I²C application fields from an environment point of view (external connections). It describes I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

19.1.2.1 I²C Typical Application

Figure 19-2 shows the multimaster I²C controllers and their related connections with I²C-compliant devices.

Figure 19-2. I²C and Typical Connections to I²C Devices

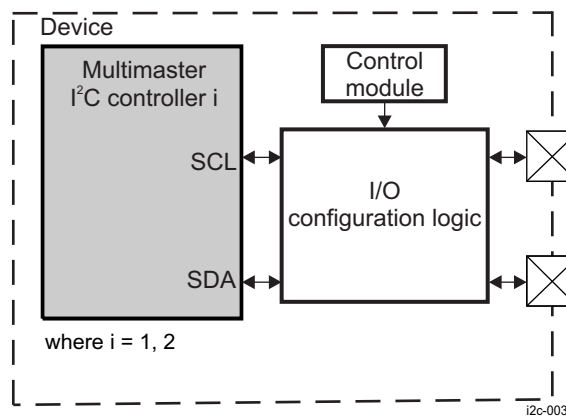

i2c-002

19.1.2.1.1 I²C Pins for Typical Connections in I²C Mode

Figure 19-3 shows the multimaster I²C controller pins used for typical connections with I²C devices.

Figure 19-3. I²C Interface Signals

i2c-003

19.1.2.1.2 I²C Interface Typical Connections

Table 19-1 lists the pins associated with the I²C interface.

Table 19-1. I²C Input/Output

Signal	Device Level Signal	I/O ⁽¹⁾	Description	Reset Value
SCL	i2cj_scl ⁽²⁾	I/O	I ² C serial clock line.	1

⁽¹⁾ I = Input; O = Output

⁽²⁾ j = 1 and 2

Table 19-1. I²C Input/Output (continued)

Signal	Device Level Signal	I/O ⁽¹⁾	Description	Reset Value
SDA	i2cj_sda ⁽²⁾	I/O	I ² C serial data line.	1

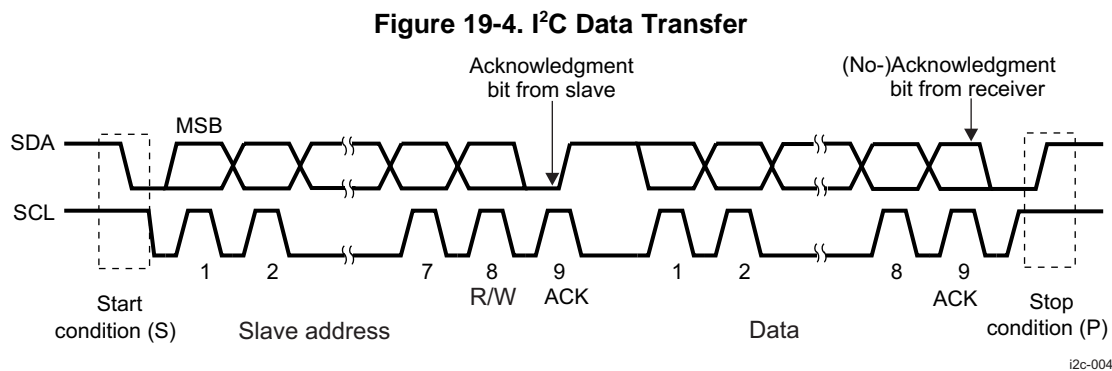

NOTE: For the i2cj_scl and i2ci_scl signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. Refer to the sections [Section 14.4.6.1 Pad Functional Multiplexing](#) of the chapter *Control Module*, for more information.

19.1.2.2 I²C Typical Connection Protocol and Data Format

19.1.2.2.1 I²C Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. [Figure 19-4](#) shows a typical I²C communication format.

19.1.2.2.2 I²C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

[Figure 19-5](#) is an example of data validity requirements.

Figure 19-5. I²C Bit Transfer on the I²C Bus

i2c-005

19.1.2.2.3 I²C Start and Stop Conditions

The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2Ci. [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C_IRQSTATUS_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 19-6 shows the waveforms that occur during an S and a P condition.

Figure 19-6. I²C S and P Condition Events

i2c-006

NOTE: I²C controller does not support messages non-compliant with I2C standard. Void messages are non-standard I²C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next master transfer which would never complete. A soft reset of the controller is recommended for recovery.

19.1.2.2.4 I²C Addressing

The I²C module supports two data formats in fast/standard (F/S) modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

19.1.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 19-7 shows the I²C data transfer formats in F/S mode.

Figure 19-7. I²C Data Transfer Formats in F/S Mode

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

19.1.2.2.5 I²C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

19.1.2.2.6 I²C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 19-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDAI are shifted in synchronization with the self-generated clock pulses on SCLI.

19.1.2.2.7 I²C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 19-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

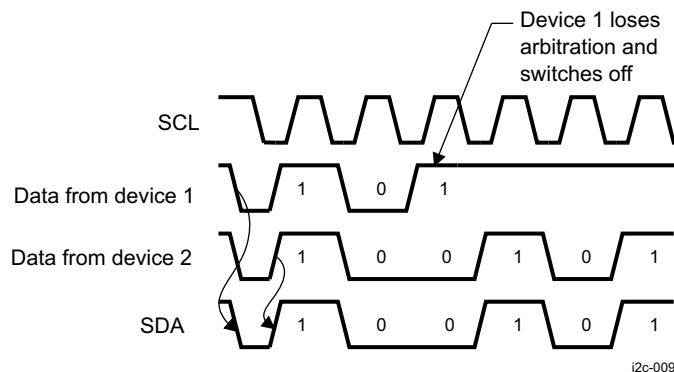

19.1.2.2.8 I²C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

19.1.2.2.9 I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 19-8 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 19-8. I²C Arbitration Between Master Transmitters

19.1.2.2.10 I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. However, there are two or more master devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

NOTE: In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 19-9 shows clock synchronization.

Figure 19-9. I²C Clock Generators Synchronization

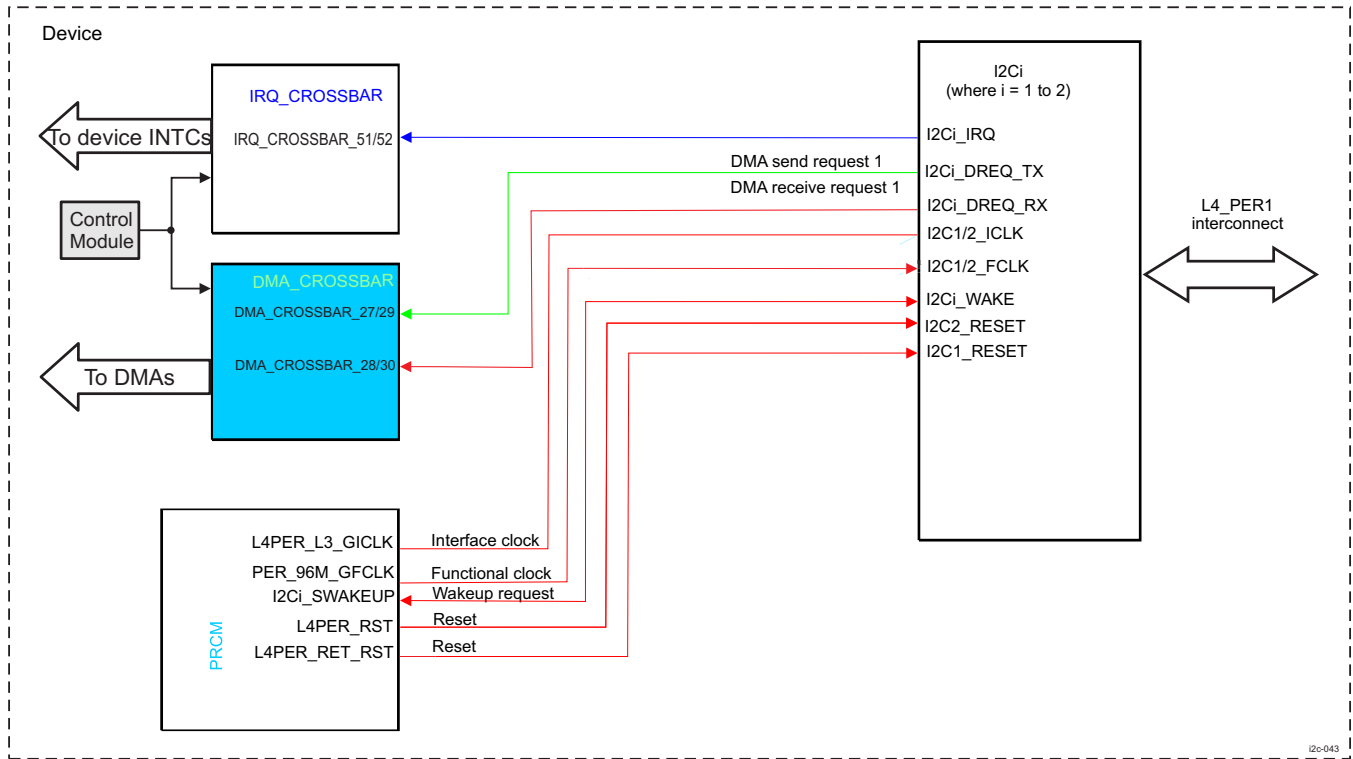

19.1.3 I²C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 19-10 shows the integration of the two I²C controllers in the device.

Figure 19-10. I²C Integration

NOTE: For more information about the slave idle protocol and the wake-up request, see [Section 3.7, Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 19-2 through Table 19-4 summarize the integration of the module in the device.

Table 19-2. I²C Integration Attributes

	I2C2_DREQ_RX	DMA_CROSSBAR_30	DMA_EDMA_DREQ_29	I2C2 DMA receive request

NOTE: The “Default Mapping” column in [Table 19-4 I²C Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Section 14.4.6.5 Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

NOTE:

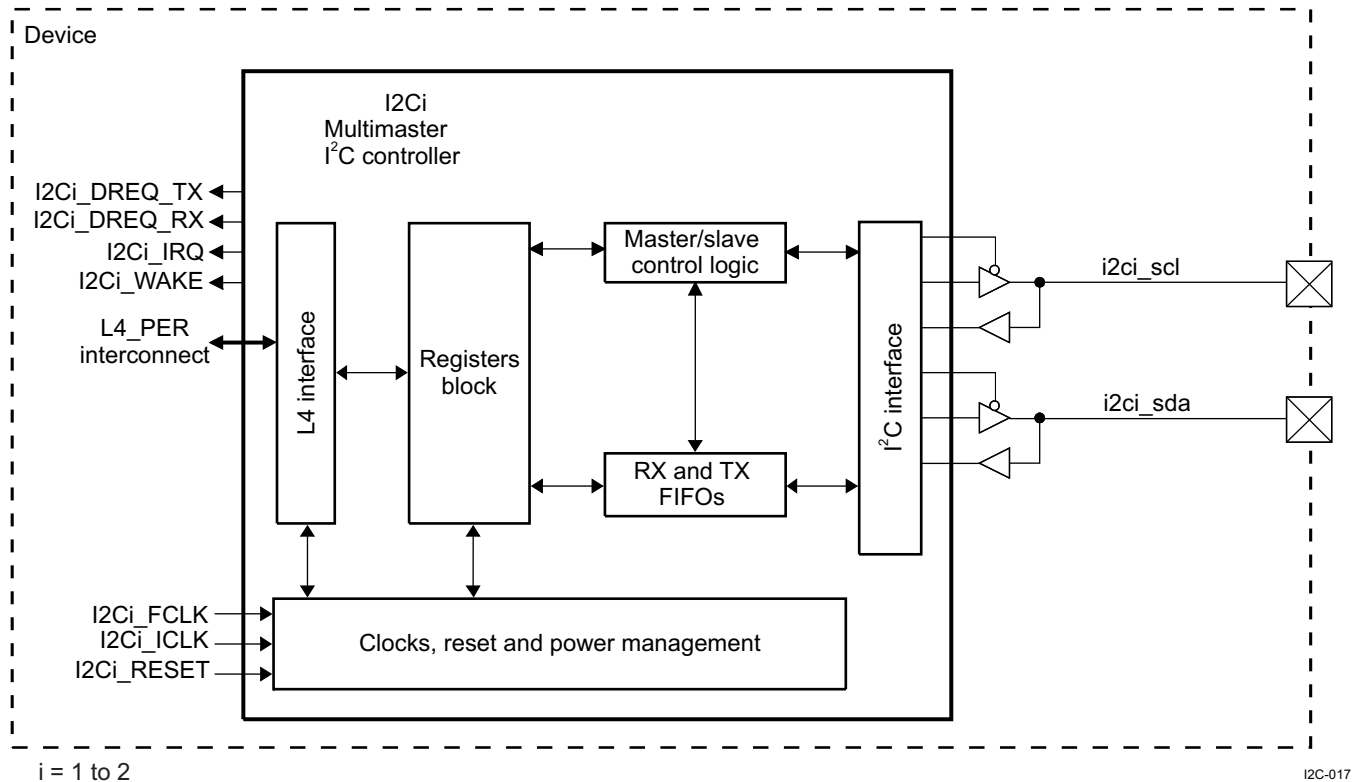

- For a description of interrupt source, see [Table 19-10](#).
- For a description of DMA source, see [Table 19-11](#).

19.1.4 I²C Functional Description

19.1.4.1 I²C Block Diagram

Figure 19-11 is the multimaster I²C controller block diagram.

Figure 19-11. I²C Block Diagram

The two multimaster I²C controllers can be configured in F/S I²C mode . The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE bit field. Table 19-5 lists the available operation modes.

Table 19-5. I²C Operation Mode Selection

Operation Mode	Value of I2Ci.I2C_CON[13:12] OPMODE Bit Field
F/S I ² C	0x0
Reserved	0x1
Reserved	0x2
Reserved (not used)	0x3

19.1.4.2 I²C Clocks

19.1.4.2.1 I²C Clocking

Each multimaster I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by the I2Ci.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode.

The low time of the I2Ci_SCLL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL bit field in F/S mode.

The high time of the I2Ci_SCLL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH bit field in F/S mode.

Table 19-6 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 19-6. I²C t_{LOW} and t_{high} Values of the I²C Clock

Mode	I2C/ Clock	t _{LOW}	t _{high}
F/S first phase	$I2Ci_INTERNAL_CLK = \frac{I2Ci_FCLK}{(I2Ci.I2C_PSC[7:0] \text{ PSC bit field} + 1)}$	$(I2Ci.I2C_SCLL[7:0] \text{ SCLL bit field value} + 7) \times I2Ci_INTERNAL_CLK \text{ period}$	$(I2Ci.I2C_SCLH[7:0] \text{ SCLH bit field value} + 5) \times I2Ci_INTERNAL_CLK \text{ period}$

NOTE: The equations in Table 19-6 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I²C controller outputs. Actual t_{low} and t_{high} periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 19-7 lists the register values for obtaining the maximum I²C bit rates and the maximum period of the filtered spikes in F/S modes.

Table 19-7. I²C Register Values for Maximum I²C Bit Rates in I²C F/S Modes⁽¹⁾

	I ² C Mode for I2C _i		Description
	Standard Mode	Fast Mode	
I2C _i _FCLK frequency (MHz)	96		
I2C i .I2C_PSC[7:0] PSC bit field value	23	9	Prescaler value for F/S modes
I2C _i _INTERNAL_CLK frequency (MHz)	4	9.6	
I2C i .I2C_SCLL[7:0] SCLL bit field value	13	5	Value for F/S mode
I2C i .I2C_SCLH[7:0] SCLH bit field value	15	7	Value for F/S mode
Maximum bit rate (Mbps)	0.1	0.4	F/S mode maximum bit rate
Maximum filter period (ns)	250	104.2	
Maximum filter period (ns)			

⁽¹⁾ Programmable fields are in bold.

NOTE: This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

NOTE: For I2C_i (where i=1, 2)

$$I2C_i_INTERNAL_CLK \text{ freq} = I2C_i_FCLK / (PSC + 1)$$

$$F/S \text{ filter period} = 1 / I2C_i_INTERNAL_CLK$$

$$FS \text{ bit rate} = I2C_i_INTERNAL_CLK / (SCLL + 7 + SCLH + 5)$$

19.1.4.2 I²C Automatic Blocking of the I²C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2Ci.I2C_OA, and I2Ci.I2C_OAx registers, where $i = 1$ to 2, $x = 1, 2, 3$) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

19.1.4.3 I²C Software Reset

Each multimaster I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

19.1.4.4 I²C Power Management

Table 19-8 describes power-management features available for the multimaster I²C controllers.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
 - For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
-

Table 19-8. I²C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2Ci.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2Ci.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 19-9.
Global wake-up enable	I2Ci.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

NOTE: The voltage controllers, in which the I²C controller is implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 19-9. I²C Clock Activity Settings

I2C <i>i</i> .I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2C <i>i</i> _ICLK	I2C <i>i</i> _FCLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled.

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I²C CLOCKACTIVITY and I²C clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

19.1.4.5 I²C Interrupt Requests

[Table 19-10](#) lists the event flags, and their mask, that can cause module interrupts.

Table 19-10. I²C Events

Event Flag	Event Unmask	Event Mask	Map to	Description
I2C <i>i</i> .I2C_IRQSTATUS[0] AL	I2C <i>i</i> .I2C_IRQENABLE_SET[0] AL_IE	I2C <i>i</i> .I2C_IRQENABLE_C LR[0] AL_IE	I2C <i>i</i> _IRQ	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the IRQ_Crossbar. During reads, it always returns 0.
I2C <i>i</i> .I2C_IRQSTATUS[1] NACK	I2C <i>i</i> .I2C_IRQENABLE_SET[1] NACK_IE	I2C <i>i</i> .I2C_IRQENABLE_C LR[1] NACK_IE	I2C <i>i</i> _IRQ	No acknowledgement IRQ enabled status. Bit is set when No Acknowledge is received, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear this bit.
I2C <i>i</i> .I2C_IRQSTATUS[2] ARDY	I2C <i>i</i> .I2C_IRQENABLE_SET[2] ARDY_IE	I2C <i>i</i> .I2C_IRQENABLE_C LR[2] ARDY_IE	I2C <i>i</i> _IRQ	Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the IRQ_Crossbar. Write 1 to clear.
I2C <i>i</i> .I2C_IRQSTATUS[3] RRDY	I2C <i>i</i> .I2C_IRQENABLE_SET[3] RRDY_IE	I2C <i>i</i> .I2C_IRQENABLE_C LR[3] RRDY_IE	I2C <i>i</i> _IRQ	Receive data ready IRQ enabled status. Set to 1 by core when receiver mode, a new data can be read. When set to 1 by core, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear.

Table 19-10. I²C Events (continued)

Event Flag	Event Unmask	Event Mask	Map to	Description
I2Ci.I2C_IRQSTATUS[4] XRDY	I2Ci.I2C_IRQENABLE_SET[4] XRDY_IE	I2Ci.I2C_IRQENABLE_C LR[4] XRDY_IE	I2Ci_IRQ	Transmit data ready IRQ enabled status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[5] GC	I2Ci.I2C_IRQENABLE_SET[5] GC_IE	I2Ci.I2C_IRQENABLE_C LR[5] GC_IE	I2Ci_IRQ	General call IRQ enabled status. Set to 1 by core when General call address detected and interrupt signaled to the IRQ_Crossbar. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[6] STC	I2Ci.I2C_IRQENABLE_SET[6] STC_IE	I2Ci.I2C_IRQENABLE_C LR[6] STC_IE	I2Ci_IRQ	Start condition IRQ enabled status.
I2Ci.I2C_IRQSTATUS[7] AERR	I2Ci.I2C_IRQENABLE_SET[7] AERR_IE	I2Ci.I2C_IRQENABLE_C LR[7] AERR_IE	I2Ci_IRQ	Access Error IRQ enabled status.
I2Ci.I2C_IRQSTATUS[8] BF	I2Ci.I2C_IRQENABLE_SET[8] BF_IE	I2Ci.I2C_IRQENABLE_C LR[8] BF_IE	I2Ci_IRQ	Access Error IRQ enabled status.
I2Ci.I2C_IRQSTATUS[9] AAS	I2Ci.I2C_IRQENABLE_SET[9] AAS_IE	I2Ci.I2C_IRQENABLE_C LR[9] AAS_IE	I2Ci_IRQ	Address recognized as slave IRQ enabled status.
I2Ci.I2C_IRQSTATUS[10] XUDF	I2Ci.I2C_IRQENABLE_SET [10] XUDF_IE	I2Ci.I2C_IRQENABLE_C LR[10] XUDF_IE	I2Ci_IRQ	Transmit underflow enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[11] ROVR	I2Ci.I2C_IRQENABLE_SET [11] ROVR_IE	I2Ci.I2C_IRQENABLE_C LR[11] ROVR_IE	I2Ci_IRQ	Receive overrun enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[12] BB	Reserved	Reserved	I2Ci_IRQ	Bus busy enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[13] RDR	I2Ci.I2C_IRQENABLE_SET [13] RDR_IE	I2Ci.I2C_IRQENABLE_C LR[13] RDR_IE	I2Ci_IRQ	Receive draining IRQ enabled status.
I2Ci.I2C_IRQSTATUS[14] XDR	I2Ci.I2C_IRQENABLE_SET [14] XDR_IE	I2Ci.I2C_IRQENABLE_C LR[14] XDR_IE	I2Ci_IRQ	Transmit draining IRQ enabled status.

19.1.4.6 I²C DMA Requests

Each multimaster I²C controller can generate two DMA requests to the device DMA controllers through the DMA_CROSSBAR module. Table 19-11 lists the DMA requests. For information about DMA generation, see Section 19.1.4.8.3, I²C FIFO DMA Mode (I²C Mode Only).

Table 19-11. I²C DMA Requests

Name	Source	Description
I2C1_DREQ_TX	I2C1	I2C1 DMA write request to inform the DMAs to write new data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C1_DREQ_RX	I2C1	I2C1 DMA read request to inform the DMAs to read the data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_TX	I2C2	I2C2 DMA write request to inform the DMAs to write new data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_RX	I2C2	I2C2 DMA read request to inform the DMAs to read the data in the I2C2.I2C_DATA[7:0] DATA bit field

NOTE: For more information about I2Ci_DREQ_TX and I2Ci_DREQ_RX (where *i* = 1 to 2) signals mapping to DMA_CROSSBAR, see Section 12.3.2, Mapping of DMA Requests to DMA_CROSSBAR Inputs, in Table 19-4, I²C Hardware Requests.

19.1.4.7 I²C Programmable Multislave Channel Feature

This feature allows each multimaster I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OA and I2Ci.I2C_OAx registers (where = 1 to 2, x = 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA0, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

19.1.4.8 I²C FIFO Management

Each multimaster I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

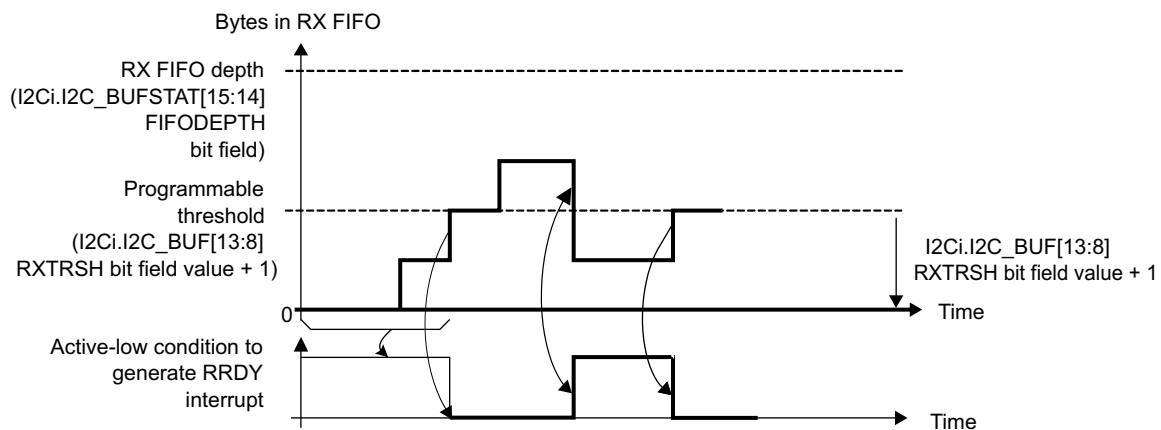

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

19.1.4.8.1 I²C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 19-12 and Figure 19-13 show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 19-12. I²C Receive FIFO Interrupt Request Generation

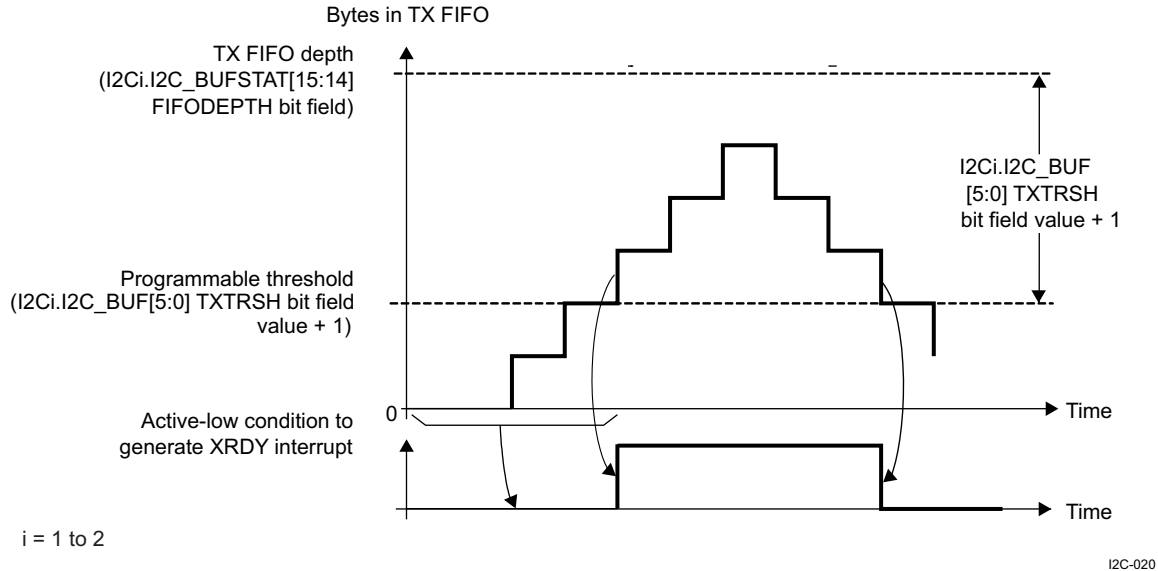

i = 1 to 2

I2C-019

In Figure 19-12, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Figure 19-13. I²C Transmit FIFO Interrupt Request Generation

In Figure 19-13, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2Ci.I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 19.1.4.8.4, *Draining Feature [I²C Mode Only]*).

NOTE: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

19.1.4.8.2 I²C FIFO Polling Mode

In FIFO polling mode (the I2Ci.I2C_IRQENABLE_SET [4] XRDY_IE and I2Ci.I2C_IRQENABLE_SET [3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_IRQSTATUS_RAW [4] XRDY and the I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bits (the I2Ci.I2C_IRQSTATUS_RAW [13] RDR and I2Ci.I2C_IRQSTATUS_RAW [14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_IRQSTATUS_RAW [4] XRDY and I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

19.1.4.8.3 I²C FIFO DMA Mode

In receive mode, a DMA request is generated by the I2Ci_DREQ_RX signal as soon as the RX FIFO exceeds its threshold level (the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 19-14 shows the DMA request generation in receive mode.

Figure 19-14. I²C Receive FIFO DMA Request Generation

In transmit mode, a DMA request is automatically asserted by the I2Ci_DREQ_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the DMA request remains active, and show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] TXTRSH bit field.

Figure 19-15. I²C Transmit FIFO Request Generation (High Threshold)

Figure 19-16. I²C Transmit FIFO Request Generation (Low Threshold)

I2C-022

The I2C module provides the possibility to the user to clear the RX or TX FIFO, by setting the I2Ci.I2C_BUF[14]RXFIFO_CLR and I2Ci.I2C_BUF[6]TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the following conditions are met:

1. The module is configured as a transmitter
2. The external receiver responds with a NACK in the middle of the transfer
3. There is still data in TX FIFO waiting to be transferred

19.1.4.8.4 I²C Draining Feature

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold and the I2Ci.I2C_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_IRQSTATUS_RAW [7] AERR bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_IRQSTATUS_RAW [13] RDR or I2Ci.I2C_IRQSTATUS_RAW [14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_IRQSTATUS_RAW [13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_IRQSTATUS_RAW [14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2Ci.I2C_CNT[15:0] DATACOUNT bit field value modulo I2Ci.I2C_BUF[13:8] RXTRSH or I2Ci.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IRQENABLE_SET [14] XDR_IE or I2Ci.I2C_IRQENABLE_SET [13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold).

19.1.4.9 I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes. The noise filter is always one period of the I2Ci.INTERNAL_CLK clock.

For standard mode (for example, the I2Ci.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C_PSC[7:0] PSC bit field.

19.1.4.10 I²C System Test Mode

A system test mode is available for multimaster I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci.I2C_SYSTEST [13:12] TMODE bit field selects the type of test. [Table 19-12](#) lists the tests available for the multimaster I²C controllers.

Table 19-12. I²C List of Tests

I2Ci.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
11	Loop-back mode + i2ci_scl/ i2ci_sda I/O	In master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl and i2ci_sda are controlled with the I2Ci.I2C_SYSTEST[3:0] bits.

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I²C controller must be configured in I²C F/S (I2Ci.I2C_CON[13:12] OPMODE set to 00).

NOTE: In normal operation mode (the I2Ci.I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2Ci.I2C_SYSTEST[3:0] bits that control the i2ci_scl, i2ci_sda lines in system test mode are read-only bits.

In system test mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit set to 1), the I2C*i*.I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK status bits can be set to 1 when the I2C*i*.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C*i*.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C*i*.I2C_IRQSTATUS_RAW bits to 0. The I2C*i*.I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

19.1.5 I²C Programming Guide

19.1.5.1 I²C Low-Level Programming Models

19.1.5.1.1 I²C Programming Model

This section describes the programming model of the multimaster I²C controllers configured in I²C mode.

19.1.5.1.1.1 Main Program

19.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Table 19-3](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (I2Ci_FCLK).
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 kbps or 400 kbps. These values depend on the internal sampling clock frequency (see [Table 19-6](#)).
4. Configure the Own Address of the I²C controller by storing it in the I2Ci.I2C_OA register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OA and I2Ci.I2C_OAx registers (where x = 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

5. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0] TXTRSH bit field to (TX threshold – 1) and the I2Ci.I2C_BUF[13:8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
6. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

19.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave; 1: master).
 - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2Ci.I2C_IRQENABLE_SET register to 1 (the I2Ci.I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2Ci.I2C_BUF register to 1 (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

19.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

19.1.5.1.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

19.1.5.1.1.1.5 Receive Data

Poll the I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1 together with I2C_DMARXENABLE_SET) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

19.1.5.1.1.1.6 Transmit Data

Poll the I2Ci.I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1 together with I2C_DMATXENABLE_SET) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2Ci.I2C_BUF[5:0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2Ci.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

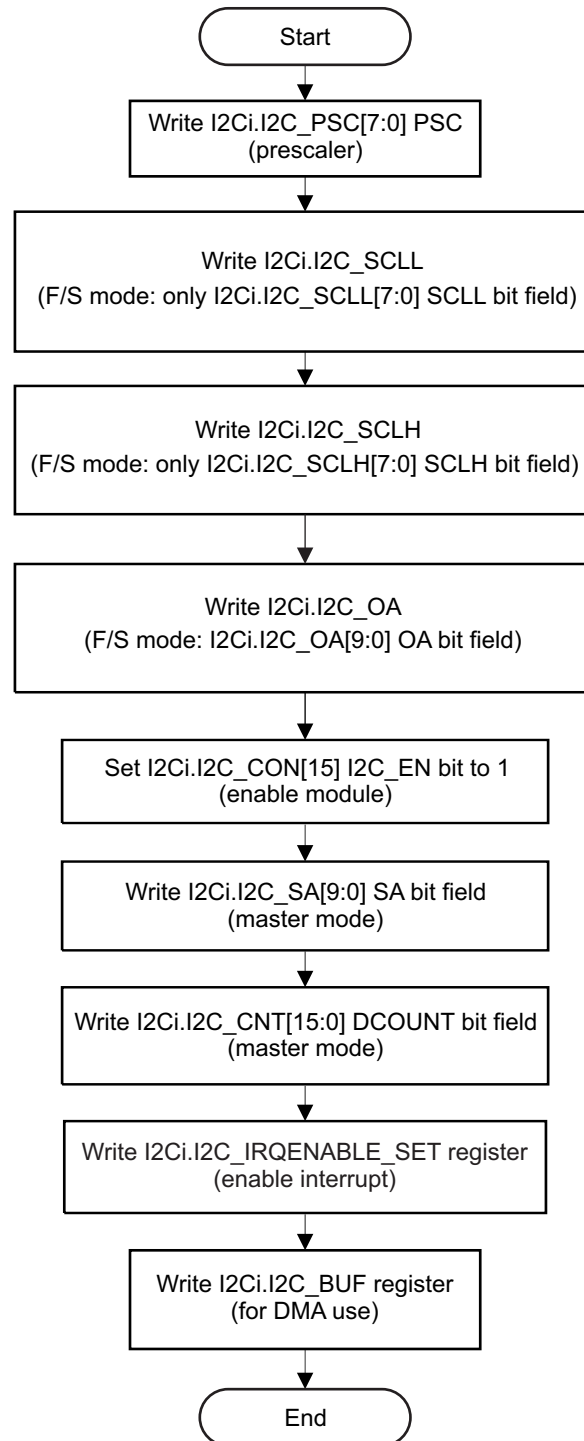

19.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2Ci.I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2Ci.I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

19.1.5.1.1.3 Programming Flow Diagrams

Figure 19-17 through Figure 19-25 are procedure flow charts for programming the F/S I²C modes.

Figure 19-17. I²C Setup Procedure

I2C-024

Table 19-13. Subprocess Call Summary for Sequence – I²C Setup Procedure

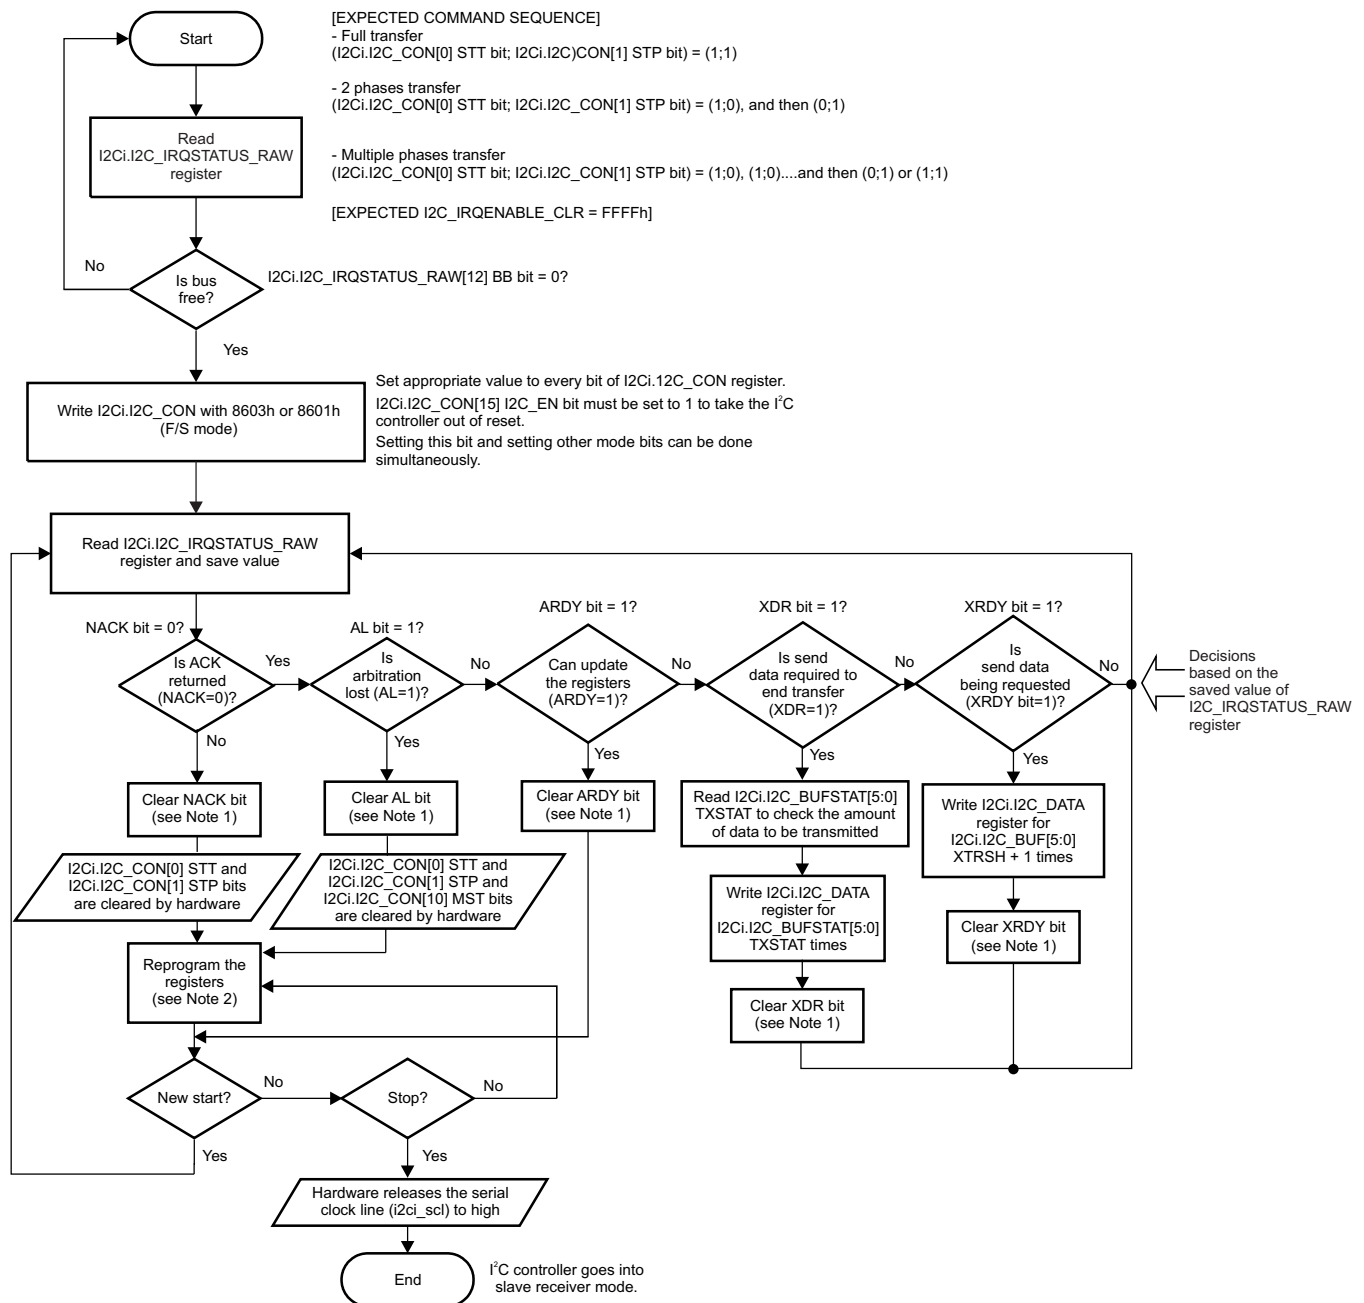

Subprocess Name	Cross-Reference
Pad configuration	See Section 14.4.6.1, PAD Configuration Registers in Chapter 14 Control Module

Table 19-14. I²C Register Call Summary for Sequence – Setup Procedure

Register Name	Register Name	Register Name
