Table 19-33. I2C_IRQSTATUS_RAW

Address Offset	0x0000 0024	Instance	I2C1
Physical Address	0x4807 0024 0x4807 2024		I2C2
Description	Per-event raw interrupt status vector. The raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0
12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0

Bits	Field Name	Description	Type	Reset
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: Transmission ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to IRQ_Crossbar. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

⁽¹⁾ Writing 1 in the bit field will only set the respective field to 1, used mainly for debug.

19.2 UART

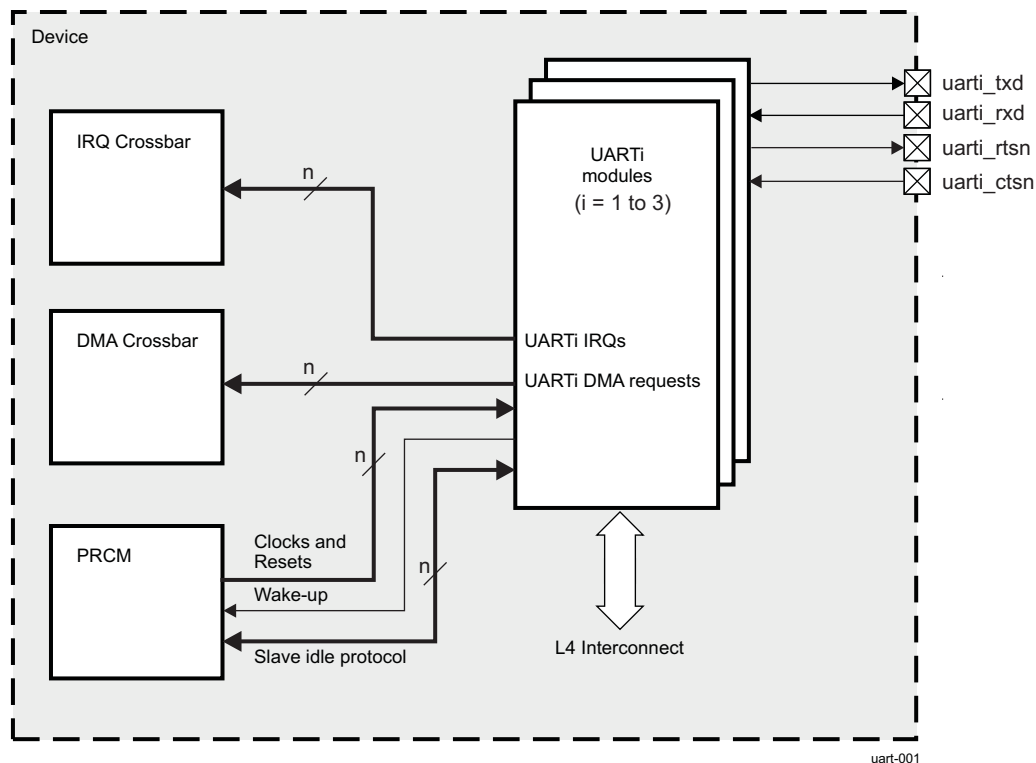

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART) module in the device.

19.2.1 UART Overview

The UART is a simple L4 slave peripheral that utilizes the EDMA for data transfer or IRQ polling via CPU. There are 3 UART modules in the device. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 19-26 shows the UART module overview.

Figure 19-26. UART Overview

19.2.1.1 UART Features

The UART_i (where $i = 1$ to 3) include the following features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (where $N = 1 \dots 16,384$) operating from a fixed functional clock of 48 MHz or 192 MHz

Oversampling is programmed by software as 16 or 13. Thus, the baud rate computation is one of two options:

- Baud rate = (functional clock / 16) / N
- Baud rate = (functional clock / 13) / N
- This software programming mode enables higher baud rates with the same error amount without changing the clock source
- Break character detection and generation
- Configurable data format:

- Data bit: 5, 6, 7, or 8 bits
- Parity bit: Even, odd, none
- Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- The 48 MHz functional clock option allows baud rates up to 3.6Mbps
- The 192 MHz functional clock option allows baud rates up to 12Mbps

19.2.2 UART Environment

This section describes the UART connection with an external device.

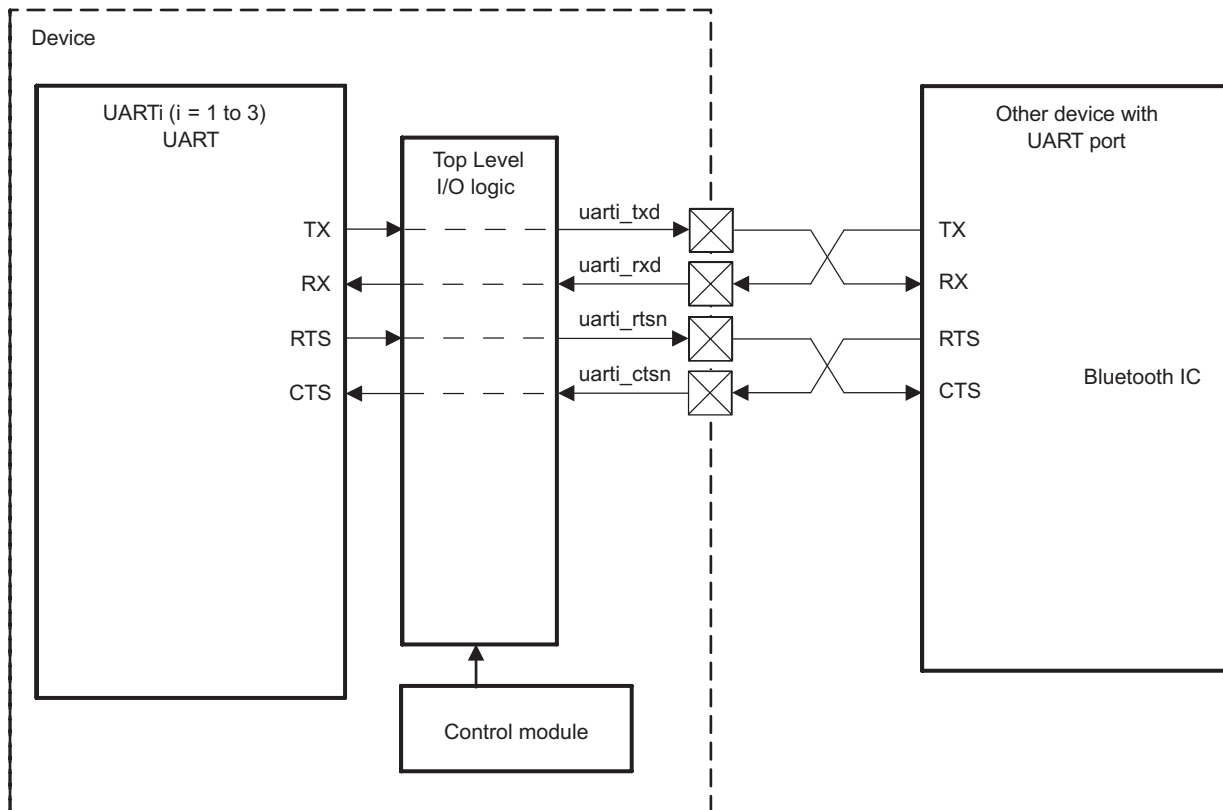

- The UART interface is described in [Section 19.2.2.1](#).

19.2.2.1 UART Interface

19.2.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see [Figure 19-27](#)).

Figure 19-27. UART Mode Bus System Overview

uart-002

19.2.2.1.2 UART Interface Description

[Table 19-89](#) lists the UART interface input/output (I/O) signals.

Table 19-89. UART Interface Signals

Signal	I/O ⁽¹⁾	Description	Module Level Reset Value
UARTi Interface Signals⁽²⁾			
uarti_rxd	I	Serial data input.	Unknown
uarti_txd	O	Serial data output This pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the inactive level when the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes).	0
uarti_ctsn	I	Clear to send	Unknown

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ i = 1 to 3

Table 19-89. UART Interface Signals (continued)

Signal	I/O ⁽¹⁾	Description	Module Level Reset Value
		Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_ctsn. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_ctsn since the last read of the modem status register. The auto-CTS mode uses uarti_ctsn to control the transmitter.	
uarti_rtsn	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rtsn, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rtsn becomes inactive as a result of the receiver threshold logic.	1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on control module settings, see [Section 14.4.6.1, Pad Configuration Registers](#), in [Chapter 14, Control Module](#).

19.2.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

CAUTION

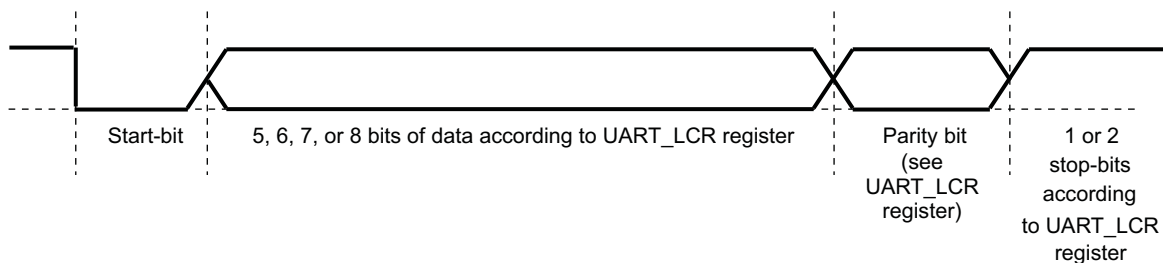

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 19-28 shows the UART frame data format.

Figure 19-28. UART Frame Data Format

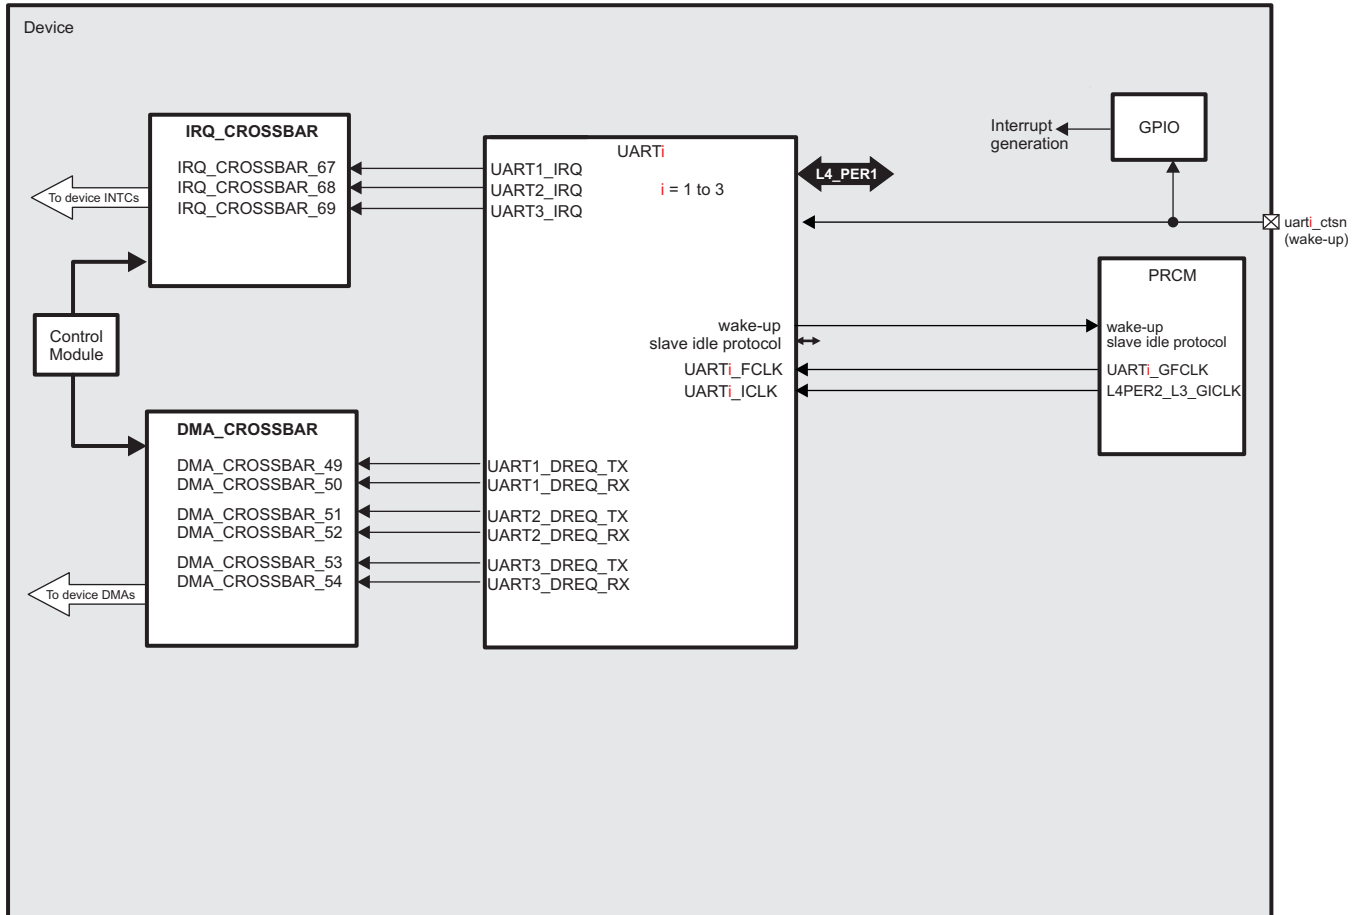

uart-005

19.2.3 UART Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 19-29 shows the device internal connections with related modules for UART functions.

Figure 19-29. UART Integration

uart-021

NOTE: For more information about the slave idle and master standby protocols and the wake-up request, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)

Table 19-90 through Table 19-92 summarize the integration of the module in the device.

Table 19-90. UART Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_COREAON	Yes	L4_PER1
UART2	PD_COREAON	Yes	L4_PER1
UART3	PD_COREAON	Yes	L4_PER1

Table 19-91. UART Clocks and Resets

Clocks				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_ICLK	L4PER_L3_GICLK	PRCM	UART1 interface clock
	UART1_FCLK	UART1_GFCLK	PRCM	UART1 functional clock
UART2	UART2_ICLK	L4PER_L3_GICLK	PRCM	UART2 interface clock
	UART2_FCLK	UART2_GFCLK	PRCM	UART2 functional clock
UART3	UART3_ICLK	L4PER_L3_GICLK	PRCM	UART3 interface clock
	UART3_FCLK	UART3_GFCLK	PRCM	UART3 functional clock
Resets				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_RST	L4PER_RET_RST	PRCM	UART1 reset
UART2	UART2_RST	L4PER_RET_RST	PRCM	UART2 reset
UART3	UART3_RST	L4PER_RET_RST	PRCM	UART3 reset

Table 19-92. UART Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR input	Default Mapping	Description
UART1	UART1_IRQ	IRQ_CROSSBAR_67	-	UART module 1 IRQ line
UART2	UART2_IRQ	IRQ_CROSSBAR_68	-	UART module 2 IRQ line
UART3	UART3_IRQ	IRQ_CROSSBAR_69	IPU_IRQ_45	UART module 3 IRQ line
Direct Memory Access (DMA) Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR input	Default Mapping	Description
UART1	UART1_DREQ_TX	DMA_CROSSBAR_49	DMA_EDMA_DREQ_48	UART module 1 – transmit request
	UART1_DREQ_RX	DMA_CROSSBAR_50	DMA_EDMA_DREQ_49	UART module 1 – receive request
UART2	UART2_DREQ_TX	DMA_CROSSBAR_51	DMA_EDMA_DREQ_50	UART module 2 – transmit request
	UART2_DREQ_RX	DMA_CROSSBAR_52	DMA_EDMA_DREQ_51	UART module 2 – receive request
UART3	UART3_DREQ_TX	DMA_CROSSBAR_53	DMA_EDMA_DREQ_52	UART module 3 – transmit request
	UART3_DREQ_RX	DMA_CROSSBAR_54	DMA_EDMA_DREQ_53	UART module 3 – receive request

NOTE: The “**Default Mapping**” column in [Table 19-92, UART Hardware Requests](#), shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

19.2.4 UART Functional Description

19.2.4.1 Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to UART and enables UART function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see [Section 19.2.4.7, Mode Selection](#).

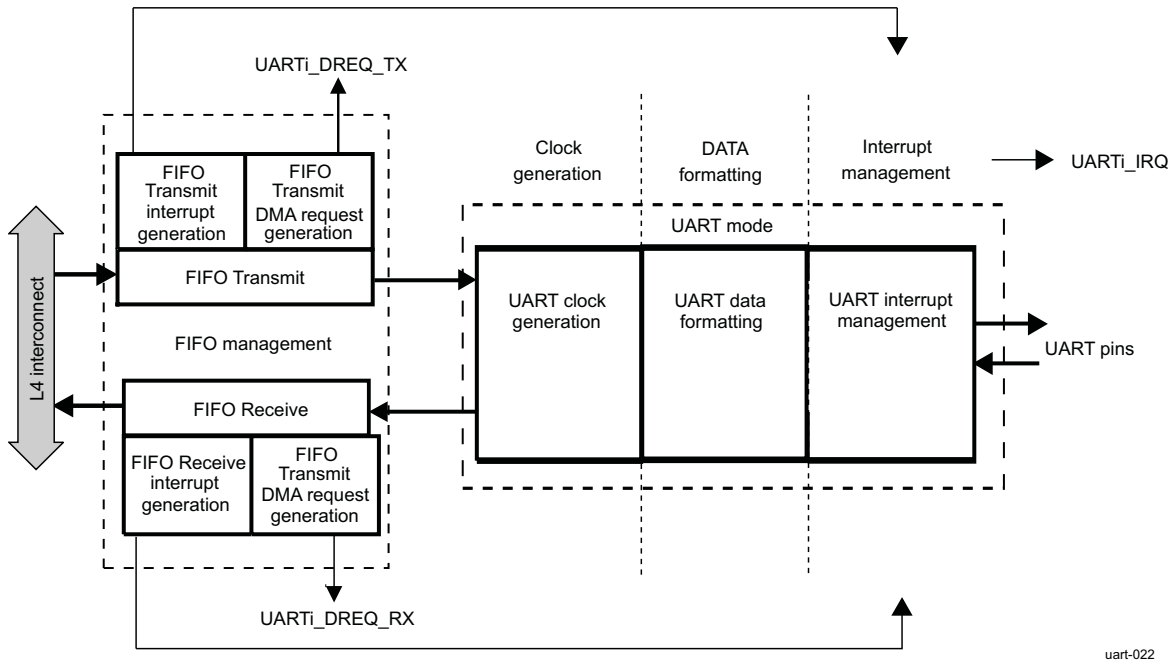

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: When an interrupt is generated, the [UART_IIR](#) register indicates the interrupt type.
 - Seven interrupts prioritized in six different levels

In parallel with these functional blocks, a power-saving strategy exists for each function.

[Figure 19-30](#) is the UART block diagram.

Figure 19-30. UART Functional Block Diagram

19.2.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The `UARTi.UART_SYSC[4:3] IDLEMODE` bit field controls UART idle mode.

19.2.4.3 Software Reset

The `UARTi.UART_SYSC[1] SOFTRESET` bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

19.2.4.4 Power Management

19.2.4.4.1 UART Mode Power Management

19.2.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the `UARTi.UART_IER[4] SLEEP_MODE` bit to 1 (when the `UARTi.UART_EFR[4] ENHANCED_EN` bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, `uarti_rxd`, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rxd line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see [Section 19.2.4.5.1.2, Wake-Up Interrupt](#).

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL or UARTi.UART_DLH register.

19.2.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

19.2.4.4.2 Local Power Management

[Table 19-93](#) describes power-management features available for the UART.

NOTE: For information about source clock gating and the sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

Table 19-93. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

19.2.4.5 Interrupt Requests

19.2.4.5.1 UART Interrupt Management

19.2.4.5.1.1 UART Interrupts

UART includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 19-94 summarizes the interrupt control functions.

Table 19-94. UART Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
000010	3	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.
000000	4	Modem status	See the UART_MSR register.	Read the MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read the UART_IIR register.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

19.2.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UART3.UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

19.2.4.6 FIFO Management

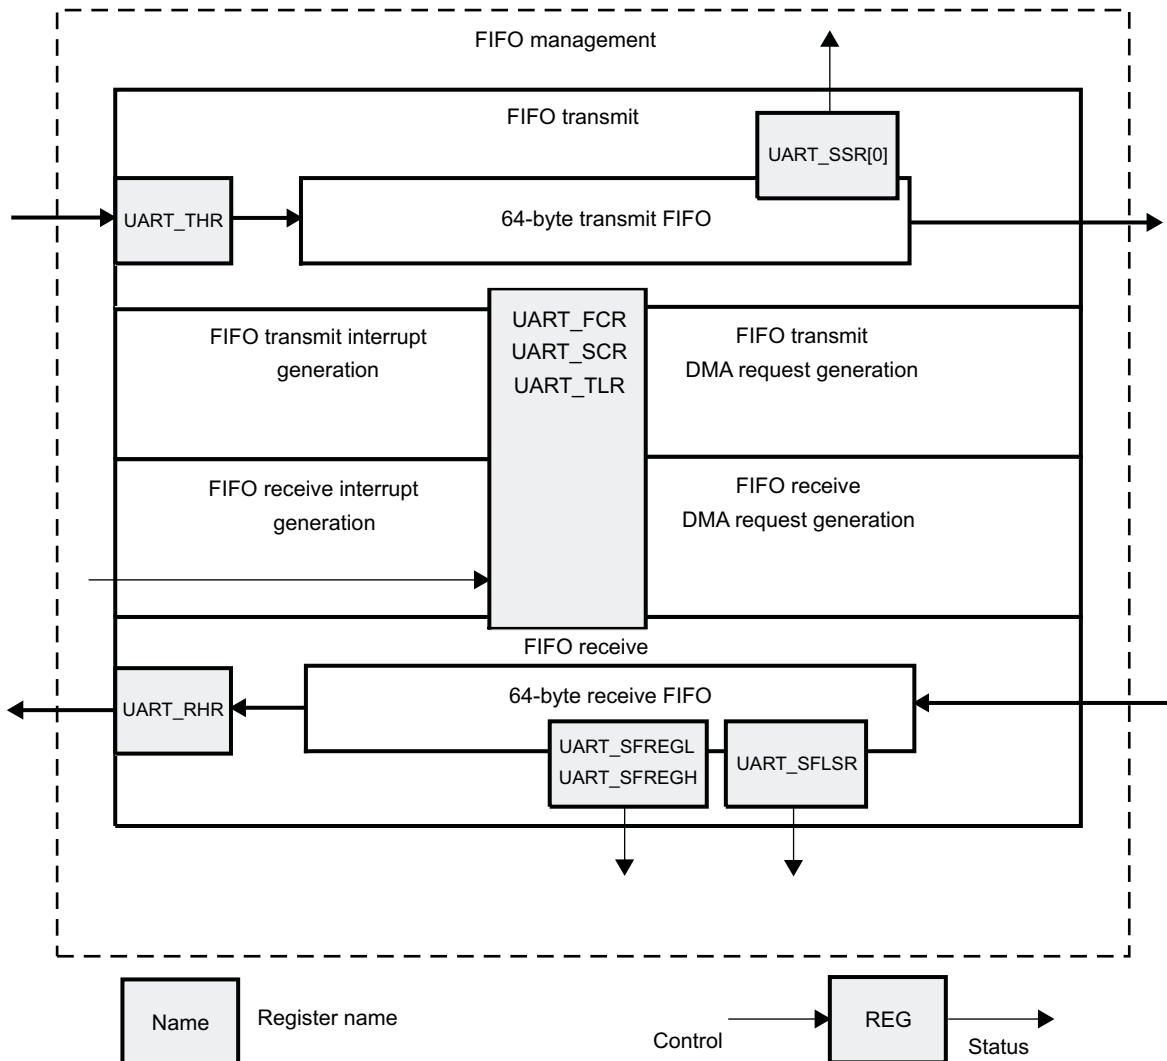

The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 19-31 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: Bits UARTi.UART_FCR[2] TX_FIFO_CLEAR and UARTi.UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after $4 * \text{UARTi_ICLK} + 5 * \text{UARTi_FCLK}$ clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

Figure 19-31. FIFO Management Registers

uart-023

19.2.4.6.1 FIFO Trigger

19.2.4.6.1.1 Transmit FIFO Trigger

Table 19-95 lists the TX FIFO trigger level settings.

Table 19-95. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) Note: The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

19.2.4.6.1.2 Receive FIFO Trigger

Table 19-96 lists the RX FIFO trigger-level settings.

Table 19-96. RX FIFO Trigger-Level Setting Summary

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) Note: The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud_rate} + 4 \times \text{FCLK}$$

NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

19.2.4.6.2 FIFO Interrupt Mode

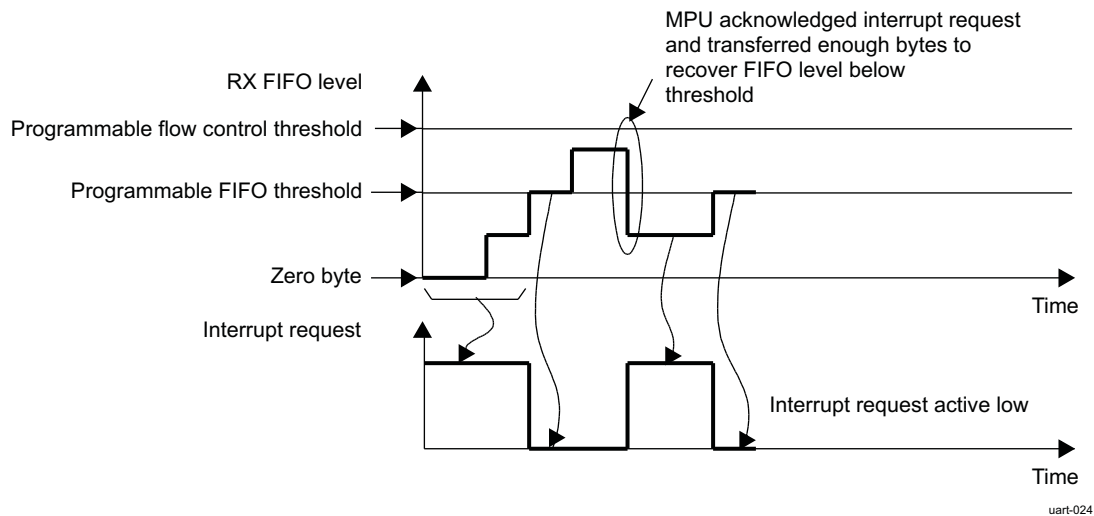

In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 19-32 shows the generation of the RX FIFO interrupt request.

Figure 19-32. RX FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 19-33 shows the generation of the TX FIFO interrupt request.

Figure 19-33. TX FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

19.2.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the `UARTi.UART_FCR[0]` `FIFO_EN` bit is set to 0 and the relevant interrupts are disabled by the `UARTi.UART_IER` register), the status of the receiver and transmitter can be checked by polling the line status register (`UARTi.UART_LSR`).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the CPU.

19.2.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in [Table 19-92, Hardware Requests](#), assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the `UARTi_DREQ_TX` signals (where $i = 1$ to 10).

The `UARTi_DREQ_RX` signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit is set to 0, setting the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 0 enables DMA mode 0. Setting the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 1 enables DMA mode 1.
- When the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit is set to 1, the `UARTi.UART_SCR[2:1]` `DMA_MODE_2` bit field determines DMA mode 0 to mode 3 based on the supplementary control register (SCR) description.

For example:

- If no DMA operation is desired, set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 1 and the `UARTi.UART_SCR[2:1]` `DMA_MODE_2` bit field to 0x0. (The `DMA_MODE` bit is discarded.)
- If DMA mode 1 is desired, set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 0 and the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 1, or set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 1 and the `SCR[2:1]` `DMA_MODE_2` bit field to 01. (The `UARTi.UART_FCR[3]` `DMA_MODE` bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UARTi.UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

The threshold value will be the value of the TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.

- SET_TX_DMA_THRESHOLD = 0:

The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower than the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

19.2.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART_SCR[0] = 0 and UARTi.UART_FCR[3] = 1:

- A. Set the UARTi.UART_SCR[2:1]DMA_MODE_2 bit fields to 01 (DMA mode 1)
- B. Set the UARTi.UART_SCR[0]DMA_MODE_CTL bit to 1 (this setting of UARTi.UART_SCR[0]DMA_MODE-CTL will ignores UARTi.UART_FCR[3]DMA_MODE_CTL bit)

NOTE: It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- C. Set the UARTi.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- D. Set the UARTi.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- E. Set the UARTi.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- F. Set the UARTi.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- G. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

2. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART_FCR[3] = 0 and UARTi.UART_SCR[0] = 1, UARTi.UART_SCR[2:1] = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:

- A. Set the UARTi.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- B. Set the UARTi.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its

- counter logic to 0. Returns to 0 after clearing FIFO).
- C. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- E. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
- 3. DMA mode 3 is set (TX DMA only) by registers UARTI.UART_FCR[3] = 0 and UARTI.UART_SCR[0] = 1, UARTI.UART_SCR[2:1] = 11. It is the same as above:
 - A. Set the UARTI.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTI.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

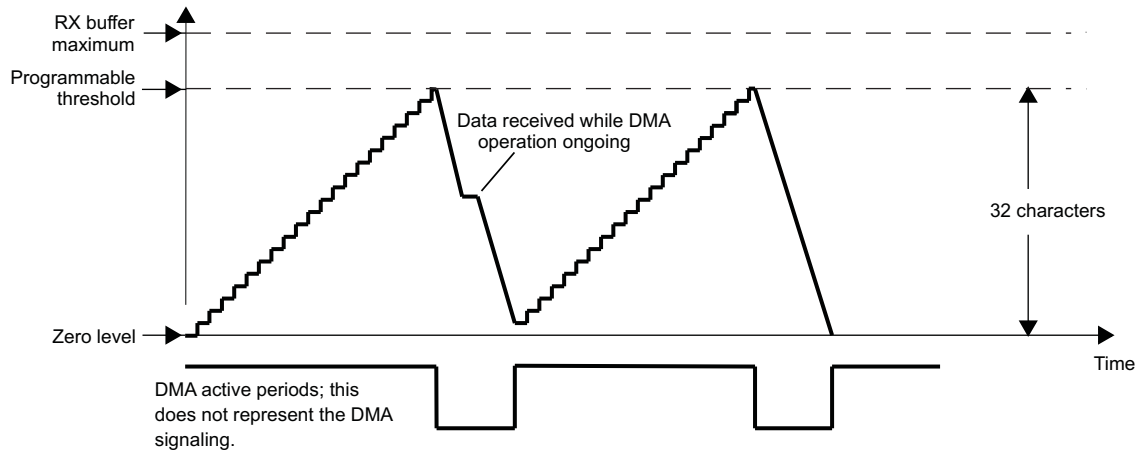

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- B. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- C. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- E. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

19.2.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 19-34 through Figure 19-37 show the supported DMA operations.

Figure 19-34. Receive FIFO DMA Request Generation (32 Characters)

uart-026

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

Figure 19-35. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 19-35 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

Figure 19-36 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

Figure 19-36. Transmit FIFO DMA Request Generation (8 Spaces)

uart-028

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 19-37). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 19-37. Transmit FIFO DMA Request Generation (1 Space)

uart-029

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting `UART_MDR3[1]` `NONDEFAULT_FREQ` bit and `UART_TX_DMA_THRESHOLD` register (see Figure 19-38). In the example, `UART_TX_DMA_THRESHOLD[5:0]` `TX_DMA_THRESHOLD` = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the `UART_DLL` and `UART_DLH` registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the `UART_MDR3[1]` `NONDEFAULT_FREQ` value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

Figure 19-38. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)

uart-036

19.2.4.6.4.3 DMA Transmission

Figure 19-39 shows DMA transmission.

Figure 19-39. DMA Transmission

uart-030

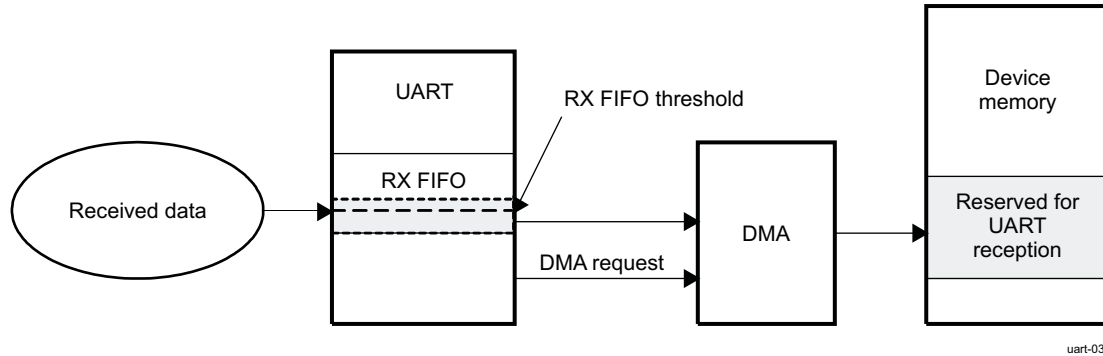

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:

- a. Until the TX FIFO trigger level is not reached, a DMA request is generated
- b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

19.2.4.6.4.4 DMA Reception

Figure 19-40 shows DMA reception.

Figure 19-40. DMA Reception

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
 - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

19.2.4.7 Mode Selection

19.2.4.7.1 Register Access Modes

19.2.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 19-97).

Table 19-97. UART Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

19.2.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Table 19-116](#), *UART Register Manual*.

[Table 19-98](#) through [Table 19-100](#) summarize the register access submodes.

Table 19-98. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 19-99. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 19-100. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

19.2.4.7.2 UART Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see [Table 19-101](#)).

Table 19-101. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	Reserved
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	Reserved
0x5:	Reserved
0x6:	Reserved
0x7:	Disable (default state)

MODE_SELECT is effective when the module is in operational mode (see [Section 19.2.4.7.1](#), *Register Access Modes*).

19.2.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 19-102](#) are used for the UART function.

Table 19-102. UART Mode Register Overview

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode	
	Read	Write	Read	Write	Read	Write

19.2.4.8 Protocol Formatting

19.2.4.8.1 UART Mode

19.2.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 19-41 shows the baud rate generator and associated controls.

Figure 19-41. Baud Rate Generation

CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

19.2.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency / (16x baud rate)
- UART 13x mode: Divisor value = Operating frequency / (13x baud rate)

Table 19-103 and Table 19-104 describe the UART baud rate settings.

Table 19-103. UART Baud Rate Settings (48-MHz Clock)

19.2.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

19.2.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see [Table 19-105](#)).

Table 19-105. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

19.2.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, `uarti_ctsn` must be active before the module can transmit data.

Auto-RTS activates the `uarti_rtsn` output only when there is enough room in the RX FIFO to receive data. It deactivates the `uarti_rtsn` output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which `uarti_rtsn` is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. `uarti_rtsn` is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, `uarti_rtsn` is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

`uarti_rtsn` is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

In this case, `uarti_rtsn` is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks `uarti_ctsn` before sending the next data byte. When `uarti_ctsn` is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, `uarti_ctsn` must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the `uarti_ctsn` state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, `uarti_ctsn` is an active-low signal.

19.2.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 19-106).

Two other enhanced features relate to software flow control:

- XON-any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 19-106. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2

Table 19-106. UART_EFR[3:0] Software Flow Control Options (continued)

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾

⁽¹⁾ In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

19.2.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

19.2.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

19.2.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

```

AT      DATA  <CR>
at      DATA  <CR>
A/
a/
  
```

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
 - 115.2K baud
 - 57.6K baud
 - 38.4K baud
 - 28.8K baud
 - 19.2K baud
 - 14.4K baud
 - 9.6K baud
 - 4.8K baud
 - 2.4K baud
 - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

19.2.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 19-94 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 19-94 for the UART mode interrupts).

19.2.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the CPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the CPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

19.2.4.8.1.3.7 Time-Out and Break Conditions

19.2.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rxd) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rxd is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rxd.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rxd or when the UARTi.UART_RHR register is read.

19.2.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_txd is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).

3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

19.2.5 UART Basic Programming Model

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 19.2.4.7.1, Register Access Modes](#).

19.2.5.1 Global Initialization

19.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART.

For more information, see [Section 19.2.3, UART Integration](#).

Table 19-107. Global Initialization of Surrounding Modules for UART

Surrounding Modules	Comments
PRCM	UART functional and interface clocks must be enabled. For more information, see Chapter 3, Power, Reset, and Clock Management .
Control module	Module-specific pad muxing must be set in the control module. For more information, see Chapter 14, Control Module .
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For information about enabling interrupts, see Chapter 13, Interrupt Controllers .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 14.4.6.4, DMA_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
DMA controllers	DMA controllers configuration must be done to enable the module DMA channel request.
Interconnects	For information about the L4 interconnect configuration, see Chapter 10, Interconnect .

19.2.5.1.2 UART Module Global Initialization

The procedure in [Table 19-108](#) can be used to initialize UART when performing software reset.

Table 19-108. UART Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	0x1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	= 0x1

19.2.5.2 Mode selection

The [Table 19-109](#) describes how to set different register access mode.

Table 19-109. Configure register access mode

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7]DIV_EN	0x1
	UART_LCR[7:0]	!=0xBF
Set the register access mode B	UART_LCR[7:0]	0xBF
Set the operational mode	UART_LCR[7]DIV_EN	0x1

19.2.5.3 Submode selection

This section describes how to set different register access submode.

Table 19-110. Configure register access submode TCR_TLR

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see Table 19-109	
Enable writing to register bits UART_MCR[7:5]	UART_EFR[4]ENHANCED_EN	0x1
Configure mode A	see Table 19-109	0x1
Set the submode TCR_TLR	UART_MCR[6]TCR_TLR	0x1

Table 19-111. Configure register access submode MSR_SPR

Step	Register/Bit Field/Programming Model	Value
First option configure the submode MSR_SPR		
Configure mode B	see Table 19-109	
Set the submode MSR_SPR	UART_EFR[4]ENHANCED_EN	0x0
Second option configure the submode MSR_SPR		
Configure mode B	see Table 19-109	
Enable writing to register bits UART_MCR[7:5]	UART_EFR[4]ENHANCED_EN	0x1
Set the submode MSR_SPR	UART_MCR[6]TCR_TLR	0x0

Table 19-112. Configure register access submode XOFF

Step	Register/Bit Field/Programming Model	Value
Configuration of the XOFF		
Configure B	see Table 19-109	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0x0

19.2.5.4 Load FIFO trigger and DMA mode settings

19.2.5.4.1 DMA mode Settings

To enable and configure the DMA mode, perform the following steps:

Table 19-113. DMA mode settings

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration.	UART_SCR[0] DMA_MODE_CTL	0x-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	0x0
Select the DMA mode, for more information see Section 19.2.4.6.4	UART_FCR[3] DMA_MODE	0x-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	0x1
Select the DMA mode, for more information see Section 19.2.4.6.4	UART_SCR[2:1] DMA_MODE_2	0x-

19.2.5.4.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

Table 19-114. Load FIFO triggers defined by the FCR

Step	Register/Bit Field/Programming Model	Value
Configure register submodule TCR_TLR	see Table 19-110	0x-
Set the desire RX FIFO trigger level	UART_FCR[5:4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7:6] RX_FIFO_TRIG	0x-

Table 19-115. Load FIFO triggers defined by the TLR

Step	Register/Bit Field/Programming Model	Value
Configure register submodule TCR_TLR	see Table 19-110	0x-
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA	0x-

Table 19-116. Load FIFO triggers defined by the concatenated value

Step	Register/Bit Field/Programming Model	Value
Configure register submodule TCR_TLR	see Table 19-110	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	0x1
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA UART_FCR[7:6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	0x1
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA UART_FCR[5:4] TX_FIFO_TRIG	0x-

19.2.5.5 Protocol, Baud rate and interrupt settings

19.2.5.5.1 Baud rate settings

Table 19-117. Baud rate settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Switch to register configuration mode B	see Table 19-109	
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	0x1
Switch register operational mode	see Table 19-109	
Disable sleep mode	UART_IER[4] SLEEP_MODE	0x0
Switch to register configuration mode A or B	see Table 19-109	
Set the appropriate divisor value	UART_DLL[7:0] CLOCK_LSB UART_DLH[5:0] CLOCK_MSB	0x-

19.2.5.5.2 Interrupt settings

Table 19-118. Interrupt settings

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see Table 19-109	0x7
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	
Switch register operational mode	see Table 19-109	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER[7] CTS_IT UART_IER[6] RTS_IT UART_IER[5] XOFF_IT UART_IER[4] SLEEP_MODE UART_IER[3] MODEM_STS_IT UART_IER[2] LINE_STS_IT UART_IER[1] THR_IT UART_IER[0] RHR_IT	0x-

19.2.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

Table 19-119. Protocol settings

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see Section 19.2.4.8.1.3.1, Frame Formatting	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1:0] PARITY_LENGTH	0x-
Switch to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0x0

19.2.5.5.4 UART Mode Selection

Table 19-120. UART mode selection

Step	Register/Bit Field/Programming Model	Value
Load the desired UART mode, see Section 19.2.4.7.2, UART Mode Selection	UART_MDR1[2:0] MODE_SELECT	0x-

19.2.5.6 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

19.2.5.6.1 Hardware Flow Control Configuration

Table 19-121. Hardware Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 19-110	0x7
Load the start and halt trigger value.	UART_TCR[7:4] AUTO_RTS_START UART_TCR[3:0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

19.2.5.6.2 Software Flow Control Configuration

Table 19-122. Software Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see Table 19-112	
Load the software control characters	UART_XON1_ADDR1[7:0] XON_WORD1 UART_XON2_ADDR2[7:0] XON_WORD2 UART_XOFF1[7:0] XOFF_WORD1 UART_XOFF2[7:0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see Table 19-110	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	0x-
Load start and halt trigger value for software flow control	UART_TCR[7:4] AUTO_RTS_START UART_TCR[3:0] AUTO_RTS_HALT	0x-
Enable or disable special character function(0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3:0] SW_FLOW_CONTROL	0x-

19.2.6 UART Register Manual

19.2.6.1 UART Instance Summary

19.2.6.2.2 UART Register Description

Table 19-125. UART_THR

Address Offset	0x0000 0000
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000
Description	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.

Table 19-127. UART_RHR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000	Instance	UART1 UART2 UART3
Description	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. Note: If an overflow occurs, the data in the RHR is not overwritten.		
Type	R

Address Offset	0x0000 0018		
Physical Address	0x4806 A018 0x4806 C018 0x4802 0018	Instance	UART1 UART2 UART3
Description	Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that <code>UART_TCR[3:0] > UART_TCR[7:4]</code> when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (<code>UART_TLR[7:4]</code> or <code>UART_FCR[7:6]</code>); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.

Address Offset	0x0000 0020		
Physical Address	0x4806 A020	Instance	UART1
	0x4806 C020		UART2
	0x4802 0020		UART3
Description	Mode definition register 1 The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL , UART_DLH , and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. Note: If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (UART_IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (UART_IIR) shows UART mode interrupt flags.		
Type	RW

Address Offset	0x0000 0038		
Physical Address	0x4806 A038 0x4806 C038 0x4802 0038	Instance	UART1 UART2 UART3
Description	UART autobauding status register This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. Note: When the UART is in autobauding mode, this register, instead of the UART_LCR , UART_DLL , and UART_DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set UART_MDR1[2:0] to 111 (reset value), then set UART_MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set UART_MDR1[2:1] to 000.

Address Offset	0x0000 005C		
Physical Address	0x4806 A05C 0x4806 C05C 0x4802 005C	Instance	UART1 UART2 UART3
Description	Wake-up enable register The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. An event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt.

19.3 Multichannel Serial Peripheral Interface

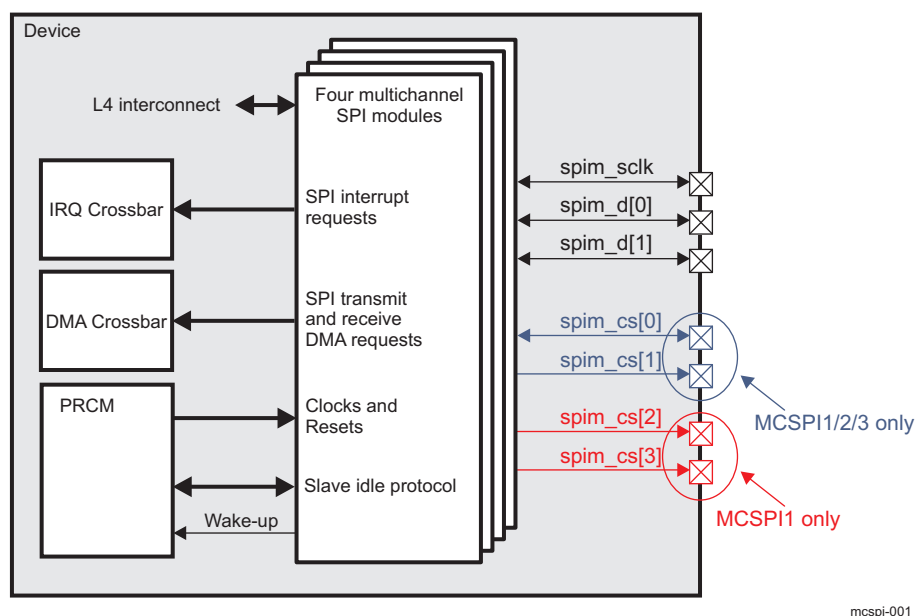

This section describes the four Multichannel Serial Peripheral Interface (McSPI) modules for the device.

19.3.1 McSPI Overview

The SPI is a master/slave synchronous serial bus. There are four separate McSPI modules (McSPI1, McSPI2, McSPI3, and McSPI4) in the device (see [Figure 19-42](#)). All these four modules are able to work as both master and slave and support the following chip selects:

- McSPI1: spi1_cs[0], spi1_cs[1], spi1_cs[2], spi1_cs[3]
- McSPI2: spi2_cs[0], spi2_cs[1]
- McSPI3: spi3_cs[0], spi3_cs[1]
- McSPI4: spi4_cs[0]

Figure 19-42. Multichannel SPI Modules

The McSPI modules include the following main features:

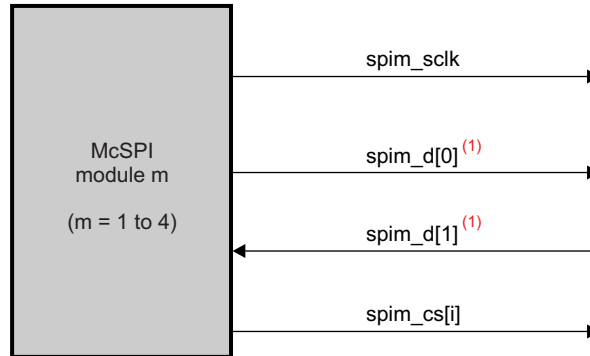

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes
 - Flexible input/output (I/O) port controls per channel
 - Programmable clock granularity
 - SPI configuration per channel. This means, clock definition, polarity enabling and word width
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

19.3.2 McSPI Environment

19.3.2.1 Basic McSPI Pins for Master Mode

Figure 19-43 shows all of the McSPI interface signals in master mode.

Figure 19-43. McSPI Interface Signals in Master Mode

(1) Direction depends on bits IS, DPE1 and DPE0 in MCSPI_CHxCONF

mcspi-006

Table 19-193 describes the McSPI I/O in master mode.

Table 19-193. McSPI I/O Description (Master Mode)

Device-Level Signal Name	Module Signal Name	I/O ⁽¹⁾	Description
spim_sclk	SPICLK	O	SPI _m module serial clock output
spim_d[0]	SPIDAT[0]	O ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	I ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	O	SPI _m module chip-select i output

⁽¹⁾ I = Input; O = Output

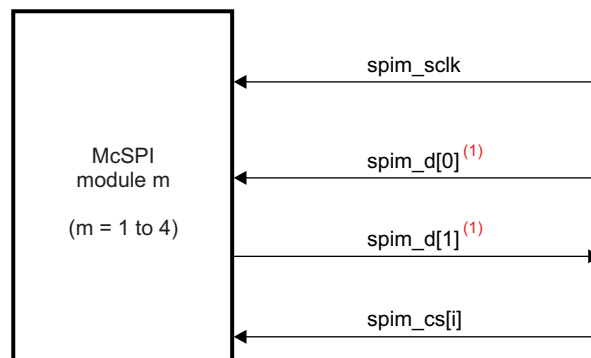

⁽²⁾ Example configuration only.

NOTE: For the spim_sclk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

19.3.2.2 Basic McSPI Pins for Slave Mode

Figure 19-44 shows all of the McSPI interface signals in slave mode.

Figure 19-44. McSPI Interface Signals in Slave Mode

⁽¹⁾ Direction depends on bits IS, DPE1 and DPE0 in MCSPI_CHxCONF

mcspi-007

Table 19-194 describes the McSPI I/O in slave mode.

Table 19-194. McSPI I/O Description (Slave Mode)

Device-Level Signal Name	Module Signal Name	I/O ⁽¹⁾	Description
spim_sclk	SPICLK	I	McSPI _m module serial clock input
spim_d[0]	SPIDAT[0]	I ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	O ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	I	McSPI _m module chip-select i input. Can be selected through MCSPI_CH0CONF[22:21] SPIENSLV bit field

⁽¹⁾ I = Input; O = Output

⁽²⁾ Example configuration only.

19.3.2.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (SPIEN[x]) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- **Word length**
 McSPI supports any SPI word ranging from 4 bits to 32 bits long (the MCSPI_CHxCONF[11:7] WL bit field).
 SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- **SPI enable (SPIEN[x], for channel x of instance m)**
 The polarity of the SPI enable signals is programmable (the MCSPI_CHxCONF[6] EPOL bit). SPIEN[x] signals can be active high or low.
 Assertion of the SPIEN[x] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. SPIEN[x] can be kept active between words with the MCSPI_CHxCONF[20] FORCE bit.
 Two consecutive words for two different slave devices can go along with active SPIEN[x] signals with different polarity.

- Programmable start-bit
 In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the [MCSPI_CHxCONF\[23\]](#) SBE bit to 1. The [MCSPI_CHxCONF\[24\]](#) SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
 - Bit rate
 In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 19-195](#) lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the [MCSPI_CHxCONF\[5:2\]](#) CLKD bit field).

Table 19-195. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz ⁽¹⁾
2	24 MHz ⁽¹⁾
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

⁽¹⁾ These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

- Polarity and phase
 The polarity (the [MCSPI_CHxCONF\[1\]](#) POL bit) and the phase (the [MCSPI_CHxCONF\[0\]](#) PHA bit) of the SPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 19-196](#) and [Figure 19-45](#).

Table 19-196. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

Figure 19-45. Phase and Polarity Combinations

19.3.2.3.1 Transfer Format

In master and slave modes, the McSPI drives the data lines when SPIEN[x] is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN.

Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 19-46](#).

Figure 19-46. Full-Duplex Transfer Format With PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of SPIEN[x] and the first SPICLK edge. The received data bit is shifted into the shift register on the third SPICLK edge.

This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

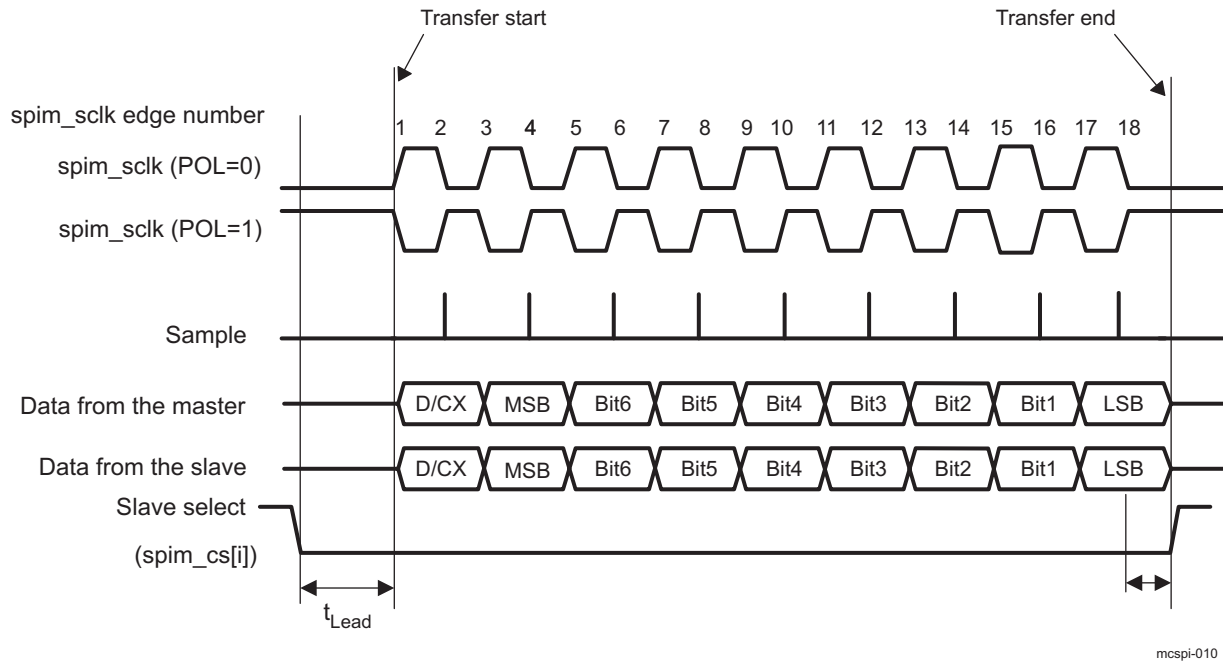

NOTE: The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of SPI_m_FCLK (McSPI_m functional clock) in master mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of SPI_m_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the [MCSPI_CHxCONF\[23\]](#) SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 19-47](#) shows an example of a data transfer with an extra start-bit.

Figure 19-47. Extended SPI Transfer With a Start-Bit (SBE = 1)

19.3.2.4 SPI in Master Mode

Figure 19-48 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

Figure 19-48. McSPI Master Mode (Full Duplex)

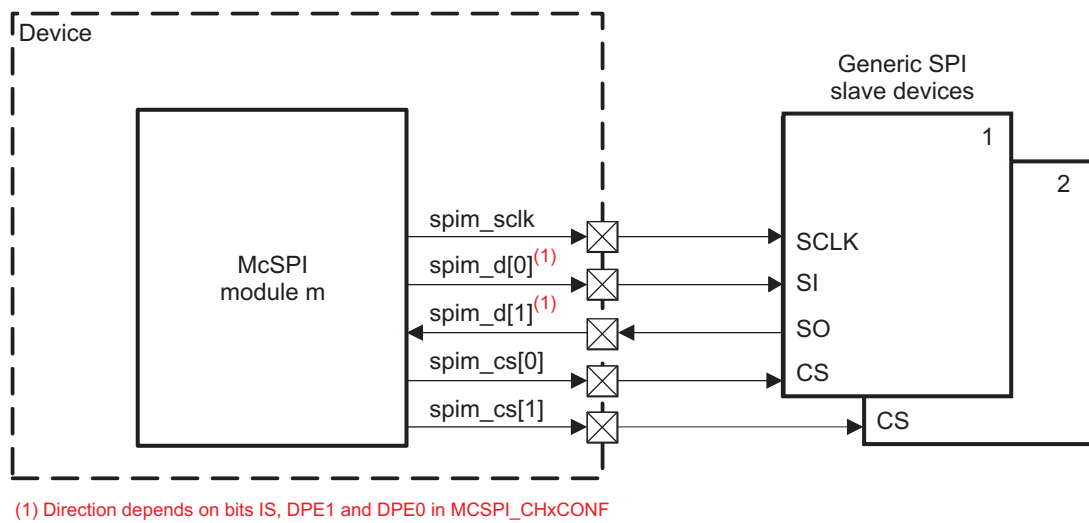

Figure 19-49 shows the master single mode, which can also be configured in receive-only mode.

Figure 19-49. McSPI Master Single Mode (Receive Only)

k = 0 or 1 depending on bits IS, DPE1 and DPE0 in MCSPI_CHxCONF

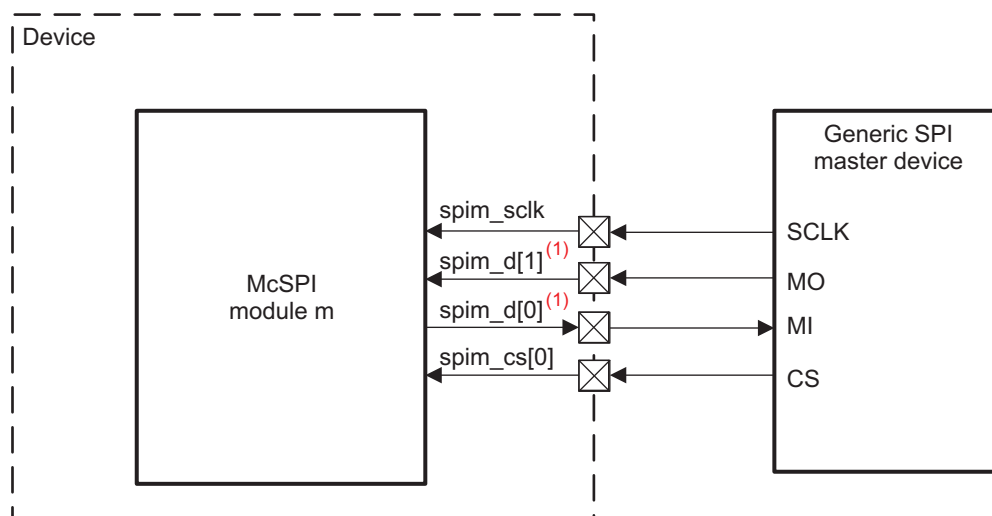

mcspi-003

19.3.2.5 SPI in Slave Mode

Figure 19-50 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any SPIEN[x] pin and then rerouted internally to channel 0 (the MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 19.3.4.4, Slave Mode.

Figure 19-50. McSPI Slave Mode (Full Duplex)

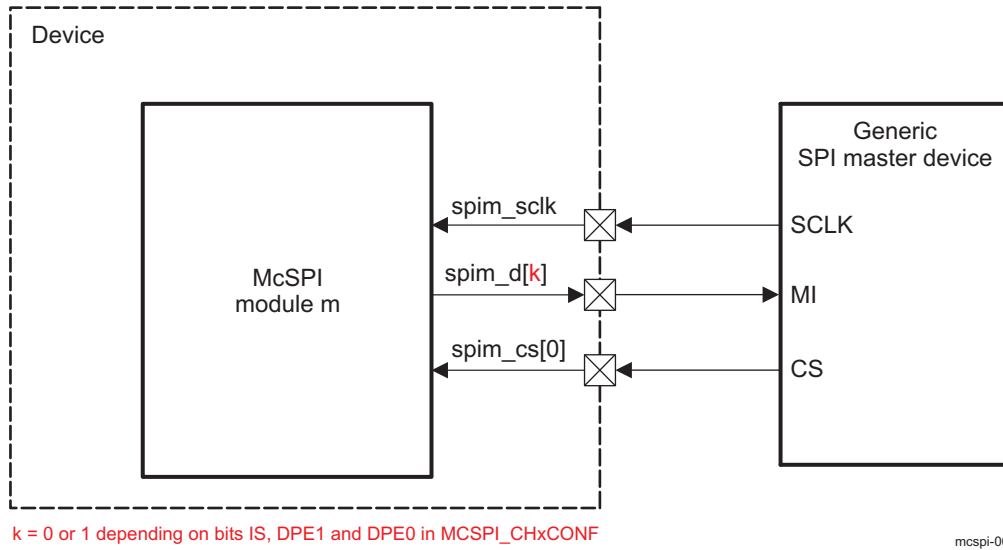

(1) Direction depends on bits IS, DPE1 and DPE0 in MCSPI_CHxCONF

mcspi-004

Figure 19-51 shows the slave single mode, which can also be configured in transmit-only mode.

Figure 19-51. McSPI Slave Single Mode (Transmit Only)

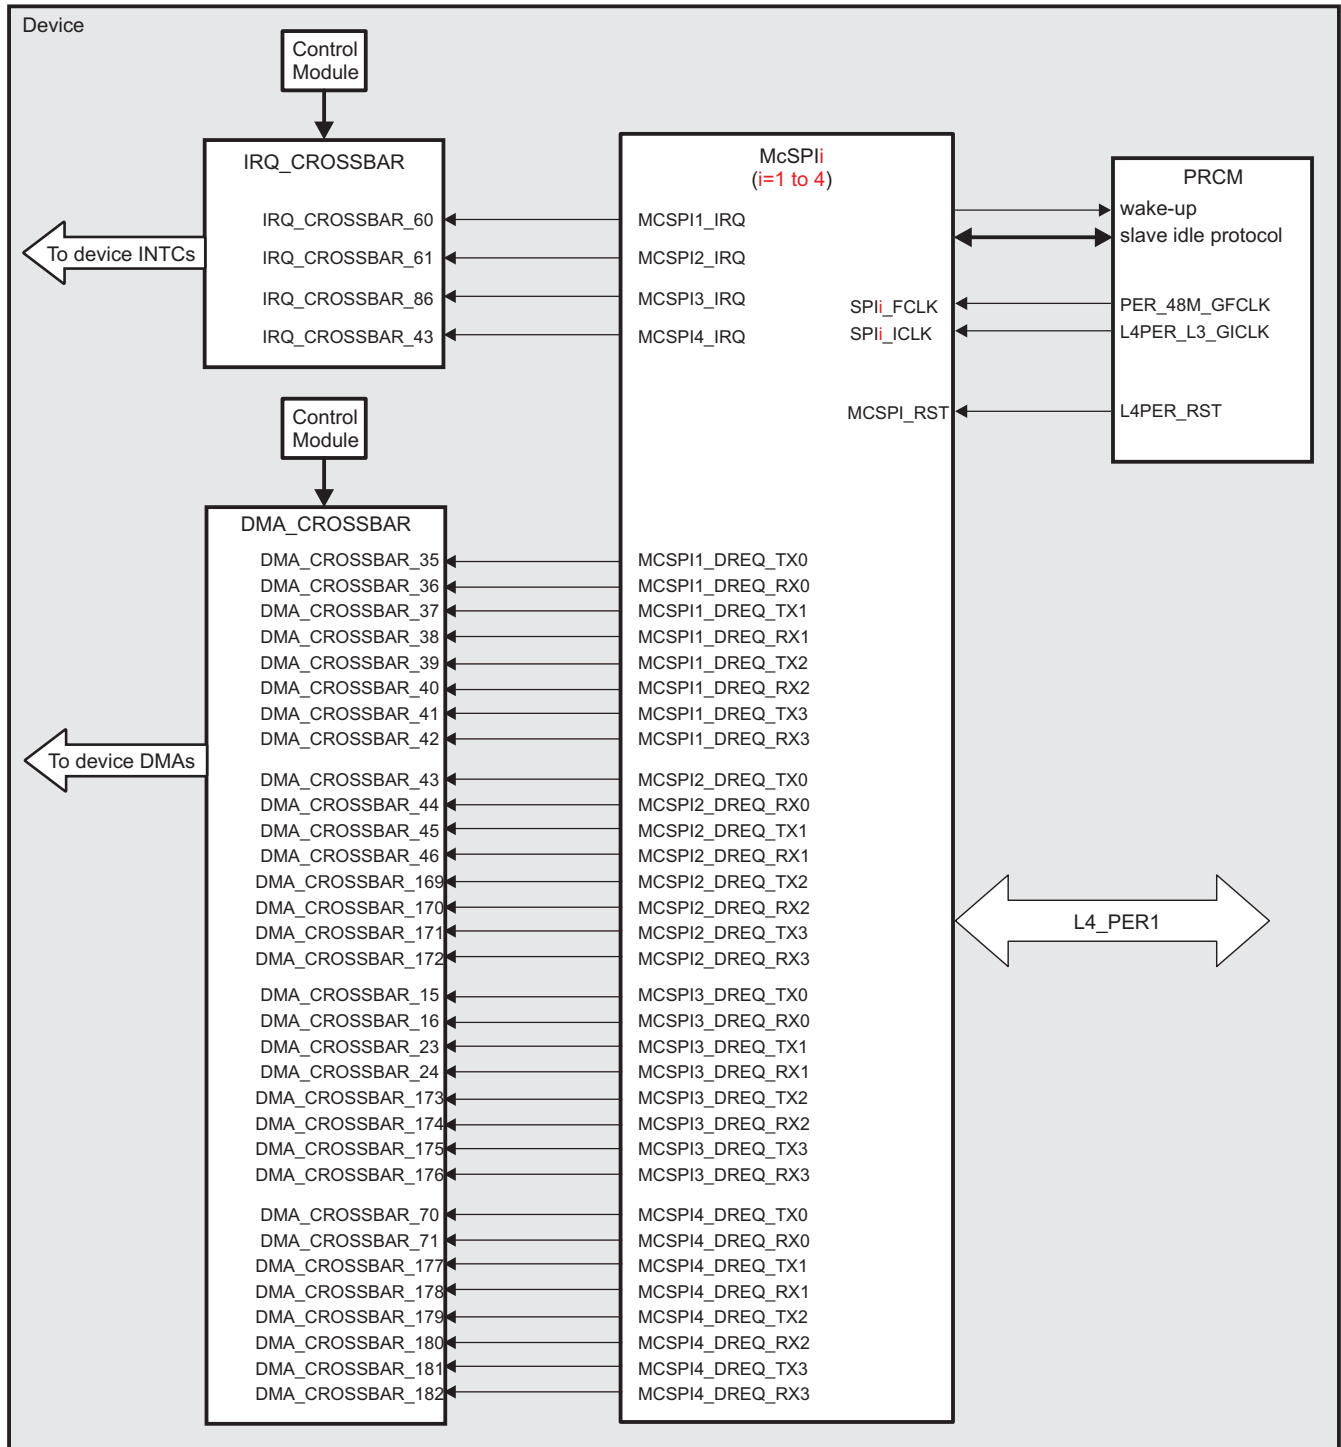

19.3.3 McSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 19-52 shows McSPI integration.

Figure 19-52. McSPI Integration

mcspi-011

Table 19-197 through Table 19-199 summarize the integration of the module in the device.

NOTE: The Default Mapping column in [Table 19-199 McSPI Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

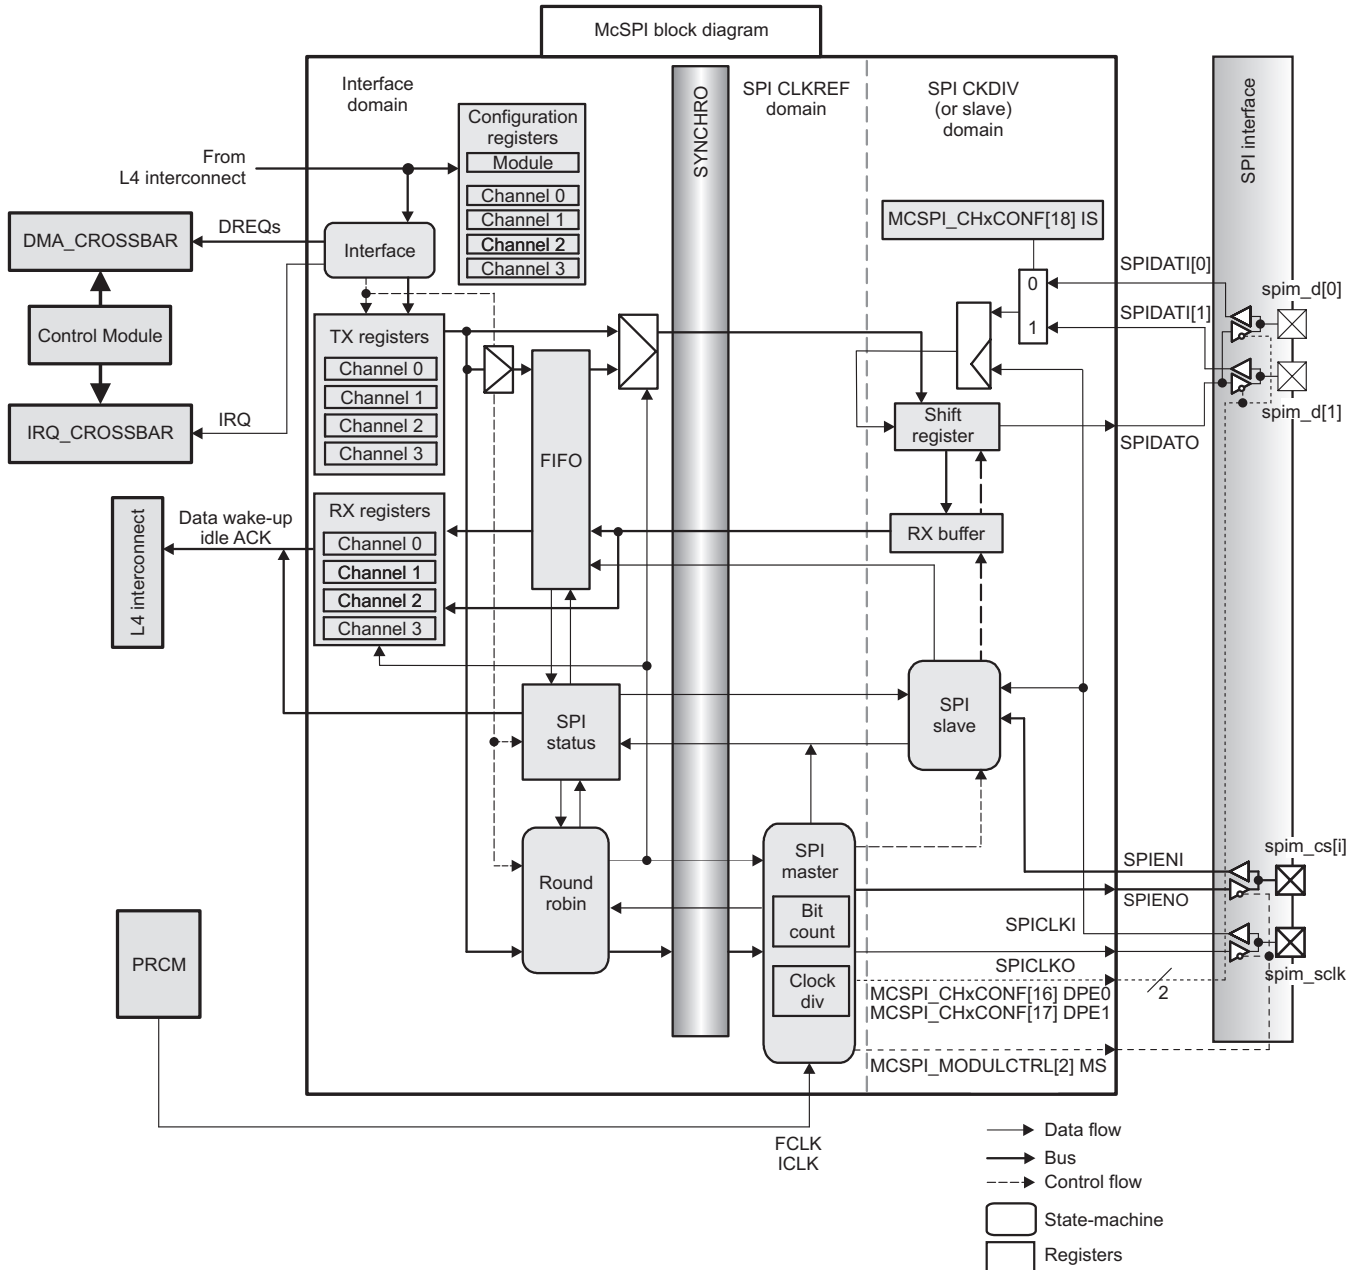

NOTE: For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

19.3.4 McSPI Functional Description

19.3.4.1 McSPI Block Diagram

Figure 19-53 shows the McSPI module.

Figure 19-53. McSPI Block Diagram

mcspi-012

19.3.4.2 Reset

The McSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPi_RST). McSPI can be reset by software through the [MCSPi_SYSCONFIG\[1\] SOFTRESET](#) bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the [MCSPi_SYSCONFIG](#) register is not affected by that software reset.

19.3.4.3 Master Mode

19.3.4.3.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN) signals.

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

NOTE: There is a fixed chip select line allocation in multichannel master mode. Channel x SPIEN[x] is mapped to spim_cs[i] pin.

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see [Section 19.3.4.7.1, Interrupt Events in Master Mode](#)).

19.3.4.3.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the [MCSPI_CHxCONF\[13:12\]](#) TRM bit field).

Channel access to the shift registers for transmission/reception is based on the [MCSPI_TXx](#) transmitter register state, the [MCSPI_RXx](#) receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

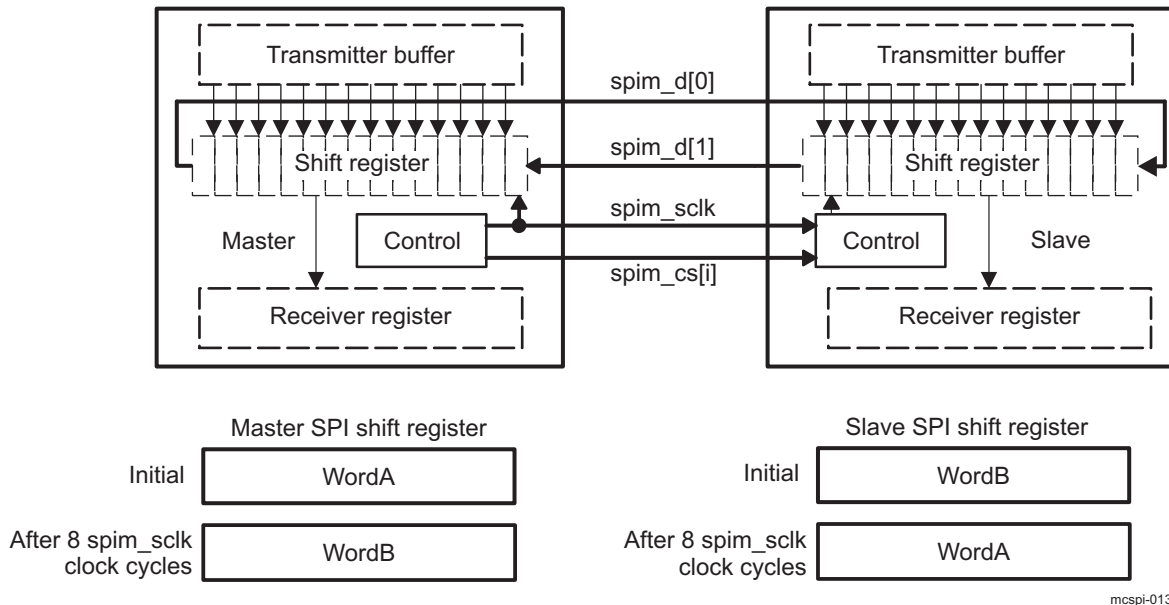

- **Rule 1:** Only enabled channels (the [MCSPI_CHxCTRL\[0\]](#) EN bit) can be scheduled for transmission and/or reception.
- **Rule 2:** If its [MCSPI_TXx](#) transmitter register is not empty (the [MCSPI_CHxSTAT\[1\]](#) TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the [MCSPI_TXx](#) register is empty when the shift register is assigned, the [TXx_UNDERFLOW](#) event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- **Rule 3:** An enabled channel can be scheduled if its receive register is not full (the [MCSPI_CHxSTAT\[0\]](#) RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the [MCSPI_RXx](#) register cannot be overwritten. The SPI1.[MCSPI_IRQSTATUS\[3\]](#) [RX0_OVERFLOW](#) bit is never set to this mode.

When SPI word transfer completes (the [MCSPI_CHxSTAT\[2\]](#) EOT bit is set), the updated [MCSPI_TXx](#) register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 19-54](#) shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 19-54. SPI Full-Duplex Transmission (Example)

19.3.4.3.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents a device initiator from reading the `MCSPi_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `MCSPi_CHxCONF[13:12]` TRM bit field). Transmission starts only after data is loaded into the `MCSPi_TXx` register.

Rule 1 and Rule 2, defined in Section 19.3.4.3.2, apply in this mode.

Rule 3, defined in Section 19.3.4.3.2, does not apply.

In master transmit-only mode, the `MCSPi_RXx` register state FULL does not prevent transmission and the `MCSPi_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `MCSPi_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `MCSPi_CHxSTAT[2]` EOT bit.

19.3.4.3.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents a device initiator from refilling the `MCSPi_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `MCSPi_CHxCONF[13:12]` TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPi_RXx` register.

Rule 1 and Rule 3, defined in Section 19.3.4.3.2, apply in this mode.

Rule 2, defined in Section 19.3.4.3.2, does not apply.

In the master receive-only mode, software must write dummy data to the `MCSPi_TXx` register. Only one dummy write is enough to receive any number of words from the slave. Software must ensure that the `MCSPi_TXx` register is always full (the `TXx_EMPTY` bits of `MCSPi_IRQSTATUS`) when receiving. The content of the `MCSPi_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPi_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `MCSPi_IRQSTATUS` register are never set in receive-only mode.

The `MCSPI_CHxSTAT[2]` EOT bit gives the status of serialization. The `RXx_FULL` bits of the `MCSPI_IRQSTATUS` register are set when received data is loaded from the shift register to the corresponding `MCSPI_RXx` register. The `MCSPI_IRQSTATUS[3]` `RX0_OVERFLOW` bit is never set in this mode.

19.3.4.3.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel (`MCSPI_MODULCTRL[2]` `MS` = 0 and `MCSPI_MODULCTRL[0]` `SINGLE` = 1), the assertion of the `SPIEN[x]` signal is optional depending on device connected to the controller. In 3-pin mode (`MCSPI_MODULCTRL[1]` `PIN34` = 1) the controller starts transmitting data when a write to the `MCSPI_TXx` register or the FIFO is performed. In 4-pin mode (`MCSPI_MODULCTRL[1]` `PIN34` = 0) the assertion and de-assertion of `SPIEN[x]` is controlled by software using the `MCSPI_CHxCONF[20]` `FORCE` bit.

19.3.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the SPI word transfer to complete (wait until the `MCSPI_CHxSTAT[2]` EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

19.3.4.3.5.2 Force SPIEN[x] Mode

Continuous transfers are allowed manually by keeping the `SPIEN[x]` signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the `SPIEN[x]` line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the `SPIEN[x]` active mode is supported when:

- A single channel is used (with the `MCSPI_MODULCTRL[0]` `SINGLE` bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (`MCSPI_CHxCONF`).

The state of the `SPIEN[x]` signal is programmable:

- Writing 1 to the `MCSPI_CHxCONF[20]` `FORCE` bit drives the `SPIEN[x]` line high when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 0. `SPIEN[x]` is driven low when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 1.
- Writing 0 to the `MCSPI_CHxCONF[20]` `FORCE` bit drives the `SPIEN[x]` line low when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 0. `SPIEN[x]` is driven high when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 1.
- A single channel is enabled (the `MCSPI_CHxCTRL[0]` `EN` bit is set to 1). The first enabled channel activates the `SPIEN[x]` line.

When the channel is enabled, the `SPIEN[x]` signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the `MCSPI_TXx` register (the `MCSPI_CHxSTAT[1]` `TXS` bit), the status of the `MCSPI_RXx` register (the `MCSPI_CHxSTAT[1]` `RXS` bit), and the defined mode (the `MCSPI_CHxCONF[13:12]` `TRM` bit field) of the channel enabled.

The `MCSPI_CHxSTAT[2]` EOT bit gives the transfer status of each SPI word. The `RXx_FULL` bit in the `MCSPI_IRQSTATUS` register is set when received data is loaded from the shift register to the `MCSPI_RXx` register.

A change in the configuration parameters is propagated directly on the SPI interface. If the `SPIEN[x]` signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, `SPIEN` polarity and `SPICLK` phase and `SPICLK` polarity must not be modified when the `SPIEN[x]` signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the `MCSPI_CHxCTRL[0] EN` bit set to 0) and `SPIEN[x]` can be forced to its INACTIVE state using the `MCSPI_CHxCONF[20] FORCE` bit.

Figure 19-55 and Figure 19-56 show successive transfers with `SPIEN[x]` maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 19-55. Continuous Transfers With `SPIEN[x]` Maintained Active (Single-Data-Pin Interface Mode)

Figure 19-56. Continuous Transfers With `SPIEN[x]` Maintained Active (Dual-Data-Pin Interface Mode)

NOTE: The `SPIEN[x]` signal can be maintained active via software using the `MCSPI_CHxCONF[20] FORCE` bit only when the `MCSPI_MODULCTRL[0] SINGLE` bit is set to 0x1.

19.3.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the `MCSPI_RXx` register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the `SPI1.MCSPI_CHxCONF[9] TURBO` bit).

When several channels are enabled, the `TURBO` bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 19.3.4.3.2, *Master Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the `MCSPI_CHxSTAT[0] RXS` bit) when the shift-register is assigned until the shift register is full.

The `MCSPI_RXx` register cannot be overwritten in turbo mode. Consequently, the `MCSPI_IRQSTATUS[3] RX0_OVERFLOW` bit is never set in this mode.

19.3.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[x] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the [MCSPI_CHxCONF\[23\]](#) SBE bit to 1. The polarity of the extended bit is programmable per channel. When the [MCSPI_CHxCONF\[24\]](#) SBPOL bit is set to 0, the SPI word must be handled as a command. When the [MCSPI_CHxCONF\[24\]](#) SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the [MCSPI_CHxCONF\[24\]](#) SBPOL bit before writing the SPI word to be transmitted to the TX register.

19.3.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the [MCSPI_MODULCTRL\[0\]](#) SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when [MCSPI_MODULCTRL\[1\]](#) PIN34 set to 0.

This mode is programmable per channel through the [MCSPI_CHxCONF\[26:25\]](#) TCS0 bit field.

[Figure 19-57](#) shows the CS SPIEN timing controls.

Figure 19-57. CS (SPIEN) Timing Controls

mcspi-016

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

19.3.4.3.8 Programmable SPI Clock

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the [MCSPI_CHxCONF\[5:2\]](#) CLKD bit field) to generate the bit rate of the serial output clock SPICLK. [Table 19-200](#) summarizes the supported divisor values.

Table 19-200. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz ⁽¹⁾
2	24 MHz ⁽¹⁾
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

⁽¹⁾ These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

19.3.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the `MCSPI_CHxCONF[5:2]` CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the `MCSPI_CHxCONF[29]` CLKG bit, clock division granularity can be changed to one clock cycle; in that case the `MCSPI_CHxCTRL[15:8]` EXTCLK bit field is concatenated with the `MCSPI_CHxCONF[5:2]` CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the `MCSPI_CHxCONF[1]` POL and `MCSPI_CHxCONF[0]` PHA bits (see [Table 19-201](#)).

Table 19-201. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even ≥ 2	$T_ref \times (F_{RATIO}/2)$	$T_ref \times (F_{RATIO}/2)$
Odd \geq (POL = PHA)	$T_ref \times (F_{RATIO} - 1)/2$	$T_ref \times (F_{RATIO} + 1)/2$
Odd \geq (POL \neq PHA)	$T_ref \times (F_{RATIO} + 1)/2$	$T_ref \times (F_{RATIO} - 1)/2$

NOTE: F_{RATIO} = SPICLK frequency (F_{OUT}) division ratio
 T_{HIGH} = SPICLK high time period
 T_{LOW} = SPICLK low time period
 T_ref = FCLK period
 T_{HIGH_REF} = FCLK high time period
 T_{LOW_REF} = FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty_cycle} = (1 - 1/F_{RATIO})/2$$

[Table 19-202](#) shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 19-202. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F _{RATIO}	PHA	POL	T _{HIGH} (ns)	T _{LOW} (ns)	T _{PERIOD} (ns)	Duty Cycle	F _{OUT} (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

19.3.4.4 Slave Mode

To select the McSPI slave mode, set the [MCSPI_MODULCTRL\[2\]](#) MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[x]) and receives an SPI clock (SPICLK) from the external SPI master device. Only channel 0 can be configured as a slave but through the [MCSPI_CH0CONF\[22:21\]](#) SPIENSLV bit field any of the SPIEN[x] signals can be used to select the McSPI module. In slave mode and when the [MCSPI_MODULCTRL\[1\]](#) PIN34 is set to 0x0 (default behavior), the McSPI uses the edge of SPIEN[x] to detect word length. For this reason, SPIEN[x] must become inactive between each word.

When the [MCSPI_MODULCTRL\[1\]](#) PIN34 is set to 0x0, the McSPI does not support SPIEN[x] active between SPI words. In this case, the McSPI uses the edge to detect word length.

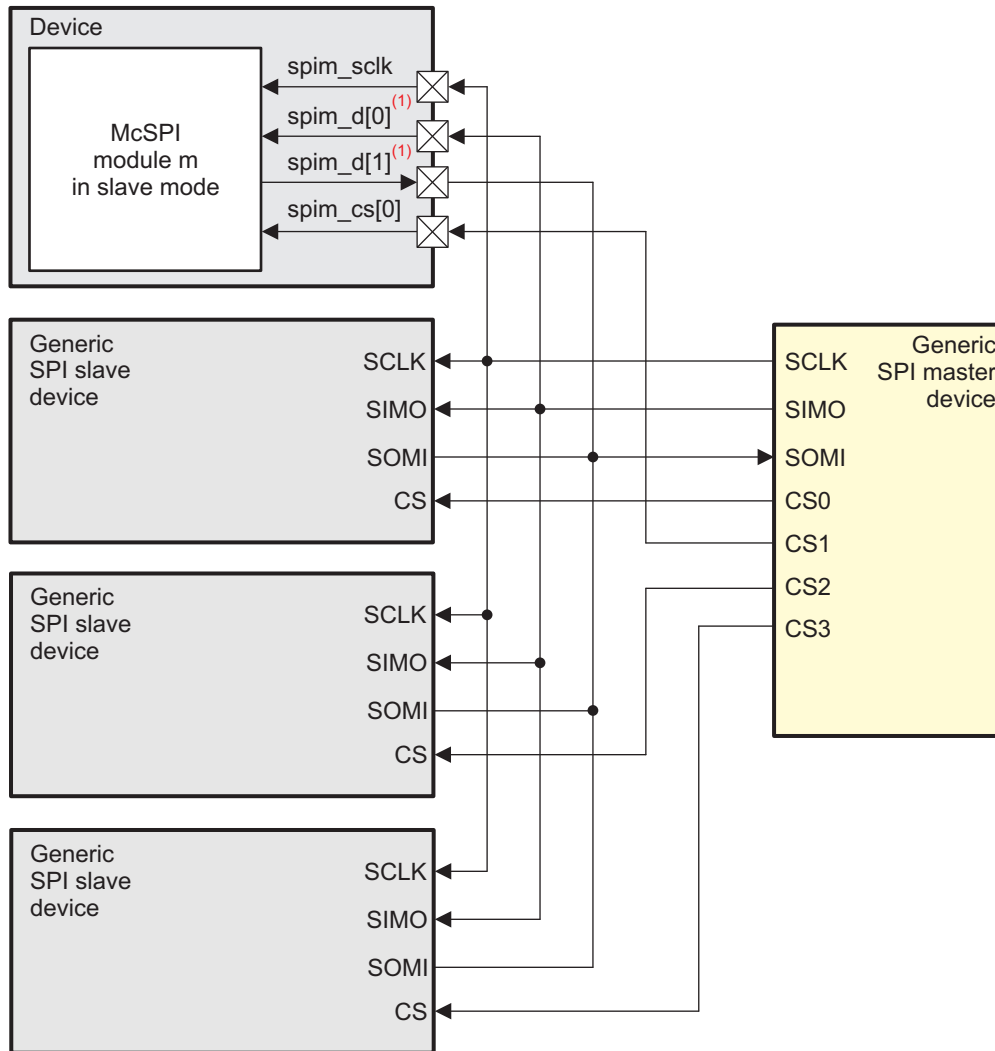

When the [MCSPI_MODULCTRL\[1\]](#) PIN34 is set to 0x1, a multiword transfer can be performed without needing the external SPI master to deactivate SPIEN[x] between each word as in this case the McSPI module works in 3-pin slave mode and SPIEN[x] is not needed.

19.3.4.4.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section, register names such as [SPI1.MCSPI_CHxCTRL](#) stand for [SPI1.MCSPI_CH0CTRL](#), where x = 0 (channel 0 control register).

[Figure 19-58](#) shows an example of four slaves wired on a single master device.

Figure 19-58. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

(1) Direction depends on bits IS, DPE1 and DPE0 in MCSPI_CHxCONF

mcspl-017

Channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the [MCSPI_CHxCTRL\[0\] EN](#) bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any of the [SPIEN\[x\]](#) ports. This is programmable with the [MCSPI_CHxCONF\[22:21\] SPIENSLV](#) bit field (where x = 0).
- Its own transmitter register, [MCSPI_TXx](#) (where x = 0), on top of the common transmit shift register. If the [MCSPI_TXx](#) register is empty, the [MCSPI_CHxSTAT\[1\] TXS](#) bit (where x = 0) is set. If McSPI is selected by an external master (the active signal on the [SPIEN\[x\]](#) port assigned to channel 0), the [MCSPI_TXx](#) register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The [MCSPI_TXx](#) register must be loaded before McSPI is selected by a master.
- Its own receiver register, [MCSPI_RXx](#) (where x = 0), on top of the common receive shift register. If the [MCSPI_RXx](#) register is full, the [MCSPI_CHxSTAT\[0\] RXS](#) bit (where x = 0) is set.

NOTE: The [MCSPI_TXx](#) and [MCSPI_RXx](#) registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the [MCSPI_CHxCONF](#) register (where x = 0):

- Transmit and receive modes, programmable with the TRM field
- Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPI modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
- SPI word length, programmable with the WL bits
- SPIEN[x] polarity, programmable with the EPOL bit
- SPICLK polarity, programmable with the POL bit
- SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The [MCSPI_CHxCONF\[5:2\] CLKD](#) bit field (where x = 0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the [MCSPI_CHxCONF](#) register (where x = 0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the [MCSPI_CHxCONF\[15\] DMAR](#) bit (where x = 0) for reading and the [MCSPI_CHxCONF\[14\] DMAW](#) bit (where x = 0) for writing.
- Four interrupt events (see [Section 19.3.4.7.2, Interrupt Events in Slave Mode](#))

19.3.4.4.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the [MCSPI_CHxCONF\[13:12\] TRM](#) bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the [MCSPI_TXx](#) register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The [MCSPI_TXx](#) register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the [MCSPI_CHxSTAT0\[2\] EOT](#) bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the [MCSPI_RXx](#) register (see [Section 19.3.4.7.2, Interrupt Events in Slave Mode](#)).

19.3.4.4.3 Slave Transmit-Only Mode

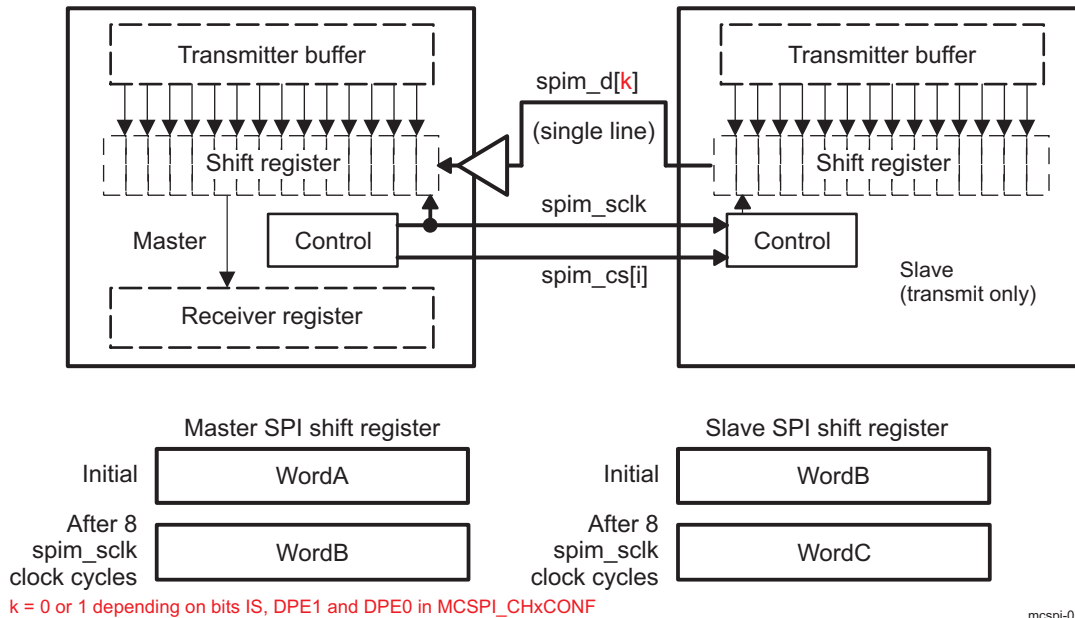

The slave transmit-only mode is programmable (set the [MCSPI_CHxCONF\[13:12\] TRM](#) bit field [where x = 0] to 0x2) and avoids the requirement for a device initiator to read the [MCSPI_RXx](#) register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the [MCSPI_RXx](#) register.

When the SPI word transfer completes, the [MCSPI_CHxSTAT\[2\] EOT](#) bit is set (where x = 0).

[Figure 19-59](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave, 1 bit transfers in the master. After eight cycles of the serial clock SPICLK, WordB transfers from the slave to the master.

Figure 19-59. SPI Half-Duplex Transmission (Transmit-Only Slave)

mcspi-031

19.3.4.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the `MCSPi_CHxCONF`[13:12] TRM bit field [where x = 0] to 0x1).

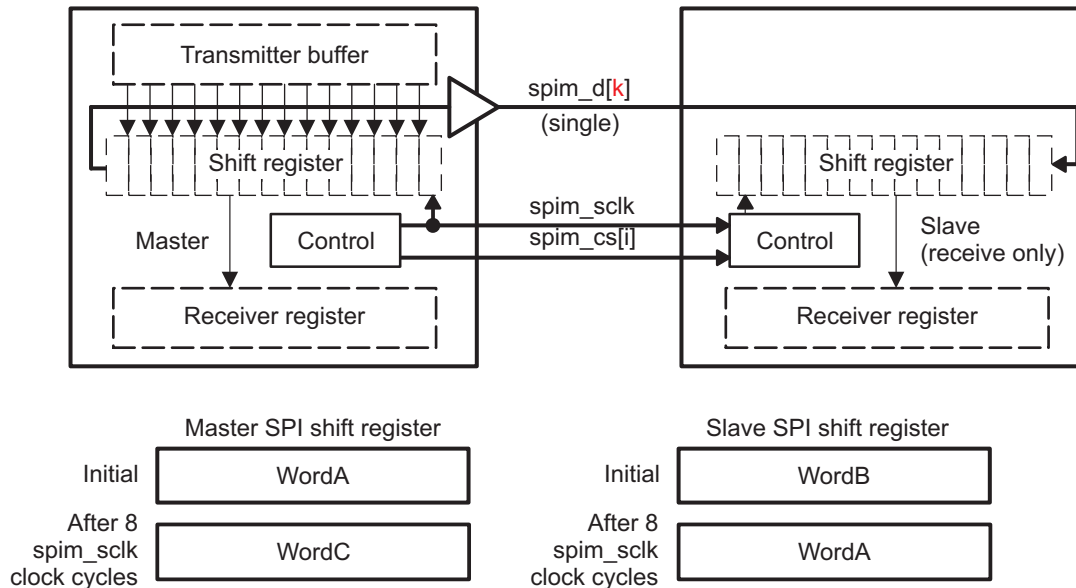

In receive-only mode, the `MCSPi_TXx` register must be loaded before the McSPI is selected by an external SPI master device. The `MCSPi_TXx` register content is always loaded into the shift register whether it is updated or not. The `TXx_UNDERFLOW` event is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the `MCSPi_CHxSTAT0`[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the `TXx_EMPTY` and `TXx_UNDERFLOW` interrupts and the DMA write requests must be disabled due to the state of the `MCSPi_TXx` register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 19-60 shows a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave.

Figure 19-60. SPI Half-Duplex Transmission (Receive-Only Slave)

`k = 0 or 1 depending on bits IS, DPE1 and DPE0 in MCSPI_CHxCONF`

mcspi-032

19.3.4.5 3-Pin or 4-Pin Mode

Depending on targeted application the SPI interface can be configured to use 3 or 4 pins through the `MCSPI_MODULCTRL[1]` PIN34 bit. If this bit is set to 0, McSPI is in 4-pin mode using the `SPICLK`, `SPIDAT[0]`, `SPIDAT[1]` and `SPIEN[x]` signals. If PIN34 is set to 1 the controller is in 3-pin mode and `SPIEN[x]` is not used. In this mode all options related to chip select management are useless (`EPOL`, `FORCE` and `TCS0` bits of `MCSPI_CHxCONF`). 3-pin and 4-pin operation applies to both master and slave modes.

19.3.4.6 FIFO Buffer Management

The McSPI controller has a built-in 128-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the `MCSPI_CHxCONF[28]` FFER or `MCSPI_CHxCONF[27]` FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

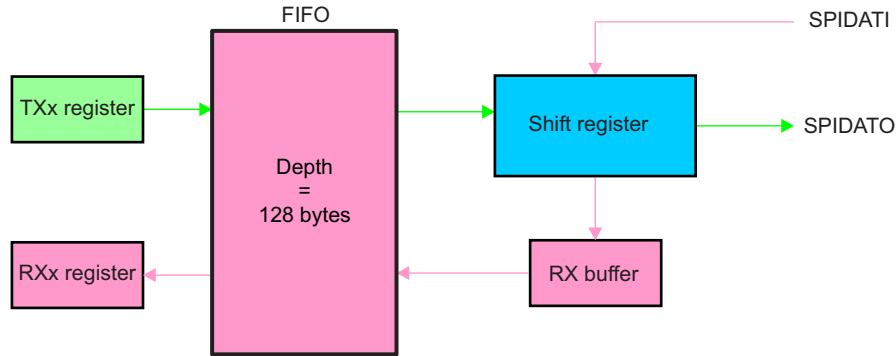

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (`MCSPI_CHxCONF[11:7]` WL) is supported.

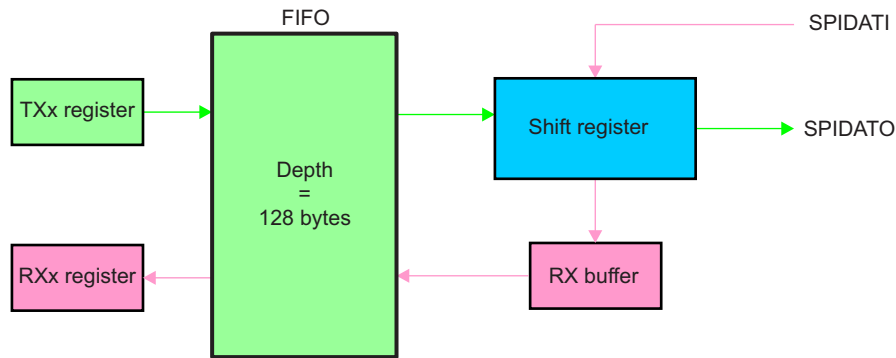

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 19-61](#)) or receive (see [Figure 19-62](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 19-63](#)).

Figure 19-61. Buffer Used in Transmit Direction Only

mcspi-102

Figure 19-62. Buffer Used in Receive Direction Only

mcspi-103

Figure 19-63. Buffer Used for Transmit and Receive Directions

mcspi-101

Two levels ([MCSPI_XFERLEVEL\[5:0\]](#) AEL and [MCSPI_XFERLEVEL\[13:8\]](#) AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in [MCSPI_CHXCONF\[11:7\]](#) WL. [Table 19-203](#) lists the number of bytes written in the FIFO, depending on the word length.

Table 19-203. FIFO Writes, Word Length Relationship

	SPI Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

19.3.4.6.1 Buffer Almost Full

The `MCSPi_XFERLEVEL[15:8]` AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the `MCSPi_CHxCONF[28]` FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 19-64.

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the `IRQ_CROSSBAR` and then to the desired `INTC` to enable the system to read `AFL + 1` bytes from the receive register.

NOTE: `AFL + 1` must correspond to a multiple value of the `MCSPi_CHxCONF[11:7]` WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

NOTE: The `MCSPi_IRQSTATUS` register bits are not available in DMA mode. In DMA mode, the `SPIm_DMA_RXx` request is asserted on the same conditions as the `MCSPi_IRQSTATUS` `Rxx_FULL` flag.

19.3.4.6.2 Buffer Almost Empty

The `MCSPi_XFERLEVEL[7:0]` AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the `MCSPi_CHxCONF[27]` FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 19-65.

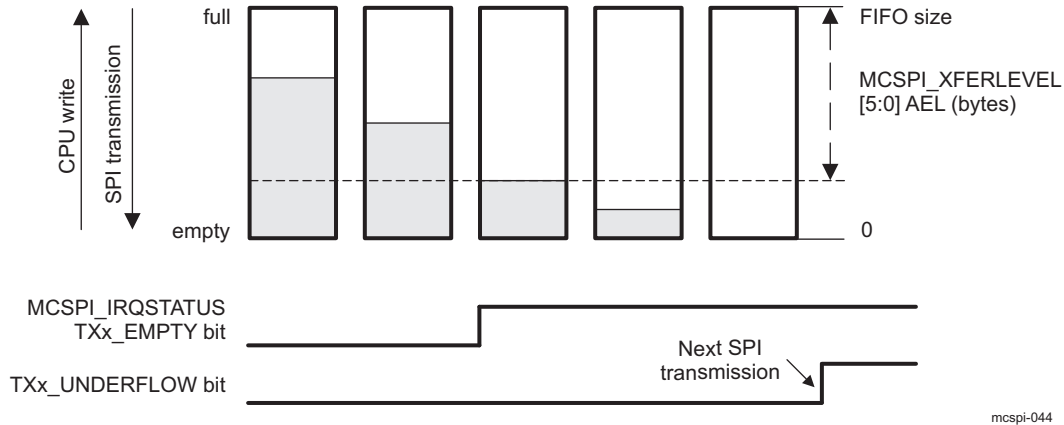

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the `IRQ_CROSSBAR` and then to the desired `INTC` to enable the system to write `AEL + 1` bytes to the transmit register.

NOTE: `AEL + 1` must correspond to a multiple value of the `MCSPi_CHxCONF[11:7]` WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

Figure 19-65. Buffer Almost Empty Level (AEL)

NOTE: The [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm_DMA_TXx](#) request is asserted on the same conditions as the [MCSPI_IRQSTATUS TXx_EMPTY](#) flag.

19.3.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the [MCSPI_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPI_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the [CHxSTAT\[5\] RXFFE](#) bit and read the [MCSPI_RXx](#) receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the [MCSPI_IRQSTATUS\[17\] EOW](#) bit is set), the user can disable the channel and poll the [MCSPI_CHxSTAT\[5\] RXFFE](#) bit to know the last SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

19.3.4.7 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the [MCSPI_IRQSTATUS](#) register ([RXx_FULL](#), [TXx_UNDERFLOW](#), [TXx_EMPTY](#), etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the [MCSPI_IRQENABLE](#) register ([RXx_FULL_ENABLE](#), [TXx_UNDERFLOW_ENABLE](#), [TXx_EMPTY_ENABLE](#), etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

19.3.4.7.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the state of the [MCSPI_TXx](#) register are [TXx_EMPTY](#) and [TXx_UNDERFLOW](#). The interrupt event related to the state of the [MCSPI_RXx](#) register is [RXx_FULL](#).

19.3.4.7.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 19.3.4.3.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as a device initiator has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. This device initiator must perform the correct number of writes.

19.3.4.7.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.1.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as a device initiator has not performed AFL + 1 reads into MCSPI_RXx. This device initiator must perform the correct number of reads.

19.3.4.7.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the state of the [MCSPI_TXx](#) register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the state of the [MCSPI_RXx](#) are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the [MCSPI_IRQSTATUS](#) register.

19.3.4.7.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the [MCSPI_CHxCONF\[27\]](#) FFEW bit is set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the [MCSPI_IRQSTATUS](#) TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as a device initiator has not performed the number of writes into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field. This device initiator must perform the correct number of writes.

19.3.4.7.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the [MCSPI_TXx](#) register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the [MCSPI_TXx](#) register because the channel is enabled.

The [MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the [MCSPI_RXx](#) register is being filled (transient event). When the FIFO buffer is enabled (the [MCSPI_CHxCONF\[28\]](#) FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the [MCSPI_XFERLEVEL\[13:8\]](#) AFL bit field.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the [MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as a device initiator has not performed AFL + 1 reads into [MCSPI_RXx](#). This device initiator must perform the correct number of reads.

19.3.4.7.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the [MCSPI_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in slave mode.

The [MCSPI_IRQSTATUS](#)[3] `RX0_OVERFLOW` interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.2.5 End Of Word Count

The [MCSPI_IRQSTATUS](#)[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the [MCSPI_XFERLEVEL](#)[31:16] `WCNT` bit field. If `WCNT` is set to `0x0000`, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as `WCNT` is not reloaded and the channel is not re-enabled.

The [MCSPI_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the [MCSPI_IRQENABLE](#) register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the following must be performed:

1. Read the [MCSPI_IRQSTATUS](#) register to identify which event occurred.
2. Read the [MCSPI_RXx](#) register that corresponds to the event to remove the source of an `RXx_FULL` event or write into the [MCSPI_TXx](#) register that corresponds to the event to remove the source of a `TXx_EMPTY` event. No action is required to remove the source of the `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW` events.
3. Set the corresponding bit of the [MCSPI_IRQSTATUS](#) register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

19.3.4.7.4 Polling

When the interrupt capability of an event is disabled in the [MCSPI_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the [MCSPI_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- `RXx_FULL`: To remove the source of the event, the corresponding [MCSPI_RXx](#) register must be read.
- `TXx_EMPTY`: To remove the source of the event, it must be written into the corresponding [MCSPI_TXx](#) register.
- `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW`: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the [MCSPI_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

19.3.4.8 DMA Requests

Each McSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the `SPI1.MCSPI_CHxCONF`[15] `DMAR` bit. The DMA read request line is deasserted when reading of the [MCSPI_RXx](#) register of the McSPI channel completes.

The DMA write request line is asserted when the McSPI channel is enabled and the [MCSPI_TXx](#) register of the McSPI channel is empty. A DMA write request can be individually masked with the [SPI1.MCSPI_CHxCONF\[14\]](#) DMAW bit. The DMA write request line is deasserted when loading of the [MCSPI_TXx](#) register of the channel completes.

19.3.4.9 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

19.3.4.9.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The [MCSPI_SYSCONFIG\[0\]](#) AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

19.3.4.9.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the [PER_48M_GFCLK](#) or [L4PER_L3_GICLK](#) output clock, the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM IDLE request is configurable through the [MCSPI_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the [MCSPI_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field is set to 0x0): The McSPI module acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The McSPI never acknowledges an IDLE request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The McSPI acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the McSPI also offers an additional granularity on the [PER_48M_GFCLK](#) and [L4PER_L3_GICLK](#) gating. The [MCSPI_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field determines which clock shuts down (the [PER_48M_GFCLK](#), [L4PER_L3_GICLK](#), neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the McSPI to determine on which part of the module the conditions to acknowledge the PRCM IDLE request are tested. For example, if [PER_48M_GFCLK](#) is not shut down on a PRCM IDLE request, the McSPI considers only [L4PER_L3_GICLK](#) and the associated pending activities before acknowledging the request.

Some McSPI features are associated with L4PER_L3_GICLK and others with PER_48M_GFCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the McSPI acknowledges an IDLE request.

The settings of the CLOCKACTIVITY bit field and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM IDLE request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM IDLE request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM IDLE request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the McSPI can potentially acknowledge the IDLE request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the PER_48M_GFCLK and L4PER_L3_GICLK control bits in the PRCM module. If the McSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

19.3.4.9.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the [MCSPI_SYSCONFIG\[2\]](#) ENAWAKEUP and [MCSPI_WAKEUPENABLE\[0\]](#) WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wakeup is requested when channel 0 is enabled and an asynchronous selection occurs on the mcs pim.csx port associated with channel 0 (see the definition for the [MCSPI_CHxCONF\[22:21\]](#) SPIENSLV bit field [where x = 0] in the register table description).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the [MCSPI_RXx](#) register (where x = 0) before the completion of the second SPI word serialization.

[Table 19-204](#) lists the supported cases in smart-idle mode.

Table 19-204. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the SPIEN[x] port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

19.3.4.9.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the [MCSPI_IRQSTATUS](#)[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the [MCSPI_IRQENABLE](#)[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the [MCSPI_IRQENABLE](#) and [MCSPI_WAKEUPENABLE](#) registers. Software must ensure the overall consistency.

The interrupt status register [MCSPI_IRQSTATUS](#) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

19.3.4.9.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the [MCSPI_SYSCONFIG](#)[4:3] SIDLEMODE bit field is set to 0x0.
 - In force-idle mode, the McSPI responds unconditionally to the IDLE request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the [MCSPI_SYSCONFIG](#)[2] ENAWAKEUP and [MCSPI_WAKEUPENABLE](#)[0] WKEN bits are set.
 - The transition from normal mode to idle mode does not affect the interrupt event bits of the [MCSPI_IRQSTATUS](#) register.
 - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.
 - An IDLE request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

19.3.5 McSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the McSPI module.

19.3.5.1 Global Initialization

19.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McSPI. For further information, see [Section 19.3.3, McSPI Integration](#) and [Section 19.3.2, McSPI Environment](#).

[Table 19-205](#) lists the information on the global initialization of the surrounding modules.

Table 19-205. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See Section 3.1.1.1.2, Module-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management .
L4 Interconnect	For information about L4_PER1 interconnect configuration, see Section 10.3, L4 Interconnects , in Chapter 10, Interconnect .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 14.4.6.5, DMA_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
EDMA	EDMA configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 13 Interrupt Controllers .

19.3.5.1.2 McSPI Global Initialization

19.3.5.1.2.1 Main Sequence – McSPI Global Initialization

The procedure in [Table 19-206](#) can be used to initialize McSPI when performing software reset.

Table 19-206. McSPI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPI_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	MCSPI_SYSSTATUS[0] RESETDONE	=1
Configure static settings (such as SPI master or slave) as required.	MCSPI_MODULCTRL[8:0]	0x-
Write MCSPI_SYSCONFIG	MCSPI_SYSCONFIG	0x-

19.3.5.2 Operational Mode Configuration

19.3.5.2.1 McSPI Operational Modes

The selection of the working mode is done with the [MCSPI_CHxCONF](#) register.

Table 19-207. McSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHxCONF [13:12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 19-208. McSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPI_CHxCONF [13:12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 19-209. McSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPI_CHxCONF [13:12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

19.3.5.2.1.1 Common Transfer Sequence

McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[x] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

[Table 19-210](#) represents the main sequence which is common to all transfers.

In multi-channel master mode, the sequences of different channels can be run simultaneously.

Table 19-210. Common Transfer Sequence (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	0x-
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPI_TXx	0x-
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL [0] EN	0

19.3.5.2.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. [Table 19-211](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 19-211. End of Transfer Sequences

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
MASTER Normal	End of transfer sequence	See Section 19.3.5.2.1.3		See Section 19.3.5.2.1.4.1	See Section 19.3.5.2.1.4.2	See Section 19.3.5.2.1.5.1	See Section 19.3.5.2.1.5.2
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
MASTER Turbo	End of transfer sequence	See Section 19.3.5.2.1.3		See Section 19.3.5.2.1.4.1	See Section 19.3.5.2.1.4.2	See Section 19.3.5.2.1.6.1	See Section 19.3.5.2.1.6.2
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
SLAVE	End of transfer sequence	See Section 19.3.5.2.1.3		See Section 19.3.5.2.1.4.1	See Section 19.3.5.2.1.4.2	See Section 19.3.5.2.1.7	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = 0
- read_count = 0
- channel_enable = FALSE
- last_transfer = FALSE
- last_request = FALSE

They are initialized before starting the channel.

19.3.5.2.1.3 Transmit-and-Receive (Master and Slave)

If the requests are configured in DMA, write_count and read_count are assigned with 'N' when the DMA handlers have completed their 'N' OCP accesses.

Table 19-212. Transmit-and-Receive (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait for write_count = N AND read_count = N		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 19-213. Transmit-and-Receive (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
IF: TXx_EMPTY		
Write the transmitter register with data	MCSPI_TXx	0x-
Increment write_count +1		
IF: RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

19.3.5.2.1.4 Transmit-Only (Master and Slave)

19.3.5.2.1.4.1 Based on Interrupt Requests

Table 19-214. Transmit-Only With Interrupts (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT [2] EOT	=1
Stop the channel	MCSPI_CHxCTRL [0] EN	0

Table 19-215. Transmit-Only With Interrupts (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
IF: TXx_EMPTY AND write_count < N		
Write the transmitter register with data	MCSPI_TXx	0x-
Increment write_count +1		
ELSEIF: write_count ≥ N		
last_transfer = TRUE		
ENDIF		

19.3.5.2.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its 'N' OCP accesses, write_count is assigned with 'N'.

Table 19-216. Transmit-Only With DMA (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPI_CHxCONF [14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT [2] EOT	=1
Stop the channel	MCSPI_CHxCTRL [0] EN	0

Table 19-217. Transmit-Only With DMA (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
IF: TXx_EMPTY AND write_count = N		
last_transfer = TRUE		
ENDIF		

19.3.5.2.1.5 Master Normal Receive-Only

19.3.5.2.1.5.1 Based on Interrupt Requests

Table 19-218. Receive-Only With Interrupt (Master Normal) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait until last_request = TRUE		
Stop the channel	MCSPI_CHxCTRL [0] EN	0
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		

Table 19-219. Receive-Only With Interrupt (Master Normal) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
IF: RXx_FULL AND read_count = N - 1		
last_request = TRUE		
ELSEIF: read_count ≠ N - 1		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

19.3.5.2.1.5.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-1' OCP accesses, read_count is assigned with 'N-1'.

Table 19-220. Receive-Only With DMA (Master Normal) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait until read_count = N - 1		
Disable DMA read request	MCSPI_CHxCONF [15] DMAR	0
Wait until last_transfer = TRUE		
Stop the channel	MCSPI_CHxCTRL [0] EN	0
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		

Table 19-221. Receive-Only With DMA (Master Normal) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
IF: RXx_FULL AND read_count = N		
last_transfer = TRUE		
ENDIF		

19.3.5.2.1.6 Master Turbo Receive-Only

19.3.5.2.1.6.1 Based on Interrupt Requests

Table 19-222. Receive-Only With Interrupt (Master Turbo) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait until channel_enable = TRUE		
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT [2] EOT	=1
Stop the channel	MCSPI_CHxCTRL [0] EN	0
Wait until channel_enable = FALSE		

Table 19-223. Receive-Only With Interrupt (Master Turbo) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS [channel x bits]	0b1111
IF: RXx_FULL		
IF: read_count = N - 2		
last_transfer = TRUE		
Wait until channel_enable = FALSE		
ENDIF		
IF: read_count < N		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		
ENDIF		

19.3.5.2.1.6.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-2' OCP accesses read_count is assigned with 'N-2'.

Table 19-224. Receive-Only With DMA (Master Turbo) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL [0] EN	1
Wait until channel_enable = TRUE		
Wait until read_count = TRUE		
Disable DMA read request	MCSPI_CHxCONF [15] DMAR	0

Table 19-224. Receive-Only With DMA (Master Turbo) (Main Process) (continued)

Step	Register/Bit Field/Programming Model	Value
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel	MCSPI_CHxCTRL[0] EN	0
Wait until channel_enable = FALSE		

Table 19-225. Receive-Only With DMA (Master Turbo) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: RXx_FULL		
IF: read_count = N - 2		
last_transfer = TRUE		
Wait until channel_enable = FALSE		
ENDIF		
IF: read_count < N		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		
ENDIF		

19.3.5.2.1.7 Slave Receive-Only

If the requests are configured in DMA, read_count is assigned with 'N' when the DMA handler has completed its 'N' OCP accesses.

Table 19-226. Receive-Only (Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until read_count = N		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 19-227. Receive-Only (Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

19.3.5.2.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see [Section 19.3.4.6, FIFO Buffer Management](#).

Table 19-228. FIFO Mode Common Sequence (Master) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS	1
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	1
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Write MCSPI_XFERLEVEL	MCSPI_XFERLEVEL	0x-
Start the channel	MCSPI_CHxCTRL[0] EN	1
IF: Receive only		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPI_TXx	0x-
ENDIF		
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

19.3.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in [Section 19.3.5.2.1.8, Transfer Procedures With FIFO](#).

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel ([MCSPI_CHxCONF\[28\] FFER](#) and [MCSPI_CHxCONF\[27\] FFEW](#) bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Slave mode, the channel 0 only can be activated. The correct SPIEN line is chosen in [MCSPI_CHxCONF\[22:21\] SPIENSLV](#) bits (where x = 0).

The McSPI module can start the transfer only when the first write request has been released by writing the [MCSPI_TXx](#) register, even in receive-only mode (only one write request occurs in this case).

19.3.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

[Table 19-229](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 19-229. End of Transfer Sequences in FIFO Mode

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See Figure 19-66	See Figure 19-68	See Figure 19-69
No	See Figure 19-67	See Figure 19-68	See Figure 19-70

The end of transfer sequences are described from the start of the channel.

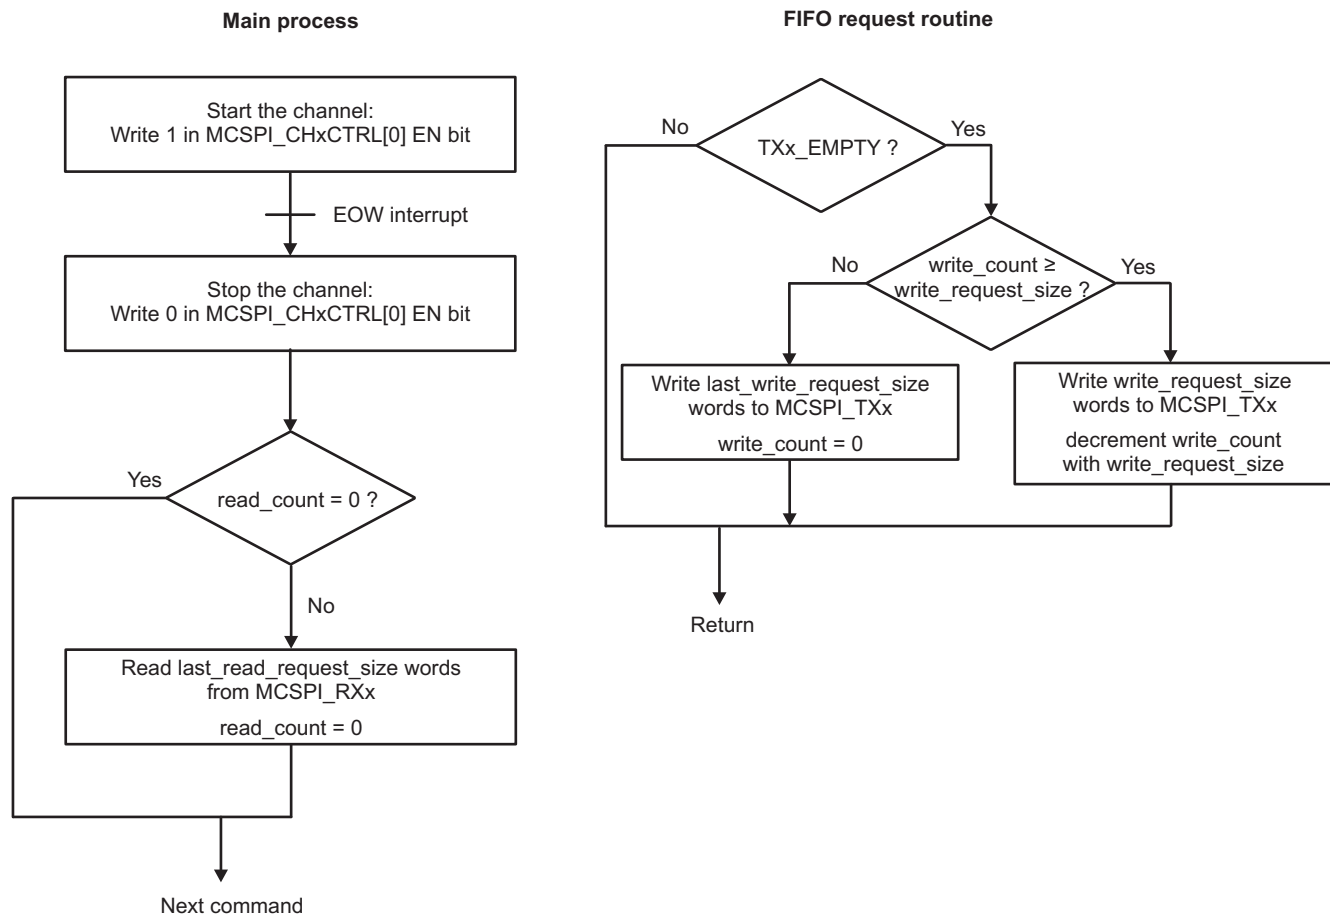

In these sequences, some soft variables are used:

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

19.3.5.2.1.8.3 Transmit-and-Receive With Word Count

Figure 19-66 shows the flow of a transfer in transmit-and-receive mode, with word count.

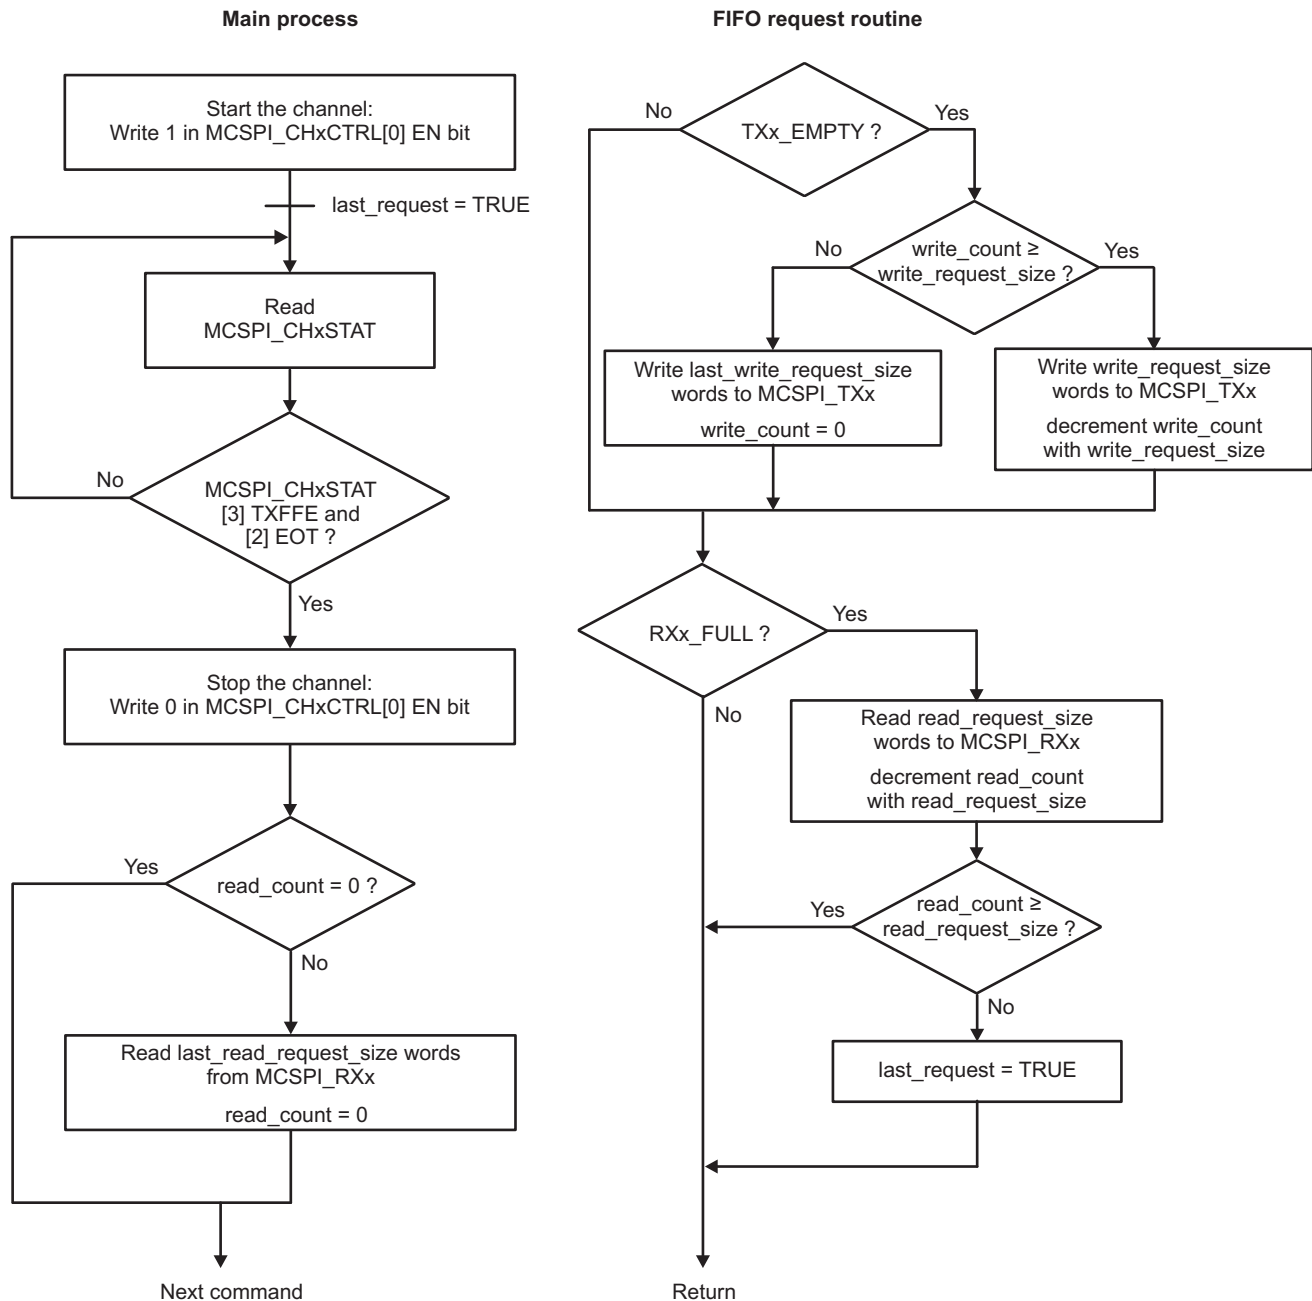

mcspi-045

Figure 19-66. FIFO Mode Transmit-and-Receive With Word Count (Master)

19.3.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 19-67 shows the flow of a transfer in transmit-and-receive mode, without word count.

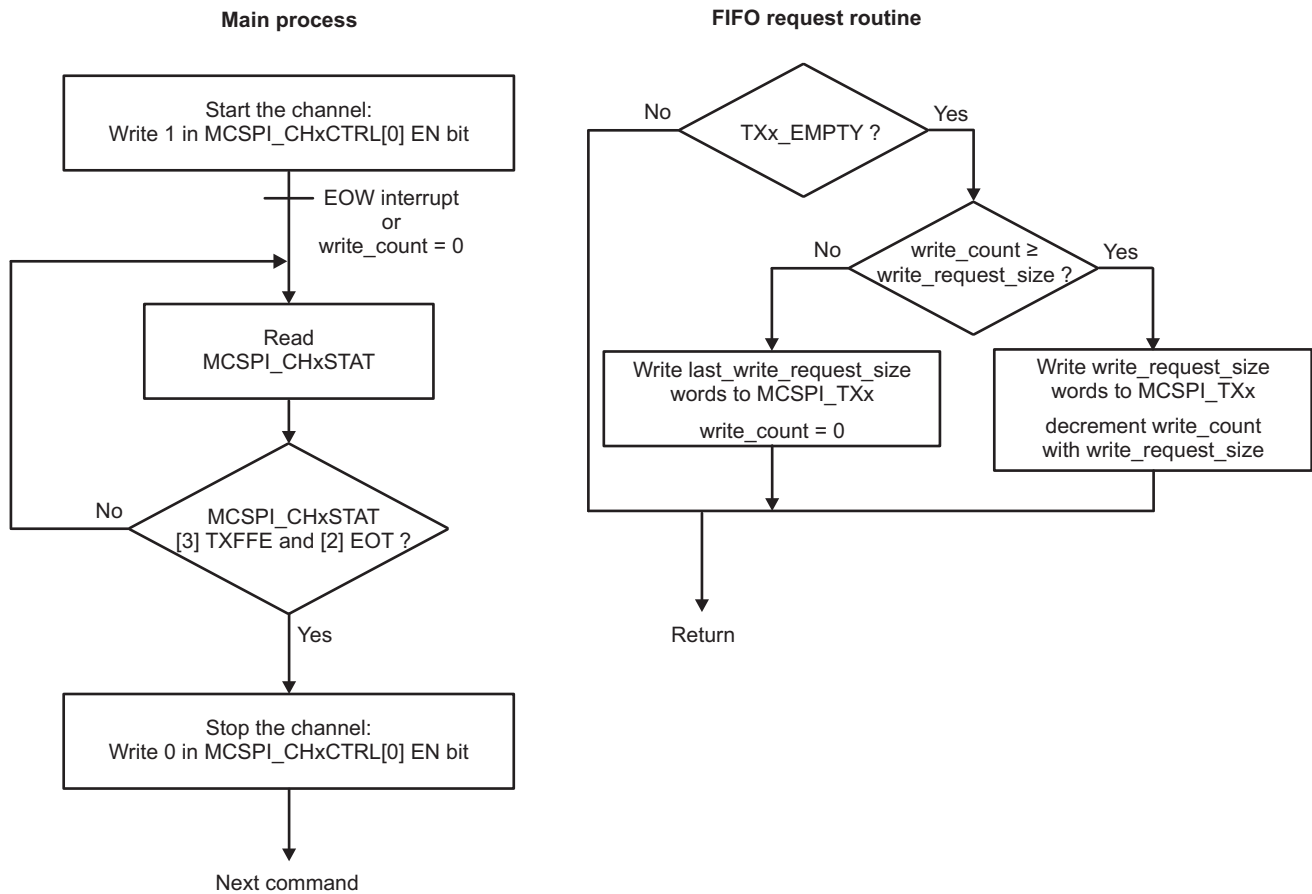

mcspi-046

Figure 19-67. FIFO Mode Transmit-and-Receive Without Word Count (Master)

19.3.5.2.1.8.5 Transmit-Only

Figure 19-68 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write_count = 0

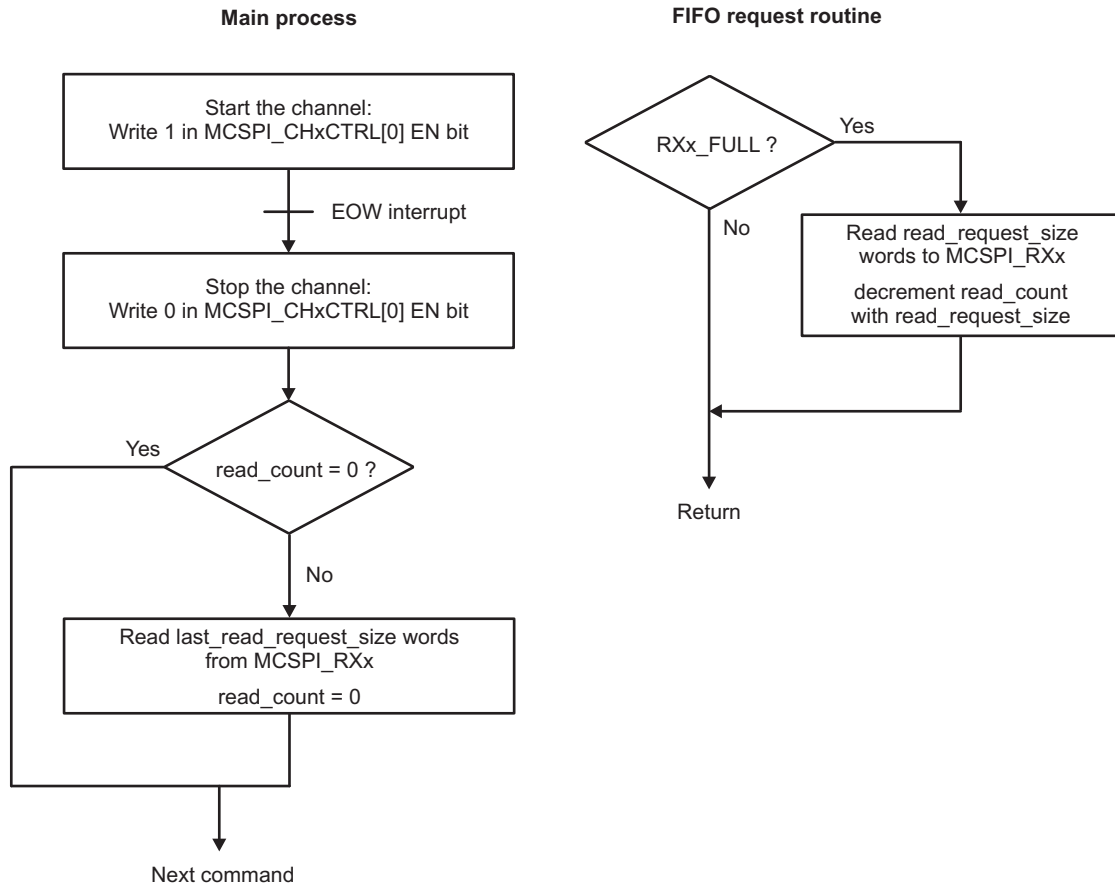

mcspi-047

Figure 19-68. FIFO Mode Transmit-Only (Master)

19.3.5.2.1.8.6 Receive-Only With Word Count

Figure 19-69 shows the flow of a transfer in receive-only mode, with word count.

19.3.5.3 Common Transfer Procedures Without FIFO – Polling Method

19.3.5.3.1 Receive-Only Procedure – Polling Method

Table 19-230 lists the receive-only procedure using the polling method.

Table 19-230. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 19-207.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1

Table 19-230. Receive-Only Procedure – Polling Method (continued)

Step	Register/Bit Field/Programming Model	Value
Wait for end-of-transfer.	MCSPi_CHxSTAT[2] EOT	=1
Read the receiver register.	MCSPi_RXx	0x-
Stop the channel if no more data is expected.	MCSPi_CHxCTRL[0] EN	0

19.3.5.3.2 Receive-Only Procedure – Interrupt Method

Table 19-231 lists the receive-only procedure using the interrupt method.

Table 19-231. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-207.	
Start the channel.	MCSPi_CHxCTRL[0] EN	1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPi_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPi_CHxCTRL[0] EN	0
Read the receiver register.	MCSPi_RXx	0x-

19.3.5.3.3 Transmit-Only Procedure – Polling Method

Table 19-232 lists the transmit-only procedure using the polling method.

Table 19-232. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-208	
Start the channel.	MCSPi_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPi_TXx	0x-
Wait until end of transfer?	MCSPi_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0

19.3.5.3.4 Transmit-and-Receive Procedure – Polling Method

Table 19-233 lists the transmit-and-receive procedure using the polling method.

Table 19-233. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-209.	
Start the channel.	MCSPi_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPi_TXx	0x-
Wait until transmit/receive word?	MCSPi_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0
Read the receiver register.	MCSPi_RXx	0x-

19.3.6 McSPI Register Manual

19.3.6.1 McSPI Instance Summary

Table 19-234. McSPI Instance Summary

Module Name	Base Address	Size
McSPI1	0x4809 8000	4 KiB

Physical Address	0x4809 8010 0x4809 A010 0x480B 8010 0x480B A010	Instance	McSPI1 McSPI2 McSPI3 McSPI4
Description	Clock management configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	FREEEMU	SOFTRESET	

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0000000
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's IDLE state follows (acknowledges) the system's IDLE requests unconditionally, that is, regardless of the module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the module's internal requirements. Module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module "swake-up" output(s) is (are) implemented.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. 0x0: Module is sensitive to emulation suspend. 0x1: Module is not sensitive to emulation suspend.	RW	0

Bits	Field Name	Description	Type	Reset
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset	RW	0

Table 19-244. MCSPI_SYSCONFIG

Address Offset	0x110		
Physical Address	0x4809 8110 0x4809 A110 0x480B 8110 0x480B A110	Instance	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register allows controlling various parameters of the configuration interface and is not affected by software reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY	RESERVED	SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE										

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads return 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: Interface and functional clocks may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. Interface clock may be switched off. 0x3: Interface and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the [2] ENAWAKEUP bit is set. 0x1: If an IDLE request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an IDLE request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit [2] ENAWAKEUP is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface clock gating strategy is applied, based on the interface activity.	RW	1

Address Offset	0x124		
Physical Address	0x4809 8124 0x4809 A124 0x480B 8124 0x480B A124	Instance	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device I/O pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	SPIEN_2	SPIEN_1	SPIEN_0				

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If [10] SPIENDIR = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this bit.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If [9] SPIDATDIR1 = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this bit. If [9] SPIDATDIR1 = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0

Bits	Field Name	Description	Type	Reset
4	SPIDAT_0	SPIDAT[0] line (signal data value) If [8] SPIDATDIR0 = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this bit. If [8] SPIDATDIR0 = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0
3	SPIEN_3	SPIEN[3] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[3] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[2] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[1] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[0] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

Table 19-255. Register Call Summary for Register MCSPI_SYST

Multichannel Serial Peripheral Interface

- [McSPI Register Summary: \[0\]](#)

Table 19-256. MCSPI_MODULCTRL

Address Offset	0x128	Instance	McSPI1
Physical Address	0x4809 8128 0x4809 A128 0x480B 8128 0x480B A128		McSPI2 McSPI3 McSPI4
Description	This register is dedicated to the configuration of the serial peripheral interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																FDAA	MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000
8	FDAA	<p>FIFO DMA address 256-bit aligned</p> <p>This bit is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TXx and MCSPI_RXx registers.</p> <p>0x0: FIFO data managed by MCSPI_TXx and MCSPI_RXx registers.</p> <p>0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.</p>	RW	0
7	MOA	<p>Multiple word interface access: this bit can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit interface word access. This is possible for WL < 16.</p> <p>0x0: Multiple word access disabled</p> <p>0x1: Multiple word access enabled with FIFO</p>	RW	0
6:4	INITDLY	<p>Initial SPI delay for first transfer: this field is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period.</p> <p>0x0: No delay for first spi transfer.</p> <p>0x1: The controller wait 4 SPI bus clock</p> <p>0x2: The controller wait 8 SPI bus clock</p> <p>0x3: The controller wait 16 SPI bus clock</p> <p>0x4: The controller wait 32 SPI bus clock</p>	RW	0x0
3	SYSTEM_TEST	<p>Enables the system test mode</p> <p>0x0: Functional mode</p> <p>0x1: System test mode (SYSTEST)</p>	RW	0
2	MS	<p>Master/slave</p> <p>0x0: Master - The module generates the SPICLK and SPIEN[3:0].</p> <p>0x1: Slave - The module receives the SPICLK and SPIEN[3:0].</p>	RW	1
1	PIN34	<p>Pin mode selection:</p> <p>This bit is used in master or slave mode to configure the SPI pin mode (3-pin or 4-pin). If asserted the controller only uses SIMO, SOMI, and SPICLK clock pin for SPI transfers.</p> <p>0x0: SPIEN is used as a chip-select.</p> <p>0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.</p>	RW	0
0	SINGLE	<p>Single channel/Multi Channel (master mode only)</p> <p>0x0: More than one channel will be used in master mode.</p> <p>0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN[x] mode.</p>	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity this bit defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHxCTRL[15:8] EXTCLK must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of [5:2] CLKD and MCSPI_CHxCTRL[15:8] EXTCLK values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0

Bits	Field Name	Description	Type	Reset
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by bit [24] SBPOL	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when [6] EPOL=0, and drives it high when [6] EPOL=1. 0x1: Writing 1 into this bit drives high the SPIEN line when [6] EPOL=0, and drives it low when [6] EPOL=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0
15	DMAR	DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0
14	DMAW	DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0

Bits	Field Name	Description	Type	Reset

19.4 Quad Serial Peripheral Interface

19.4.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. [Figure 19-71](#) shows the QSPI module overview.

Figure 19-71. QSPI Overview

The QSPI supports the following features:

- General SPI features:
 - Programmable clock divider
 - Six pin interface
 - Programmable length (from 1 to 128 bits) of the words transferred
 - Programmable number (from 1 to 4096) of the words transferred
 - 4 external chip-select signals
 - Support for 3-, 4-, or 6-pin SPI interface
 - Optional interrupt generation on word or frame (number of words) completion
 - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
 - Programmable signal polarities
 - Programmable active clock edge
 - Software-controllable interface allowing for any type of SPI transfer
 - Control through L3_MAIN configuration port
- Serial flash interface (SFI) features:
 - Serial flash read/write interface
 - Additional registers for defining read and write commands to the external serial flash device
 - 1 to 4 address bytes
 - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
 - Dual read support

- Quad read support
- Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)
- Linear increment addressing mode only

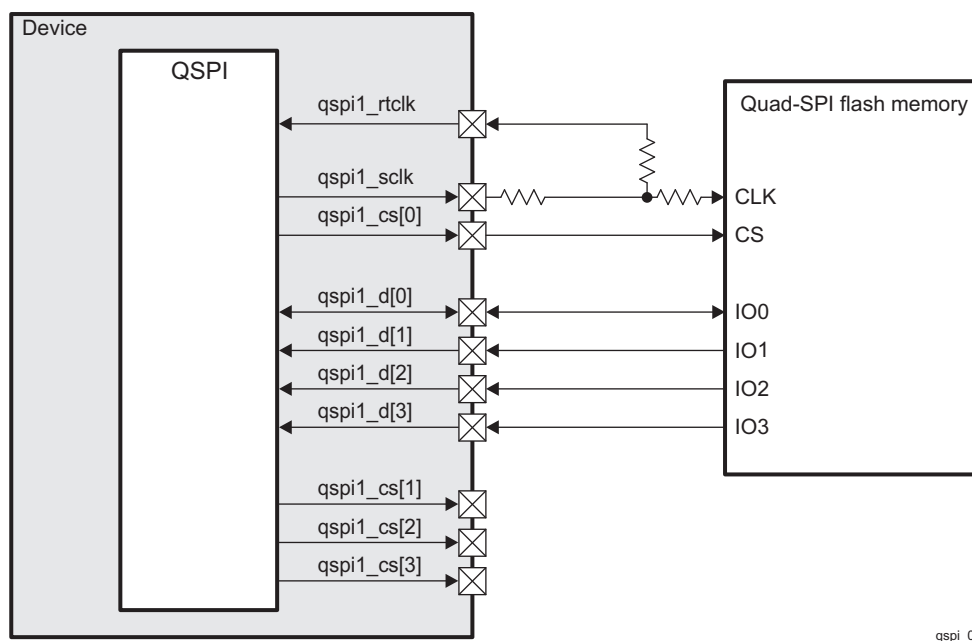

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

NOTE: The QSPI module does not support cache line wrap mode.

19.4.2 QSPI Environment

Figure 19-72 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

Figure 19-72. QSPI Connected to an External Quad-SPI Flash Memory

qspi_002

Table 19-274 lists and describes the QSPI I/O signals.

Table 19-274. QSPI I/O Signals

QSPI Signal/Pad name	I/O ⁽¹⁾	Description					
		3-pin ⁽²⁾ SPI Read (Single Read)	3-pin ⁽²⁾ SPI Write (Single Write)	4-pin ⁽²⁾ SPI Read (Single Read)	4-pin ⁽²⁾ SPI Write (Single Write)	4-pin ⁽²⁾ SPI Read (Dual Read)	6-pin ⁽²⁾ SPI Read (Quad Read)
qspi1_d[0]	IO	Used as SPI data input	Used as SPI data output	Not used	Used as SPI data output	Used as SPI data input 0	Used as SPI data input 0

qspi1_d[2]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 2
qspi1_d[3]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 3
qspi1_sclk	O	Clock for the external SPI device					
qspi1_cs[0]	O	External SPI device chip-select 0					
qspi1_cs[1]	O	External SPI device chip-select 1					
qspi1_cs[2]	O	External SPI device chip-select 2					
qspi1_cs[3]	O	External SPI device chip-select 3					
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

⁽¹⁾ I = Input; O = Output

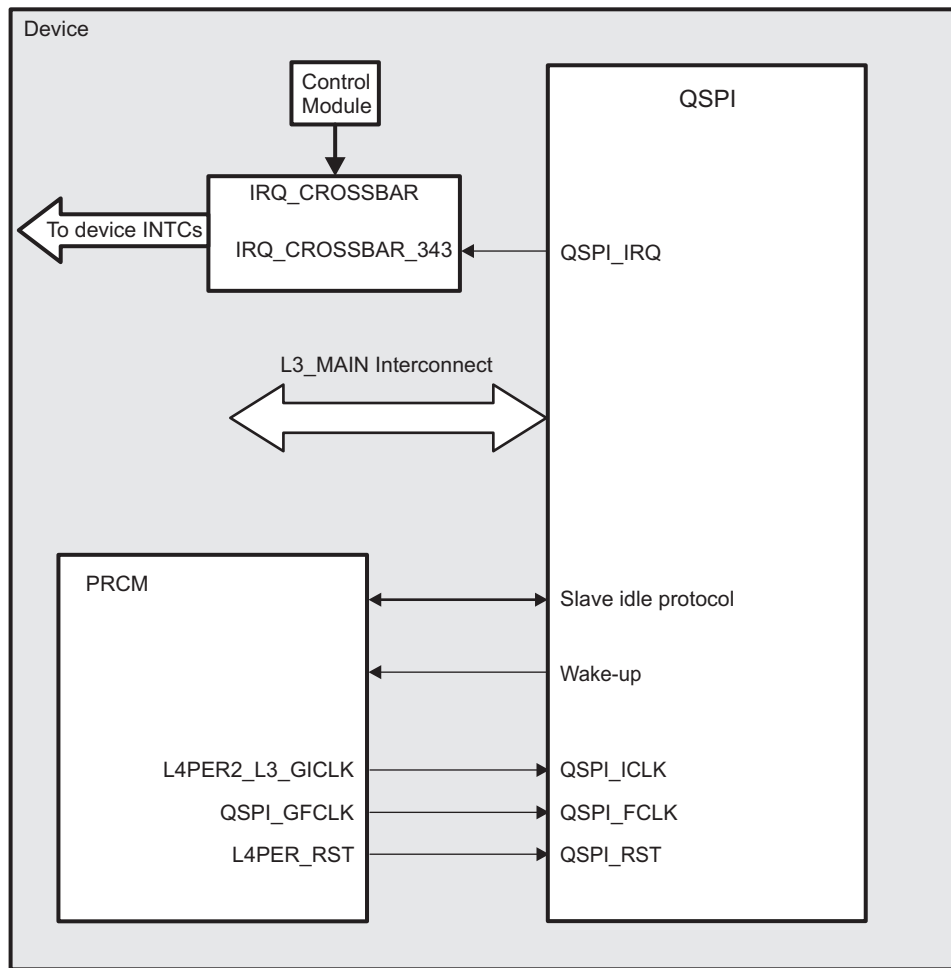

⁽²⁾ This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

NOTE: In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

19.4.3 QSPI Integration

Figure 19-73 shows the integration of the QSPI module in the device.

Figure 19-73. QSPI Integration

qspi_003

Table 19-275 through Table 19-277 summarize the integration of the QSPI in the device.

Table 19-275. QSPI Integration Attributes

Module Instance	Attributes

Table 19-277. QSPI Hardware Requests

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination	Default Mapping	
		IRQ_CROSSBAR Input		
QSPI	QSPI_IRQ	IRQ_CROSSBAR_343	–	QSPI interrupt request

NOTE: The Default Mapping column in [Table 19-277](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller (INTC) through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device INTCs, see [Chapter 13, Interrupt Controllers](#).

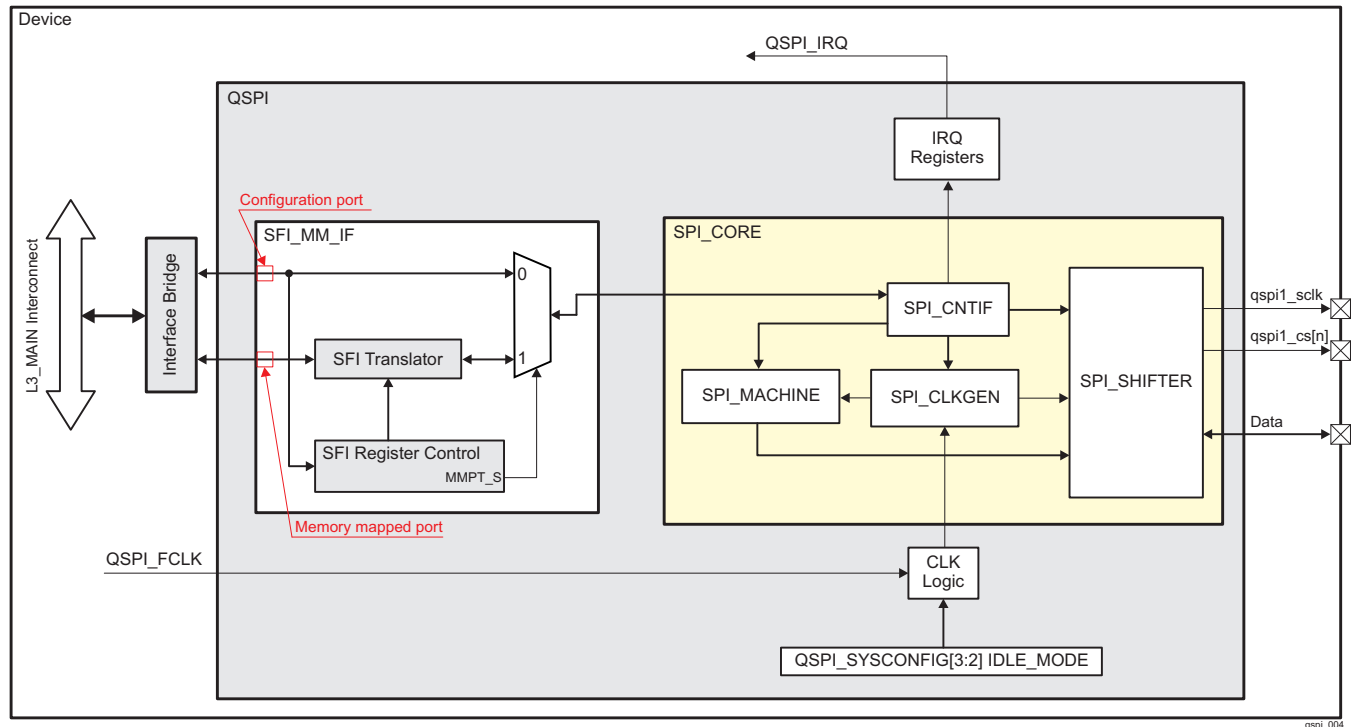

NOTE: For the description of the interrupt source, see [Section 19.4.4.3, QSPI Interrupt Requests](#).

19.4.4 QSPI Functional Description

19.4.4.1 QSPI Block Diagram

Initial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. [Figure 19-74](#) shows the QSPI block diagram.

Figure 19-74. QSPI Block Diagram

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

NOTE: The SFI_MM_IF block only allows reading and writing to an externally connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

19.4.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- [QSPI_SPI_SETUP0_REG](#)
- [QSPI_SPI_SETUP1_REG](#)
- [QSPI_SPI_SETUP2_REG](#)
- [QSPI_SPI_SETUP3_REG](#)
- [QSPI_SPI_SWITCH_REG](#)

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUP_i_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUP_i_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the

QSPI_SPI_SETUP_i_REG[9:8] NUM_A_BYTES bit field

- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUP_i_REG[11:10] NUM_D_BYTES bit field specifies the number of “dummy bits.” In addition, the QSPI_SPI_SETUP_i_REG[28:24] NUM_D_BITS bit field can also specify the number of “dummy bits.”
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUP_i_REG[13:12] READ_TYPE bit field. (*i* is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUP_i_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in [Figure 19-74](#)) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in [Figure 19-74](#)) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

19.4.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

19.4.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is

also used to configure and transfer data.

- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
 - [QSPI_SPI_DATA_REG](#)
 - [QSPI_SPI_DATA_REG_1](#)
 - [QSPI_SPI_DATA_REG_2](#)
 - [QSPI_SPI_DATA_REG_3](#)
 These four registers compose a 128-bit shift register.
- The [QSPI_SPI_STATUS_REG](#) register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit is 0x0. The QSPI becomes busy when a write to the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group [QSPI_SPI_DATA_REG_3](#), [QSPI_SPI_DATA_REG_2](#), [QSPI_SPI_DATA_REG_1](#) and [QSPI_SPI_DATA_REG](#) is treated as a single 128-bit word for shifting data in and out. The [QSPI_SPI_DATA_REG_3](#) register is used for the most significant bits and the [QSPI_SPI_DATA_REG](#) is used for the least significant bits. This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at [QSPI_SPI_DATA_REG_3\[31\]](#) position and the least significant bit, that is bit 0 of the data read, will be located at the [QSPI_SPI_DATA_REG\[0\]](#) position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The [QSPI_SPI_CMD_REG\[25:19\]](#) WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the [QSPI_SPI_DATA_REG](#) register. By setting the word length to 0x7 the [QSPI_SPI_DATA_REG](#) register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the [QSPI_SPI_DATA_REG](#) and the rest 8 most significant bits of data should be written to the lower byte of the [QSPI_SPI_DATA_REG_1](#) register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the [QSPI_SPI_DATA_REG_2](#) register is also used and the previously described logic applies. The [QSPI_SPI_DATA_REG_3](#) register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the [QSPI_SPI_CMD_REG\[11:0\]](#) FLEN bit field.

NOTE: The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

19.4.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the [QSPI_SPI_CLOCK_CNTRL_REG\[15:0\]](#) DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the [QSPI_SPI_CLOCK_CNTRL_REG\[31\]](#) CLKEN bit is set to 0x1. [Figure 19-75](#) shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field is not executed and the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

Figure 19-75. SPI_CLKGEN Block

19.4.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field sets immediately the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when [QSPI_SPI_CMD_REG\[25:19\]](#) WLEN number of bits are shifted in or out. If the value of the [QSPI_SPI_STATUS_REG\[27:16\]](#) WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length ([QSPI_SPI_CMD_REG\[11:0\]](#) FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the [QSPI_SPI_CMD_REG\[25:19\]](#) WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

19.4.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. [Table 19-278](#) lists the four defined clock modes of operation for the QSPI.

Table 19-278. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock

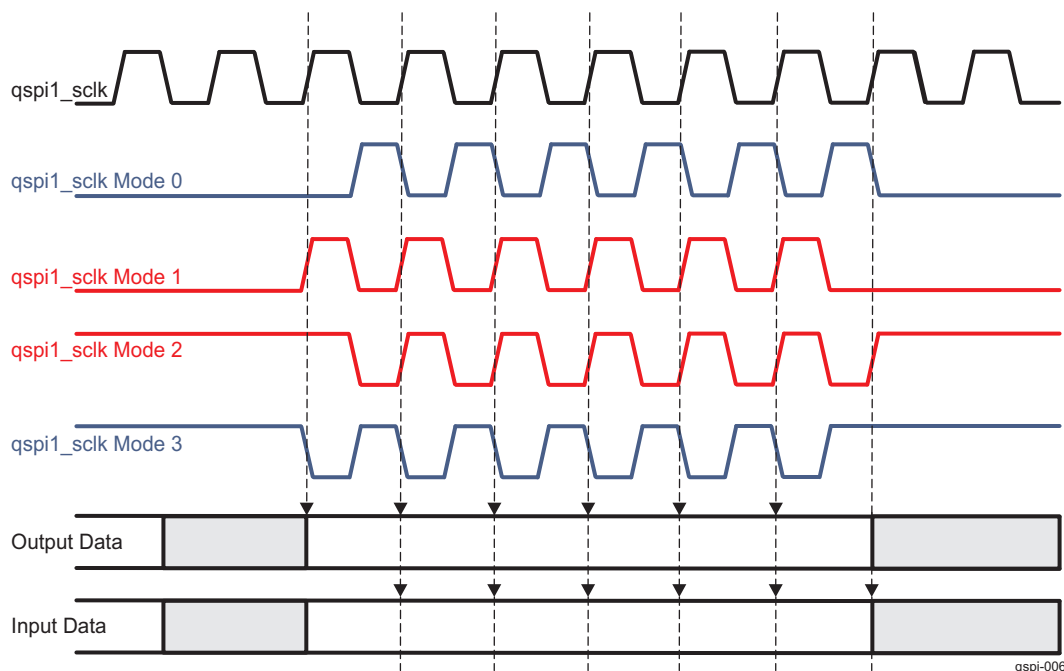

Table 19-278. SPI Clock Modes Definition (continued)

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

NOTE: Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the [QSPI_SPI_DC_REG](#) register control the clock modes. Each of these 4 bits corresponds to an output chip select.

[Figure 19-76](#) shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the [QSPI_SPI_DC_REG](#) register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the [QSPI_SPI_DC_REG](#) register.

Figure 19-76. SPI Clock Modes

19.4.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the [QSPI_SYSCONFIG\[3:2\] IDLE_MODE](#) bit field. Three modes are supported:

- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

19.4.4.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in [Table 19-279](#).

Figure 19-77 shows a logical representation of the QSPI interrupt generation scheme.

Figure 19-77. Logical Representation of the QSPI Interrupt Generation Scheme

QSPI_SPI_STATUS_REG[1] WC and **QSPI_SPI_STATUS_REG[2] FC** are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (**WIRQ** or **FIRQ**) in the **QSPI_SPI_CMD_REG** register allows these events (**WC** and **FC**) to generate an interrupt. The **WC** and **FC** bits are reset every time the user writes to the **QSPI_SPI_CMD_REG** register or reads the **QSPI_SPI_STATUS_REG** register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the **QSPI_SPI_SWITCH_REG[1] MM_INT_EN** bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the **QSPI_SPI_CMD_REG[14] WIRQ** and **QSPI_SPI_CMD_REG[15] FIRQ** bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the **QSPI_INTR_ENABLE_SET_REG** register. These interrupts can be disabled by setting the corresponding bits in the **QSPI_INTR_ENABLE_CLEAR_REG** register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the **QSPI_INTR_STATUS_ENABLED_CLEAR** register to 0x1, which also clears the corresponding bit in the **QSPI_INTR_STATUS_RAW_SET** register. The status flags in the **QSPI_INTR_STATUS_RAW_SET** register are set even if the corresponding interrupt is disabled unlike those in the **QSPI_INTR_STATUS_ENABLED_CLEAR** register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the **QSPI_INTR_STATUS_RAW_SET** register is set to 0x1 and the corresponding interrupt is enabled through the **QSPI_INTR_ENABLE_SET_REG** register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the **QSPI_INTR_STATUS_RAW_SET** register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the **QSPI_INTR_STATUS_RAW_SET** register can also be cleared by setting to 0x1 the corresponding bit in the

[QSPI_INTR_STATUS_ENABLED_CLEAR](#) register.

It must be considered that the previously described scenario applies if the [QSPI_SPI_CMD_REG\[14\]](#) WIRQ and [QSPI_SPI_CMD_REG\[15\]](#) FIRQ bits are set to 0x1.

NOTE: The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
 - during operations using the memory-mapped port by setting to 0x1 both the [QSPI_SPI_SWITCH_REG\[1\]](#) MM_INT_EN and [QSPI_INTR_ENABLE_SET_REG\[1\]](#) WIRQ_ENA_SET bits.
 - during operations using the configuration port by setting to 0x1 both the [QSPI_SPI_CMD_REG\[14\]](#) WIRQ and [QSPI_INTR_ENABLE_SET_REG\[1\]](#) WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the [QSPI_SPI_CMD_REG\[15\]](#) FIRQ and [QSPI_INTR_ENABLE_SET_REG\[0\]](#) FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 19-279 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 19-279. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA	QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR	
QSPI_SPI_STATUS_REG[1] WC	QSPI_SPI_CMD_REG[14] WIRQ	
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET	Frame complete interrupt event. Asserted each time after a frame is transferred or received.
QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA	QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR	
QSPI_SPI_STATUS_REG[2] FC	QSPI_SPI_CMD_REG[15] FIRQ	

19.4.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the four supported external SPI devices. The L3_MAIN start address at which the configuration port is available is 0x4B30 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x5C00 0000 and ends at 0x5FFF FFFF L3_MAIN address.

The CTRL_CORE_CONTROL_IO_2[10:8] QSPI_MEMMAPPED_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL_CORE_CONTROL_IO_2 register resides in the CTRL_MODULE_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 19-281. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available through these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

19.5 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

19.5.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

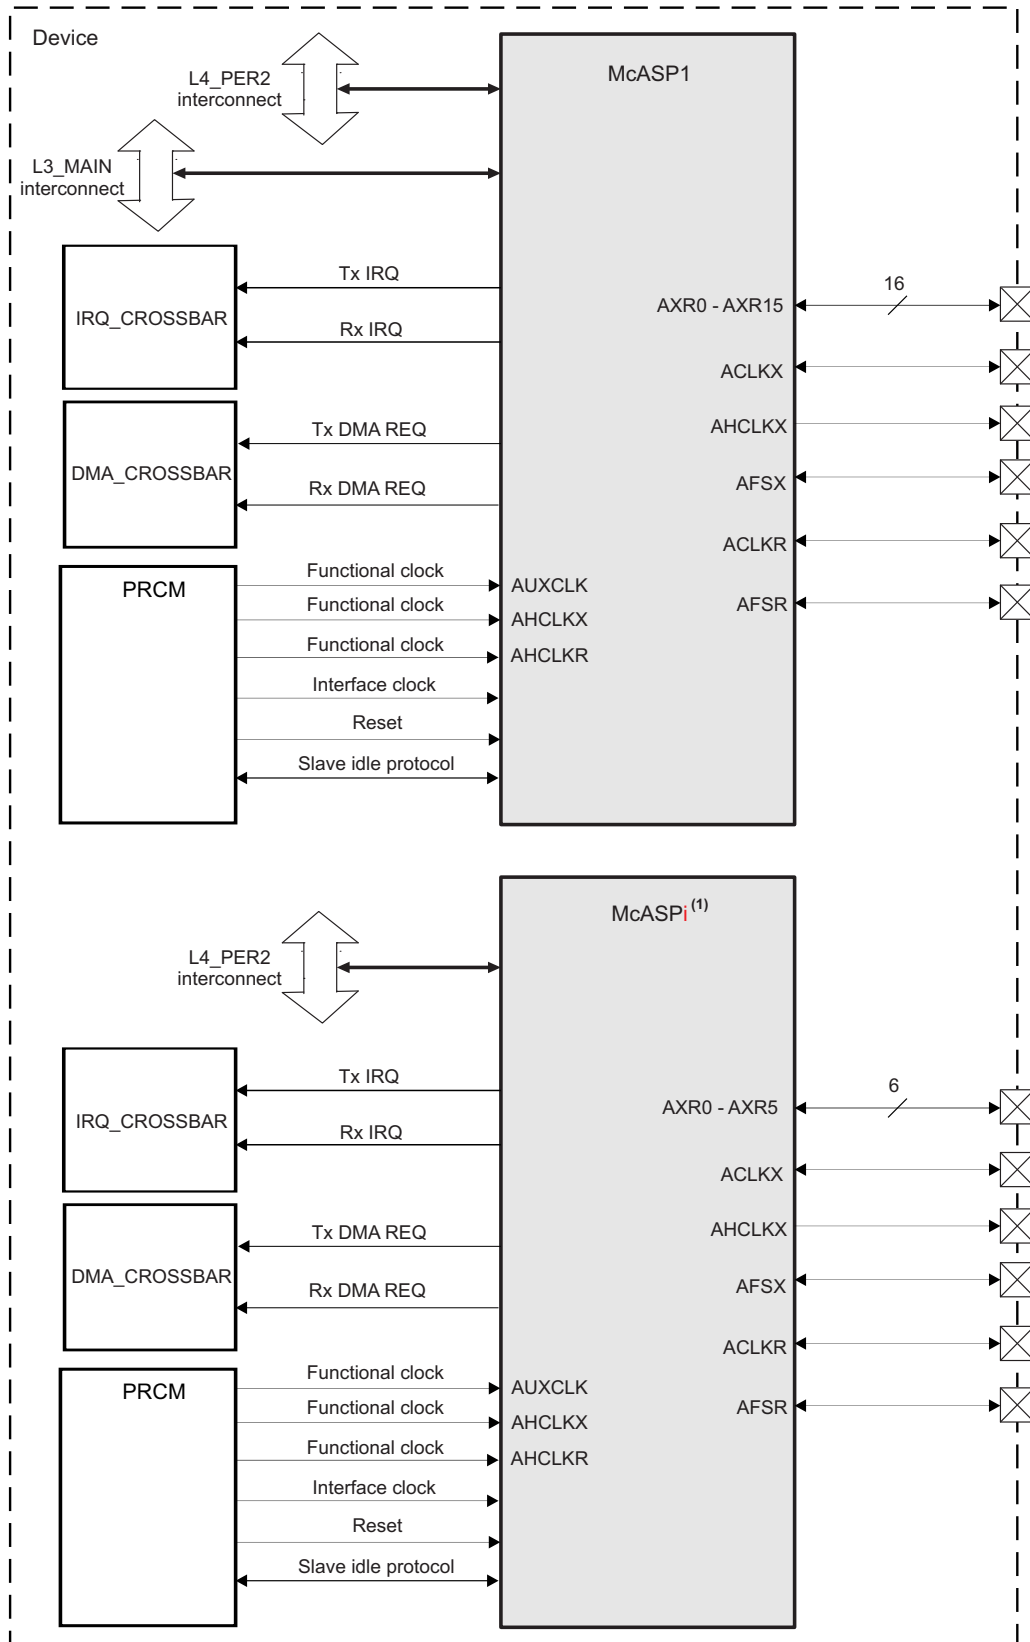

The device have integrated three McASP modules with:

- McASP1 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP2 and McASP3 support up to 6 channels with independent TX/RX clock/sync domain. McASP2 and McASP3 are introduced in silicon revision SR2.0.

NOTE: There is only one McASP module on SR1.0 devices called McASP. On SR2.0, there are three McASP modules called McASP1, McASP2 and McASP3. McASP1 in SR2.0 is the McASP module in SR1.0.

[Figure 19-78](#) shows the McASP modules in the device.

Figure 19-78. McASP Modules Overview

mcasp-001

(1) i = 2 and 3 (SR2.0 Only)

McASP module includes the following main features:

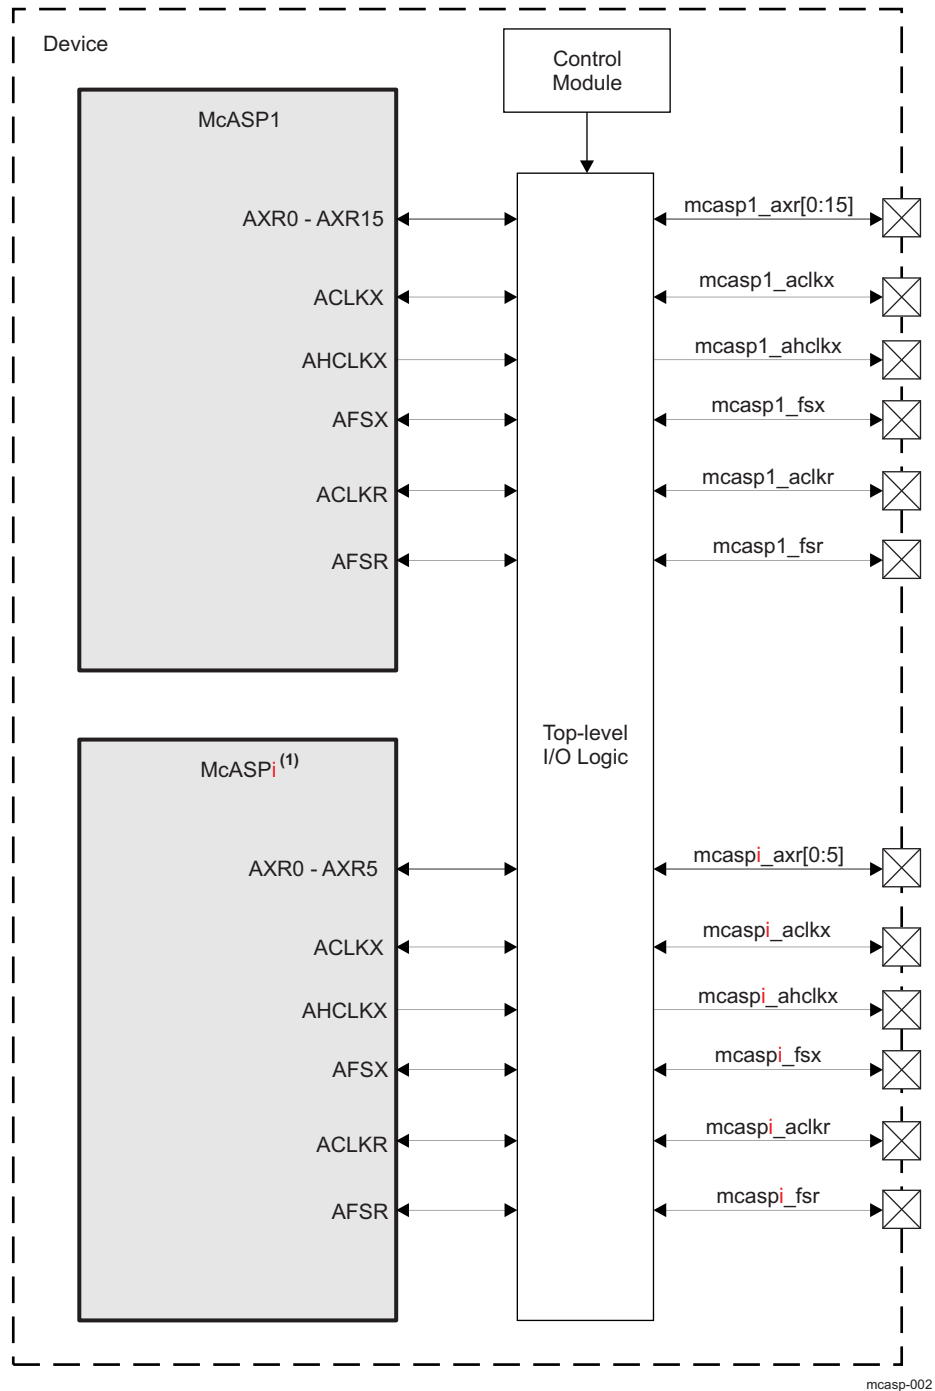

- McASP1 supports up to 16 channels and independent TX/RX clock/sync domains.
- Two modules (McASP2 and McASP3) supporting up to 6 channels each and independent TX/RX clock/sync domains. McASP2 and McASP3 are introduced with SR2.0.
- Independent serializer for each AXRx channel of each McASP_x module.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
 - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
 - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
 - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
 - internally (master mode)
 - supplied over McASP serial interface (slave mode)
 - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
 - Programmable clock and frame sync generator.
 - TDM streams from 2 to 32, and 384 time slots.
 - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
 - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
 - S/PDIF, IEC60958-1, AES-3 formats.
 - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
 - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
 - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
 - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
 - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

NOTE: Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

19.5.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 19-79 shows the McASP modules in their environment in the device.

Figure 19-79. McASP Environment

(1) *i* = 2 and 3 (SR2.0 Only)

NOTE: There is only one McASP module in SR1.0 devices called McASP and equal to McASP1 in SR2.0.

19.5.2.1 McASP Signals

Table 19-322 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

Table 19-322. McASP I/O Signals

AHCLKX	mcas3_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcas3_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcas3_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcas3_fsr	I/O	Receive frame synchronization	HiZ

NOTE: For the mcasp_x_aclkx, mcasp_x_ahclkx and mcasp_x_aclkr signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the [Section 14.4.6.1, Pad Configuration Registers](#), and [Section 14.5, Control Module Register Manual](#), in [Chapter 14, Control Module](#).

NOTE: Except the pad configuration registers, additional Control Module registers have to be configured to map McASP2 and McASP3 signals to the device pads. The MUXMODE field of the corresponding pad configuration register has to be set to 0xF and the corresponding bit in [CTRL_CORE_SMA_SW_14](#) and [CTRL_CORE_SMA_SW_15](#) has to be set to 0x1.

NOTE: A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the [MCASP_PDIR](#) and the function (Tx or Rx) is selected in the corresponding serializer control register [MCASP_XRSRCTLn](#).

19.5.2.2 Protocols and Data Formats

19.5.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.

- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
 - Automatically aligns data internally in either Q31 or integer formats.
 - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

NOTE: In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

NOTE: The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

NOTE: An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

19.5.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 19-80](#) shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. [Figure 19-80](#) does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- **Word:**

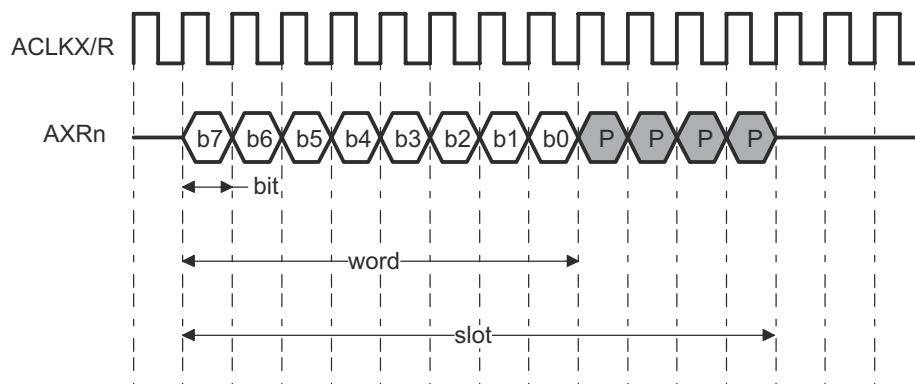

A word is a group of bits that make up the data being transferred between the McASP and the external device. [Figure 19-80](#) shows an 8-bit word.

- **Slot:**

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In [Figure 19-80](#), the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. [Figure 19-81](#) shows these options.

Figure 19-80. Definition of Bit, Word, and Slot

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-003

Figure 19-81. Bit Order and Word Alignment Within a Slot Examples

mcasp-004

• **Frame**

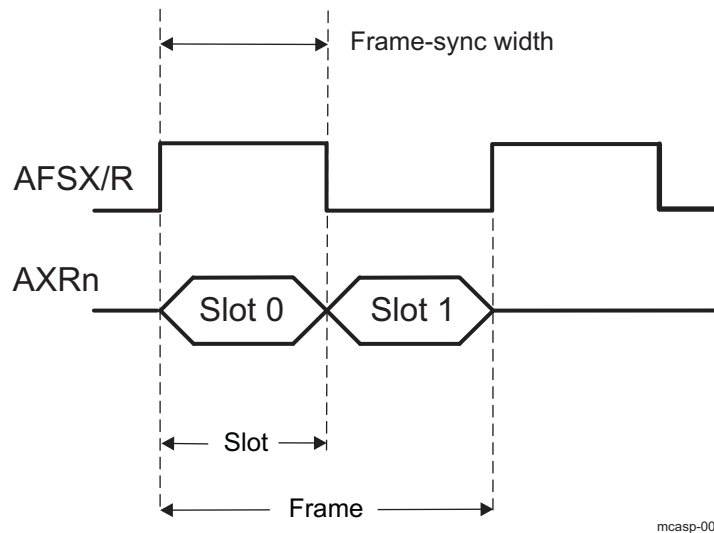

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 19-82](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. [Figure 19-82](#) does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see [Section 19.5.2.2.3, TDM Format](#) and [Section 19.5.2.2.5, S/PDIF-Coding Format](#).

NOTE: All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:

- AHCLKX, ACLKX, and AFSX for the transmitting section
- ACLKR and AFSR for the receiving section

Figure 19-82. Definition of Frame and Frame-Sync Width

mcasp-005

The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See [Section 19.5.2.2.3](#) for details on the TDM protocol
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

19.5.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin - AXRn is illustrated on [Figure 19-83](#).

Figure 19-83. TDM Format - 6 channel example

- (1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported
- (2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

The TDM format uses three signals in a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 19.5.2.2.2), the latter being also referred to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-, 1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

In a typical audio system involving McASP module, a single TDM data frame is transferred during each sample period T_s of a data converter. The user has following choices to implement multiple channels:

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

19.5.2.2.4 I2S Format

The TDM transfer mode of the McASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on Figure 19-84.

Figure 19-84. I2S Format Overview

(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-036

19.5.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphasemark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

NOTE: The DIR- reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

19.5.2.2.5.1 Biphasemark Code

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). For each serializer transmitter n , the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 19-85](#) and [Table 19-323](#) show how data is encoded to the BMC format.

As shown in [Figure 19-85](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to $128 \times f_s$, where f_s is the sample rate (see [Section 19.5.2.2.5.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

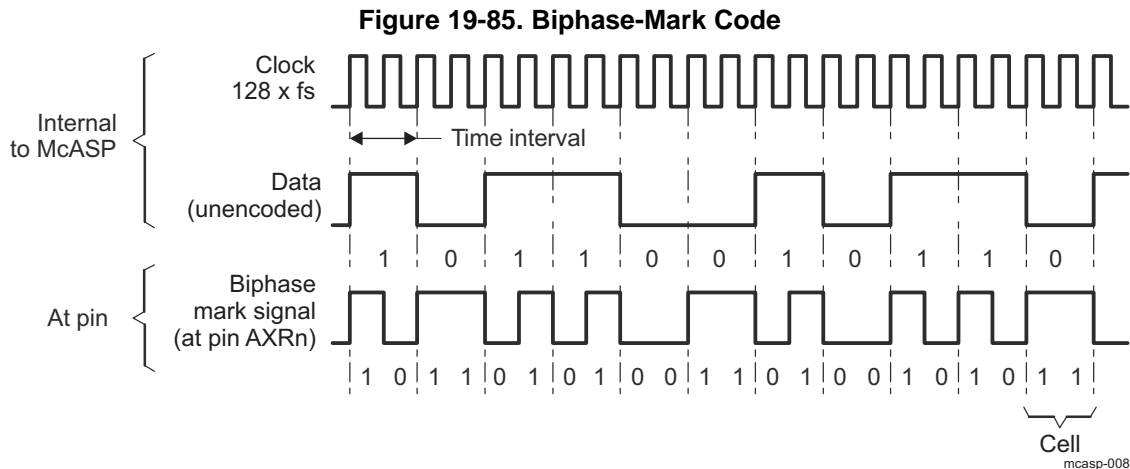

Table 19-323. Biphase-Mark Encoder

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

19.5.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 19-86 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 19-324.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8–27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 19-324, the preambles (time intervals 0–3) are also defined with even parity.

Figure 19-86. S/PDIF Subframe Format

As listed in Table 19-324, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 19-324. Preamble Codes

Preamble Code ⁽¹⁾	Previous Logical State	Logical States on pin AXRn ⁽²⁾	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

⁽¹⁾ Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

⁽²⁾ The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

19.5.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 19-87). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s . The S/PDIF format clock rate is therefore $128 \times f_s$ ($128 = 32$ cells per subframe $\times 2$ clocks per cell $\times 2$ subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128×192 kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 19-87. S/PDIF Frame Format

19.5.3 McASP Integration

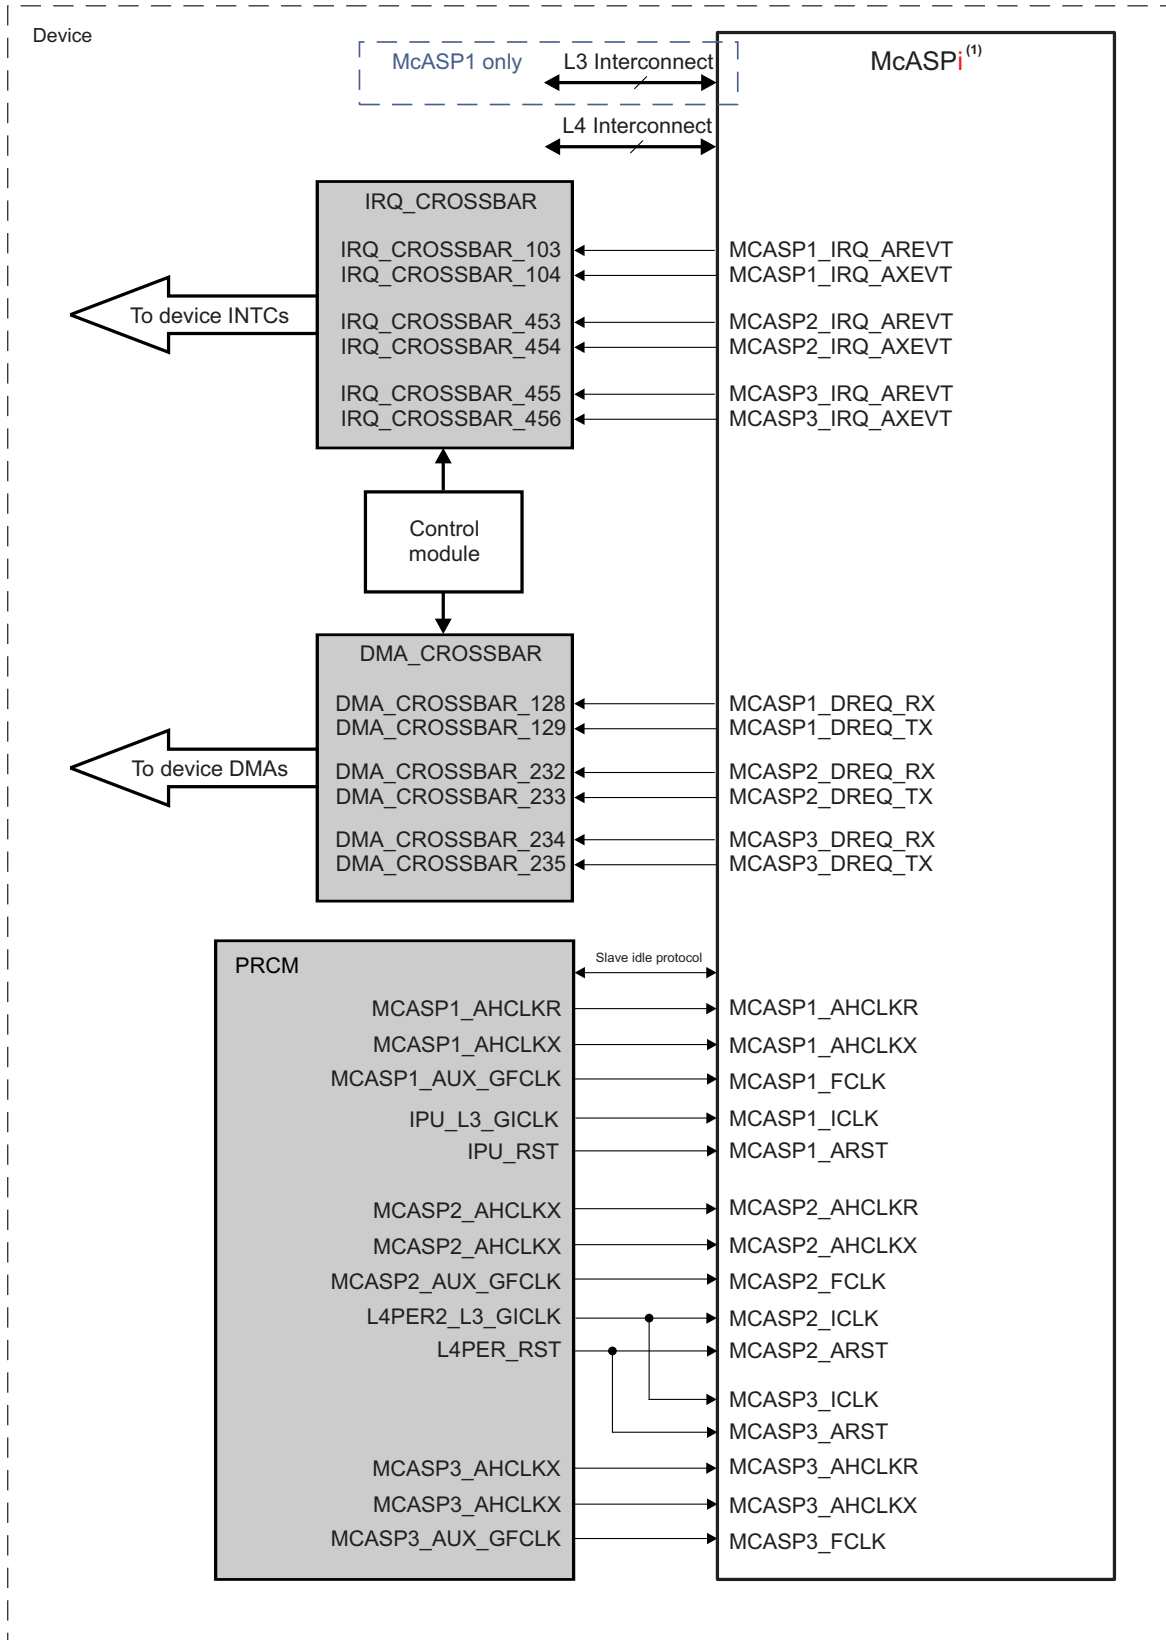

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

McASP module includes the following features:

- Slave idle protocol
- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

[Figure 19-88](#) shows McASP integration.

Figure 19-88. McASP Integration

mcasp-011

(1) *i* = 1 to 3 (2 and 3 only on SR2.0)

NOTE: There is only one McASP module on SR1.0 devices called McASP. On SR2.0 there are 3 McASP modules called McASP1, McASP2 and McASP3. McASP1 on SR2.0 is same as McASP on SR1.0.

NOTE: For more information about the slave idle protocol, see [Section 3.1.1.1.2, Module Level Clock Management](#) of [Chapter 3, Power, Reset, and Clock Management](#).

Table 19-325 through Table 19-327 summarize McASP integration in the device.

Table 19-325. McASP Integration Attributes

Table 19-327. McASP Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
McASP1	MCASP1_IRQ_AREVT	IRQ_CROSSBAR_103	-	McASP1 module receive interrupt request
	MCASP1_IRQ_AXEVT	IRQ_CROSSBAR_104	-	McASP1 module transmit interrupt request
McASP2 (SR2.0 Only)	MCASP2_IRQ_AREVT	IRQ_CROSSBAR_453	-	McASP2 module receive interrupt request
	MCASP2_IRQ_AXEVT	IRQ_CROSSBAR_454	-	McASP2 module transmit interrupt request
McASP3 (SR2.0 Only)	MCASP3_IRQ_AREVT	IRQ_CROSSBAR_455	-	McASP3 module receive interrupt request
	MCASP3_IRQ_AXEVT	IRQ_CROSSBAR_456	-	McASP3 module transmit interrupt request
DMA Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
McASP1	MCASP_DREQ_RX	DMA_CROSSBAR_128	DMA_DSP1_DREQ_0 DMA_DSP2_DREQ_0	McASP module receive event request
	MCASP_DREQ_TX	DMA_CROSSBAR_129	DMA_DSP1_DREQ_1 DMA_DSP2_DREQ_1	McASP module transmit event request
McASP2 (SR2.0 Only)	MCASP2_DREQ_RX	DMA_CROSSBAR_232	-	McASP2 module receive event request
	MCASP2_DREQ_TX	DMA_CROSSBAR_233	-	McASP2 module transmit event request
McASP3 (SR2.0 Only)	MCASP3_DREQ_RX	DMA_CROSSBAR_234	-	McASP3 module receive event request
	MCASP3_DREQ_TX	DMA_CROSSBAR_235	-	McASP3 module transmit event request

NOTE: The **Default Mapping** column in [Table 19-327 McASP Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device DSP1_EDMA and DSP2_EDMA modules, see [Section 4.3.7, DSP Integrated EDMA Subsystem](#).

NOTE:

- For the description of the interrupt source, see [Section 19.5.4.12, McASP Events and Interrupt Requests](#).
- For the description of the DMA source, see [Section 19.5.4.13, DMA Requests](#).

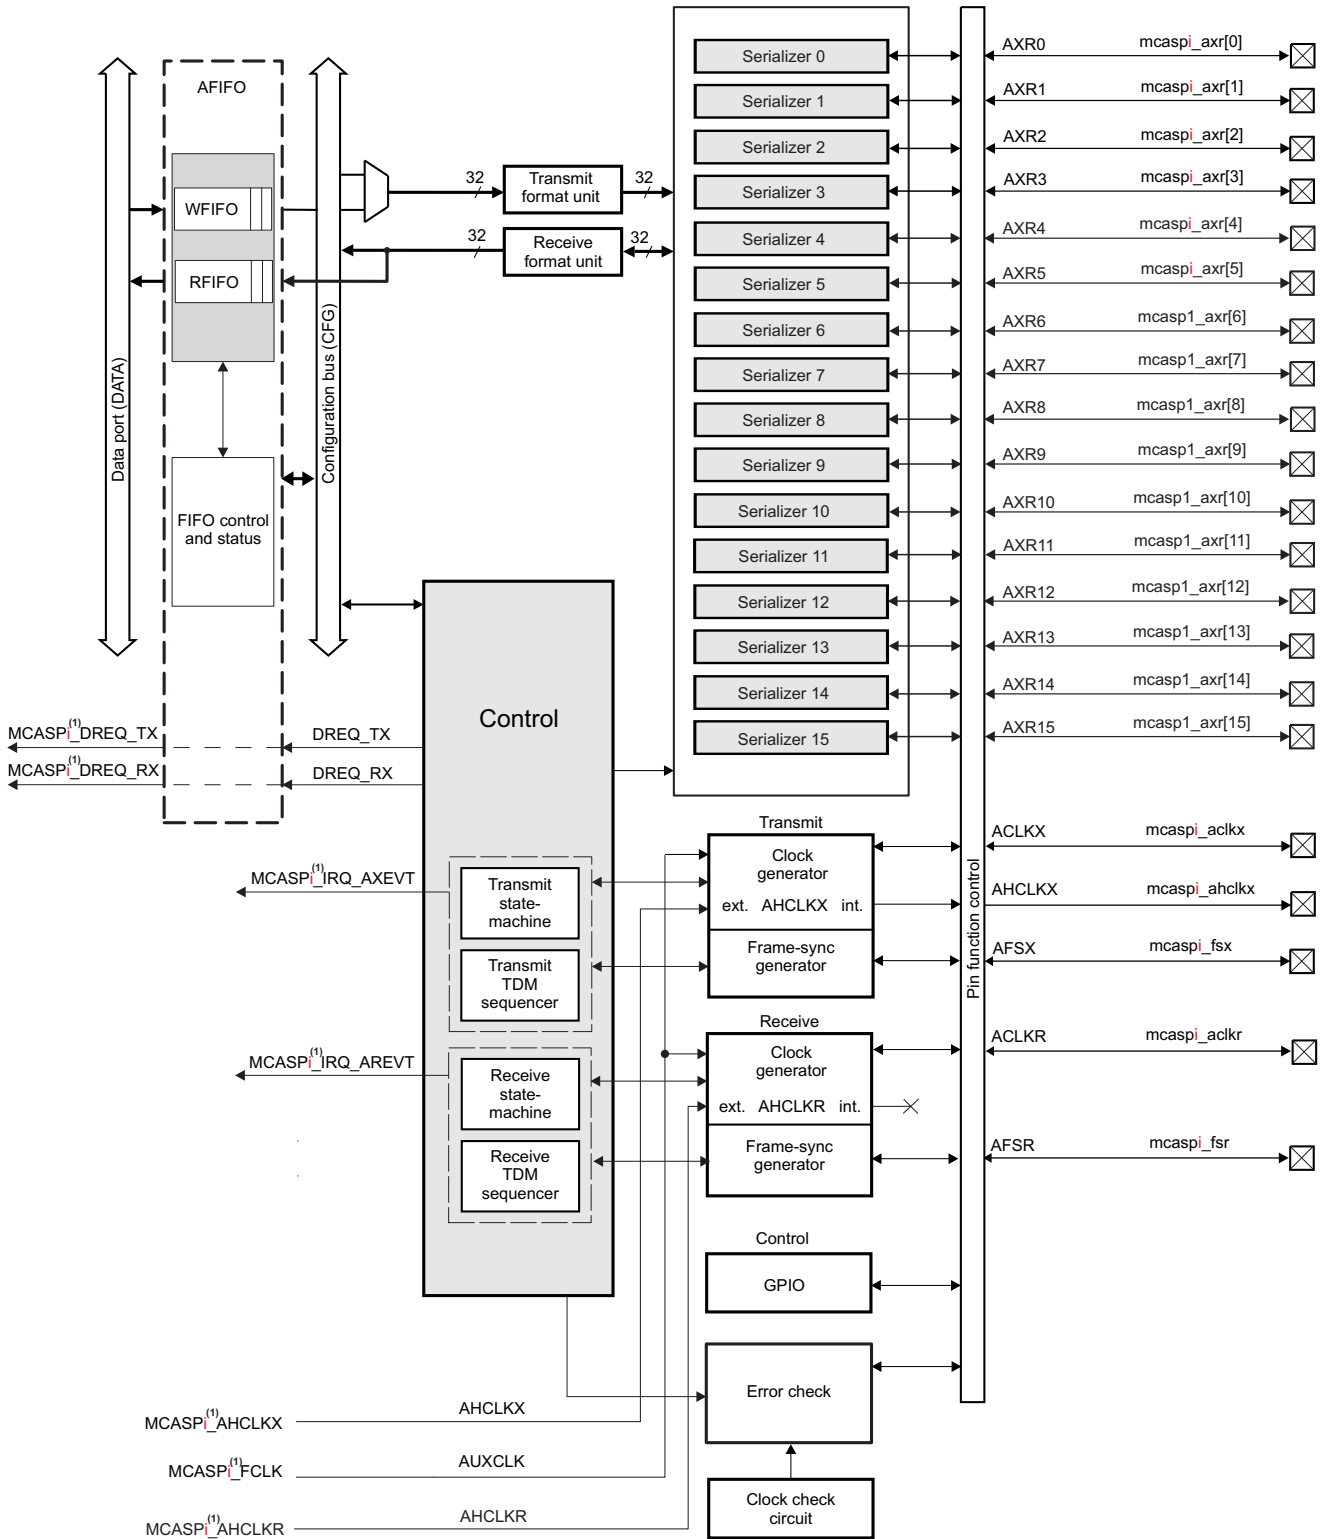

19.5.4 McASP Functional Description

In the text throughout this section a single instance of McASP is described assuming that all modules are functionally identical. For module availability and integration differences, see [Section 19.5.2, McASP Environment](#), and [Section 19.5.3, McASP Integration](#)

19.5.4.1 McASP Block Diagram

[Figure 19-89](#) shows the major blocks of the McASP module. McASP1 has 16 serializers, and McASP2 and McASP3 have 6 serializers each. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

Figure 19-89. McASP Module Block Diagram

(1) *i* = 1 to 3 (2 and 3 only on SR2.0)

mcasp-012

NOTE: The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

19.5.4.2 McASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx part of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

19.5.4.2.1 McASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- [MCASP_ACLKXCTL](#)
- [MCASP_AHCLKXCTL](#)

In case, the transmit bit clock, ACLKX, is generated internally, the [MCASP_ACLKXCTL](#)[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the [MCASP_ACLKXCTL](#)[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 19.5.4.2](#), the [MCASP_AHCLKXCTL](#)[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the [MCASP_AHCLKXCTL](#)[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 19-90](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If [MCASP_ACLKXCTL](#)[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If [MCASP_ACLKXCTL](#)[7] CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 19-90](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

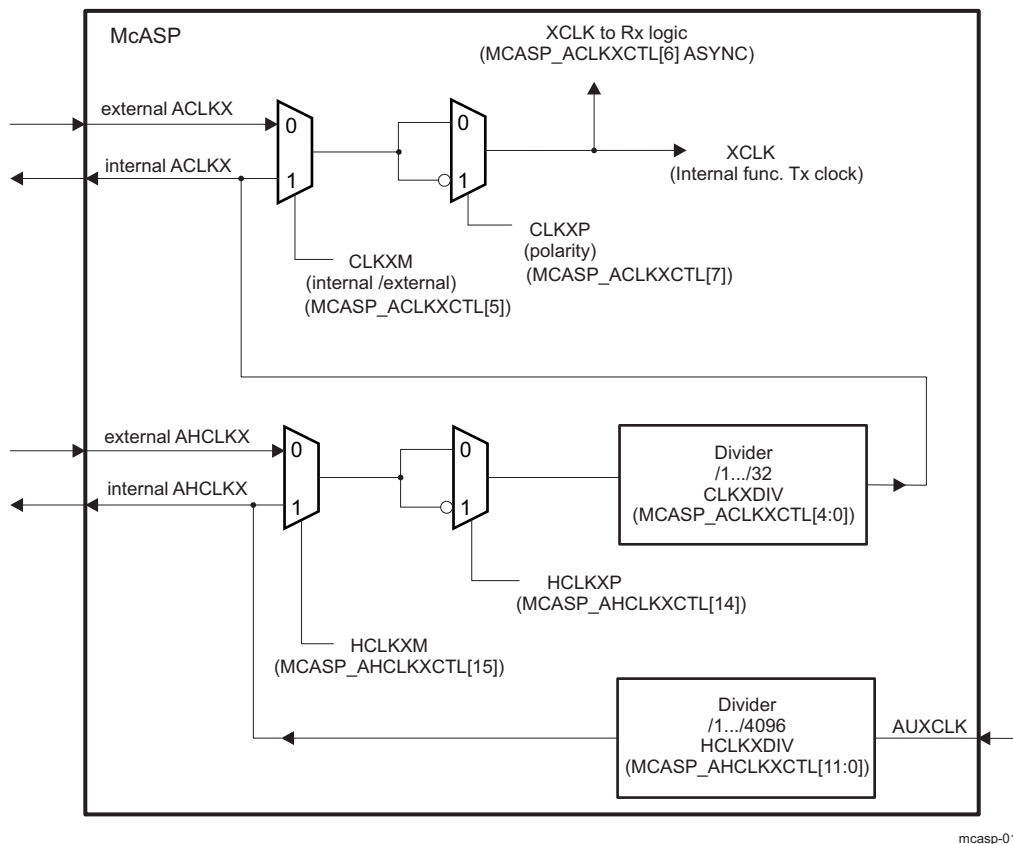

NOTE: The polarity of ACLKX can be controlled in [MCASP_ACLKXCTL\[7\]](#) CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the [MCASP_AHCLKXCTL\[14\]](#) HCLKXP bit.

NOTE: In a similar way, the polarity of AHCLKX clock can be controlled in [MCASP_AHCLKXCTL\[14\]](#) HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

[Figure 19-90](#) is the block diagram of the transmit clock generator.

Figure 19-90. Transmit Clock Generator Block Diagram

mcasp-013

NOTE: In this device:

- ACLKX is mapped on the device ball `mcaspi_aclkx`, where $i = 1$ to 3
- internal AHCLKX is mapped on the device ball `mcaspi_ahclkx`
- external AHCLKX is mapped on `MCASPi_AHCLKX` clock from the PRCM

For more on McASP integration, see [Section 19.5.2, McASP Environment](#), and [Section 19.5.3, McASP Integration](#).

19.5.4.2.2 McASP Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- [MCASP_ACLKRCTL](#)
- [MCASP_AHCLKRCTL](#)

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the [MCASP_ACLKRCTL](#)[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the [MCASP_ACLKRCTL](#)[4:0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 19.5.4.2](#)) and the [MCASP_AHCLKRCTL](#)[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the [MCASP_AHCLKRCTL](#)[11:0] HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

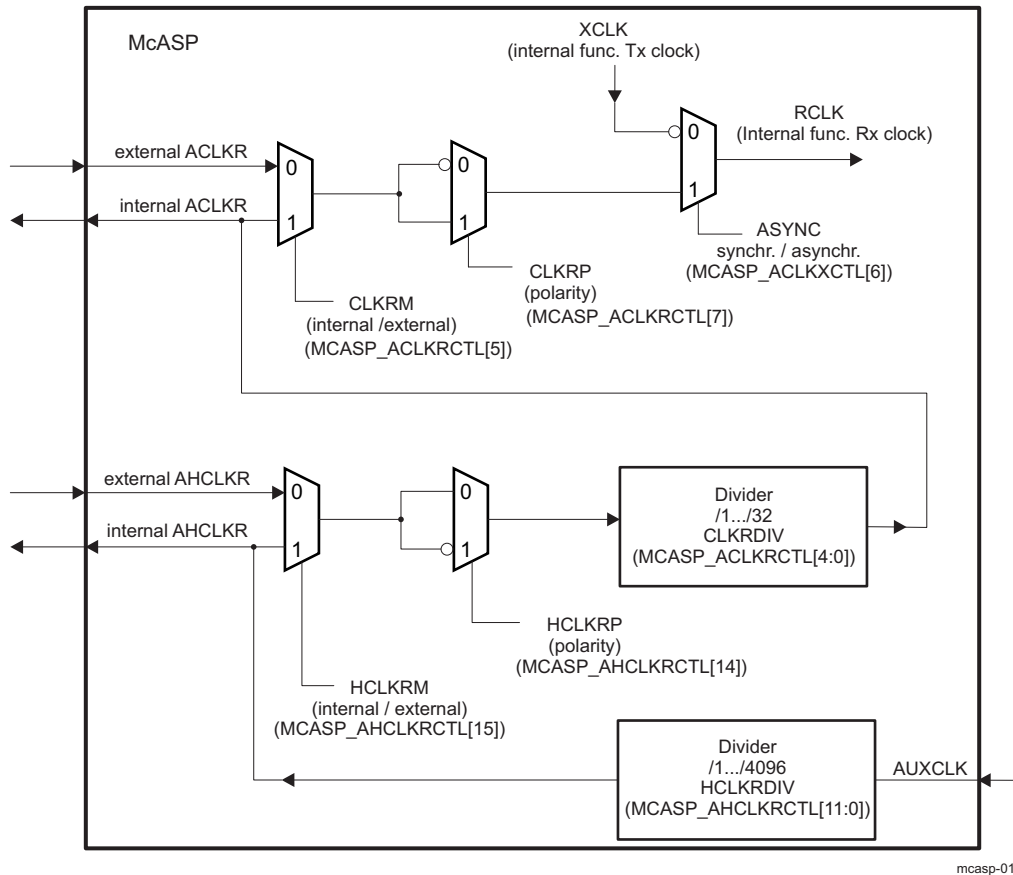

NOTE: The polarity of ACLKR can be controlled in [MCASP_ACLKRCTL](#)[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in [MCASP_AHCLKRCTL](#)[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 19-90](#) and [Figure 19-91](#)) becomes source of the receive clock (RCLK output), when the [MCASP_ACLKXCTL](#)[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 19.5.4.2.4](#).

[Figure 19-91](#) is the block diagram of the receive clock generator.

Figure 19-91. Receive Clock Generator Block Diagram

NOTE: In this device:

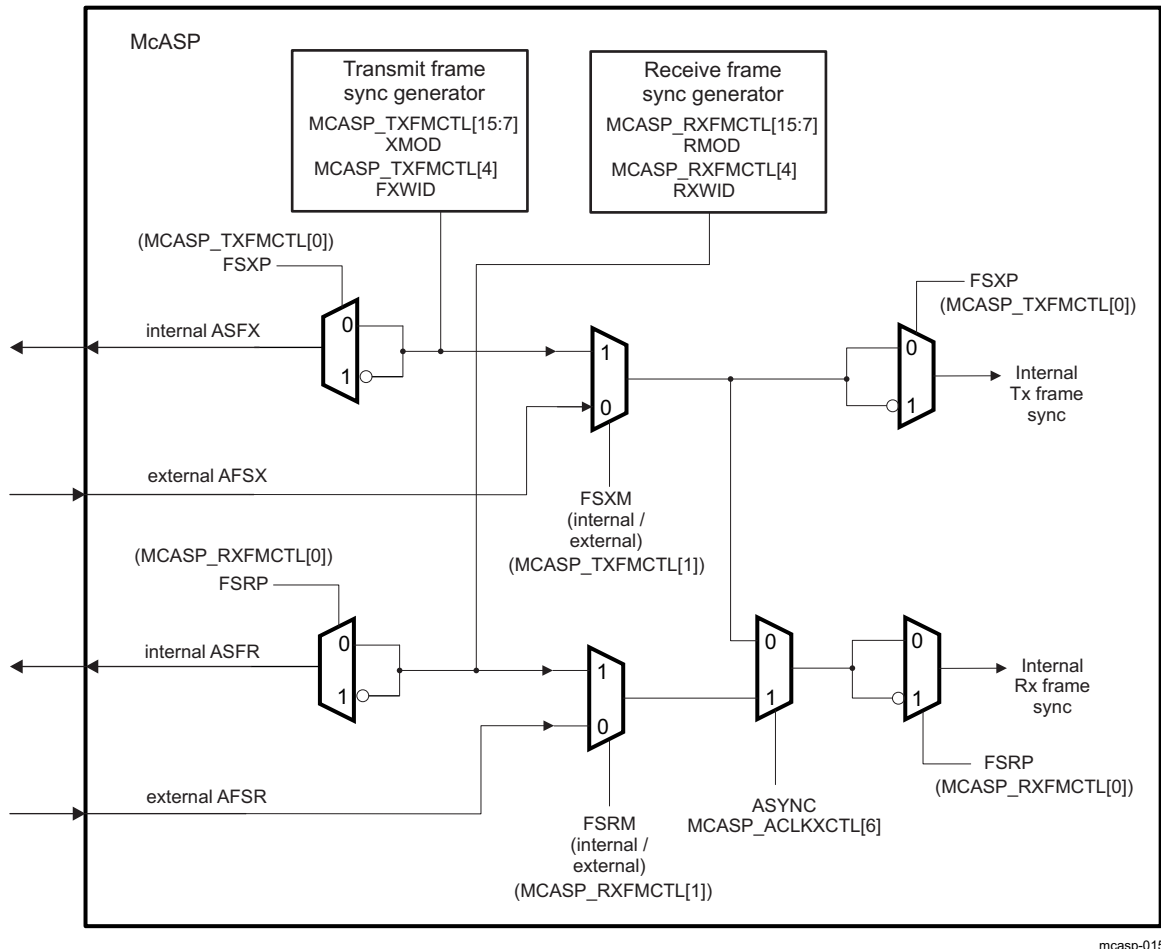

- ACLKR is mapped on the device ball mcaspi_aclkr, where i = 1 to 3
- internal AHCLKR is tied-off
- external AHCLKR is mapped on PRCM MCASPi_AHCLKR from PRCM

For more on McASP integration, see [Section 19.5.2, McASP Environment](#), and [Section 19.5.3, McASP Integration](#).

19.5.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in [Figure 19-92](#). I/O buffers are not part of the McASP module, and are not shown in the figure.

Figure 19-92. Frame Sync Generator Block Diagram

NOTE: For more on McASP integration, see [Section 19.5.2, McASP Environment](#), and [Section 19.5.3, McASP Integration](#).

For the transmit logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit [MCASP_TXFMCTL\[1\]](#) FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit [MCASP_TXFMCTL\[0\]](#) FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit [MCASP_TXFMCTL\[4\]](#) FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield [MCASP_TXFMCTL\[15:7\]](#) XMOD, as follows:
 - For DIT mode (384 slots) - [MCASP_TXFMCTL\[15:7\]](#) XMOD = 0x180
 - For I2S mode (2 TDM slots) - [MCASP_TXFMCTL\[15:7\]](#) XMOD = 0x2
 - For TDM mode (from 3 to 32 TDM slots) - [MCASP_TXFMCTL\[15:7\]](#) XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in [MCASP_TXFMT\[17:16\]](#) XDATDLY

For the receive logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit [MCASP_RXFMCTL\[1\]](#) FSRM
- Frame-sync polarity: Rising edge or falling edge via configuring bit [MCASP_RXFMCTL\[0\]](#) FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit [MCASP_RXFMCTL\[4\]](#) FRWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is

defined in the bitfield [MCASP_RXFMCTL\[15:7\]](#) RMOD, as follows:

- For I2S mode (2 TDM slots) - [MCASP_RXFMCTL\[15:7\]](#) RMOD = 0x2
- For TDM mode (from 3 to 32 TDM slots) - [MCASP_RXFMCTL\[15:7\]](#) RMOD set in range 0x3 - 0x20
- For the special 384-slot TDM mode - [MCASP_RXFMCTL\[15:7\]](#) RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in [MCASP_RXFMT\[17:16\]](#) RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - [MCASP_ACLKXCTL\[6\]](#) ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 19.5.4.2.4](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

NOTE: Certain restrictions apply to the receive and transmit logic settings, when [MCASP_ACLKXCTL\[6\]](#) ASYNC is set to 0b0. They are described in [Section 19.5.4.2.4](#).

19.5.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When [MCASP_ACLKXCTL\[6\]](#) ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 19-91](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When [MCASP_ACLKXCTL\[6\]](#) ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- [MCASP_TXDITCTL\[0\]](#) DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in [MCASP_ACLKRCTL](#) are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When [MCASP_ACLKXCTL\[6\]](#) ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

NOTE: Synchronous transmit and receive operations are allowed only in the McASP TDM (I2S) mode (i.e. when [MCASP_TXDITCTL\[0\]](#) DITEN=0b0).

19.5.4.3 Serializers

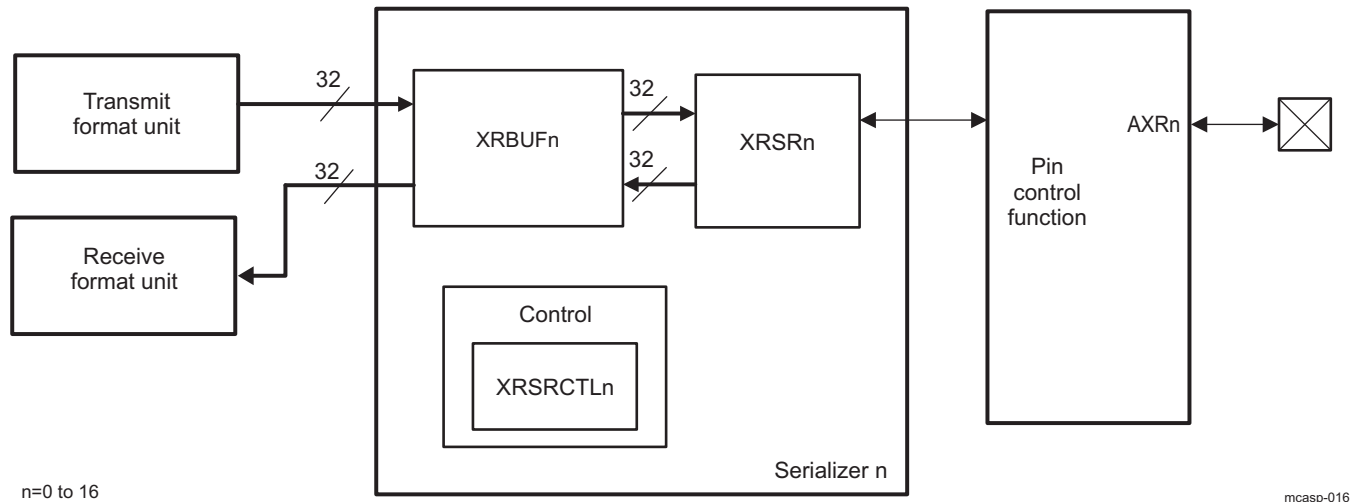

The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register [MCASP_TXBUFn](#)) or for receiving (read accessible in register [MCASP_RXBUFn](#)) data. In addition, each serializer has a dedicated control register ([MCASP_XRSRCTLn](#)) and a serial bidirectional data pin - AXRn. The register [MCASP_XRSRCTLn](#) allows n-th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in `MCASP_XRSRCTLn`, shifts in data through McASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in `MCASP_XRSRCTLn`, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 19-93 is the serializer block diagram.

Figure 19-93. Individual Serializer and Connections Within McASP

Transmission on the n-th serializer is performed as follows:

The McASP is serviced by writing data into the register `MCASP_TXBUFn`, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer is performed as follows:

The data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn, and can be accessed in the `MCASP_RXBUFn` register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the McASP passes the data through the receive format unit, hence it returns the formatted data.

Serializer controls:

A serializer n is configured as inactive via setting bitfield `MCASP_XRSRCTLn[1:0] SRMOD` to 0x0.

For a transmitting serializer, the `MCASP_XRSRCTLn[3:2] DISMOD` bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield `MCASP_XRSRCTLn[1:0] SRMOD` to 0x1.

Receive function for the n-th serializer is selected via setting bitfield `MCASP_XRSRCTLn[1:0] SRMOD` to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see [Section 19.5.2.2.5](#)

19.5.4.4 Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

NOTE: The McASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the [MCASP_RXFMT/MCASP_TXFMT](#) register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the [MCASP_RXFMT/MCASP_TXFMT](#) also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in [MCASP_RXFMT/MCASP_TXFMT](#) means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

19.5.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

[Figure 19-94](#) shows the transmit formatting unit.

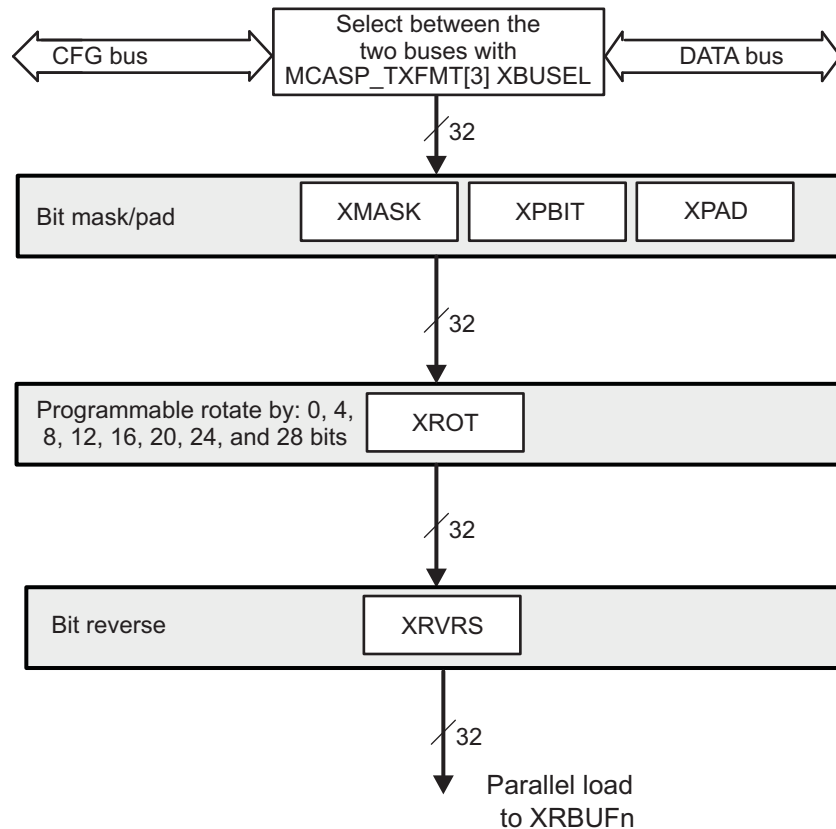

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB
 - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - [MCASP_TXFMT](#):

- XRVR: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

Figure 19-94. Transmit Format Unit

mcasp-017

As shown in [Figure 19-94](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the `MCASP_TXFMT[3] XBUSEL` bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 19.5.4.10.1.3, Transfers Through the DATA Port](#), and [Section 19.5.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the `MCASP_TXMASK[31:0] XMASK` contents. The masked data is then right-rotated to `MCASP_TXFMT[2:0] XROT` positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

19.5.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

NOTE: Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 19-328](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 19-328](#) assumes that all slot size (SLOT in [Table 19-328](#)) and word size (WORD in [Table 19-328](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter (typically Q31 or integer).

Table 19-328. McASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT ⁽¹⁾	XRVRS
MSB first ⁽²⁾	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first ⁽²⁾	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

⁽¹⁾ WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

⁽²⁾ To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

19.5.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The [MCASP_TXFMT\[17:16\]](#) XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- [MCASP_TXFMT\[2:0\]](#) XROT =
 - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
 - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
 - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- [MCASP_TXFMT\[15\]](#) XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- [MCASP_TXMASK\[32\]](#) XMASK = 0xFFFFFFFF00 – 0xFFFF0000
- [MCASP_TXFMT\[14:13\]](#) XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- [MCASP_TXFMT\[2:0\]](#) XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- [MCASP_TXFMT\[15\]](#) XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- [MCASP_TXMASK\[32\]](#) XMASK = 0x00FFFFFF – 0x0000FFFF
- [MCASP_TXFMT\[14:13\]](#) XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 19-329](#) should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 19-329. McASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFF000	0x3
LEFT	24	8	0xFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 19-329](#), the user must set XMASK=0xFFFF000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVR = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

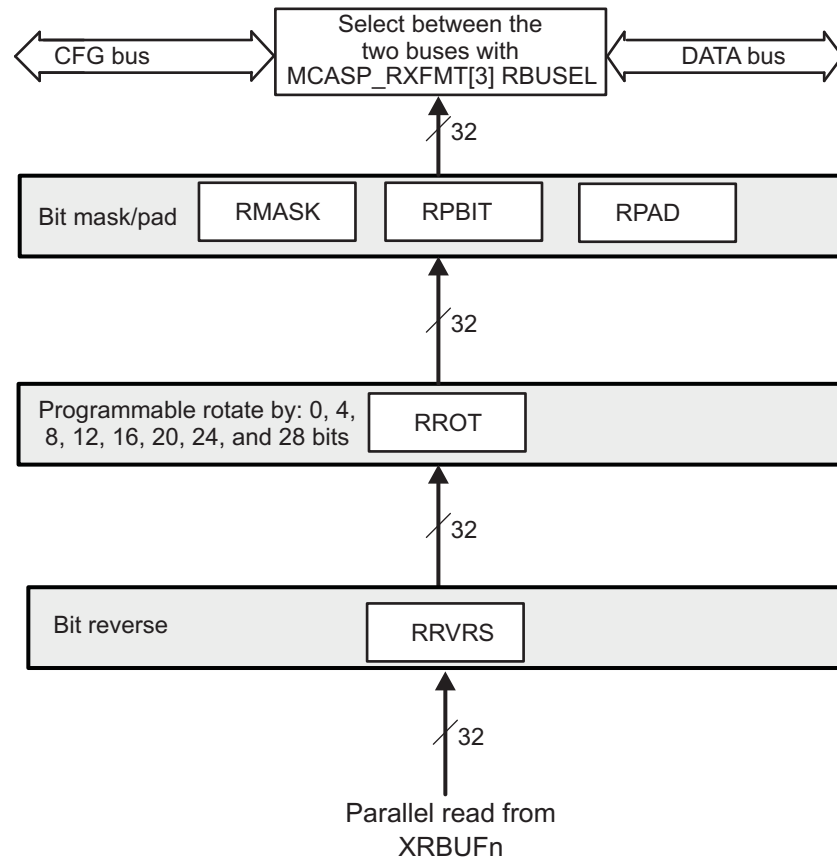

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

19.5.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 19-95](#) shows the receive format unit (RFU).

Figure 19-95. Receive Format Unit

mcaspp-018

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size \leq Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB
 - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - [MCASP_RXFMT](#):

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 19-95](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the [MCASP_RXFMT\[3\] RBUSEL](#) bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 19.5.4.10.1.3, Transfers Through the DATA Port](#), and [Section 19.5.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

19.5.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

NOTE: Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 19-330 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 19-330. McASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT ⁽¹⁾	RRVRS
MSB first ⁽²⁾	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first ⁽²⁾	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

⁽¹⁾ WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

⁽²⁾ To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 19-330 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 19-95), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer, for example).

19.5.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RXFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP_RXSTAT).

19.5.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RXTDM/MCASP_TXTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register `MCASP_XRSRCTLn[3:2]` DISMOD. Refer also to [Section 19.5.4.9.2.1, TDM Time Slots Generation and Processing](#), for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a `MCASP_TXBUFn` register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the `MCASP_TXTDM` register and reports the current transmit slot to the `MCASP_TXTDMSLOT[9:0]` XSLOT CNT bit field.

19.5.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (`MCASP_GBLCTL`). A valid serial clock must be supplied to the McASP to assert the software reset bits in the `MCASP_GBLCTL` register.

19.5.4.8 McASP Power Management

[Table 19-331](#) describes power-management features available to the McASP.

Table 19-331. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	<code>PWRIDLESYSCONFIG[1:0]</code> <code>IDLE_MODE</code>	Force-idle, no-idle, and smart-idle modes are available.

CAUTION

No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device PRCM level, the user software is strongly recommended to choose *No Idle* mode, setting `PWRIDLESYSCONFIG[1:0]` `IDLE_MODE` to 0x1. Before disabling McASP at device PRCM level, user software is strongly recommended to choose a *Smart-Idle* mode, setting `PWRIDLESYSCONFIG[1:0]` `IDLE_MODE` to 0x2.

19.5.4.9 Transfer Modes

19.5.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

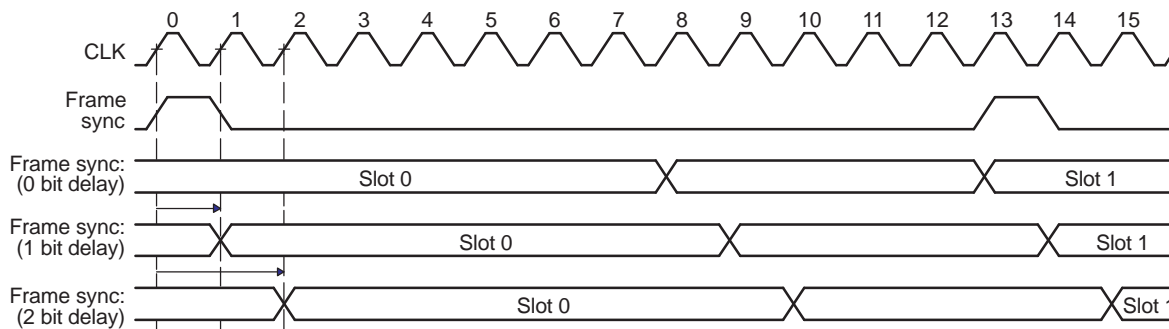

When operating in burst frame sync mode (see [Figure 19-96](#)), as specified for transmit (`MCASP_TXFMCTL[15:7] = 0`) and receive (`MCASP_RXFMCTL[15:7]` RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (`MCASP_RXFMCTL[4]` FRWID = 0, `MCASP_TXFMCTL[4]` FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF_n (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF_n (for every serializer set to operate as a receiver) has been read.

Figure 19-96. Burst Frame Sync Mode

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- **MCASP_PFUNC**: The clock, frame, data pins must be configured for McASP function.
- **MCASP_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP_PDOUT**, **MCASP_PDIN**, **MCASP_PDSET**, **MCASP_PDCLR**: Not applicable. Leave at default.
- **MCASP_GBLCTL**: Follow the initialization sequence in [Section 19.5.5.1.2, McASP Global Initialization](#), to configure this register.
- **MCASP_AMUTE**: Not applicable. Leave at default.
- **MCASP_LBCTL**: If loopback mode is desired, configure this register according to [Section 24.6.4.14 Loopback Modes](#), otherwise leave this register at default.
- **MCASP_TXDITCTL**: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- **MCASP_RXMASK/MCASP_TXMASK**: Mask desired bits according to [Section 19.5.4.4, Format Units](#).
- **MCASP_RXFMT/MCASP_TXFMT**: Program all fields according to data format desired. See [Section 19.5.4.4, Format Units](#).
- **MCASP_RXFMT/MCASP_TXFMT**: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- **MCASP_ACLKRCTL/MCASP_ACLKXCTL**: Program all fields according to bit clock desired. See [Section 19.5.4.2, McASP Clock and Frame-Sync Configurations](#).
- **MCASP_AHCLKRCTL/MCASP_AHCLKXCTL**: Program all fields according to high-frequency clock desired. See [Section 19.5.4.2, McASP Clock and Frame-Sync Configurations](#).
- **MCASP_RXTDM/MCASP_TXTDM**: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- **MCASP_EVTCTLR/MCASP_EVTCTLX**: Program all fields according to interrupts desired.
- **MCASP_RXCLKCHK/MCASP_TXCLKCHK**: Not applicable. Leave at default.
- **MCASP_XRSRCTL_n**: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- **MCASP_DITCSRA_i**, **MCASP_DITCSRB_i**, **MCASP_DITUDRA_i**, **MCASP_DITUDRB_i**: Not applicable. Leave at default.

19.5.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in [Section 19.5.2.2.3](#).

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXR_n, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the [Section 19.5.4.2.1, Transmit Clock](#), and [Section 19.5.4.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXR_n, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to [Section 19.5.4.2.2, Receive Clock](#), and [Section 19.5.4.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- **MCASP_PFUNC**: The clock, frame, data pins must be configured for McASP function.
- **MCASP_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP_PDOUT**, **MCASP_PDIN**, **MCASP_PDSET**, **MCASP_PDCLR**: Not applicable. Leave at default.
- **MCASP_GBLCTL**: Follow the initialization sequence is described in the [Section 19.5.5.2, Operational Modes Configuration](#).
- **MCASP_AMUTE**: Leave this register at default state.
- **MCASP_LBCTL**: If loopback mode is desired, configure this register according to [Section 19.5.4.14](#), otherwise leave this register at default.
- **MCASP_TXDITCTL**: DITEN must be left at default 0 to select TDM mode (transmitters only).
- **MCASP_RXMASK/MCASP_TXMASK**: Mask desired bits according to [Section 19.5.4.4, Format Units](#).
- **MCASP_RXFMT/MCASP_TXFMT**: Program all fields according to data format desired. See the [Section 19.5.4.4, Format Units](#).
- **MCASP_RXFMCTL/MCASP_TXFMCTL**: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- **MCASP_ACLKRCTL/MCASP_ACLKXCTL**: Program all fields according to bit clock desired. For more information, refer to [Section 19.5.4.2](#).
- **MCASP_AHCLKRCTL/MCASP_AHCLKXCTL**: Program all fields according to high-frequency clock desired. For more details, refer to [Section 19.5.4.2](#).
- **MCASP_RXTDM/MCASP_TXTDM**: Program all fields according to the time slot characteristics desired.
- **MCASP_EVTCTLX**: Program all fields according to transmit interrupts desired.
- **MCASP_RXCLKCHK/MCASP_TXCLKCHK**: Program all fields according to clock checking desired.
- **MCASP_XRSRCTL_n**: Program all fields according to serializer operation desired.

NOTE: The **MCASP_DITCSRA_i**, **MCASP_DITCSRB_i**, **MCASP_DITUDRA_i**, **MCASP_DITUDRB_i** (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

19.5.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring **MCASP_TXTDM** and/or **MCASP_RXTDM** registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either `MCASP_TXTDM` or `MCASP_RXTDM` to determine if the McASP transmits/receives in that time slot.

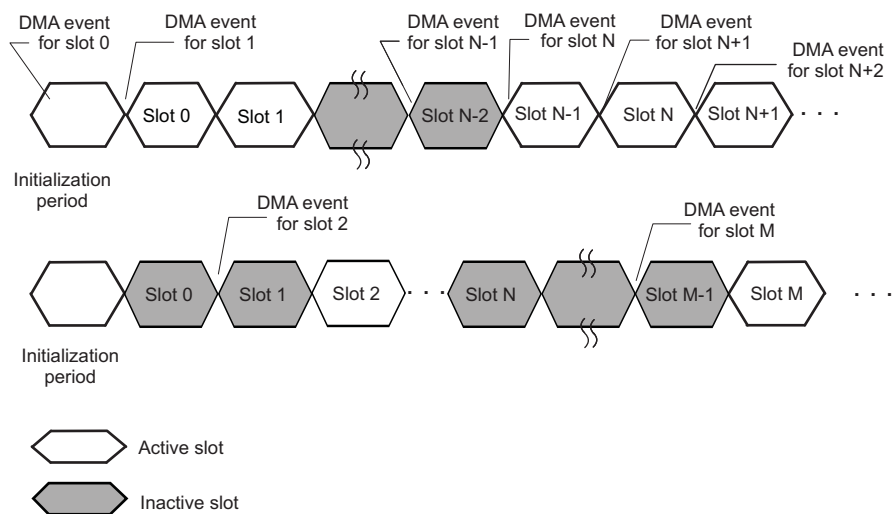

NOTE: If a `MCASP_TXTDM/MCASP_RXTDM` bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield `MCASP_XRSRCTLn[3:2] DISMOD`.

Figure 19-97 shows when the transmit DMA event - AXEVT is generated. See Section 19.5.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from `XRBUFn` to `XRSRn` generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 19-97. Transmit DMA Event (AXEVT) Generation in TDM Time Slots

mcasp-019

19.5.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (`MCASP_RXTDM`) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, `AXRn`, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set

RMOD in [MCASP_RXFMCTL](#) to 384 (0x180) to receive 384 time slots

19.5.4.9.3 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see [Section 19.5.2.2.5, S/PDIF Coding Format](#).

19.5.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphasic-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

NOTE: The transmit TDM time slot register ([MCASP_TXTDM](#)) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 19.5.4.4.1.2](#).

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

19.5.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register ([MCASP_TXFMCTL](#)):
 - Internally generated transmit frame sync, FSXM = 1
 - Rising-edge frame sync, FSXP = 0
 - Bit-width frame sync, FXWID = 0
 - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register ([MCASP_ACLKXCTL](#)), ASYNC = 1
- In the transmit bitstream format register ([MCASP_TXFMT](#)), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- [MCASP_PFUNC](#): The data pin - AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- [MCASP_PDIR](#): The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- [MCASP_GBLCTL](#): Global initialization
- [MCASP_AMUTE](#): Leave this register at default state.
- [MCASP_TXDITCTL](#): The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as

desired.

- **MCASP_TXMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- **MCASP_TXFMT**: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 19.5.4.4.1.2](#).
- **MCASP_TXFMCTL**: Configure the bits according to former discussions.
- **MCASP_ACLKXCTL**: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- **MCASP_AHCLKXCTL**: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- **MCASP_TXTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- **MCASP_EVTCTLX**: Program all fields according to the interrupts desired.
- **MCASP_TXCLKCHK**: Program all fields according to the clock checking desired.
- **MCASP_XRSRCTLn**: Set SRMOD = 1 (transmitter) for the DIT pins.
- **MCASP_DITCSRAi** and **MCASP_DITCSRBi**: Program the channel status bits as desired.
- **MCASP_DITUDRAi** and **MCASP_DITUDRBi**: Program the user data bits as desired.

NOTE: In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see [Section 19.5.2.2.5.1](#)).

19.5.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (**MCASP_DITCSRAi** and **MCASP_DITCSRBi**) and user data registers (**MCASP_DITUDRAi** and **MCASP_DITUDRBi**) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 19.5.2.2.5.2](#), *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- **MCASP_DITCSRA0** to **MCASP_DITCSRA5**: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- **MCASP_DITCSR0** to **MCASP_DITCSR5**: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- **MCASP_DITUDRA0** to **MCASP_DITUDRA5**: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- **MCASP_DITUDRB0** to **MCASP_DITUDRB5**: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 19-87](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 19-332](#).

19.5.4.10 Data Transmission and Reception

The McASP is serviced by writing data to the [MCASP_TXBUF_n](#) registers for transmit operations, and by reading data from the [MCASP_RXBUF_n](#) registers for receive operations. The McASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 19.5.4.10.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details.

The McASP transmit/receive XRBUF_n buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.

- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 19.5.4.10.1.3](#), *Transfers Through the Data Port (DATA)*, and [Section 19.5.4.10.1.4](#), *Transfers Through the Configuration Bus (CFG)*, discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 19.5.4.10.1.5](#), *Using the device CPUs for McASP Servicing*, and [Section 19.5.4.10.1.6](#), *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently on the L3_MAIN-interconnect or L4_PER2 interconnect, using burst transfers. The physical addresses to access these registers are listed in [Section 19.5.6.2.5](#).

19.5.4.10.1 Data Ready Status and Event/Interrupt Generation

19.5.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the [MCASP_TXSTAT](#) register reflects the data ready status of XRBUF_n buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUF_n to its corresponding XRSR_n shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUF_n is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register [MCASP_XRSRCTL_n\[4\]](#) XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When [MCASP_TXBUF_n](#) is written to by the host, the [MCASP_XRSRCTL_n\[4\]](#) XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer [MCASP_TXBUF_n](#) register has to be currently written. Once all requested [MCASP_TXBUF_n](#) are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the [MCASP_TXSTAT\[5\]](#) XDATA bit is written to 0b1, or once [MCASP_TXBUF_n](#) registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi_DREQ_TX line (if enabled in the [MCASP_XEVTCTL](#) register) to notify the DMA of the [MCASP_TXBUF_n](#) empty status. An interrupt - MCASPi_IRQ_AXEVT can be also generated if the XDATA interrupt is enabled in the [MCASP_EVTCTLX](#) register (for details, see [Section 19.5.4.12.1](#), *Transmit Data Ready Interrupt*).

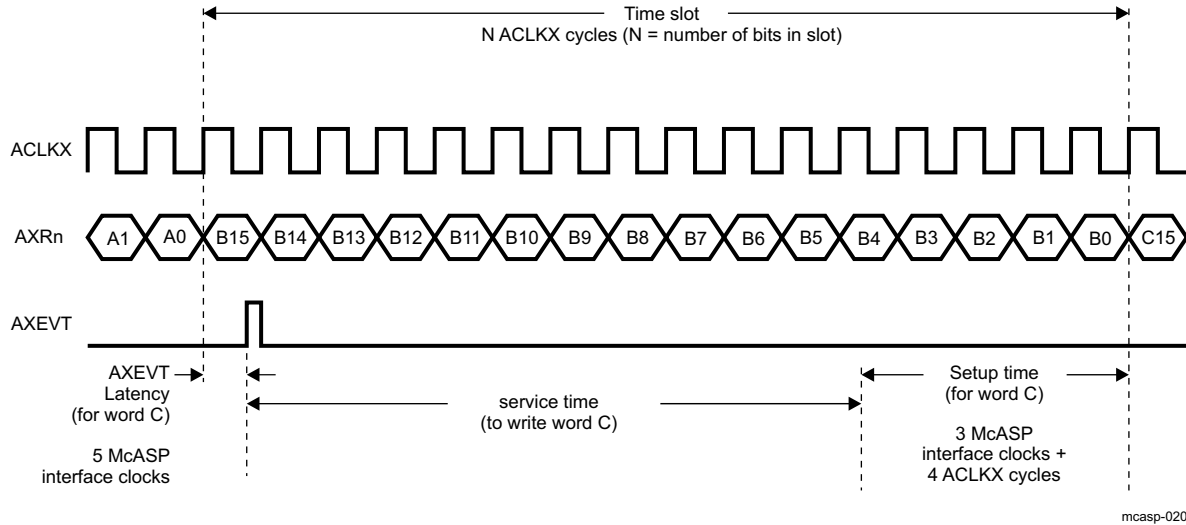

For DMA requests, the McASP does not require that [MCASP_TXSTAT](#) be read between DMA events. This means that, even if [MCASP_TXSTAT](#) already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 19-98](#) shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the CPU can begin servicing the McASP by writing word C into the [MCASP_TXBUF_n](#) (service time). The CPU must write word C into the [MCASP_TXBUF_n](#) within the setup time required by the McASP (setup time).

The maximum service time (see [Figure 19-98](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

Figure 19-98. Service Time Upon Transmit DMA Event (AXEVT)

19.5.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the [MCASP_RXSTAT](#) register reflects the data ready status of XRBUF_n buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSR_n to its corresponding XRBUF_n data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUF_n already contains received data (i.e. a buffer is full) and is ready to transfer it to the host. The receive data ready event is individually indicated per serializer in its corresponding control register [MCASP_XRSRCTL_n](#) [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When [MCASP_RXBUF_n](#) is read from the host, the [MCASP_XRSRCTL_n](#) [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer [MCASP_RXBUF_n](#) register has to be currently read. Once all requested [MCASP_RXBUF_n](#) are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the [MCASP_RXSTAT](#)[5] RDATA bit is written to 0b1, or once [MCASP_RXBUF_n](#) registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi_DREQ_RX line (if enabled in the [MCASP_REVTCTL](#) register) to notify the DMA of the [MCASP_RXBUF_n](#) full status. An interrupt - MCASPi_IRQ_AREVT can be also generated if the RDATA interrupt is enabled in the [MCASP_EVTCTLR](#) register (for details, see [Section 19.5.4.12.1, Receive Data Ready Interrupt](#)).

[Figure 19-99](#) shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the CPU can begin servicing the McASP by reading Word A from the [MCASP_RXBUF_n](#) (service time). The CPU must read Word A from the [MCASP_RXBUF_n](#) register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see [Figure 19-99](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AREVT Latency} - \text{Setup Time}$$

Figure 19-99. CPU Service Time Upon Receive Event (AREVT)

mcasp-021

19.5.4.10.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the [MCASP_TXFMT/MCASP_RXFMT](#) register, respectively. Failure to do so may result in software malfunction.

NOTE: McASP1, whose data port is accessible directly via L3_MAIN, does not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUF_n transmit buffer through the McASP data port (DATA) on L3_MAIN Interconnect for McASP1 and on L4_PER2 Interconnect for McASP2/3. CPU hosts can access both XRBUF_n transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconnect DATA port location. Refer to [Section 19.5.6.2.5](#). Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 19.5.4.11](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in [Section 19.5.6.2.5](#), the same physical DATA port address is used regardless of a read or write access is performed. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

NOTE: DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See [Section 19.5.6.2.5](#)).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

NOTE: For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See [Section 19.5.6.2.5](#)).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

NOTE: To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to [Section 19.5.6.2.5](#)), respectively.

See [Section 19.5.6.2.5, McASP_DATA Register Summary](#), for more details about XRBUF_n buffer physical address corresponding to the McASP DATA port on:

- Main Interconnect (L3_MAIN or L4_PER2)

NOTE: When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in [MCASP_TXTDM](#)) and *transmit* (Tx enabled in [MCASP_XRSRCTLn](#)) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 19.5.4.15.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in [MCASP_RXTDM](#)) and *receive* (Rx enabled in [MCASP_XRSRCTLn](#)) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 19.5.4.15.2, Buffer Overrun Error - Receiver](#)).

19.5.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the [MCASP_TXFMT/MCASP_RXFMT](#) registers, respectively. Failure to do so may result in software malfunction.

NOTE: McASP1, whose data port is accessible directly via L3_MAIN does not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the DMA/CPU accesses the XRBUF_n transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUF_n transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port actual for L4_PER2 accesses. The XRBUF_n buffer of the n-th serializer configured as a transmitter is aliased - **MCASP_TXBUF_n** in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the **MCASP_TXBUF2** register. Similarly, the XRBUF_n buffer of the n-th serializer configured as a receiver is aliased - **MCASP_RXBUF_n** in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the **MCASP_RXBUF3** register.

Accessing the XRBUF through the DATA port (see [Section 19.5.4.10.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the DMA/CPU must provide the exact **MCASP_TXBUF_n** or **MCASP_RXBUF_n** address upon accessing n-th serializer TX or RX buffer, respectively. For more details about **MCASP_TXBUF_n** and **MCASP_RXBUF_n** addresses corresponding to McASP CFG port, see [Section 19.5.6.2.1, MCASP_CFG Register Summary](#).

19.5.4.10.1.5 Using a Device CPU for McASP Servicing

The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi_IRQ_AXEVT and MCASPi_IRQ_AREVT interrupts). Because these interrupt events are connected to device IRQ_CROSSBAR module, they could be software mapped to input IRQ lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the **MCASP_TXSTAT** register and RDATA bit in the **MCASP_RXSTAT** register can be performed by device CPUs, respectively. As discussed in [Section 19.5.4.10.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 19.5.4.10.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective **MCASP_EVTCTLX/MCASP_EVTCTLR** registers, to generate interrupts MCASPi_IRQ_AXEVT/MCASPi_IRQ_AREVT to the device CPUs upon data ready

19.5.4.10.1.6 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 19-89](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 19.5.4.11](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 19.5.4.11](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASPi_DREQ_TX and MCASPi_DREQ_RX outputs. If the AFIFO is disabled (default state) it is transparent for the McASP module and all request are directly sent to the DMA controller.

Figure 19-100. DMA Transmit and Receive Event in an Audio Example – One Event

mcasp-022

In transmit mode, the DMA event - AXEVT (MCASPi_DREQ_TX output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUF_n transmit buffers. In receive mode, the DMA event AREVT (MCASPi_DREQ_RX output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUF_n receive buffers.

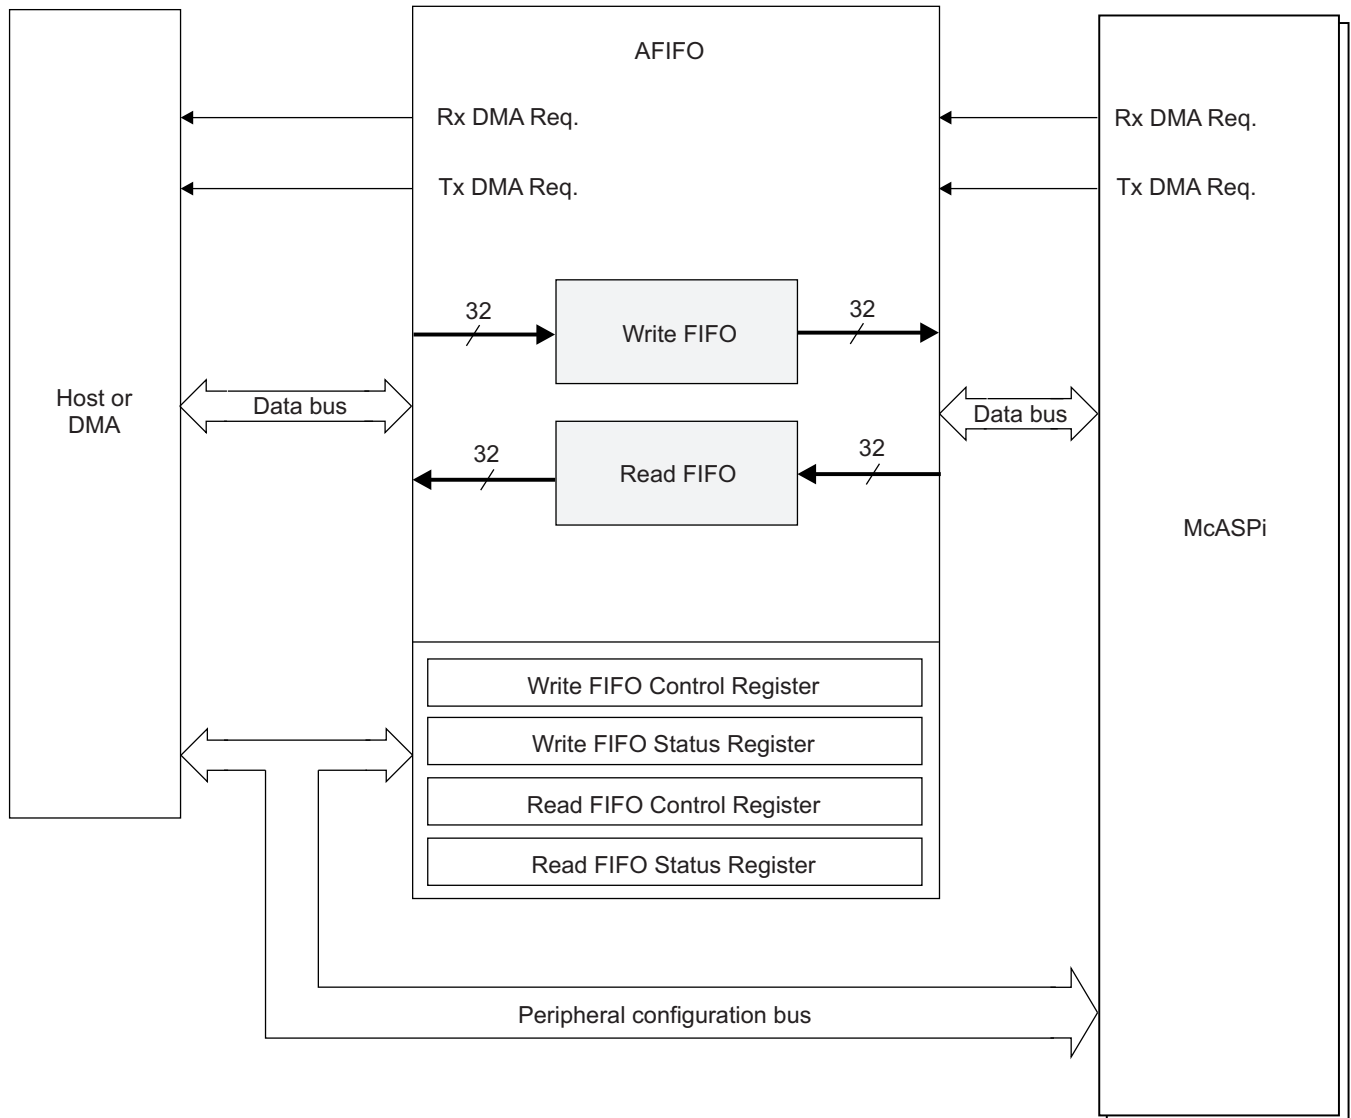

Figure 19-100 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals - AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 19-100, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_REVTCTL register.

19.5.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 19-101 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

Figure 19-101. McASP Audio FIFO (AFIFO) Block Diagram

mcasp-034

19.5.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for [WFIFOCTL\[7:0\] WNUMDMA](#).) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

19.5.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, [WFIFOCTL\[15:8\]](#) WNUMEVT should be set to a non-zero integer multiple of the value in [WFIFOCTL\[7:0\]](#) WNUMDMA. If transmit DMA event pacing is not desired, then the value in [WFIFOCTL\[15:8\]](#) WNUMEVT should be set equal to the value in [WFIFOCTL\[7:0\]](#) WNUMDMA.

19.5.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the McASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the McASP. (See description for [RFIFOCTL\[7:0\]](#) RNUMDMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than WNUMEVT words, those words will be read correctly, emptying the FIFO.

19.5.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least WNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once WNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another WNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, [RFIFOCTL\[15:8\]](#) RNUMEVT should be set to a non-zero integer multiple of the value in [RFIFOCTL\[7:0\]](#) RNUMDMA. If receive DMA event pacing is not desired, then the value in [RFIFOCTL\[15:8\]](#) RNUMEVT should be set equal to the value in [RFIFOCTL\[7:0\]](#) RNUMDMA.

19.5.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

19.5.4.12 McASP Events and Interrupt Requests

[Table 19-333](#) lists all the transmit event flags. [Table 19-334](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectively.

Table 19-333. TX Events⁽¹⁾

Event Mask	Event Flag	Map to ⁽²⁾	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASPi_IRQ_AXEVT	Transmit buffer underrun

⁽¹⁾ Global events for all transmitting serializers in a single McASPi module.

⁽²⁾ Every McASPi module generates separate IRQ event.

Table 19-333. TX Events⁽¹⁾ (continued)

Event Mask	Event Flag	Map to ⁽²⁾	Description
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASPi_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASPi_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASPi_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASPi_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASPi_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASPi_IRQ_AXEVT	Transmit start of frame interrupt
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR XCKFAIL XUNDRN XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

Table 19-334. RX Events⁽¹⁾

Event Mask	Event Flag	Map to ⁽²⁾	Description
MCASP_EVTCTLR[0] ROVRN	MCASP_RXSTAT[0] ROVRN	MCASPi_IRQ_AREVT	Receive buffer overrun
MCASP_EVTCTLR[1] RSYNCERR	MCASP_RXSTAT[1] RSYNCERR	MCASPi_IRQ_AREVT	Unexpected receive frame sync
MCASP_EVTCTLR[2] RCKFAIL	MCASP_RXSTAT[2] RCKFAIL	MCASPi_IRQ_AREVT	Receive clock failure
MCASP_EVTCTLR[3] RDMAERR	MCASP_RXSTAT[7] RDMAERR	MCASPi_IRQ_AREVT	DATA port receive error
MCASP_EVTCTLR[4] RLAST	MCASP_RXSTAT[4] RLAST	MCASPi_IRQ_AREVT	Receive last slot
MCASP_EVTCTLR[5] RDATA	MCASP_RXSTAT[5] RDATA	MCASPi_IRQ_AREVT	Receive data-ready
MCASP_EVTCTLR[7] RSTAFRM	MCASP_RXSTAT[6] RSTAFRM	MCASPi_IRQ_AREVT	Receive start of frame
n.a.	MCASP_RXSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR RCKFAIL ROVRN RSYNCERR). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RXSTAT[3] RTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

⁽¹⁾ Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

⁽²⁾ Every McASP module generates separate IRQ event.

Software has to read the [MCASP_TXSTAT/MCASP_RXSTAT](#) register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the [MCASP_XRSRCTLn](#) registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi_IRQ_AXEVT) is asserted (active high) when one of the [MCASP_TXSTAT](#) notified events occurs, provided that it is enabled in its corresponding [MCASP_EVTCTLX](#) bit. Similarly, a Rx interrupt line (MCASPi_IRQ_AREVT) is asserted (active high) when one of [MCASP_RXSTAT](#) notified events occurs, provided that it is enabled in its corresponding [MCASP_EVTCTLR](#) bit. See also [Section 19.5.4.12.4, Multiple Interrupts](#) and the [Section 19.5.4.10.1, Data Ready Status and Event/Interrupt Generation](#).

19.5.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the [MCASP_TXSTAT](#) register and XDATA is enabled in [MCASP_EVTCTLX](#). The [Section 19.5.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the [MCASP_TXSTAT](#) register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

19.5.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the [MCASP_RXSTAT](#) register and RDATA is enabled in [MCASP_EVTCTLR](#). The [Section 19.5.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when RDATA flag is set in the [MCASP_RXSTAT](#) register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

19.5.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register ([MCASP_TXSTAT](#)):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register ([MCASP_EVTCTLX](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP_TXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register ([MCASP_RXSTAT](#)) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register ([MCASP_EVTCTLR](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP_RXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

19.5.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in [MCASP_TXSTAT](#) is set and the interrupt is enabled in [MCASP_EVTCTLX](#).
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to [MCASP_TXSTAT](#) to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in [MCASP_TXSTAT/MCASP_RXSTAT](#) and the interrupt enabled in [MCASP_EVTCTLX/MCASP_EVTCTLR](#) generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to [MCASP_TXSTAT/MCASP_RXSTAT](#). If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

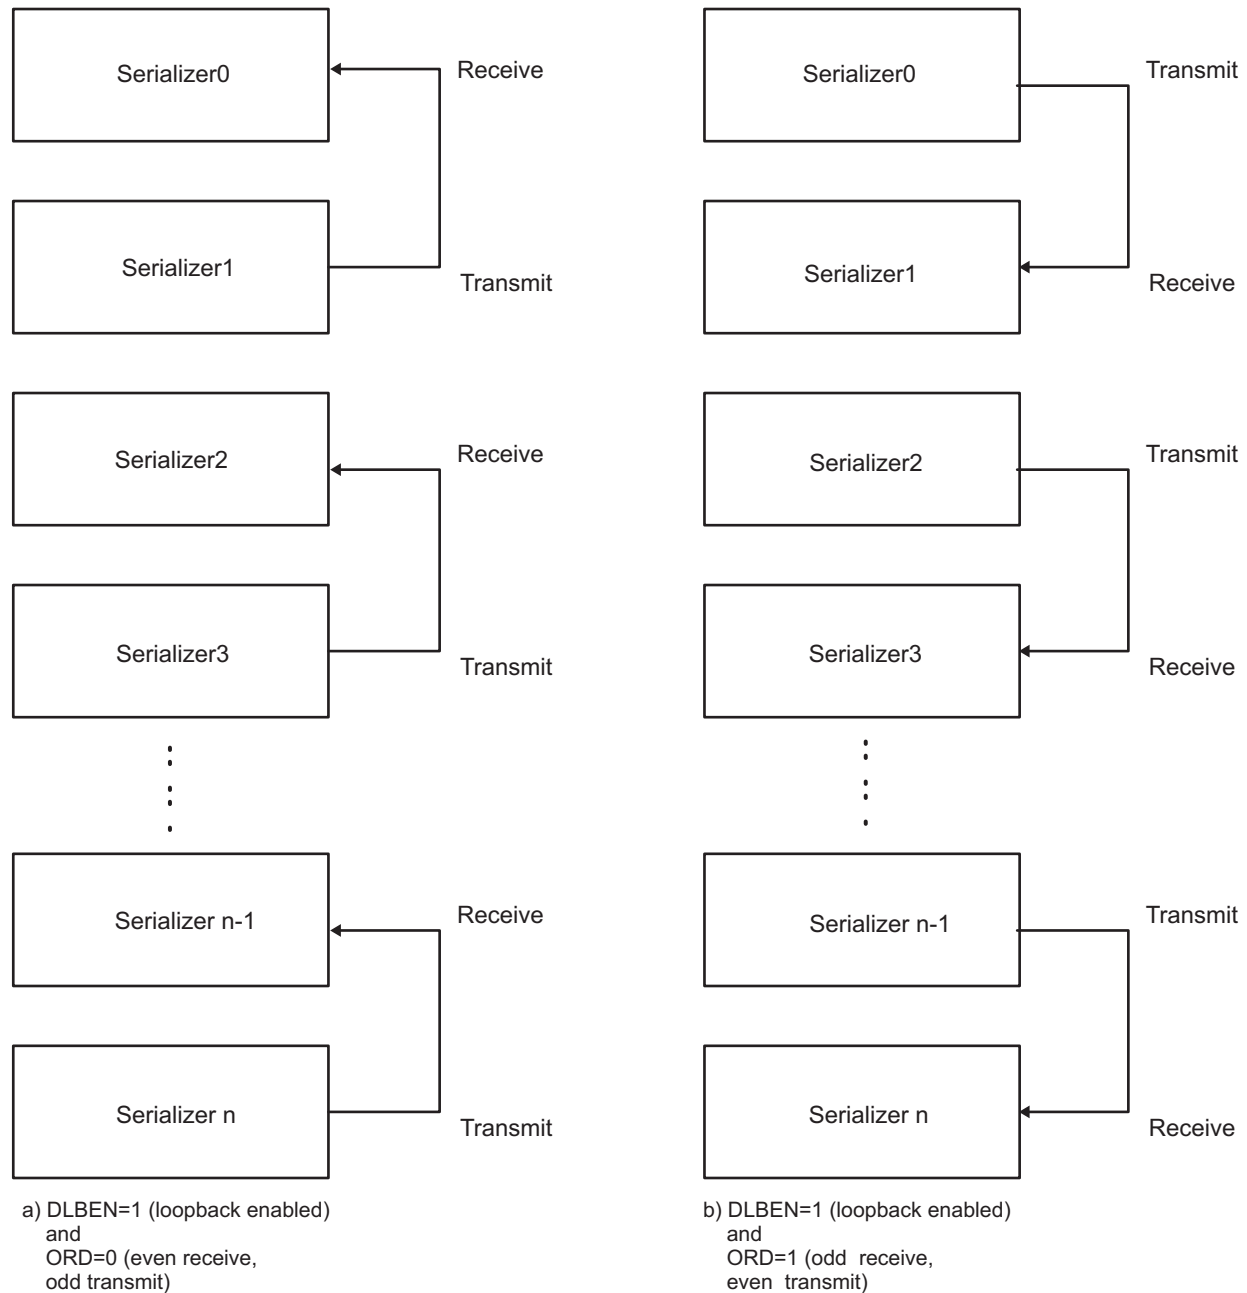

19.5.4.13 DMA Requests

The McASP can generate one DMA request to the DMA_CROSSBAR to transmit (MCASPi_DREQ_TX) or receive (MCASPi_DREQ_RX) data. A DMA request to transmit data is generated if the XDATDMA bit in the [MCASP_XEVTCTL](#) register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the [MCASP_REVTCTL](#) register is cleared.

19.5.4.14 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

[Figure 19-102](#) shows the basic logical connection of the serializers in loopback mode.

Figure 19-102. McASP Serializers Operation in Loopback Mode

mcasp-023

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - [MCASP_LBCTL](#) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the [MCASP_LBCTL](#)) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected ([MCASP_LBCTL\[4\]](#) IOLBEN=0b0), it is NOT necessary to configure [MCASP_PFUNC](#) and [MCASP_PDIR](#) registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding [MCASP_PFUNC](#) bit to 0 (i.e. to function as McASP, not GPIO) and [MCASP_PDIR](#) bit to 1 (output).

When a **device I/O level loopback** is selected ([MCASP_LBCTL\[4\]](#) IOLBEN=0b1), the [MCASP_PFUNC](#) and [MCASP_PDIR](#) registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers).

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL_MODULE_CORE_PAD. For more details, see [Section 14.4.6.1, Pad Configuration Rregisters](#), in [Chapter 14, Control Module](#).

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the [MCASP_LBCTL](#) register to 0x1 and the ASYNC bit of the [MCASP_ACLKXCTL](#) register to 0b0.

19.5.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The [MCASP_LBCTL\[0\]](#) DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The [MCASP_LBCTL\[4\]](#) IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The [MCASP_LBCTL\[3:2\]](#) MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The [MCASP_LBCTL\[1\]](#) ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - [MCASP_ACLKXCTL\[6\]](#) ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - [MCASP_RXFMCTL\[15:7\]](#) RMOD and [MCASP_TXFMCTL\[15:7\]](#) XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

NOTE: Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR - reception.

19.5.4.15 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

19.5.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUF_n buffer to XRSR_n shift register, but the corresponding ([MCASP_TXBUF_n](#)) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The [MCASP_TXSTAT\[0\]](#) XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

19.5.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding [MCASP_RXBUFn](#) register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The [MCASP_RXSTAT\[0\]](#) ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

19.5.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the [MCASP_TXSTAT](#) register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The [MCASP_TXSTAT\[7\]](#) XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in [MCASP_TXSTAT](#).

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

19.5.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the [MCASP_RXSTAT](#) register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The [MCASP_RXSTAT\[7\]](#) RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in [MCASP_RXSTAT](#).

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

19.5.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:

- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

19.5.4.15.6 Clock Failure Detection

19.5.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register ([MCASP_TXCLKCHK](#)).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register ([MCASP_TXSTAT](#)).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
 1. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register ([MCASP_EVTCTLX](#))

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register ([MCASP_RXCLKCHK](#)).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register ([MCASP_RXSTAT](#)).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
 1. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register ([MCASP_EVTCTLR](#))

19.5.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see [Figure 19-103](#)) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register ([MCASP_TXCLKCHK](#)) every 32 high-rate serial clock cycles.

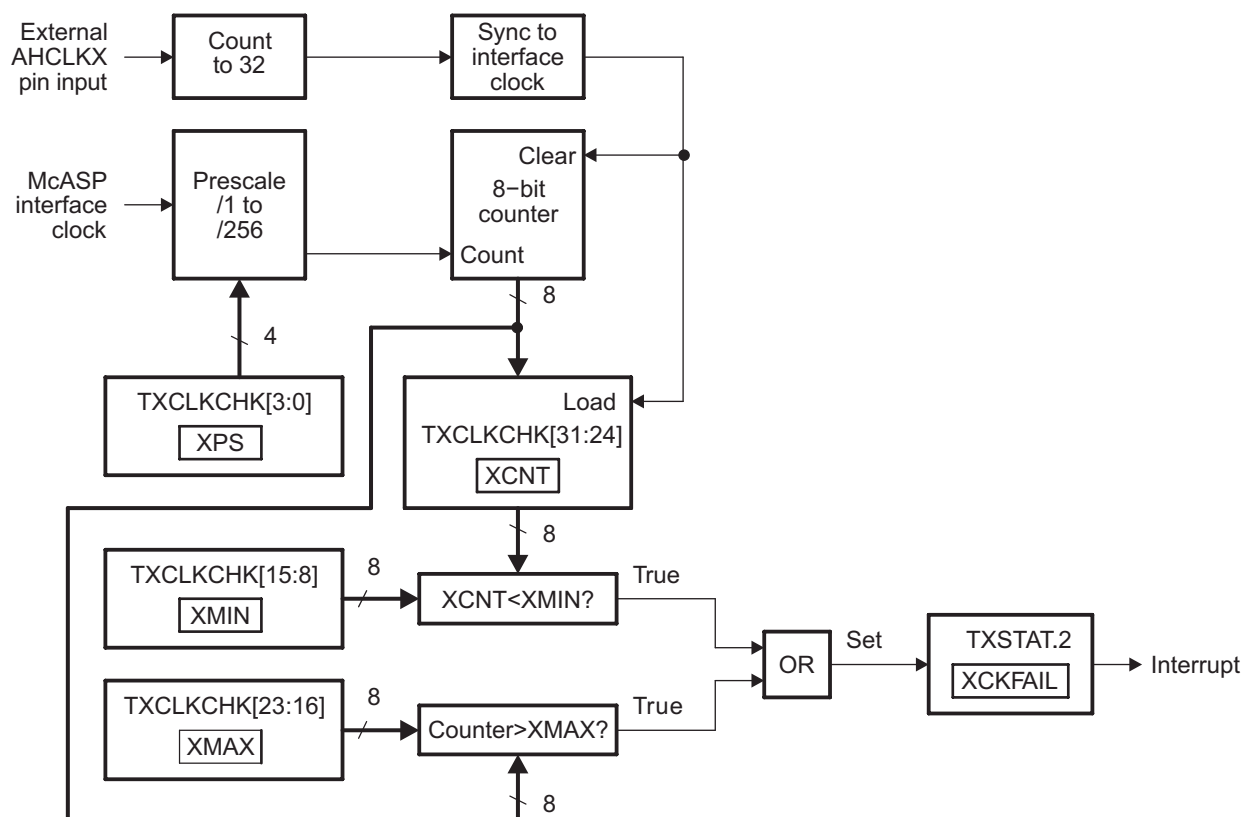

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in `MCASP_TXSTAT`) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in `MCASP_TXSTAT` is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in `MCASP_EVTCTLX` is set.

Figure 19-103. Transmit Clock Failure Detection Circuit Block Diagram

mcasp-024

19.5.4.15.6.3 Receive Clock Failure Check and Recovery

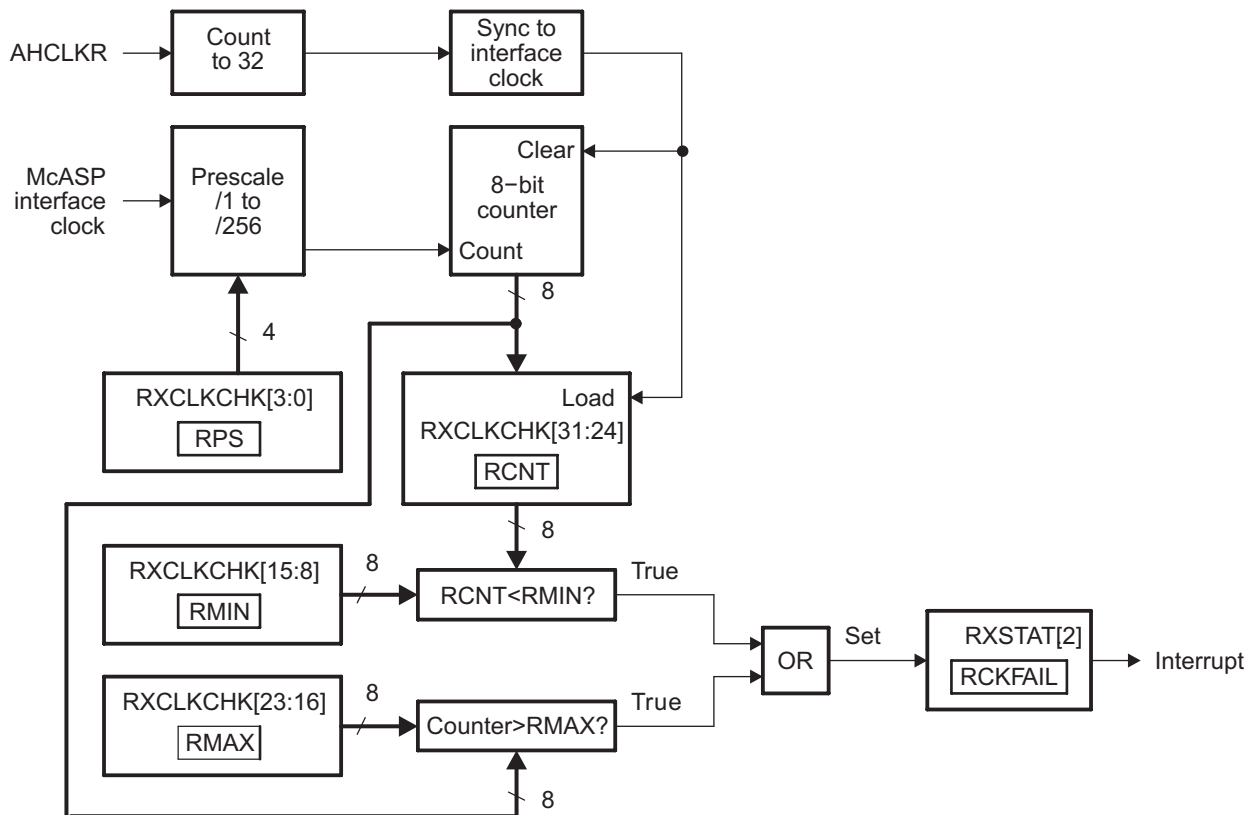

The receive clock failure check circuit (see [Figure 19-104](#)) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (`MCASP_RXCLKCHK`) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in `MCASP_RXSTAT`) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

Figure 19-104. Receive Clock Failure Detection Circuit Block Diagram

19.5.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

19.5.5.1 Global Initialization

19.5.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see [Section 19.5.3, McASP Integration](#), and [Section 19.5.2, McASP Environment](#)).

[Table 19-335](#), describes the global initialization of surrounding modules.

Table 19-335. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See Section 3.6, Clock Management Functional Description , in Chapter 3, Power, Reset, and Clock Management .)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See Section 14.4.6.1, Pad Configuration Registers , in Chapter 14, Control Module .)
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to enable the interrupts from the McASP. For more details on IRQ_CROSSBAR module, see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
(Optional) DMA_CROSSBAR	DMA configuration must be done to enable the McASP DMA data channel requests. For more information on DMA_CROSSBAR module configuration, see Section 14.4.6.5, DMA_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
(Optional) L4_PER2 and L3_MAIN Interconnects	For more information about the interconnect configuration, see Section 10.2.1, L3_MAIN Interconnect Overview in Section 10.2, L3 Interconnect .

NOTE: The IRQ_CROSSBAR and the DMA_CROSSBAR configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected IRQ and DMA controllers of the host CPU must be done for full functionality of the McASP DMA and IRQ lines.

19.5.5.1.2 McASP Global Initialization

19.5.5.1.2.1 Main Sequence – McASP Global Initialization for DIT-Transmission

The procedure in [Table 19-336](#) initializes the McASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the [MCASP_GBLCTL](#) register.

Table 19-336. McASP Transmitters Global Initialization for DIT-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 19.5.5.1.2.1.1.	
5. Configure the transmit frame sync generator.	See Section 19.5.5.1.2.1.2.	
6. Configure the transmit clock generator.	See Section 19.5.5.1.2.1.3.	
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMs	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. ⁽¹⁾	MCASP_XRSRCTLn [1:0] SRMOD	0x1
9. Configure the McASP pins functionality.	See Section 19.5.5.1.2.1.4.	
10. Enable the McASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1 ⁽²⁾
11. Configure DIT-specific subframe fields.	See Table 19-341.	
12. Release from reset state the divider that outputs the AHCLKX clock. ⁽³⁾	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. ⁽³⁾	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

⁽¹⁾ For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

⁽²⁾ This globally configures all active transmitters to operate in DIT-mode.

⁽³⁾ During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKXCTL and MCASP_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

19.5.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in Table 19-337 configures the transmit frame format unit of the McASP module for a DIT-transmission.

NOTE:

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 19-337. Transmit Format Unit Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x- ⁽¹⁾
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- ⁽¹⁾
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x- ⁽¹⁾
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
ENDIF		

⁽¹⁾ Refer to Section 19.5.4.4.1, *Transmit Fromat Unit* and Section 19.5.4.4.1.2, *DIT-Mode Transmission Data Alignment Settings*.

Table 19-337. Transmit Format Unit Configuration for DIT-Transmission (continued)

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

19.5.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in [Table 19-338](#) configures the transmit frame synchronization generator of the McASP module.

NOTE: The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 19-338. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

19.5.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

NOTE: By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in [Table 19-339](#) configures the transmit clock generator of the McASP module.

Table 19-339. Transmit Clock Generator Configuration in DIT-Mode

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 19.5.4.15.6.1, Clock Failure Check Startup .	

19.5.5.1.2.1.4 Subsequence - McASP Pins Functional Configuration

The procedure in [Table 19-340](#) configures the McASP pins for McASP functionality.

Table 19-340. McASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs:	MCASP_PDIR[28] AFSX;	0x1
AFSX	MCASP_PDIR[27] AHCLKX;	0x1
AHCLKX	MCASP_PDIR[26] ACLKX;	0x1
ACLKX	MCASP_PDIR [i] AXRi	0x1
Desired i-th McASP data pin AXRi is configured as an output for DIT-transmission.		

19.5.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in [Table 19-341](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 19-341. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5	0x-
	MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5	0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0], where i = 0 to 5	0x-
	MCASP_DITCSRBi[31:0], where i = 0 to 5	0x-

19.5.5.1.2.2 Main Sequence – McASP Global Initialization for TDM-Reception

The procedure in [Table 19-342](#) initializes a McASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by McASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the [MCASP_GBLCTL](#) register.

NOTE: The McASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device McASP receiver input (TDM-only compatible).

Table 19-342. McASP Receivers Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP receive components.	MCASP_GBLCTL[4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4:0]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See Section 19.5.5.1.2.2.1 .	
5. Configure the receive frame sync generator.	See Section 19.5.5.1.2.2.2 .	
6. Configure the receive clock generator.	See Section 19.5.5.1.2.2.3 .	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RXTDM [k] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. ⁽¹⁾	MCASP_XRSRCTLn [1:0] SRMOD	0x2
9. Configure the McASP pins functionality.	See Section 19.5.5.1.2.2.4 .	

⁽¹⁾ For an unused serializer n, write [MCASP_XRSRCTLn](#) [1:0] SRMOD=0x0 to disable it.

Table 19-342. McASP Receivers Global Initialization for TDM-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
10. Optional: Configure a McASP Rx channel for a loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 19.5.4.14.1, Loopback Mode Configurations .	0x- ⁽²⁾
11. Release from reset state the divider that outputs the AHCLKR clock. ⁽³⁾ See also ⁽⁴⁾ .	MCASP_GBLCTL [1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also ⁽⁴⁾ .	MCASP_GBLCTL [1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. ⁽³⁾ See also ⁽⁵⁾ .	MCASP_GBLCTL [0] RCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register. See also ⁽⁵⁾ .	MCASP_GBLCTL [0] RCLKRST	=0x1

⁽²⁾ In this case the receiver clock and frame sync are derived from the McASP transmitter logic, so [MCASP_ACLKXCTL](#)[6] ASYNC must be set to 0b0. Neither McASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

⁽³⁾ During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the [MCASP_AHCLKRCTL](#) and [MCASP_ACLKRCTL](#) registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.

⁽⁴⁾ This step is necessary even if external high-frequency serial clocks are used.

⁽⁵⁾ This step can be skipped if external serial clocks are used and they are running.

19.5.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in [Table 19-343](#) configures the receive frame format unit of the McASP module for TDM slots reception.

Table 19-343. Receive Format Unit Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RXFMT [7:4] RSSZ	0x- ⁽¹⁾
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RXMASK [31:0] RMASK	0x- ⁽²⁾
Select a padding value for masked-out bits.	MCASP_RXFMT [14:13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RXBUF_n which value to be used as a pad value in case MCASP_RXFMT [14:13] RPAD=0x2.	MCASP_RXFMT [12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RXFMT [2:0] RROT	0x- ⁽³⁾
Received stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RXFMT [15] RRVRS	0x- ⁽³⁾
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RXFMT [17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RXFMT [3] RBUSEL	0x-

⁽¹⁾ Refer to [Section 19.5.4.4.2, Receive Format Unit](#), regarding options for received TDM-slot sizes.

⁽²⁾ For more details on Rx masking value, refer to [Section 19.5.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#)

⁽³⁾ For more details on rotation and received TDM stream bit order, refer to [Section 19.5.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#) and [Table 19-330, McASP RFU Settings](#).

19.5.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 19-344](#) configures the transmit frame synchronization generator of the McASP module.

NOTE: The same bit - [MCASP_ACLKXCTL\[6\]](#) ASYNC which is used to determine if McASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either internally or externally sourced). Hence, the settings in below table [Table 19-344](#) have no effect, if [MCASP_ACLKXCTL\[6\]](#) ASYNC = 0.

Table 19-344. Receive Frame-Synchronization Generator Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_RXFMCTL[15:7] RMOD	0x- ⁽¹⁾
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_RXFMCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising /falling edge. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_RXFMCTL[0] FSRP	0x-
IF receive frame sync - FS is internally generated	Software test condition	
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_RXFMCTL[1] FSRM	0b1
If McASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the Table 19-342 . This must not be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
ELSE		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_RXFMCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: <code>mcaspi_fsr</code>)	MCASP_PDIR[31] AFSR	0b0
ENDIF		
To generate McASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

⁽¹⁾ Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to [Section 19.5.4.9.2](#).

19.5.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in [Table 19-345](#) configures the receive clock generator of the McASP module.

NOTE: The settings in below table [Table 19-345](#) have no effect, if [MCASP_ACLKXCTL\[6\]](#) ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when McASP loopback mode is used.

Table 19-345. Receive Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
To use the McASP receive clock generator, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
IF receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-
Optional: If McASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the Table 19-342 . This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
ELSE		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input direction for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 19.5.4.15.6.1, Clock Failure Check Startup .	

19.5.5.1.2.2.4 Subsequence—McASP Receiver Pins Functional Configuration

The procedure in [Table 19-346](#) configures the McASP pins for McASP functionality.

Table 19-346. McASP Receiver Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSR ACLKR Desired n-th McASP data pin AXRn is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[n] AXRn;	0x- ⁽¹⁾ 0x- ⁽²⁾ 0x0

⁽¹⁾ See [Table 19-344](#).

⁽²⁾ For more details on McASP clock configurations, refer to [Table 19-345](#).

19.5.5.1.2.3 Main Sequence – McASP Global Initialization for TDM -Transmission

The procedure in [Table 19-347](#) initializes a McASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the [MCASP_GBLCTL](#) register.

Table 19-347. McASP Transmitters Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP transmit components.	MCASP_GBLCTL [12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL [12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG [1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 19.5.5.1.2.3.1 .	
5. Configure the transmit frame sync generator.	See Section 19.5.5.1.2.3.2 .	
6. Configure the transmit clock generator.	See Section 19.5.5.1.2.3.3 .	
7. Program all bits - XTDMSk, where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_TXTDM [k] XTDMSk, where k=0 to 31 ⁽¹⁾	0x-
8. Configure the desired n-th serializer for transmit mode operation. ⁽²⁾	MCASP_XRSRCTLn [1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_TXDITCTL [0] DITEN	0x0 ⁽³⁾
10. Configure the McASP pins functionality.	See Section 19.5.5.1.2.3.4 .	
11. Optional: Configure a McASP Tx channel for loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 19.5.4.14.1 , <i>Loopback Mode Configurations</i> .	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See ⁽⁴⁾	MCASP_GBLCTL [9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL [9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See ⁽⁴⁾	MCASP_GBLCTL [8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL [8] XCLKRST	=0x1

⁽¹⁾ Appropriately program in bitfield [MCASP_XRSRCTLn](#) [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

⁽²⁾ For an unused serializer n, write [MCASP_XRSRCTLn](#) [1:0] SRMOD=0x0 to disable it.

⁽³⁾ All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.

⁽⁴⁾ During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the [MCASP_AHCLKX](#) and [MCASP_ACLKX](#) registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

19.5.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in [Table 19-348](#) configures the transmit frame format unit of the McASP module for TDM slots transmission.

Table 19-348. Transmit Format Unit Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x- ⁽¹⁾
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x- ⁽²⁾
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUF _n which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- ⁽³⁾
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_TXFMT[15] XRVR	0x- ⁽³⁾
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

⁽¹⁾ Refer to [Section 19.5.4.4.1, Transmit Format Unit](#), regarding options for transmitted TDM-slot sizes.

⁽²⁾ For more details on Tx masking value, refer to [Section 19.5.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#)

⁽³⁾ For more details on rotation and transmitd TDM stream bit order, refer to [Section 19.5.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#) and [Table 19-328, McASP TFU TDM Mode Settings](#).

19.5.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 19-349](#) configures the transmit frame synchronization generator of the McASP module.

Table 19-349. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_TXFMCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising /falling edge. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_TXFMCTL[0] FSXP	0x-
IF transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_TXFMCTL[1] FSXM	0b1
If McASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the Table 19-347 . This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
ELSE		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 19.5.4.2.3 .	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

19.5.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in [Table 19-350](#) configures the transmit clock generator of the McASP module.

Table 19-350. Transmit Clock Generator Configuration for TDM Cases

Step	Register/Bit Field/Programming Model	Value
IF transmit clock - XCLK is internally generated	Software test condition	
IF high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL [15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL [14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL [11:0] HCLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the Table 19-347 . This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR [27] AHCLKX	0b1
ELSE		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL [15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL [14] HCLKXP	0x-
Setup an input direction for the AHCLKX pin	MCASP_PDIR [27] AHCLKX	0b0
ENDIF		
Select an internally-generated transmit clock.	MCASP_ACLKXCTL [5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL [7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_ACLKXCTL [4:0] CLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the Table 19-347 . This must NOT be done in current step because the clock control register - MCASP_ACLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR [26] ACLKX	0b1
ELSE		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_ACLKXCTL [5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL [7] CLKXP	0x-
Setup an input direction for the ACLKX pin	MCASP_PDIR [26] ACLKX	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 19.5.4.15.6.1 , <i>Clock Failure Check Startup</i> .	

19.5.5.1.2.3.4 Subsequence—McASP Transmit Pins Functional Configuration

The procedure in [Table 19-351](#) configures the McASP pins for McASP functionality.

Table 19-351. McASP Transmit Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSX AHCLKX ACLKX Desired n-th McASP data pin AXRn is configured as an output for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[n] AXRn	0x- ⁽¹⁾ 0x- ⁽²⁾ 0x- ⁽²⁾ 0x1

⁽¹⁾ See [Table 19-349](#).

⁽²⁾ For more details on McASP clock configurations, refer to [Table 19-345](#).

19.5.5.2 Operational Modes Configuration

19.5.5.2.1 McASP Transmission Modes

19.5.5.2.1.1 Main Sequence – McASP DIT- /TDM- Polling Transmission Method

[Figure 19-105](#) shows the McASP DIT-/TDM- polling method.

Figure 19-105. McASP DIT- /TDM- Transmission Polling Method

mcasp-026

Table 19-352 summarizes the register call for the transmission DIT-/TDM- polling mode.

19.5.5.2.1.2 Main Sequence – McASP DIT- /TDM - Interrupt Transmission Method

[Figure 19-106](#) shows the initial setup for interrupt-based transmission.

Figure 19-106. Subsequence – DIT-/TDM- Transmission Startup Procedure

mcasp-027

Table 19-354 shows the configuration of the McASP using an interrupt method for DIT-/TDM-transmission.

Table 19-354. McASP DIT-/TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
IF write transfer is through the McASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the <i>McASP Transmitters Global Initialization</i> - see Table 19-336)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
ENDIF		
DIT/TDM - Transmission Startup Procedure	See Figure 19-106.	

Table 19-355 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 19-355. Register Call Summary for Subsequence – McASP DIT-/TDM- Transmission Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXSTAT

19.5.5.2.1.3 Main Sequence –McASP DIT- /TDM - Mode DMA Transmission Method

Table 19-356 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 19-355 shows the initial setup for DMA - based transmission.

NOTE: Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 19-356. McASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0

Table 19-356. McASP DMA Transmission Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 19-106 . The only difference is that DMA automatically services all the AXEVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 19-109 .	See Figure 19-106 .	

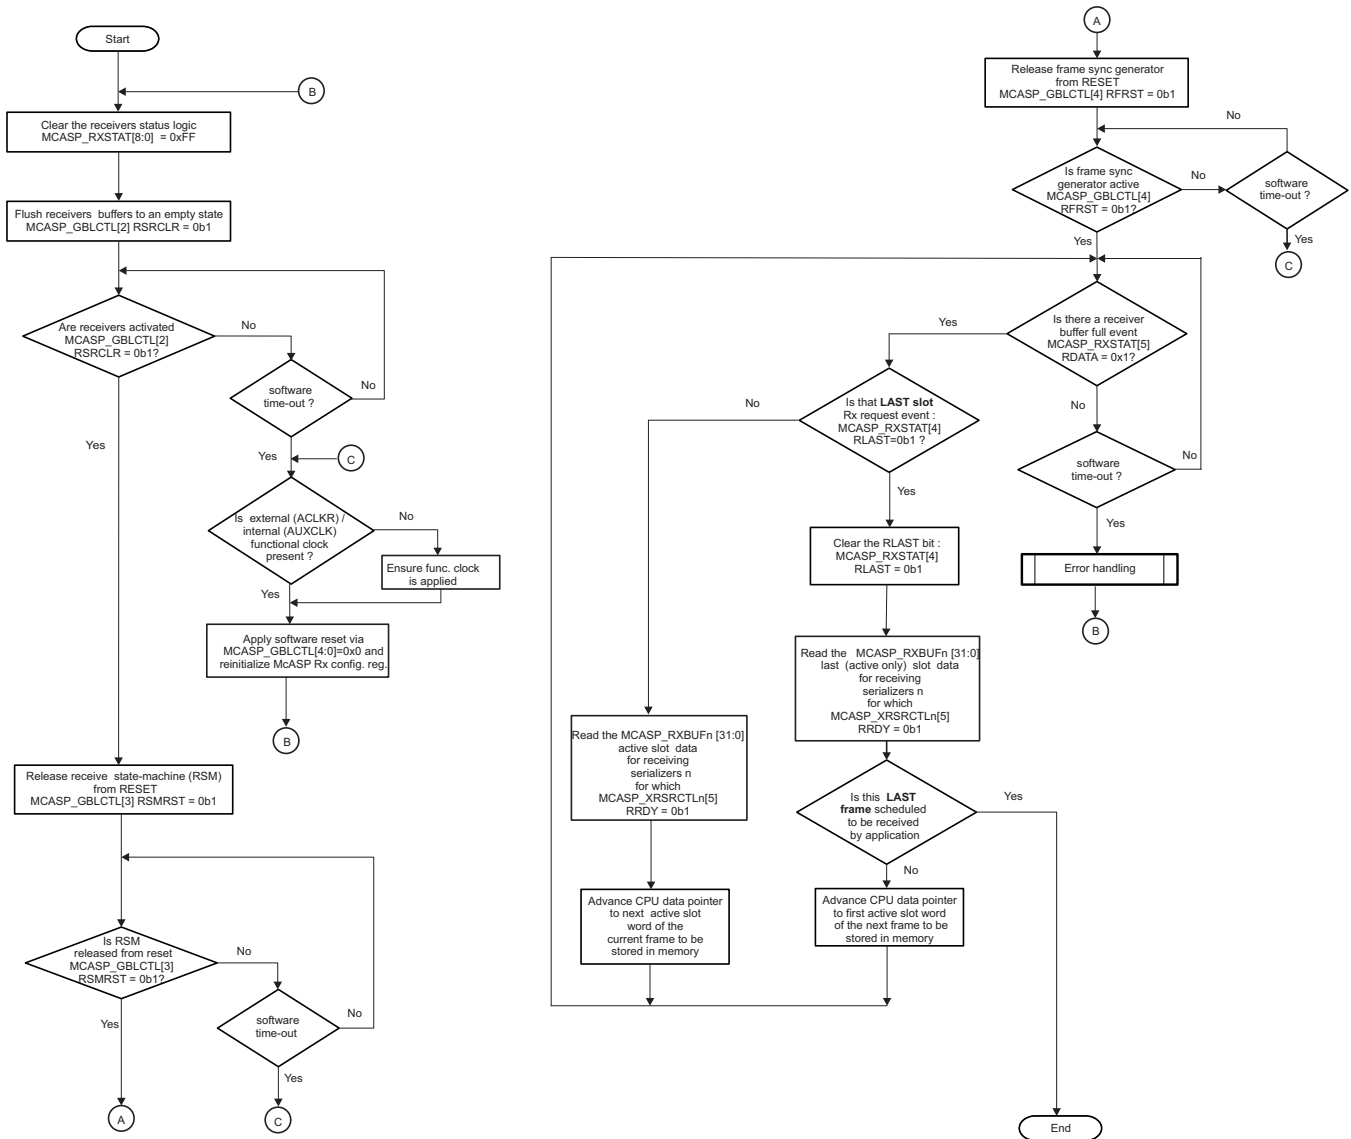

19.5.5.2.2 McASP Reception Modes

19.5.5.2.2.1 Main Sequence – McASP Polling Reception Method

[Figure 19-107](#) shows the McASP polling reception method.

NOTE: The McASP polling reception model considers the device CPUs as the accessor of audio data from the McASP receive buffers.

MCASP_TXSTAT

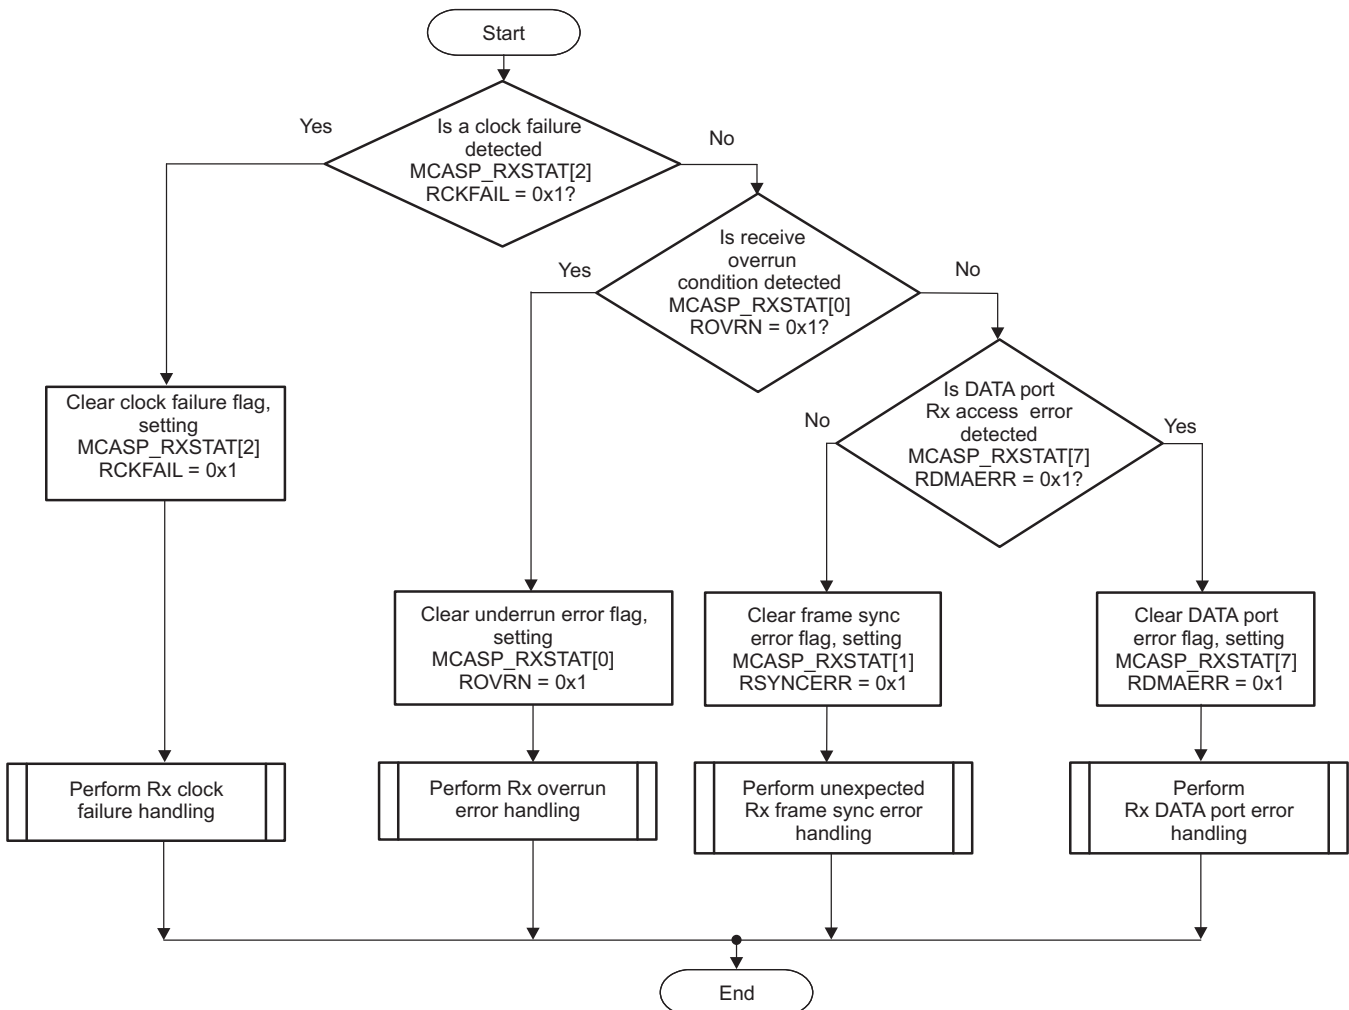

NOTE:

- For more information about transmit clock failure handling, see [Section 19.5.4.15.6.2, Transmit Clock Failure Check and Recovery.](#)
- For more information about transmit buffer underrun handling, see [Section 19.5.4.15.1, Buffer Underrun Error - Transmitter.](#)
- For more information about DATA port Tx error handling, see [Section 19.5.4.15.3, DATA Port Error - Transmitter.](#)
- For more information about unexpected Tx frame sync error handling, see [Section 19.5.4.15.5, Unexpected Frame Sync Error.](#)

19.5.5.2.3.4 Subsequence – McASP Receive Error Handling

Figure 19-112 shows the receive error handling schema for the McASP, which can ONLY be implemented as part of the Rx polling sequence.

Figure 19-112. McASP Receive Error Handling

mcasp-031

[Table 19-365](#) lists the register call summary for the McASP receive error handling.

Table 19-365. Register Call Summary for McASP Receive Error Handling

Register Name
MCASP_RXSTAT

NOTE:

- For more information about receive clock failure handling, see [Section 19.5.4.15.6.3](#), *Receive Clock Failure Check and Recovery*.
- For more information about receive buffer overrun handling, see [Section 19.5.4.15.2](#), *Buffer Overrun Error - Receiver*.
- For more information about DATA port Rx error handling, see [Section 19.5.4.15.4](#), *DATA Port Error - Receiver*.
- For more information about unexpected Rx frame sync error handling, see [Section 19.5.4.15.5](#), *Unexpected Frame Sync Error*.

⁽²⁾ n = 0 to 5

NOTE: The address locations listed in [Table 19-367](#) and [Table 19-368](#), *MCASP_CFG Register Mapping Summary*, are relevant for accessing:

- All McASP configuration registers
- [MCASP_TXBUF*n*](#) registers
- [MCASP_RXBUF*n*](#) registers

through the McASP peripheral configuration (CFG) port.

The [MCASP_TXFMT](#)[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the McASP XRBUFF*n* buffer. The [MCASP_RXFMT](#)[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the McASP XRBUFF*n* buffer.

19.5.6.2.2 MCASP_CFG Register Description

The tables below describe the individual MCASP_CFG register bits.

NOTE: For all of the below described registers the indexes n and N are applying to serializers (not slots).

Register descriptions cover the superset McASP (16 serializers and all signals pinned out). For the particular McASP instantiation, please refer to [Section 19.5.2, McASP Environment](#), and [Section 19.5.3, McASP Integration](#).

Table 19-377. MCASP_PDOUT

Address Offset	0x0000 0018		
Physical Address	0x4846 0018 0x4846 C018 0x4847 0018	Instance	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	<p>Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output).</p> <p>When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin.</p> <p>When writing data, writes to the corresponding MCASP_PDOUT[n] bit.</p> <p>PDOUT has these aliases or alternate addresses:</p> <ul style="list-style-type: none"> • MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged. • MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged <p>There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.</p> <p><i>Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.</i></p>

Bits	Field Name	Description	Type	Reset
31	AFSR	Determines drive on AFSR output pin when the corresponding MCASP_PFUNC[31] and MCASP_PDIR[31] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
30	AHCLKR	Determines drive on AHCLKR output pin when the corresponding MCASP_PFUNC[30] and MCASP_PDIR[30] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
29	ACLKR	Determines drive on ACLKR output pin when the corresponding MCASP_PFUNC[29] and MCASP_PDIR[29] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
28	AFSX	Determines drive on AFSX output pin when the corresponding MCASP_PFUNC[28] and MCASP_PDIR[28] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
27	AHCLKX	Determines drive on AHCLKX output pin when the corresponding MCASP_PFUNC[27] and MCASP_PDIR[27] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
26	ACLKX	Determines drive on ACLKX output pin when the corresponding MCASP_PFUNC[26] and MCASP_PDIR[26] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
25:16	RESERVED	Reserved	RW	0x000
15	AXR15	Determines drive on AXR15 output pin when the corresponding MCASP_PFUNC[15] and MCASP_PDIR[15] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
14	AXR14	Determines drive on AXR14 output pin when the corresponding MCASP_PFUNC[14] and MCASP_PDIR[14] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
13	AXR13	Determines drive on AXR13 output pin when the corresponding MCASP_PFUNC[13] and MCASP_PDIR[13] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
12	AXR12	Determines drive on AXR12 output pin when the corresponding MCASP_PFUNC[12] and MCASP_PDIR[12] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
11	AXR11	Determines drive on AXR11 output pin when the corresponding MCASP_PFUNC[11] and MCASP_PDIR[11] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
10	AXR10	Determines drive on AXR10 output pin when the corresponding MCASP_PFUNC[10] and MCASP_PDIR[10] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
9	AXR9	Determines drive on AXR9 output pin when the corresponding MCASP_PFUNC[9] and MCASP_PDIR[9] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
8	AXR8	Determines drive on AXR8 output pin when the corresponding MCASP_PFUNC[8] and MCASP_PDIR[8] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
7	AXR	Determines drive on AXR7 output pin when the corresponding MCASP_PFUNC[7] and MCASP_PDIR[7] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
6	AXR6	Determines drive on AXR6 output pin when the corresponding MCASP_PFUNC[6] and MCASP_PDIR[6] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
5	AXR5	Determines drive on AXR5 output pin when the corresponding MCASP_PFUNC[5] and MCASP_PDIR[5] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
4	AXR4	Determines drive on AXR4 output pin when the corresponding MCASP_PFUNC[4] and MCASP_PDIR[4] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
3	AXR3	Determines drive on AXR3 output pin when the corresponding MCASP_PFUNC[3] and MCASP_PDIR[3] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
2	AXR2	Determines drive on AXR2 output pin when the corresponding MCASP_PFUNC[2] and MCASP_PDIR[2] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
1	AXR1	Determines drive on AXR1 output pin when the corresponding MCASP_PFUNC[1] and MCASP_PDIR[1] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
0	AXR0	Determines drive on AXR0 output pin when the corresponding MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Table 19-381. MCASP_PDSET

Address Offset	0x0000 001C	Instance	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Physical Address	0x4846 001C 0x4846 C01C 0x4847 001C		
Description	The pin data set register is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDSET bit sets the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic high on the pin. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Table 19-383. MCASP_PDCLR

Address Offset	0x0000 0020		
Physical Address	0x4846 0020 0x4846 C020 0x4847 0020	Instance	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	<p>The pin data clear register is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDCLR bit clears the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic low on the pin.</p> <p>Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.</p>

Table 19-385. MCASP_GBLCTL

Address Offset	0x0000 0044		
Physical Address	0x4846 0044 0x4846 C044 0x4847 0044	Instance	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the transmitter and receiver corresponding clocks - ACLKX (bits [12:8]) and ACLKR (bits [4:0]), respectively. Before programming MCASP_GBLCTL , ensure that the serial clocks are running. If the corresponding external serial clocks - ACLKX and ACLKR, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the MCASP_GBLCTL . Also, after programming any bits in MCASP_GBLCTL , do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.

Description	The receiver status register (MCASP_RXSTAT) provides the receiver status and receive TDM time slot number.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RERR	RDMAERR	RSTAFRM	RDATA	RLAST	RTDMSLOT	RCKFAIL	RSYNCERR	ROVRN							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x00 0000
8	RERR	RERR bit always returns a logic-OR of: ROVRN RSYNCERR RCKFAIL RDMAERR Allows a single bit to be checked to determine if a receiver error has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	RDMAERR	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the DMA port in a given time slot than were programmed as receivers. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive DMA error did not occur. 0x1: Receive DMA error did occur.	RW	0
6	RSTAFRM	Receive start of frame flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new receive frame sync (AFSR) is detected. 0x1: A new receive frame sync (AFSR) is detected.	RW	0
5	RDATA	Receive data ready flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new data in RBUF. 0x1: Data is transferred from XRSR to RBUF and ready to be serviced by the CPUs or DMA. When RDATA is set, it always causes a DMA event (AREVT).	RW	0

Bits	Field Name	Description	Type	Reset
4	RLAST	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. RDATA is also set.	RW	0
3	RTDMSLOT	Returns the LSB of RSLOT. Allows a single read of MCASP_RXSTAT to determine whether the current TDM time slot is even or odd. 0x0: Current TDM time slot is odd. 0x1: Current TDM time slot is even.	RW	0
2	RCKFAIL	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive clock failure did not occur. 0x1: Receive clock failure did occur.	RW	0
1	RSYNCERR	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Unexpected receive frame sync did not occur. 0x1: Unexpected receive frame sync did occur.	RW	0
0	ROVRN	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receiver overrun did not occur. 0x1: Receiver overrun did occur.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN XSYNCERR XCKFAIL XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	XDATA	<p>Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect</p> <p>0x0: XBUF[n] is written and is full</p> <p>0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).</p>	RW	0
4	XLAST	<p>Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.</p> <p>0x0: Current slot is not the last slot in a frame.</p> <p>0x1: Current slot is the last slot in a frame. XDATA is also set.</p>	RW	0
3	XTDMSLOT	<p>Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd.</p> <p>read 0x0: Current TDM time slot is odd.</p> <p>read 0x1: Current TDM time slot is even.</p>	R	0
2	XCKFAIL	<p>Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.</p> <p>0x0: Transmit clock failure did not occur.</p> <p>0x1: Transmit clock failure occurred</p>	RW	0
1	XSYNCERR	<p>Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.</p> <p>0x0: Unexpected transmit frame sync did not occur</p> <p>0x1: Unexpected transmit frame sync occurred.</p>	RW	0
0	XUNDRN	<p>Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.</p> <p>0x0: Transmitter underrun did not occur</p> <p>0x1: Transmitter underrun occurred.</p>	RW	0

19.5.6.2.5 MCASP_DAT Register Summary

[Table 19-467](#) and [Table 19-468](#) summarize the MCASP_DAT register mapping.

Table 19-467. MCASP_DAT Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000 ⁽¹⁾	0x4580 0000
MCASP_TXBUF	W	32	0x0000 0000 ⁽¹⁾	0x4580 0000

⁽¹⁾ 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when an access is performed to XRBUF_n RX/TX buffers through the McASP DATA port.

Table 19-468. MCASP_DAT Register Summary 2

Register Name	Type	Register Width (Bits)	Address Offset	MCASP2_DAT L4_PER2 Physical Address	MCASP3_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000 ⁽¹⁾	0x4843 6000	0x4843 A000
MCASP_TXBUF	W	32	0x0000 0000 ⁽¹⁾	0x4843 6000	0x4843 A000

⁽¹⁾ 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when an access is performed to XRBUF_n RX/TX buffers through the McASP DATA port.

NOTE: For [MCASP_RXBUF](#) and [MCASP_TXBUF](#) buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The [MCASP_TXFMT\[3\]](#) XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The [MCASP_RXFMT\[3\]](#) RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

NOTE: The McASP DATA port is exclusively assigned for DMAs/device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

NOTE: The McASP1, whose data port is accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

19.5.6.2.6 MCASP_DAT Register Description

Table 19-469. MCASP_RXBUF

19.6 DCAN

This chapter describes the controller area network modules (DCAN) in the device.

19.6.1 DCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports:

- one DCAN module, referred to as DCAN (SR2.0)
- two DCAN modules, referred to as DCAN1 and DCAN2 (SR1.0)

Connection to the CAN network is performed through external (for the device) transceivers. The DCAN modules support bit rates up to 1 Mbit/s and are compliant to the CAN 2.0B protocol specification.

NOTE: There is only one DCAN module on SR2.0 devices called DCAN. On SR1.0 there are two DCAN modules called DCAN1 and DCAN2. DCAN on SR2.0 is same as DCAN1 on SR1.0.

Figure 19-113 shows the DCAN (SR2.0)/DCAN1 (SR1.0) module highlights.

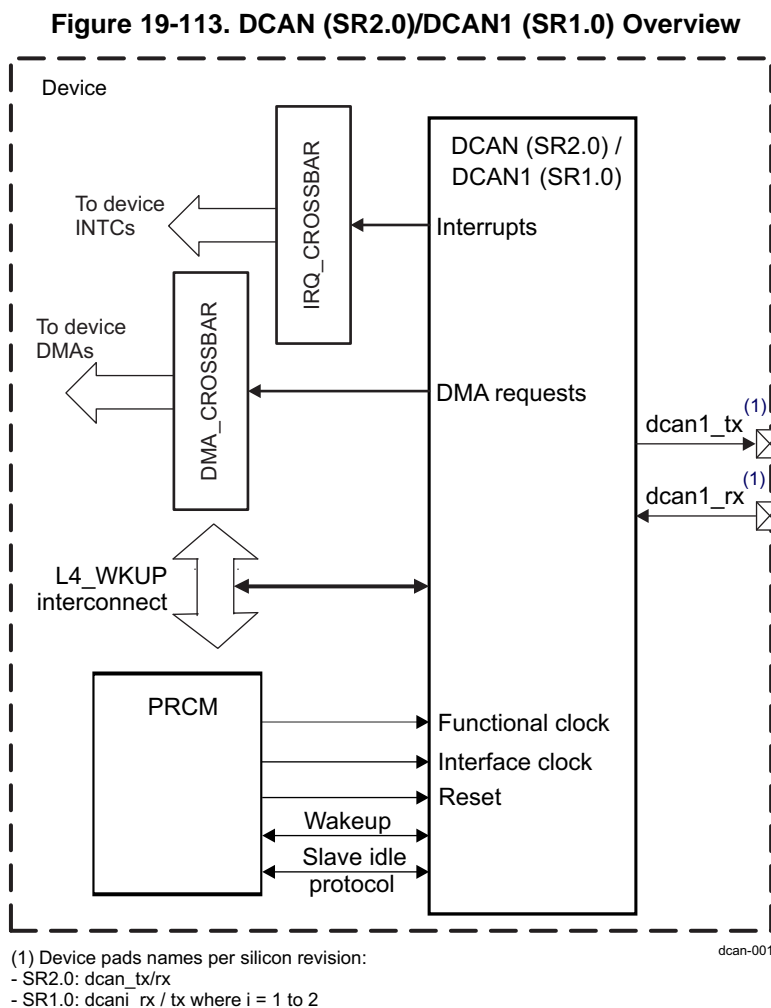

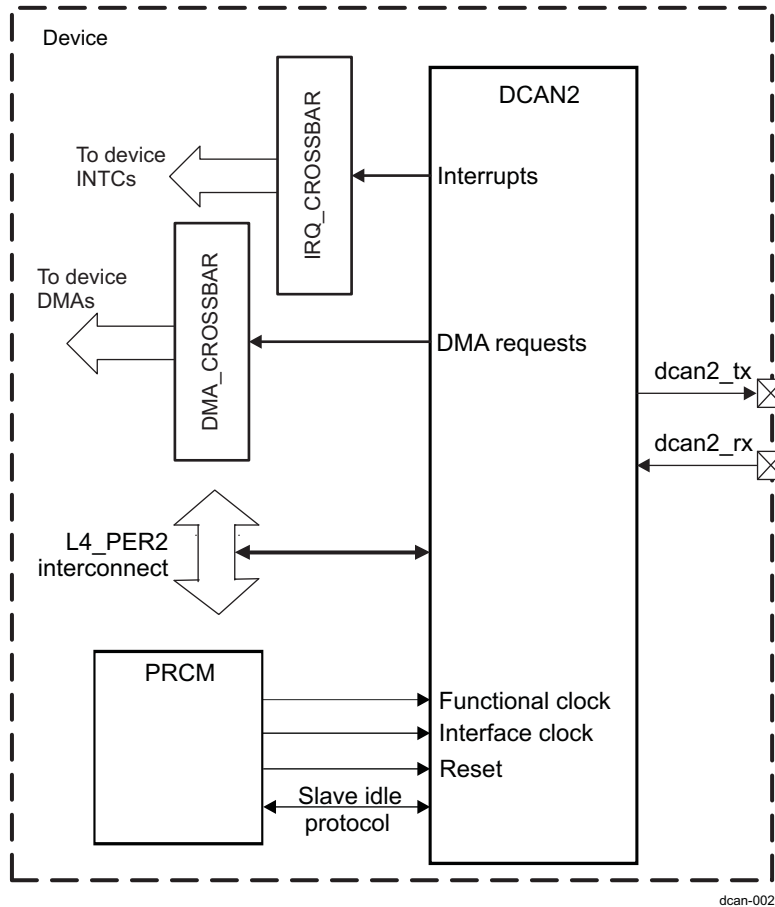

Figure 19-114 shows the DCAN2 module highlights (SR1.0).

Figure 19-114. DCAN2 Overview (SR1.0)

19.6.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM single error correction and double error detection (SECDED) mechanism
- Direct access to message RAM during test mode
- Support for two interrupt lines: Level 0 and Level 1, plus separate ECC interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

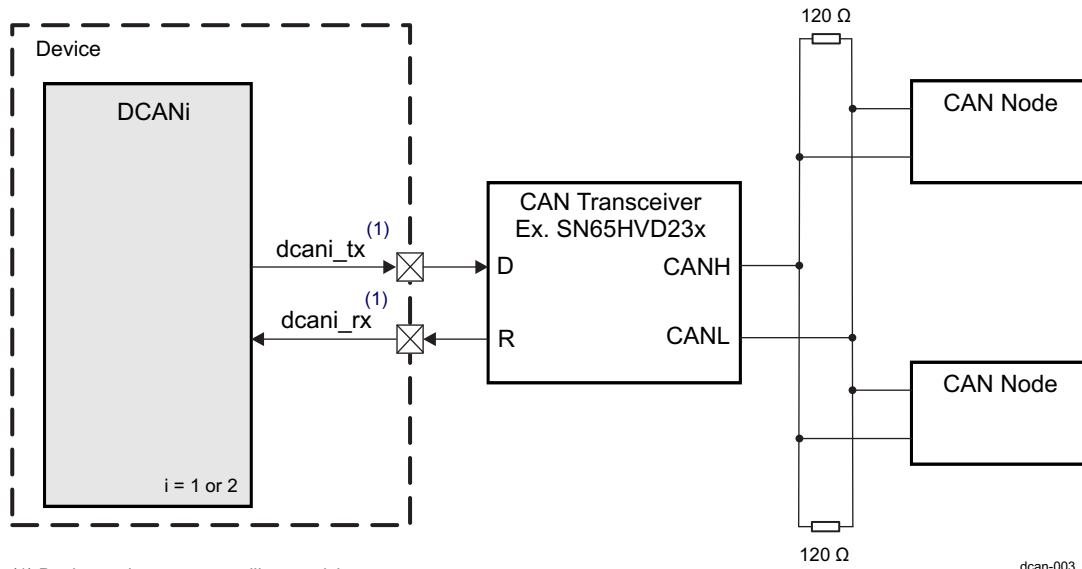

19.6.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

NOTE: There is only one DCAN module on SR2.0 devices called DCAN. On SR1.0 there are two DCAN modules called DCAN1 and DCAN2. DCAN on SR2.0 is same as DCAN1 on SR1.0.

Figure 19-115 shows an overview of a typical DCAN application.

Figure 19-115. DCAN Typical Application

(1) Device pads names per silicon revision:
 - SR2.0: dcan_tx/rx
 - SR1.0: dcani_rx / tx where i = 1 to 2

dcan-003

Table 19-473 describes the external signals of the DCAN module (SR2.0).

Table 19-473. DCAN I/O Description (SR2.0)

Module Signal	Device Signal	I/O ⁽¹⁾	Description	Value at Reset
CAN_RX	dcan_rx	I	Serial data input from external CAN transceiver	HiZ
CAN_TX	dcan_tx	O	Serial data output to external CAN transceiver	1

(1) I = Input; O = Output

Table 19-474 describes the external signals of the DCANi module (SR1.0).

Table 19-474. DCANi I/O Description (SR1.0)

Module Signal	Device Signal	I/O ⁽¹⁾	Description	Value at Reset
CAN_RX	dcani_rx ⁽²⁾	I	Serial data input from external CAN transceiver	HiZ
CAN_TX	dcani_tx ⁽²⁾	O	Serial data output to external CAN transceiver	1

(1) I = Input; O = Output

(2) i = 1 to 2

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 14.4.6.1](#), *Pad Configuration Registers* of [Chapter 14](#), *Control Module*.

19.6.2.1 CAN Network Basics

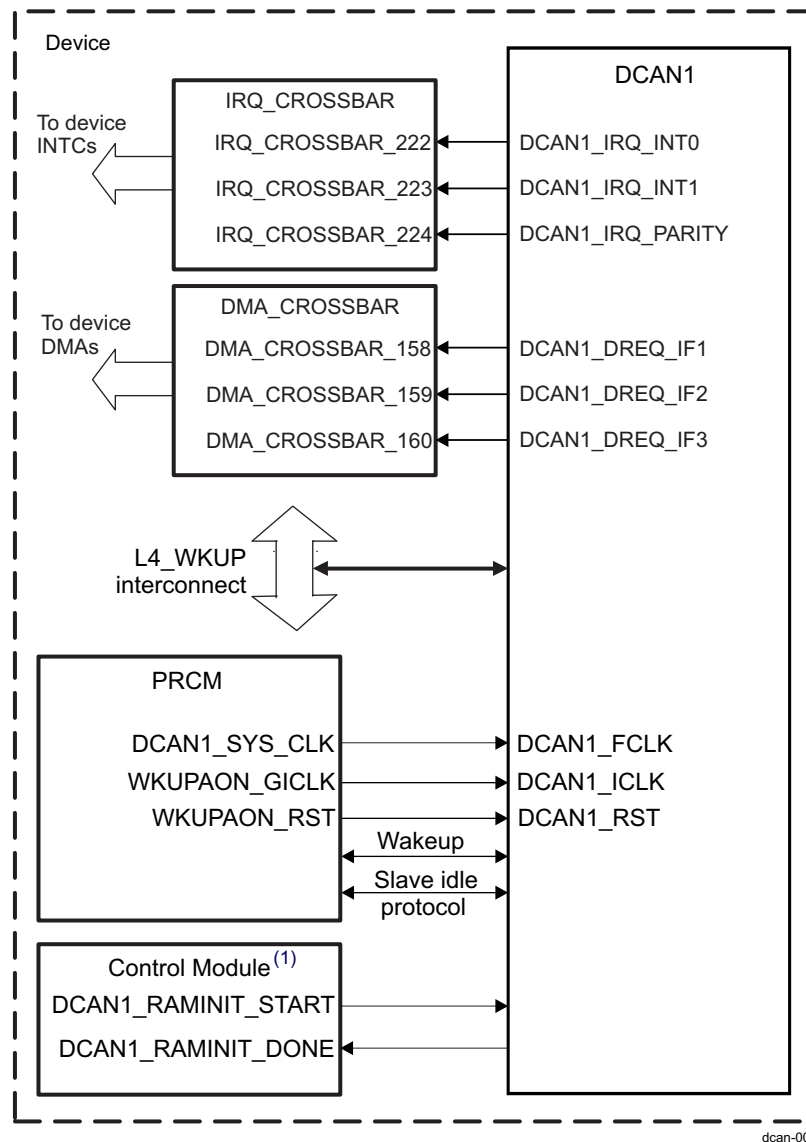

- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
 - Recessive state (logic 1)
 - Dominant state (logic 0)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, etc.)
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
 - Arbitration field
 - Control field
 - Data field (0 ÷ 8 bytes)
 - CRC field
 - ACK field.

19.6.3 DCAN Integration

NOTE: There is only one DCAN module on SR2.0 devices called DCAN. On SR1.0 there are 2 DCAN modules called DCAN1 and DCAN2. DCAN on SR2.0 is same as DCAN1 on SR1.0.

Figure 19-116 shows the integration of the DCAN (SR2.0)/DCAN1 (SR1.0) module in the device. For detailed info on integration of DCAN (SR2.0) and DCAN1 (SR1.0) see also Table 19-475 through Table 19-477

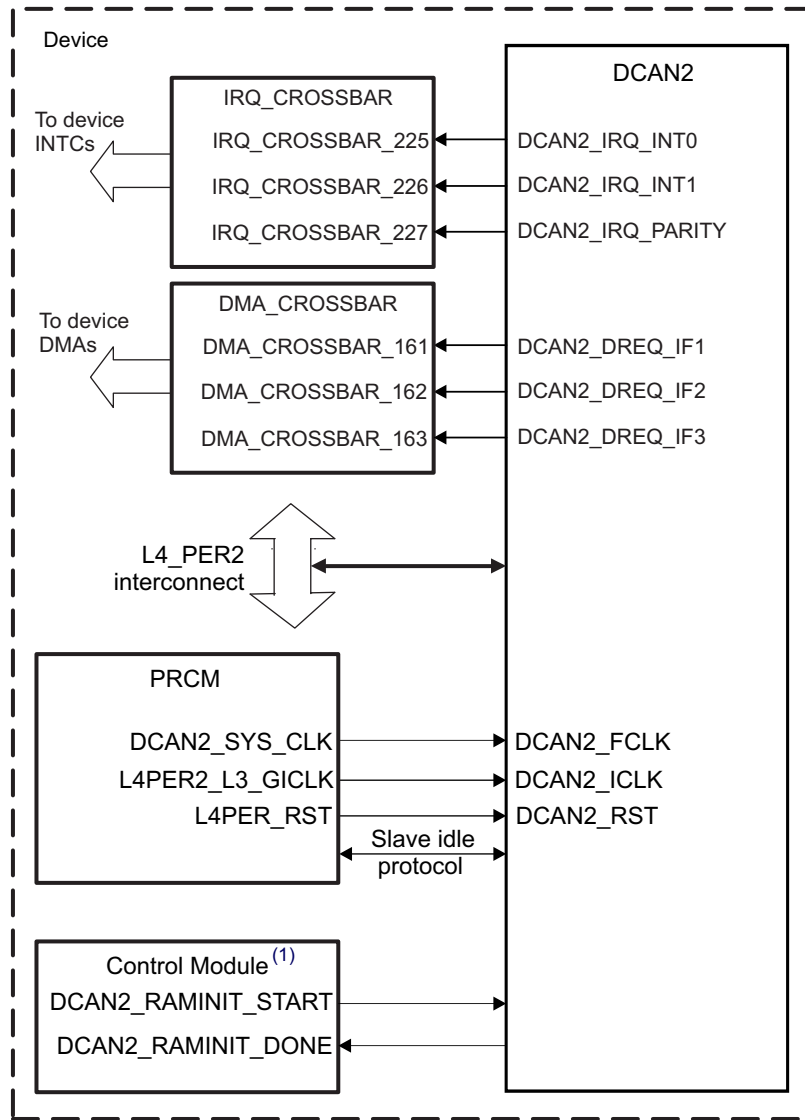

Figure 19-116. DCAN (SR2.0)/DCAN1 (SR1.0) Integration

⁽¹⁾ For more information on DCAN RAM Initialization see Section 19.6.4.12.1.3, *DCAN RAM Hardware Initialization*

Figure 19-117 shows the integration of the DCAN2 module in the device (SR1.0).

Figure 19-117. DCAN2 Integration (SR1.0)

dcan-005

⁽¹⁾ For more information on DCAN RAM Initialization see [Section 19.6.4.12.1.3, DCAN RAM Hardware Initialization](#)

[Table 19-475](#) through [Table 19-477](#) summarize the integration of the DCAN modules in the device.

Table 19-475. DCAN Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

DMA Requests				
Module Instance	Source Signal Name	DMA_CROSSBAR Input	Default Mapping	Description
DCAN (SR2.0)	DCAN_DREQ_IF1	DMA_CROSSBAR_158	-	DMA request for IF1 register set
	DCAN_DREQ_IF2	DMA_CROSSBAR_159	-	DMA request for IF2 register set
	DCAN_DREQ_IF3	DMA_CROSSBAR_160	-	DMA request for IF3 register set
DCAN1 (SR1.0)	DCAN1_DREQ_IF1	DMA_CROSSBAR_158	-	DMA request for IF1 register set
	DCAN1_DREQ_IF2	DMA_CROSSBAR_159	-	DMA request for IF2 register set
	DCAN1_DREQ_IF3	DMA_CROSSBAR_160	-	DMA request for IF3 register set

Table 19-477. DCAN Hardware Requests (continued)

DCAN2 (SR1.0)	DCAN2_DREQ_IF1	DMA_CROSSBAR_161	-	DMA request for IF1 register set
	DCAN2_DREQ_IF2	DMA_CROSSBAR_162	-	DMA request for IF2 register set
	DCAN2_DREQ_IF3	DMA_CROSSBAR_163	-	DMA request for IF3 register set

NOTE: DCAN has no default IRQ mappings through the IRQ_CROSSBAR. For DCAN, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4](#), *IRQ_CROSSBAR Module Functional Description*, in [Chapter 14, Control Module](#).
For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5](#), *DMA_CROSSBAR Module Functional Description*, in [Chapter 14, Control Module](#).

NOTE: For the description of the interrupt source, see [Section 19.6.4.2](#), *Interrupt Functionality*.

19.6.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

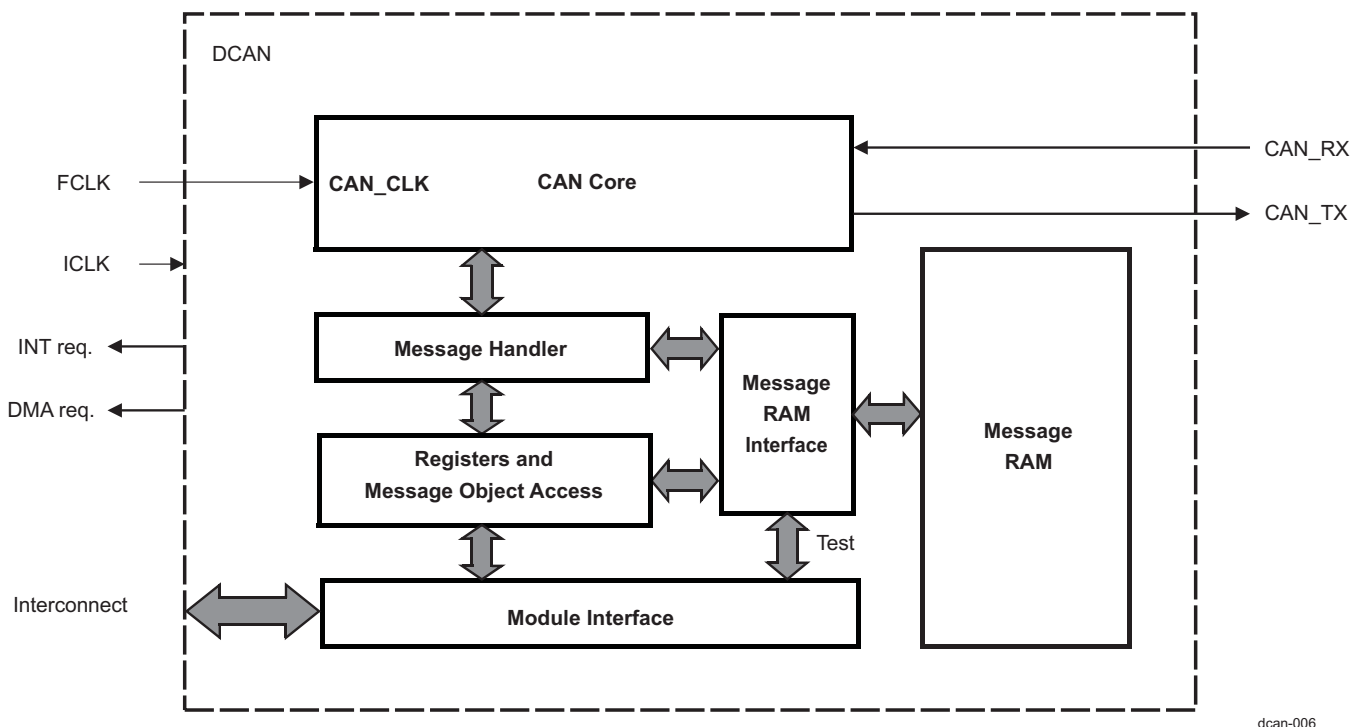

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 19-118 shows the DCAN block diagram and its features are described below.

Figure 19-118. DCAN Block Diagram

dcan-006

CAN Core: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

Message Handler: The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Message RAM: The DCAN enables a storage of 64 CAN messages.

Message RAM Interface: Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in [Section 19.6.4.8.12, Reading From a FIFO Buffer](#).

The interface registers have the same word-length as the message RAM.

Registers and Message Object Access: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

Module Interface: The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

Clocking: Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [ICLK]) and the peripheral asynchronous clock (functional clock [FCLK]) .

19.6.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

NOTE: ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated ICLK has to be considered:

$$f_{0, ICLK}(OCP) \pm \Delta f_{FM, ICLK}(OCP) \geq f_{FCLK}$$

For more information on how to configure the relevant clock source registers, see [Chapter 3, PRCM](#) and the device data manual.

19.6.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the [DCAN_CTL\[1\] IE0](#) and [\[17\] IE1](#) bits, respectively. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see [Figure 19-119, Error and Status Change Interrupts](#) and [Figure 19-120, Message Objects Interrupts](#)).

The source of an interrupt can be determined by the interrupt identifiers [DCAN_INT\[15:0\] INT0ID/\[23:16\] INT1ID](#). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register [DCAN_INT\[15:0\] INT0ID/\[23:16\] INT1ID](#) again reach zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register ([DCAN_ES](#)). This interrupt has the highest priority. The software can update (reset) the status bits [\[9\] WAKEUPPND](#), [\[4\] RXOK](#), [\[3\] TXOK](#) and [\[2:0\] LEC](#) by reading [DCAN_ES](#), but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID resp. INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time ([DCAN_IF1CMD/DCAN_IF2CMD\[19\] CLRINTPND](#) bit). When IntPnd is cleared, [DCAN_INT](#) will point to the next message object with a pending interrupt.

19.6.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in [Section 19.6.4.11.1, Structure of Message Objects](#).

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers ([DCAN_INTMUX12](#) to [DCAN_INTMUX78](#)).

19.6.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register ([DCAN_ES](#)) belong to the status change interrupts. The status change interrupt group can be enabled by [DCAN_CTL\[2\]](#) SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting [DCAN_CTL\[1\]](#) IE0 = 1.

NOTE: Reading [DCAN_ES](#) will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

19.6.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the [DCAN_ES](#) register belong to the error interrupts. The error interrupt group can be enabled by setting bit [DCAN_CTL\[3\]](#) EIE = 1.

Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting [DCAN_CTL\[1\]](#) IE0 = 1.

Figure 19-119. Error and Status Change Interrupts

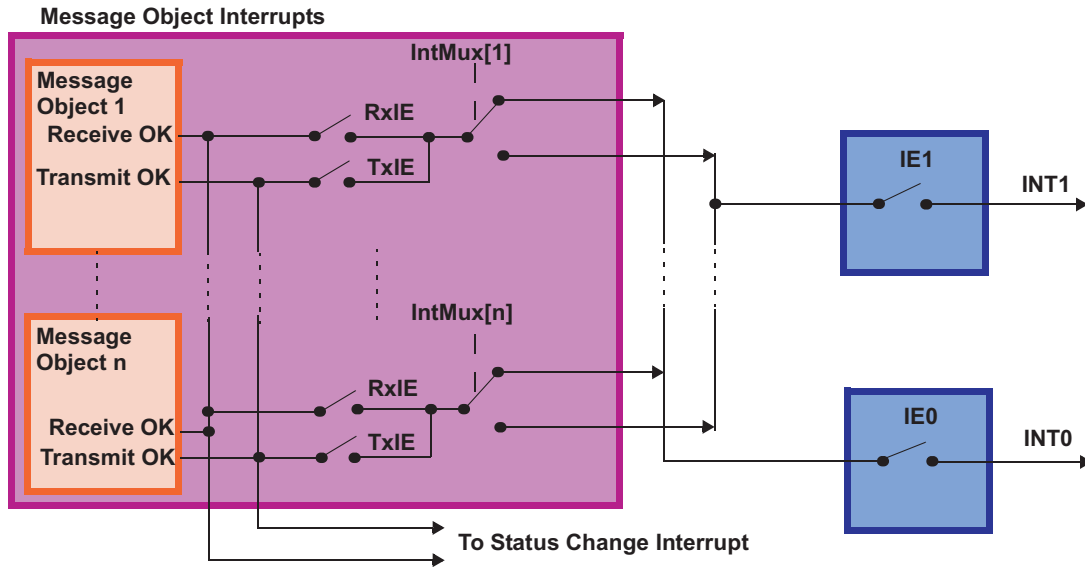

Figure 19-120. Message Objects Interrupts

19.6.4.3 DMA Functionality

The DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers ([DCAN_IF1CMD](#), [DCAN_IF2CMD](#)).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see [Section 19.6.4.10.2, IF3 Register Set](#).

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in [DCAN_CTL](#).

19.6.4.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

19.6.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the [DCAN_CTL\[24\] PDR](#) bit (=1).

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the [DCAN_CTL\[0\] INIT](#) bit to prevent any further CAN transfers, and it will also set the [DCAN_ES\[10\] PDA](#) bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see [Section 19.6.4.4.2, Wakeup From Local Power Down](#)) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

19.6.4.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

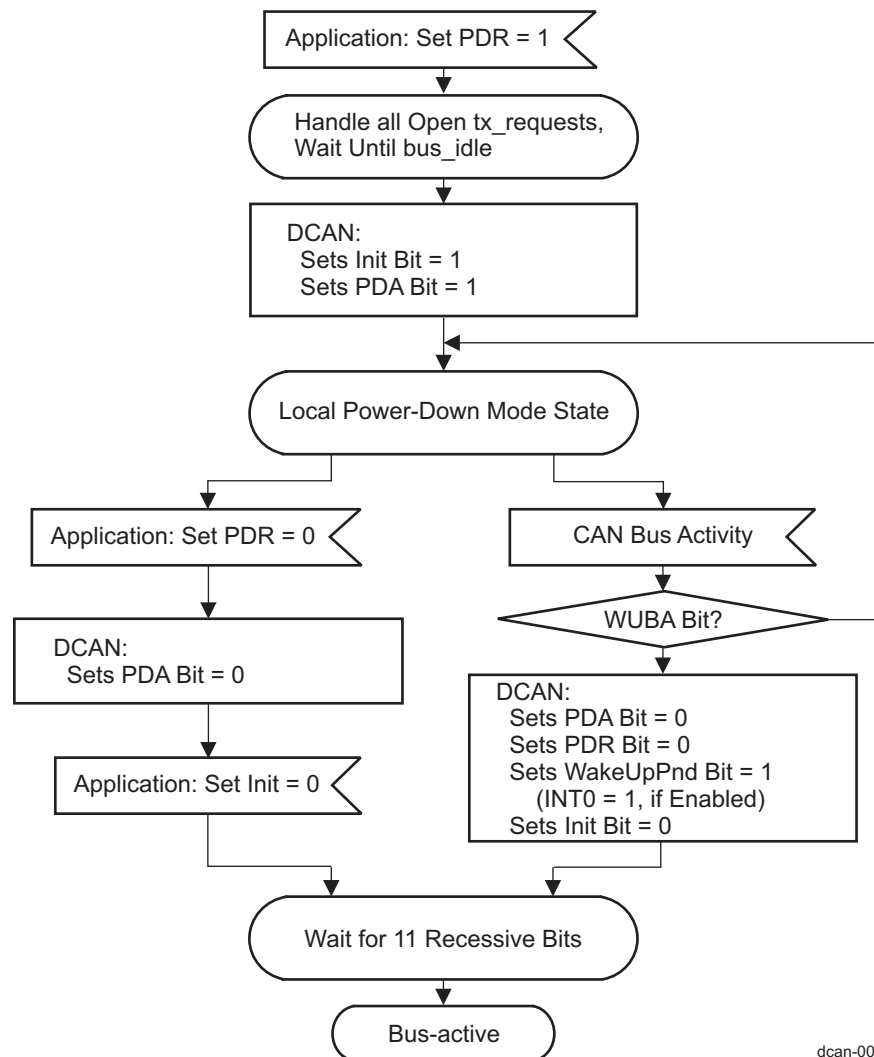

- The application could wake up the DCAN module manually by clearing the `DCAN_CTL[24]` PDR bit and then clearing the `DCAN_CTL[0]` INIT.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (`DCAN_CTL[25]` WUBA). If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the `DCAN_CTL[24]` PDR bit and also clear the `DCAN_ES[10]` PDA bit. The `DCAN_ES[10]` WAKEUPND bit will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the `DCAN_CTL[0]` INIT bit will be cleared.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

NOTE: The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 19-121 shows a flow diagram about entering and leaving local power-down mode.

Figure 19-121. Local Power-Down Mode Flow Diagram

dcan-009

19.6.4.5 SECEDED Mechanism

The DCAN module provides a single error correction and double error detection (SECEDED) mechanism to ensure data integrity of Message RAM data. For each message object (136 bits) in the Message RAM, 9 ECC bits will be calculated.

The ECC bits are stored in a dedicated RAM. They will be generated on write accesses and will be checked on read accesses.

The SECEDED functionality can be enabled or disabled by [DCAN_CTL\[13:10\]](#) PMD bit field.

In case of disabled SECEDED, the ECC bits will be left unchanged on write access to data area and no correction or check will be done on read access.

If SECEDED is enabled, ECC bits will be automatically generated and checked. The ECC bits are memory mapped as described in [Section 19.6.4.11.3, ECC RAM](#).

With the ECCMODE field in the [DCAN_ECC_CS](#) register the single bit error correction can be enabled or disabled (default: enabled).

NOTE: During RAM initialization, no SECEDED check will be done, but if the PMD bit is set, the ECC bits will be generated.

19.6.4.5.1 Behavior on Single Bit Error

If a single bit error is detected with single bit error correction enabled, the correction will be done and the SEFLG in the [DCAN_ECC_CS](#) register will be set.

If single bit error correction is disabled and a single bit error is detected then the SEFLG in the [DCAN_ECC_CS](#) register and the PER bit in the Error and Status register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

If single bit error correction is disabled and a single bit error is detected then the IRQ_PARITY signal is generating a high pulse for one interface clock period.

The message object number where the single bit error has occurred will be indicated in the [DCAN_ECC_SERR](#) Register.

When single bit error correction is disabled the message object data can be read by the host CPU, independently of single bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the [DCAN_ECC_SERR](#) on single bit error interrupt.

19.6.4.5.2 Behavior on Double Bit Error

If a double bit error is detected, then the DEFLG in the [DCAN_ECC_CS](#) register and the PER bit in [DCAN_ES](#) will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset. The message object number will be indicated in the [DCAN_PERR](#) register.

Additionally the signal IRQ_PARITY signalizes - by generating a high pulse for one interface clock period - the double bit error occurrence for the host CPU. The message object data can be read by the host CPU, independently of double bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the [DCAN_PERR](#) register on double bit error interrupt.

19.6.4.5.3 SECEDED Testing

Testing of the SECEDED mechanism can be implemented by using the diagnostic mode, which is enabled with the [DCAN_ECCDIAG](#) register. The following procedure can be used:

1. Disable SECEDED using [DCAN_CTL](#) register. Enable diagnostic mode using the [DCAN_ECCDIAG](#) register
2. Write to corrupt the data (in RDA mode) or ECC bits.
3. Enable SECEDED and read data for which ECC is corrupted (either in RDA mode or via IFx registers).

4. Single bit error or double bit error flag will be set in the diagnostic status register ([DCAN_ECCDIAG_STAT](#)) and in the [DCAN_ECC_CS](#) register, accordingly. A double bit error or a single bit error with single bit error correction disabled also triggers the PER flag.
5. Disable diagnostic mode.

19.6.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit [DCAN_CTL\[8\]](#) IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by [DCAN_CTL \[16\]](#) INITDBG flag.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see [Section 19.6.4.11.4, Message RAM Representation in Debug/Suspend Mode](#).

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- [DCAN_ES](#) register (clear of status flags by read)
- [DCAN_IF1CMD/DCAN_IF2CMD](#) command registers (clear of [14] DMAACTIVE flag by read/write)

19.6.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

19.6.4.7.1 Configuration of a Transmit Object for Data Frames

Table 19-478 shows how a transmit object can be initialized.

Table 19-478. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data length and data itself (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 19.6.4.8.8, *Reception of Remote Frames*.

Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

19.6.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

19.6.4.7.3 Configuration of a Single Receive Object for Data Frames

Table 19-479 shows how a receive object for data frames can be initialized.

Table 19-479. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to '0'.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration register (DCAN_IF1ARB, DCAN_IF2ARB, DCAN_IF3ARB) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

19.6.4.7.4 Configuration of a Single Receive Object for Remote Frames

Table 19-480 shows how a receive object for remote frames can be initialized.

Table 19-480. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 19.6.4.7.5, *Configuration of a FIFO Buffer*).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 19.6.4.8.8, *Reception of Remote Frames*.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

19.6.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

19.6.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

19.6.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

19.6.4.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

19.6.4.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register ([DCAN_MSGVAL12](#) to [DCAN_MSGVAL78](#)) and the TXRQST bits in the transmission request register ([DCAN_TXRQ12](#) to [DCAN_TXRQ78](#)) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the [DCAN_CTL\[5\]](#) DAR bit, the behavior of bits TXRQST and NEWDAT in the [DCAN_IF1CMD/DCAN_IF2CMD](#) register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit

NewDat remains set.

- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

19.6.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register ([DCAN_IF1DATA/DCAN_IF2DATA](#)) or IF1/IF2 Data B register ([DCAN_IF1DATB/DCAN_IF2DATB](#)) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register ([DCAN_IF1CMD/DCAN_IF2CMD](#)) and then the number of the message object is written to bits [7:0] MESSAGE_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see [Section 19.6.4.8.3, Transmission of Messages in Event Driven CAN Communication](#).

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

19.6.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register ([DCAN_IF1CMD/DCAN_IF2CMD](#)) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register ([DCAN_IF1CMD/DCAN_IF2CMD](#)) should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

19.6.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

19.6.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the [DCAN_INT](#) to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

19.6.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'

The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.

- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'

The remote frame is ignored, this message object remains unchanged.

- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'

The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

19.6.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] MESSAGE_NUMBER of the command register ([DCAN_IF1CMD/DCAN_IF2CMD](#)). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register ([DCAN_IF1MCTL/DCAN_IF2MCTL/DCAN_IF3MCTL](#)) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

19.6.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register ([DCAN_IF1CMD/DCAN_IF2CMD](#)).

19.6.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

19.6.4.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

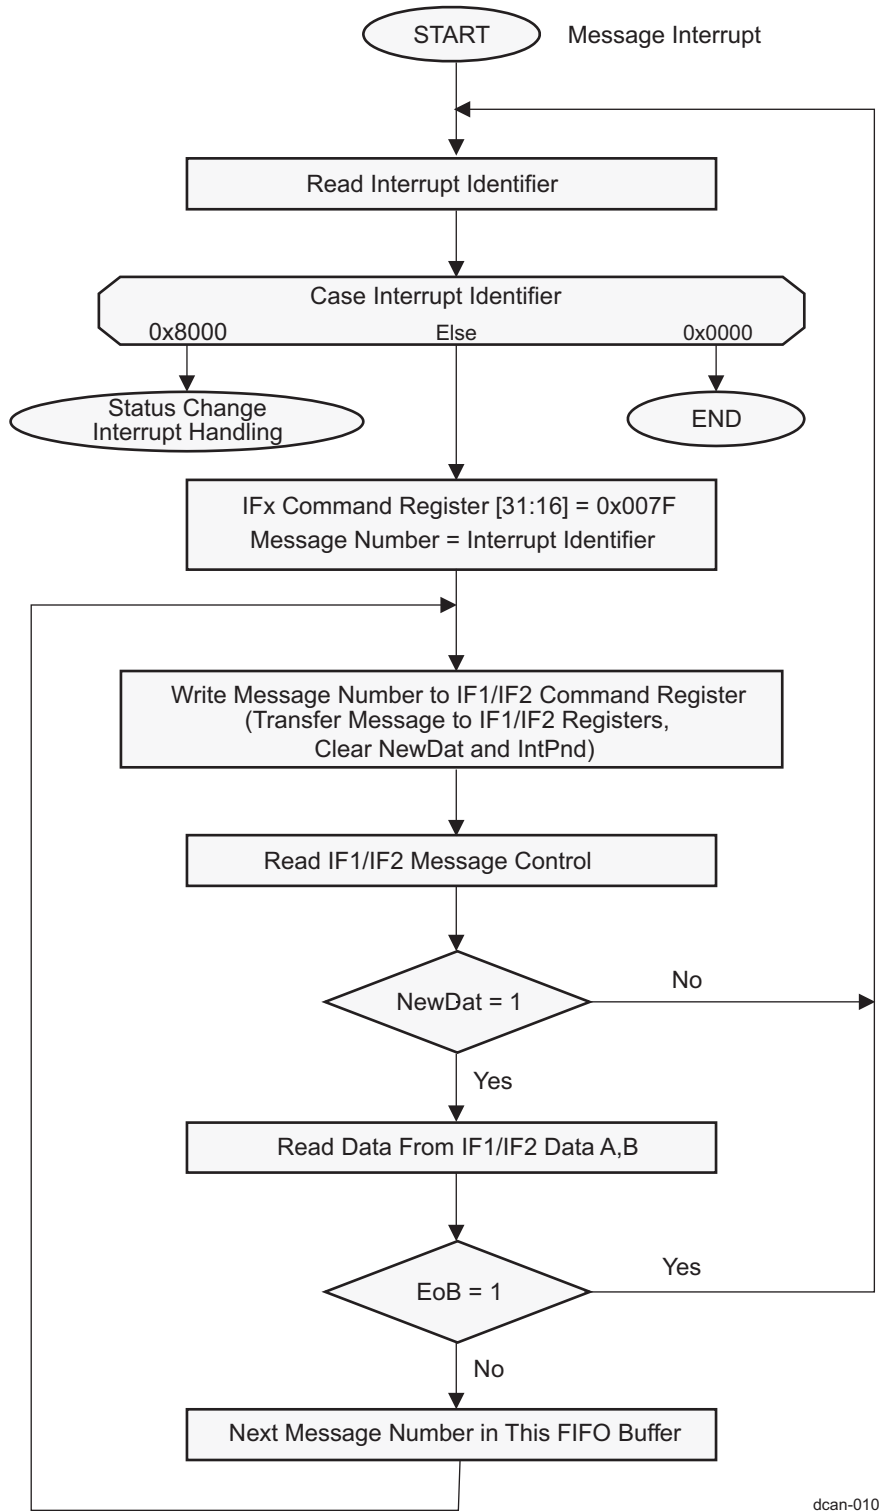

A FIFO buffer of length N will store N-1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in [Figure 19-122](#).

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

Figure 19-122. Software Handling of a FIFO Buffer (Interrupt Driven)

dcan-010

19.6.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

19.6.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 19-123):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 19-123. Bit Timing

Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the FCLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate Prescaler} / \text{FCLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 19-481 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 19-481. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to FCLK
Prop_Seg	[1 ... 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 ... 8] t_q	May be lengthened temporarily by synchronization

Table 19-481. Parameters of the CAN Bit Time (continued)

Parameter	Range	Remark
Phase_Seg2	[1 ... 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 ... 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

19.6.4.9.1.1 Synchronization Segment

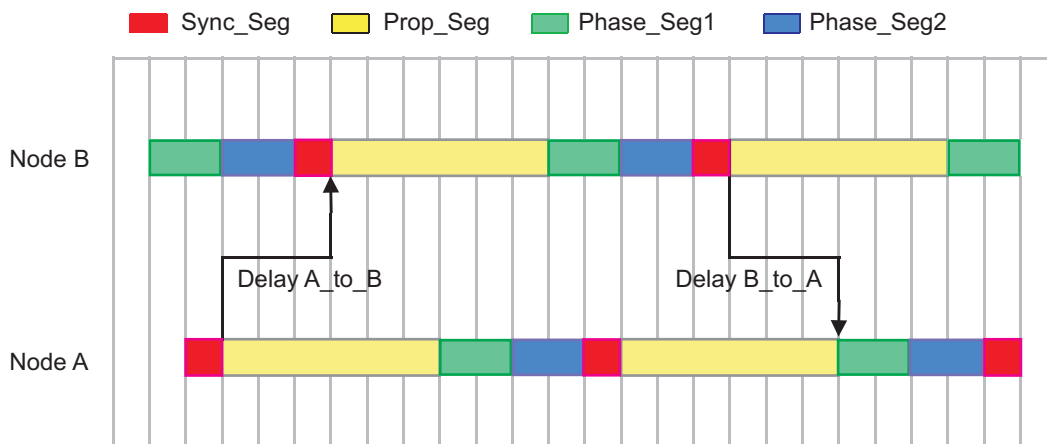

The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

19.6.4.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 19-124 shows the phase shift and propagation times between two CAN nodes.

Figure 19-124. The Propagation Time Segment

$$\text{Delay A_to_B} \geq \text{node output delay(A)} + \text{bus line delay(A/E B)} + \text{node input delay(B)}$$

$$\text{Prop_Seg} \geq \text{Delay A_to_B} + \text{Delay B_to_A}$$

$$\text{Prop_Seg} \geq 2 \cdot [\text{max}(\text{node output delay} + \text{bus line delay} + \text{node input delay})]$$

dcan-012

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of $1 t_p$, requiring a longer Prop_Seg.

19.6.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

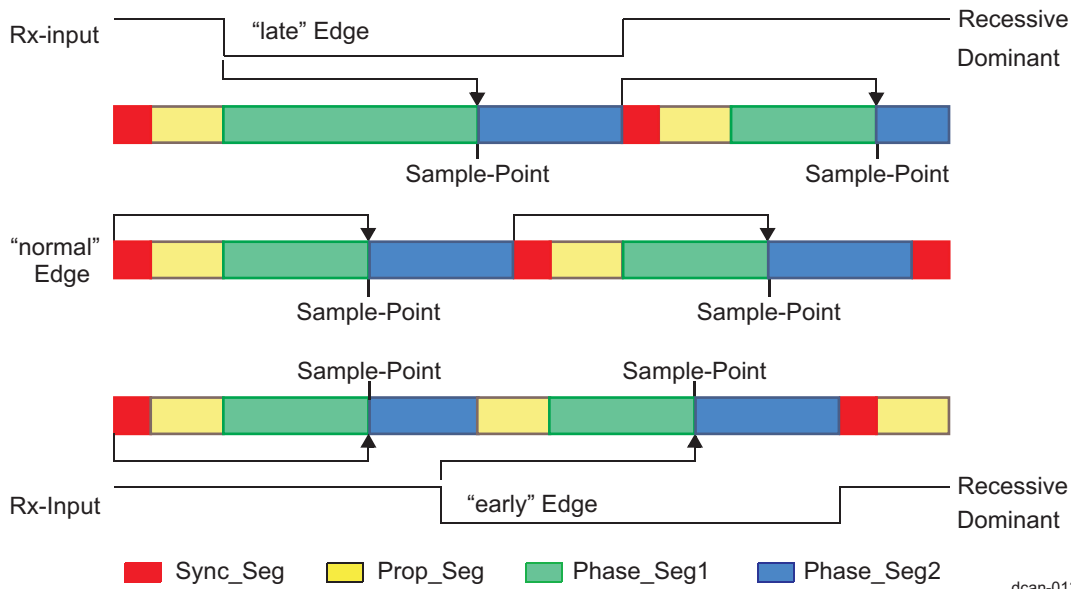

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 19-125 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 19-125. Synchronization on Late and Early Edges

In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

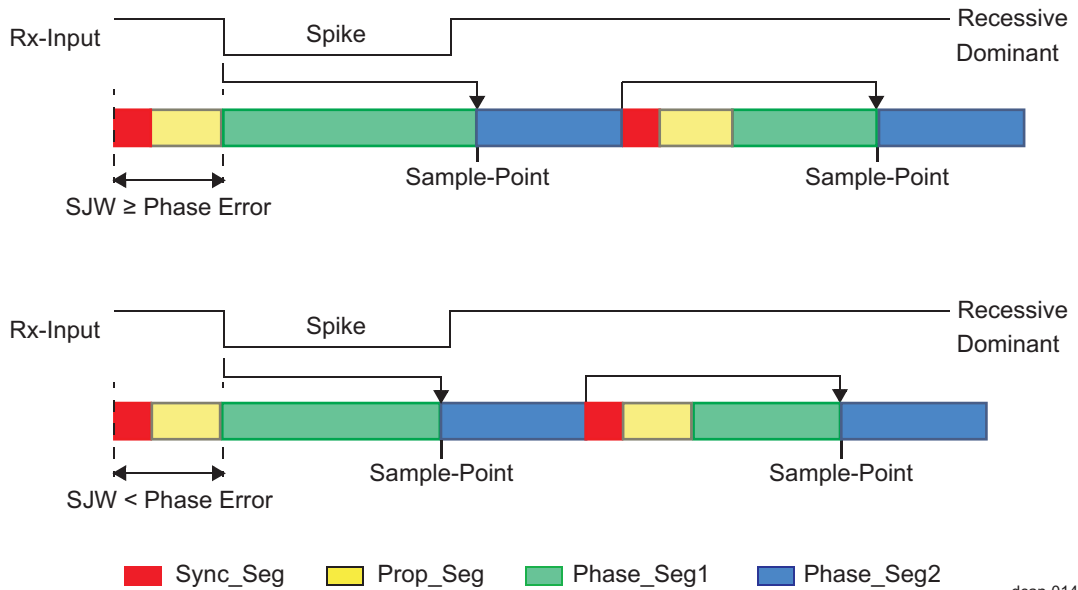

In these examples, the bit timing is seen from the point of view of the CAN implementation’s state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 19-126 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 19-126. Filtering of Short Dominant Spikes

19.6.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator’s frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \cdot f_{nom} \leq f_{osc} \leq (1 + df) \cdot f_{nom}$$

dcan-e015

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$I: df \leq \frac{\min(TSeg1, TSeg2)}{2x(13x(bit_time - TSeg2))}$$

$$II: df \leq \frac{SJW}{20xbit_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 μs) with a bus length of 40 m.

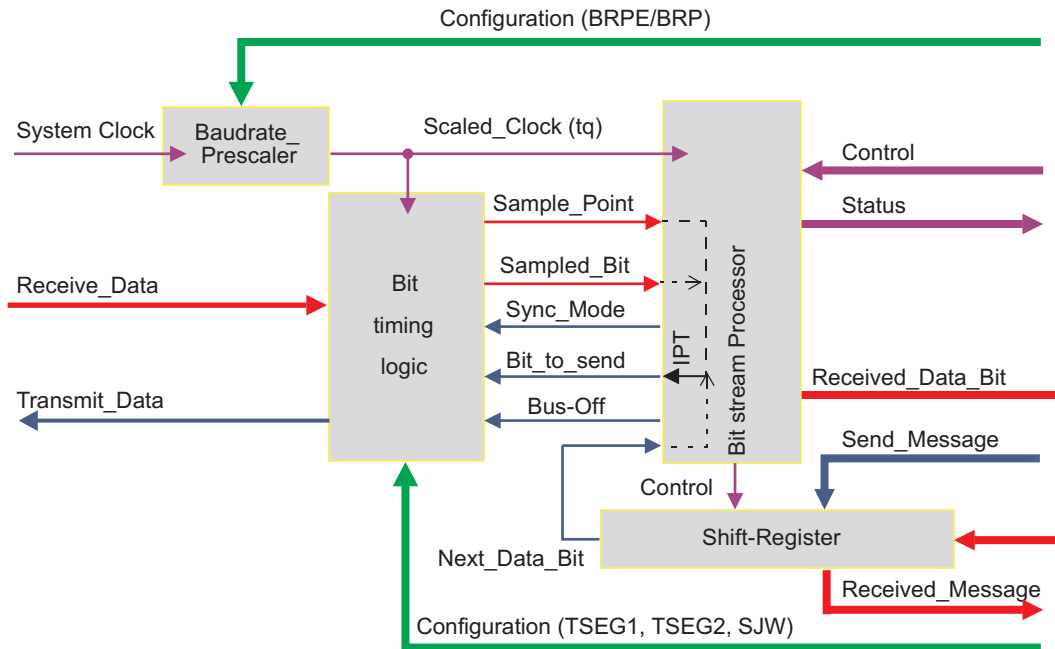

19.6.4.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in [DCAN_BTR\[14:0\]](#), additionally a baud rate prescaler extension of four bits ([DCAN_BTR\[19:16\] BRPE](#)) is provided.

- The sum of Prop_Seg and Phase_Seg1 is set in [11:8] TSEG1
- Phase_Seg2 in [14:12] TSEG2
- SynchronizationJumpWidth in [7:6] SJW
- and baud rate prescaler [5:0] BRP (plus [19:16] BRPE)

Figure 19-127 shows the CAN protocol controller.

Figure 19-127. Structure of the CAN Core's CAN Protocol Controller

dcan-017

In [DCAN_BTR](#) register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1...n], values in the range of [0...n-1] are programmed. That way, e.g., SJW (functional range of [1...4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) $[TSEG1 + TSEG2 + 3] t_q$ or (functional values) $[Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q$.

The data in the bit timing register ([DCAN_BTR](#)) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is $0 t_q$ for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than $2 t_q$. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

19.6.4.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with $t_q = (\text{Baud Rate Prescaler}) / \text{FCLK}$. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0...2] t_q .

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in [Table 19-482](#).

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register ([DCAN_BTR](#)):

[14:12] TSEG2 = Phase_Seg2 - 1

[11:8] TSEG1 = Phase_Seg1+ Prop_Seg - 1

[7:6] SJW = SynchronizationJumpWidth - 1

[5:0] BRP = Prescaler - 1

19.6.4.9.2.2 Example for Bit Timing Calculation

In this example, the frequency of FCLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

Table 19-482. Example For Bit Timing

Parameter	Formula	Value	t_q
bit time (500 KBit/s)	1/bit rate, consists of $t_{\text{Sync_Seg}} + t_{\text{TSeg1}} + t_{\text{TSeg2}}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	$16 \times 5.5 \text{ ns/m}$	88 ns	-
t_q	BRP/FCLK	100 ns	1
$t_{\text{Sync_Seg}}$	$1 \times t_q$ (fixed)	100 ns	1
$t_{\text{Prop_Seg}}$	INT ($2 \times \text{delays} + 1$) = $8 \times t_q$	800 ns	8
t_{Seg1}	$t_{\text{Prop_Seg}} + t_{\text{Phase_Seg1}}$	1400 ns	14

Table 19-482. Example For Bit Timing (continued)

Parameter	Formula	Value	t_q
t_{Seg2}	bit time - ($t_{Sync_Seg} + t_{Seg1}$)	500 ns	5
t_{SJWmax}	MIN ($4 \times t_q, t_{Phase_Seg1}$)	400 ns	4

In this example, the bit timing register [DCAN_BTR](#) is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

19.6.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in [DCAN_IF1CMD/DCAN_IF2CMD](#), will be set to the actual contents of the selected message object.

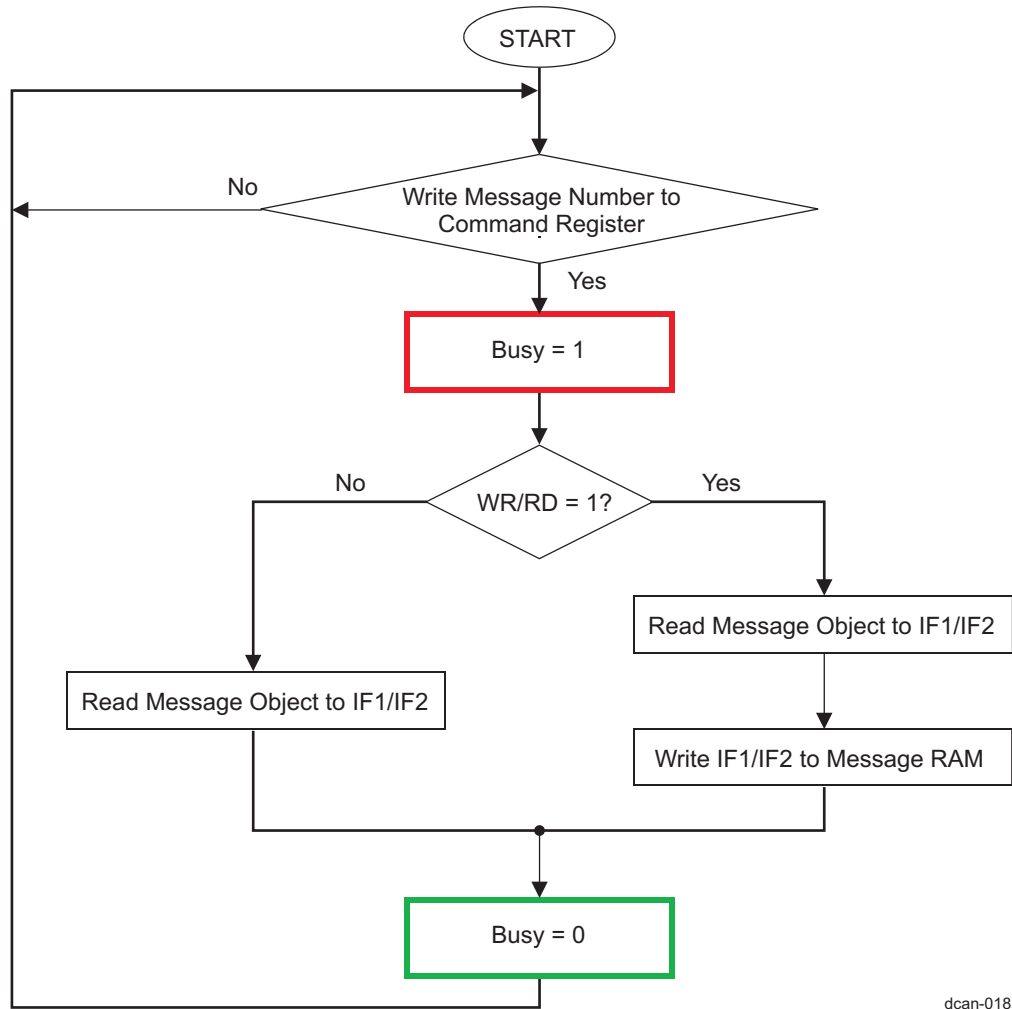

After the partial read of a message object, those parts of the interface register set that are not selected in [DCAN_IF1CMD/DCAN_IF2CMD](#), will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see [Section 19.6.4.11.1, Structure of Message Objects](#)) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see [Section 19.6.5, DCAN Register Manual](#)) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

19.6.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. [DCAN_IF1CMD/DCAN_IF2CMD](#) address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] MESSAGE_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective [DCAN_IF1CMD/DCAN_IF2CMD](#) to 1. After the transfer has completed, the BUSY bit is set back to 0 (see [Figure 19-128](#)).

Figure 19-128. Data Transfer Between IF1/IF2 Registers and Message RAM

dcan-018

19.6.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object ([DCAN_IF3UPD12](#) to [DCAN_IF3UPD78](#)).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register ([DCAN_IF3OBS](#)). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit [DCAN_CTL\[20\] DE3 = 1](#).

NOTE: The IF3 register set cannot be used for transferring data into message objects.

19.6.4.11 Message RAM

The DCAN message RAM contains message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see [Section 19.6.4.11.4, Message RAM Representation in Debug/Suspend Mode](#))
- RAM Direct Access (RDA) mode (see [Section 19.6.4.11.5, Message RAM Representation in Direct Access Mode](#))

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

19.6.4.11.1 Structure of Message Objects

[Table 19-483](#) shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 19-483. Structure of a Message Object

UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 19-484. Message Object Field Descriptions

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
<p>Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the DCAN_CTL register.</p>		

Table 19-484. Message Object Field Descriptions (continued)

Field Name	Value	Description
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering. Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering. Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.

Table 19-484. Message Object Field Descriptions (continued)

Field Name	Value	Description
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

19.6.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
 Message RAM base address + (message object number) × 0x20

That is, message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

NOTE: Because 0 is not a valid message object number, at offset 0x0000 is not located message object 0, but the last implemented: 64.

The base address for DCAN1 (SR1.0)/DCAN (SR2.0) RAM is 0x4AE3 D000 and DCAN2 RAM is 0x4848 1000(SR1.0).

Message object number 1 has the highest priority.

Table 19-485. Message RAM Addressing in Debug/Suspend and RDA Modes

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 19.6.4.11.4	RDA Mode, see Section 19.6.4.11.5
64 (last implemented)	0x0000	1	Reserved	Data Bytes 4-7

	0x07F4	6	Data Bytes 7-4	-

19.6.4.11.3 ECC RAM

On devices with SECDED implementation for the message RAM, the ECC bits are stored in a dedicated ECC RAM area which is memory mapped as follows:

The location of the ECC bits for a particular message object in RAM is:

Message RAM base address + 0x1000 + (message object number) × 0x20

NOTE: 0 is not a valid message object number. Therefore, at address 0x1000, the ECC bits of the last implemented message object are located, that is, 64-th.

Table 19-486. ECC RAM Representation

Address																Msg RAM base + 0x1000															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ECC[8:0] last implemented Message Object (here: 64)							

Address																Msg RAM base + 0x1020															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address																Msg RAM base + 0x17E0															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ECC[8:0] Message Object 63															

As shown in Figure 1-19 the ECC bits for the last implemented Message Object (here: 128) are located at offset 0x1000; the ECC bits for Message Object 1 are located at offset 0x1020, and the ECC bits for Message Object 127 are located at offset 0x1FE0.

The ECC RAM is only memory mapped if SECDED diagnostic mode is enabled.

19.6.4.11.4 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

19.6.4.11.5 Message RAM Representation in Direct Access Mode

When the [DCAN_TEST](#)[9] RDA bit is set while the DCAN module is in test mode ([DCAN_CTL](#)[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

19.6.4.12 CAN Operation

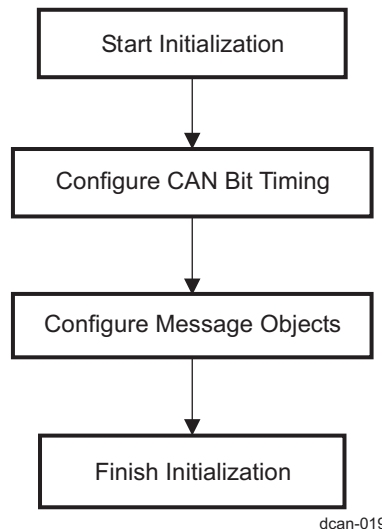

After device reset, the [DCAN_CTL\[0\] INIT](#) is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. [Figure 19-129](#) illustrates the basic initialization flow for the CAN module.

19.6.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 19-129. CAN Module General Initialization Flow

19.6.4.12.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see [Figure 19-130](#), *CAN Bit-Timing Configuration*.

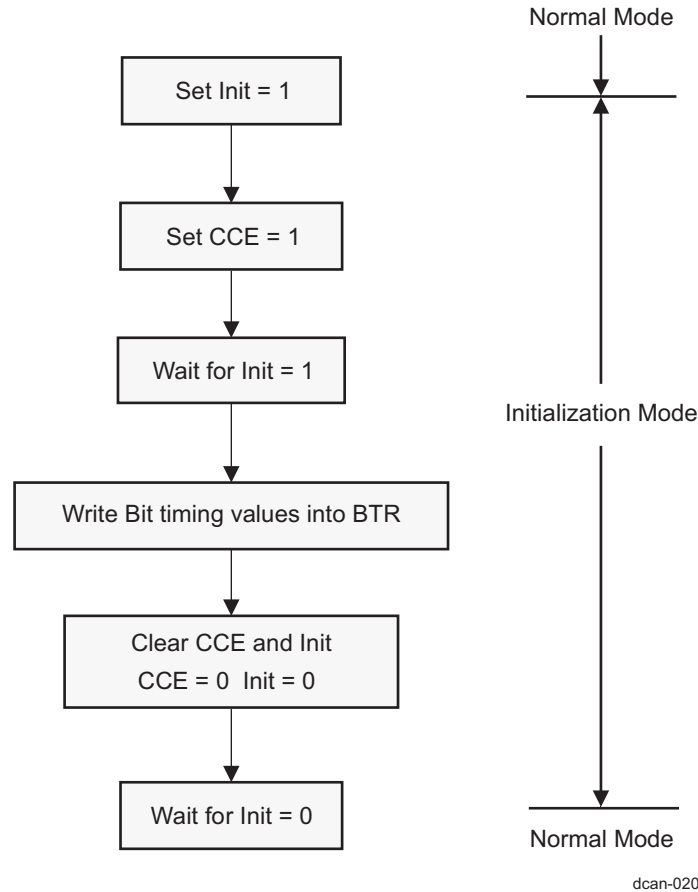

Step 1: Enter *initialization mode* (`DCAN_CTL[0] INIT = 1`).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on device reset and during Bus-Off.

Figure 19-130. CAN Bit-Timing Configuration

Step 2: Set the Configure Change Enable bit ([DCAN_CTL\[6\]](#) CCE = 1).

The access to the Bit Timing register ([DCAN_BTR](#)) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

Step 3: Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

Step 4: Write the bit timing values into [DCAN_BTR](#). See [Section 19.6.4.9.2, DCAN Bit Timing Registers](#) for the values calculation for a given bit timing.

Step 5: Clear the CCE and INIT bits (=0).

Step 6: Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the [DCAN_BTR](#) is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the Initialization mode if any incorrect [DCAN_BTR](#) values are written in step 4.

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in [Section 19.6.4.12.1, CAN Module Initialization](#).

19.6.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM). Familiarize yourself with the interface register set (IFx) usage (see [Section 19.6.4.10, Message Interface Register Sets](#)) and the message object structure (see [Section 19.6.4.11, Message RAM](#)) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see [Section 19.6.4.7, Configuration of Message Objects Description](#). All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

19.6.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control module. Setting RAMINIT_START to 1, causes RAM initialization with zeros and sets parity bits accordingly. Software must wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on CTRL_CORE_CONTROL_IO_2 register, see [Section 14.5, Control Module Register Manual](#).

19.6.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and [DCAN_CTL\[0\]](#) INIT bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines ([DCAN_CTL\[1\]](#) IE0 and [17] IE1 = 1) at the same time when it clears [0] INIT and [6] CCE = 0. The status interrupts [3] EIE and [2] SIE may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The [DCAN_INT](#) register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the host processor are disabled ([DCAN_CTL\[1\]](#) IE0 and [17] IE1 = 0).

The software may poll all MessageObject's NewDat and TxRqst bits in parallel from the [DCAN_NWDAT_X](#) and the [DCAN_TXRQ_X](#) registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

19.6.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission ([DCAN_CTL\[5\] DAR = 1](#)). Further details to this mode are provided in [Section 19.6.4.8.3, Transmission of Messages in Event Driven CAN Communication](#).

19.6.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the [DCAN_CTL\[0\] INIT](#) bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit [DCAN_CTL\[9\] ABO](#). If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register ([DCAN_ABOTR](#)).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

19.6.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the [DCAN_CTL\[7\] TEST](#) bit needs to be set to 1. This enables write access to the test register ([DCAN_TEST](#)).

NOTE: It must be ensured by software that all message transfers are completed before entering test mode.

19.6.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

[Figure 19-131](#) shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the [DCAN_TEST\[3\] SILENT](#) bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 19-131. CAN Core in Silent Mode

19.6.4.12.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 19-132 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit `DCAN_TEST[4] LBACK` to 1.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see [Section 19.6.4.12.3.3, External Loopback Mode](#).

Figure 19-132. CAN Core in Loopback Mode

19.6.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

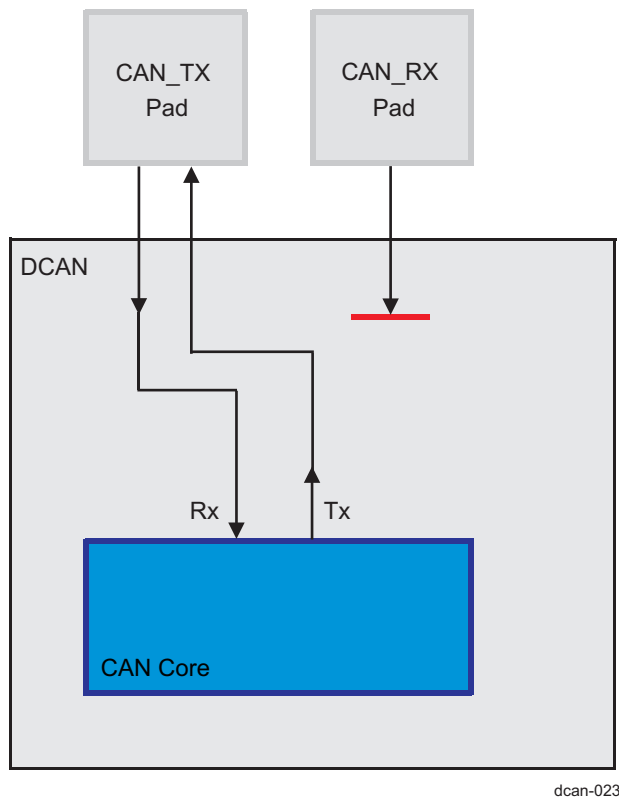

With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit `DCAN_TEST[8] EXL` to 1.

Figure 19-133 shows the connection of signals `CAN_TX` and `CAN_RX` to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

Figure 19-133. CAN Core in External Loopback Mode

19.6.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits `DCAN_TEST[4] LBACK` and `[3] SILENT` at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the `CAN_RX` pin is disconnected from the CAN core and no dominant bits will be sent on the `CAN_TX` pin.

Figure 19-134 shows the connection of the signals `CAN_TX` and `CAN_RX` to the CAN core in case of the combination of loopback mode with silent mode.

Figure 19-134. CAN Core in Loop Back Combined With Silent Mode

19.6.4.12.3.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the [DCAN_TEST\[6:5\] TX](#):

- 0x0: Normal operation, CAN_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN_TX pin
- 0x2: CAN_TX pin drives a dominant value
- 0x3: CAN_TX pin drives a recessive value.

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

19.6.4.13 GPIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register ([DCAN_TIOC](#)) and the CAN RX IO control register ([DCAN_RIOC](#)).

19.6.5 DCAN Register Manual

19.6.5.1 DCAN Instance Summary

NOTE: There is only one DCAN module on SR2.0 devices called DCAN. On SR1.0 there are 2 DCAN modules called DCAN1 and DCAN2. DCAN on SR2.0 is same as DCAN1 on SR1.0.

Table 19-489. DCAN Instance Summary

Module Name	Base Address	Size
DCAN1	0x4AE3 C000	8 KiB
DCAN2	0x4848 0000	8 KiB

19.6.5.2 DCAN Registers

NOTE: After device reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The INIT bit in the [DCAN_CTL](#) is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

19.6.5.2.2 DCAN Register Description

Table 19-491. DCAN_CTL

Address Offset	0x0000 0000		
Physical Address	0x4AE3 C000 0x4848 0000	Instance	DCAN1 DCAN2
Description	DCAN control register NOTE: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to DCAN_ES , enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								WUBA	PDR	RESERVED	DE3	DE2	DE1	IE1	INITDBG	SWR	RESERVED	PMD				ABO	IDS	TEST	CCE	DAR	RESERVED	EIE	SIE	IE0	INIT

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
25	WUBA	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0: No detection of a dominant CAN bus level while in local power-down mode. 1: Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in <i>Local Power-Down Mode</i>).	RW	0
24	PDR	Request for local low power-down mode 0: No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared. 1: Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the DCAN_ES register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in <i>Local Power-Down Mode</i>).	RW	0
23:21	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
20	DE3	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0: Disabled 1: Enabled	RW	0
19	DE2	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0: Disabled 1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
18	DE1	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0: Disabled 1: Enabled	RW	0
17	IE1	Interrupt line 1 enable 0: Disabled - Module interrupt INT1 is always low. 1: Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.	RW	0
16	INITDBG	Internal init state while debug access 0: Not in debug mode, or debug mode requested but not entered. 1: Debug mode requested and internally entered; the DCAN is ready for debug accesses.	RW	0
15	SWR	Software reset enable. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR (this) bit additionally to INIT bit. 0: Normal Operation 1: Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one OCP clock cycle.	RW	0
14	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
13:10	PMD	ECCon/off 0x5: function disabled Others: function enabled	RW	0x5
9	ABO	Auto-Bus-On enable 0: The Auto-Bus-On feature is disabled 1: The Auto-Bus-On feature is enabled	RW	0
8	IDS	Interruption debug support enable 0: When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1: When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.	RW	0
7	TEST	Test mode enable 0: Normal Operation 1: Test Mode	RW	0
6	CCE	Configuration change enable 0: The software has no write access to the configuration registers. 1: The software has write access to the configuration registers (when INIT bit is set).	RW	0
5	DAR	Disable automatic retransmission 0: Automatic retransmission of not successful messages enabled. 1: Automatic retransmission disabled.	RW	0
4	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
3	EIE	Error interrupt enable 0: Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1: Enabled - PER, BOFF and EWARN bits can generate an interrupt at INTO line and affect the interrupt register.	RW	0

Bits	Field Name	Description	Type	Reset
2	SIE	Status change interrupt enable 0: Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1: Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.	RW	0
1	IE0	Interrupt line 0 enable 0: Disabled - Module interrupt INT0 is always low. 1: Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.	RW	0
0	INIT	Initialization 0: Normal operation 1: Initialization mode is entered	RW	1

Table 19-493. DCAN_ES

Address Offset	0x0000 0004	Instance	DCAN1 DCAN2
Physical Address	0x4AE3 C004 0x4848 0004		
Description	<p>Error and Status Register</p> <p>Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in DCAN_CTL is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in DCAN_CTL is 1). A change of bit EPASS will not generate an interrupt.</p> <p>Reading the DCAN_ES clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the DCAN_INT will be replaced by the next lower priority interrupt value.</p> <p>For debug support, the auto clear functionality of DCAN_ES (clear of status flags by read) is disabled when in debug/suspend mode.</p>		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
RESERVED																						PDA	WAKEUPPND	PER	BOFF	EWARN	EPASS	RXOK	TXOK								LEC

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000
10	PDA	Local power-down mode acknowledge 0: DCAN is not in local power-down mode. 1: Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.	R	0
9	WAKEUPPND	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if DCAN_ES is read. 0: No Wake Up is requested by DCAN. 1: DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.	R	0
8	PER	Parity error detected. This bit will be reset if DCAN_ES register is read. Read 0: No parity error has been detected since last read access. Read 1: The parity check mechanism has detected a parity error in the Message RAM. Write 0: No effect Write 1: End of interrupt (EOI) for parity error on DCAN_PARITY interrupt line	RW	0
7	BOFF	Bus-Off state 0: The CAN module is not bus-off state. 1: The CAN module is in bus-off state.	R	0
6	EWARN	Warning state 0: Both error counters are below the error warning limit of 96. 1: At least one of the error counters has reached the error warning limit of 96.	R	0
5	EPASS	Error passive state 0: On CAN Bus error, the DCAN could send active error frames. 1: The CAN core is in the error passive state as defined in the CAN Specification.	R	0

Bits	Field Name	Description	Type	Reset
4	RXOK	<p>Received a message successfully. This bit will be reset if DCAN_ES register is read.</p> <p>0: No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events.</p> <p>1: A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).</p>	R	0
3	TXOK	<p>Transmitted a message successfully. This bit will be reset if DCAN_ES register is read.</p> <p>0: No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events.</p> <p>1: A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.</p>	R	0
2:0	LEC	<p>Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.</p> <p>0x0: No error</p> <p>0x1: Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.</p> <p>0x2: Form error: A fixed format part of a received frame has the wrong format.</p> <p>0x3: Ack error: The message this CAN core transmitted was not acknowledged by another node.</p> <p>0x4: Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>0x5: Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>0x6: CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).</p> <p>0x7: No CAN bus event was detected since the last time the software read DCAN_ES. Any read access to DCAN_ES re-initializes the LEC to value '7.'</p>	R	0x7

Table 19-497. DCAN_BTR

Address Offset	0x0000 000C		
Physical Address	0x4AE3 C00C 0x4848 000C	Instance	DCAN1 DCAN2
Description	Bit timing register This register is only writable if CCE and INIT bits in the DCAN_CTL are set. The CAN bit time may be programmed in the range of 8 to 25 time quanta The CAN time quantum may be programmed in the range of 1 to 1024 CAN_CLK periods.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												RESERVED	TSEG2	TSEG1	SJW	BRP															

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x000
19:16	BRPE	Baud rate prescaler extension. Valid programmed values are 0 to 15. By programming BRPE the baud rate prescaler can be extended to values up to 1024.	RW	0x0
15	RESERVED	These bits are always read as 0. Writes have no effect.	R	0
14:12	TSEG2	Time segment after the sample point Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1.	RW	0x2
11:8	TSEG1	Time segment before the sample point Valid programmed values are 1 to 15. The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1.	RW	0x3
7:6	SJW	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1.	RW	0x0
5:0	BRP	Baud rate prescaler Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1.	RW	0x1

Table 19-503. DCAN_PERR

Address Offset	0x0000 001C		
Physical Address	0x4AE3 C01C 0x4848 001C	Instance	DCAN1 DCAN2
Description	Parity Error Code Register If a parity error is detected, the PER flag will be set in the DCAN_ES . This bit is not reset by the parity check mechanism; it must be reset by reading DCAN_ES . In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number). If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

Table 19-565. DCAN_IF1CMD

Address Offset	0x0000 0100		
Physical Address	0x4AE3 C100 0x4848 0100	Instance	DCAN1 DCAN2
Description	<p>IF1 Command Register</p> <p>The IF1 Command Register (DCAN_IF1CMD) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.</p> <p>While BUSY bit is one, IF1/IF2 register sets are write protected.</p> <p>For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.</p> <p>If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.</p>		
Type	RW

Table 19-577. DCAN_IF2CMD

Address Offset	0x0000 0120		
Physical Address	0x4AE3 C120 0x4848 0120	Instance	DCAN1 DCAN2
Description	<p>IF2 Command Register</p> <p>The IF2 Command Register (DCAN_IF2CMD) configure and initiate the transfer between the IF2 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.</p> <p>While BUSY bit is one, IF1/IF2 register sets are write protected.</p> <p>For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.</p> <p>If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.</p>

RESERVED																NEWDAT	MSGLST	INTPND	UMASK	TXIE	RXIE	RMTEN	TXRQST	EOB	RESERVED	DLC						

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0000
15	NEWDAT	New data 0: No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the software. 1: The message handler or the software has written new data into the data portion of this message object.	RW	0
14	MSGLST	Message lost (only valid for message objects with direction = receive) 0: No message lost since the last time when this bit was reset by the software. 1: The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.	RW	0
13	INTPND	Interrupt pending 0: This message object is not the source of an interrupt. 1: This message object is the source of an interrupt. The Interrupt Identifier in DCAN_INT will point to this message object if there is no other interrupt source with higher priority.	RW	0
12	UMASK	Use acceptance mask 0: Mask ignored 1: Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.	RW	0
11	TXIE	Transmit interrupt enable 0: IntPnd will not be triggered after the successful transmission of a frame. 1: IntPnd will be triggered after the successful transmission of a frame.	RW	0
10	RXIE	Receive interrupt enable 0: IntPnd will not be triggered after the successful reception of a frame. 1: IntPnd will be triggered after the successful reception of a frame.	RW	0

Bits	Field Name	Description	Type	Reset
9	RMTEN	Remote enable 0: At the reception of a remote frame, TxRqst is not changed. 1: At the reception of a remote frame, TxRqst is set.	RW	0
8	TXRQST	Transmit request 0: This message object is not waiting for a transmission. 1: The transmission of this message object is requested and is not yet done.	RW	0
7	EOB	End of Block 0: The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1: The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.	RW	0
6:4	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
3:0	DLC	Data length code 0-8: Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.	RW	0x0

Address Offset	0x0000 0140		
Physical Address	0x4AE3 C140 0x4848 0140	Instance	DCAN1 DCAN2
Description	<p>IF3 Observation Register</p> <p>The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in Section 19.6.4.11.1 Structure of Message Objects). The observation flags (Bits [4:0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.</p> <p>NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.</p> <p>A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).</p>

Physical Address	0x4AE3 C16C 0x4848 016C		
Description	Update Enable Register The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UPDEN flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set NOTE: IF3 Update enable should not be set for transmit objects.		
Type	RW

19.7 MCAN

This chapter describes the Modular Controller Area Network (MCAN) module introduced in device Silicon Revision 2.0 (SR2.0).

19.7.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control with a high level of security. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

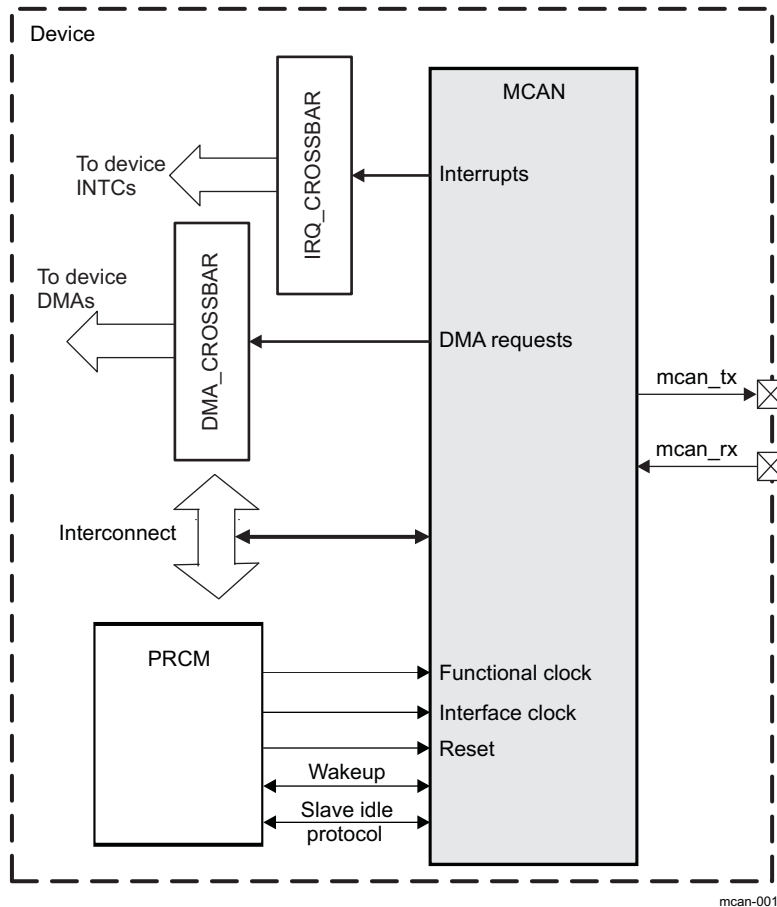

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports one MCAN module connecting to the CAN network through external (for the device) transceiver for connection to the physical layer. The MCAN module supports up to 5 Mbit/s data rate and is compliant to ISO 11898-1:2015.

NOTE: The availability of CAN FD feature is device part number dependent. Refer to device Data Manual for more information.

Figure 19-135 shows the MCAN module overview.

Figure 19-135. MCAN Module Overview

19.7.1.1 Features

The MCAN module implements the following features:

- Conforms with ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Not supported features:

- Full Message Memory capacity (4352 words). Only 1600 words implemented.
- Debug on CAN (Debug DMA)
- Host bus read and write bursts
- Host bus firewall
- GPIO mode
- External (IO) Loopback mode
- Device clock domains monitoring (using DCC module)

19.7.2 MCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the MCAN.

Figure 19-136 shows an overview of a typical MCAN application.

Figure 19-136. MCAN Typical Application

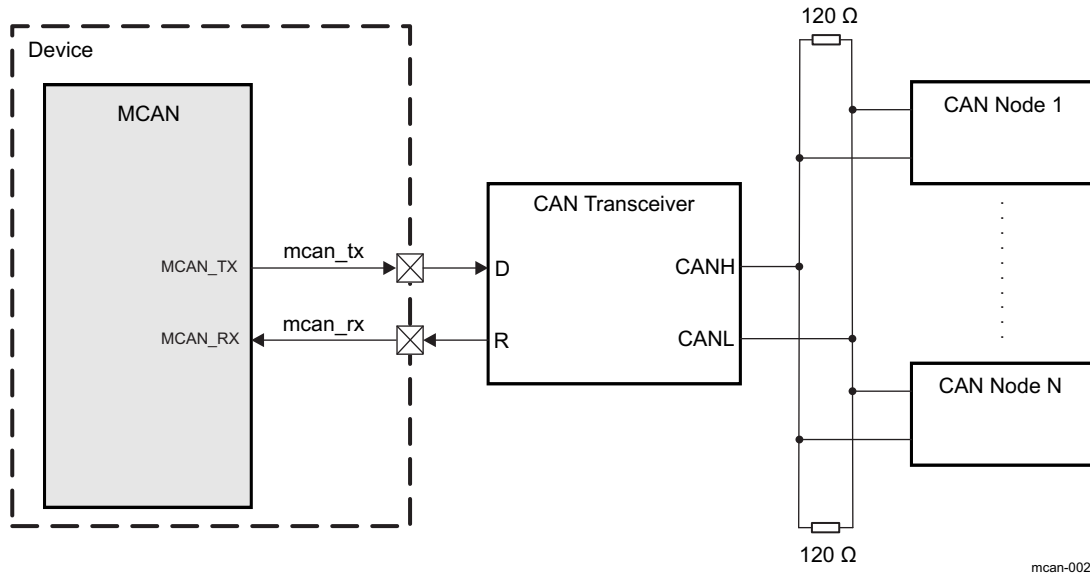

Table 19-613 describes the external signals of the MCAN module.

Table 19-613. MCAN I/O Description

Module Signal	Device Signal	I/O ⁽¹⁾	Description	Value at Reset
MCAN_RX	mcan_rx	I	Serial data input from external CAN transceiver	HiZ
MCAN_TX	mcan_tx	O	Serial data output to external CAN transceiver	1

⁽¹⁾ I = Input; O = Output

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 14.4.6.1, *Pad Configuration Registers* of Chapter 14, *Control Module*.

19.7.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using Non-Return-to-Zero (NRZ) encoding and has two states:
 - Recessive state (logical 1)
 - Dominant state (logical 0)
- The network is multimaster. When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier based, not address based.
- Content of message is labeled by the identifier that is unique throughout the network (for example: rpm, temperature, position, pressure, and so forth).
- All nodes on network receive the message and each performs an acceptance test on the identifier. If

message is relevant, it is processed, otherwise it is ignored.

- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is).
- Data is transmitted and received using message frames, consisting of the following basic fields:
 - Arbitration field
 - Control field
 - Data field (up to 8 bytes for Classical CAN and up to 64 bytes for CAN FD)
 - CRC field
 - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signalling*.

19.7.3 MCAN Integration

Figure 19-137 shows the integration of the MCAN module in the device.

Figure 19-137. MCAN Integration

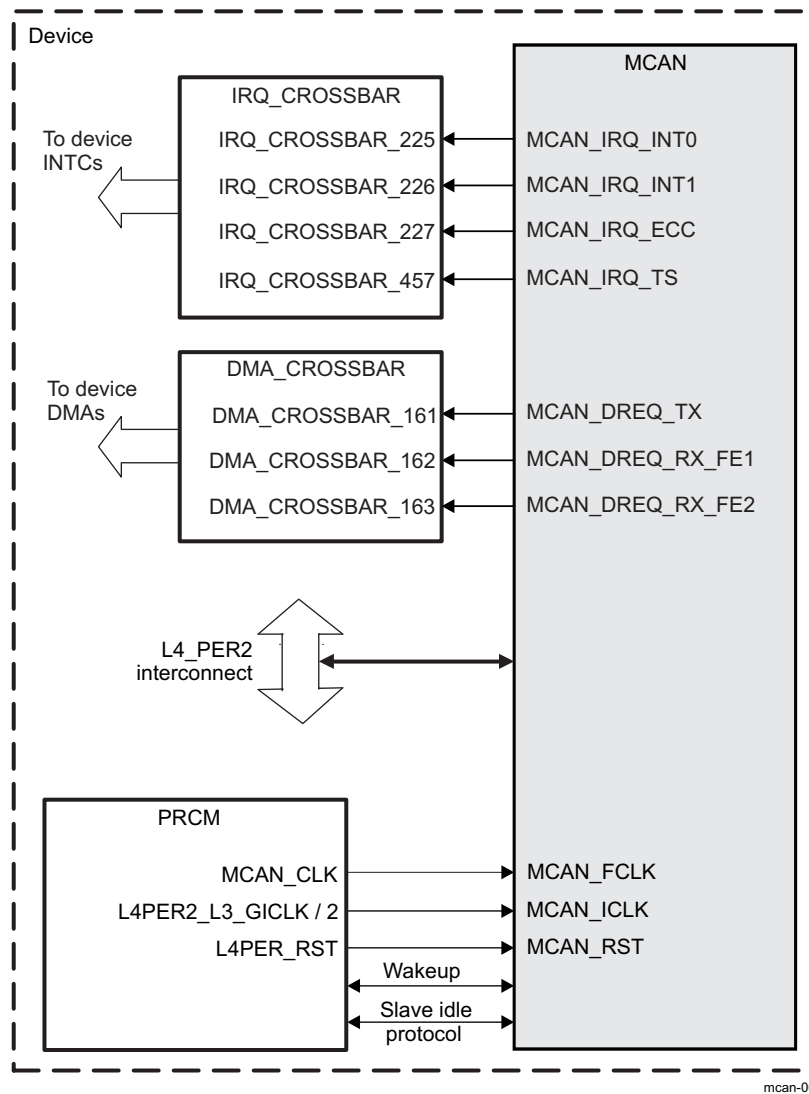

Table 19-614 through Table 19-616 summarize the integration of the MCAN module in the device.

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
MCAN	MCAN_IRQ_INT0	IRQ_CROSSBAR_225	-	MCAN interrupt 0
	MCAN_IRQ_INT1	IRQ_CROSSBAR_226	-	MCAN interrupt 1
	MCAN_IRQ_ECC	IRQ_CROSSBAR_227	-	MCAN ECC interrupt
	MCAN_IRQ_TS	IRQ_CROSSBAR_457	-	MCAN timestamp interrupt
DMA Requests				
Module Instance	Source Signal Name	DMA_CROSSBAR Input	Default Mapping	Description
MCAN	MCAN_DREQ_TX	DMA_CROSSBAR_161	-	MCAN TX DMA Event
	MCAN_DREQ_RX_FE1	DMA_CROSSBAR_162	-	MCAN RX Filter Event 1
	MCAN_DREQ_RX_FE2	DMA_CROSSBAR_163	-	MCAN RX Filter Event 2

NOTE: The MCAN module has no default IRQ mappings through the IRQ_CROSSBAR. For the MCAN module, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4](#), *IRQ_CROSSBAR Module Functional Description*, in [Chapter 14](#), *Control Module*.

For more information about the device interrupt controllers, see [Chapter 13](#), *Interrupt Controllers*.

NOTE: For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5](#), *DMA_CROSSBAR Module Functional Description*, in [Chapter 14](#), *Control Module*.

NOTE: For the description of the interrupt source, see [Section 19.7.4.2](#), *Interrupt and DMA Requests*.

19.7.4 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values up to 5 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

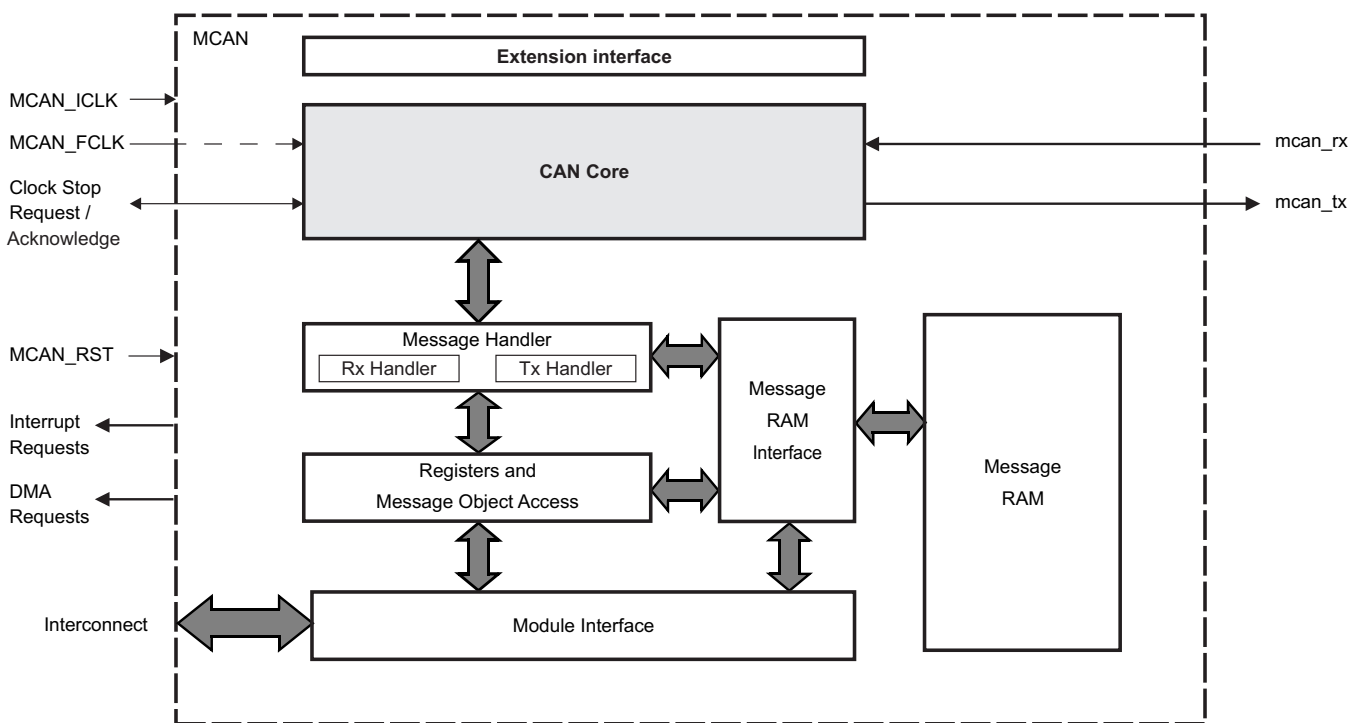

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 19-138 shows the MCAN module block diagram.

Figure 19-138. MCAN Block Diagram

mcan-004

The MCAN module blocks description:

- **CAN Core:** The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see [Section 19.7.4.11, Message RAM](#)).
- **Message RAM Interface:** enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.

- **Module Interface:** The MCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.
- **Clocking:** Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface:** All flags from the Interrupt Register (MCAN_IR) as well as selected internal status and control signals are routed to this interface.

19.7.4.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN_ICLK) as the general module clock source
- and the peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There are synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

NOTE: MCAN_ICLK must always be higher or equal to MCAN_FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated MCAN_ICLK has to be considered:

$$f_{0, ICLK}(OCP) \pm \Delta f_{FM, ICLK}(OCP) \geq f_{FCLK}$$

CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than Classic CAN. For optimal performance, TI recommends using the lowest N-divider value that maintains a working PLL REF_CLK (GMAC_DSP_DPLL_CLK) for the system. Lower N-divider values increase the loop bandwidth of the PLL which in turn improves timing margins for CAN-FD.

For CAN-FD operations > 2 Mbps:

- For 20 MHz input clocks, N = 0 is the preferred configuration.

For CAN-FD operations < 2 Mbps:

- For 20 MHz input clocks, N = 0 is the preferred configuration.
- For 19.2 MHz input clocks, N = 11 is the preferred configuration.

For more information on how to configure the relevant clock source registers, see [Chapter 3, PRCM](#) and the device data manual.

19.7.4.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode prevents the interrupt and DMA requests from propagating to the Host CPU (for more information, see [Section 19.7.4.4.8.2, Suspend Mode](#)).

19.7.4.2.1 Interrupt Requests

The MCAN module has two interrupt lines. The first interrupt line (INT0) is associated with the MCAN core. There are 30 internal interrupt sources. The interrupts are 'level high' interrupts.

For more information, see the following registers:

- Interrupt Register ([MCAN_IR](#))
- Interrupt Enable ([MCAN_IE](#))
- Interrupt Line Select ([MCAN_ILS](#))
- Interrupt Line Enable ([MCAN_ILE](#))

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write 1 to [MCANSS_ECC_EOI\[8\]](#) ECC_EOI bit (for more information, see [Section 19.7.4.7.2, ECC Aggregator](#)).

The second interrupt line (INT1) is associated with the External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see [Section 19.7.4.5.1, External Timestamp Counter](#)).

For more information, see the following registers:

- Interrupt Clear Shadow Register ([MCANSS_ICS](#))
- Interrupt Raw Status Register ([MCANSS_IRS](#))
- Interrupt Enable Clear Shadow Register ([MCANSS_IECS](#))
- Interrupt Enable Register ([MCANSS_IE](#))
- Interrupt Enable Status ([MCANSS_IES](#))
- End Of Interrupt ([MCANSS_EOI](#))
- External Timestamp Prescaler ([MCANSS_EXT_TS_PRESCALER](#))
- External Timestamp Unserviced Interrupts Counter ([MCANSS_EXT_TS_UNSERVICED_INTR_CNTR](#))

19.7.4.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extension Interface. The DMA signaling uses a simple DMA request active high pulse. Only one Tx DMA event is provided by the MCAN module.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle (MCAN_ICLK) pulses. Only two Filter DMA events are provided by the MCAN module.

For more information about available Interrupt and DMA Requests, see [Section 19.7.3, MCAN Integration](#).

19.7.4.3 Fuseable CAN FD Operation Enable

The Flexible Datarate feature of the MCAN module can be enabled by writing 1 to [MCAN_CCCR\[8\]](#) FDOE bit. A value of 0 on the primary configuration port (mcanss_enable_fdoe) will force the [MCAN_CCCR\[8\]](#) FDOE bit during write to the [MCAN_CCCR](#) register which will prevent the device from enabling and using the CAN FD mode.

19.7.4.4 Operating Modes

19.7.4.4.1 Software Initialization

Setting the [MCAN_CCCR\[0\]](#) INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the [MCAN_CCCR\[0\]](#) INIT bit is set, the message transfer is stopped and the status of the output MCAN_TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the [MCAN_CCCR\[0\]](#) INIT bit does not change any configuration register. Resetting the [MCAN_CCCR\[0\]](#) INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both [MCAN_CCCR\[0\]](#) INIT and [MCAN_CCCR\[1\]](#) CCE bits are set (write protection).

The [MCAN_CCCR\[1\]](#) CCE bit can only be set/reset while the [MCAN_CCCR\[0\]](#) INIT = 1. The [MCAN_CCCR\[1\]](#) CCE bit is automatically reset when the [MCAN_CCCR\[0\]](#) INIT bit is reset.

The following registers are reset when the [MCAN_CCCR\[1\]](#) CCE bit is set:

- [MCAN_HPMS](#) - High Priority Message Status
- [MCAN_RXF0S](#) - Rx FIFO 0 Status
- [MCAN_RXF1S](#) - Rx FIFO 1 Status

- [MCAN_TXFQS](#) - Tx FIFO/Queue Status
- [MCAN_TXBRP](#) - Tx Buffer Request Pending
- [MCAN_TXBTO](#) - Tx Buffer Transmission Occurred
- [MCAN_TXBCF](#) - Tx Buffer Cancellation Finished
- [MCAN_TXEFS](#) - Tx Event FIFO Status

The Timeout Counter value [MCAN_TOCV](#)[15:0] TOC field is preset to the value configured by the [MCAN_TOCC](#)[31:16] TOP field when the [MCAN_CCCR](#)[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while [MCAN_CCCR](#)[1] CCE = 1.

The following registers are only writeable while [MCAN_CCCR](#)[1] CCE = 0

- [MCAN_TXBAR](#) - Tx Buffer Add Request
- [MCAN_TXBCR](#) - Tx Buffer Cancellation Request

[MCAN_CCCR](#)[7] TEST and [MCAN_CCCR](#)[5] MON bits can only be set by the Host CPU while [MCAN_CCCR](#)[0] INIT = 1 and [MCAN_CCCR](#)[1] CCE = 1. Both bits may be reset at any time. The [MCAN_CCCR](#)[6] DAR bit can only be set/reset while [MCAN_CCCR](#)[0] INIT = 1 and [MCAN_CCCR](#)[1] CCE = 1.

19.7.4.4.2 Normal Operation

Once the MCAN module is initialized and the [MCAN_CCCR](#)[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

NOTE: Automated transmission on reception of remote frames is not supported.

19.7.4.4.3 CAN FD Operation

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the [MCAN_PSR](#)[14] EXE bit. When Protocol Exception Handling is enabled ([MCAN_CCCR](#)[12] PXHD = 0), this causes the operation state to change from Receiver ([MCAN_PSR](#)[4:3] ACT = 10) to Integrating ([MCAN_PSR](#)[4:3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled ([MCAN_CCCR](#)[12] PXHD = 1), the MCAN will treat a recessive res bit as a form error and will respond with an error frame.

CAN FD operation is enabled by programming the [MCAN_CCCR](#)[8] FDOE bit. In case [MCAN_CCCR](#)[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With [MCAN_CCCR\[8\]](#) FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The [MCAN_CCCR\[8\]](#) FDOE and [MCAN_CCCR\[9\]](#) BRSE bits can only be changed while the [MCAN_CCCR\[0\]](#) INIT and [MCAN_CCCR\[1\]](#) CCE bits are both set. With [MCAN_CCCR\[8\]](#) FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With [MCAN_CCCR\[8\]](#) FDOE = 1 and [MCAN_CCCR\[9\]](#) BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With [MCAN_CCCR\[8\]](#) FDOE = 1 and [MCAN_CCCR\[9\]](#) BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

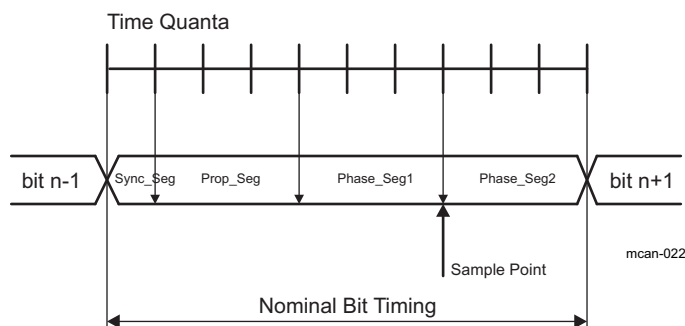

In the CAN FD format, the DLC coding differs from the standard CAN format (see [Table 19-617](#)).

Table 19-617. DLC Coding

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames with bit rate switching, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 19-139](#)) is used as configured by the Nominal Bit Timing and Prescaler Register [MCAN_NBTP](#). In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register [MCAN_DBTP](#). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

Figure 19-139. CAN Bit Timing

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

For both CAN FD without and CAN FD with bit rate switching the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see [MCAN_PSR\[11\]](#) RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

19.7.4.4.4 Transmitter Delay Compensation

19.7.4.4.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the MCAN_TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the MCAN_RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

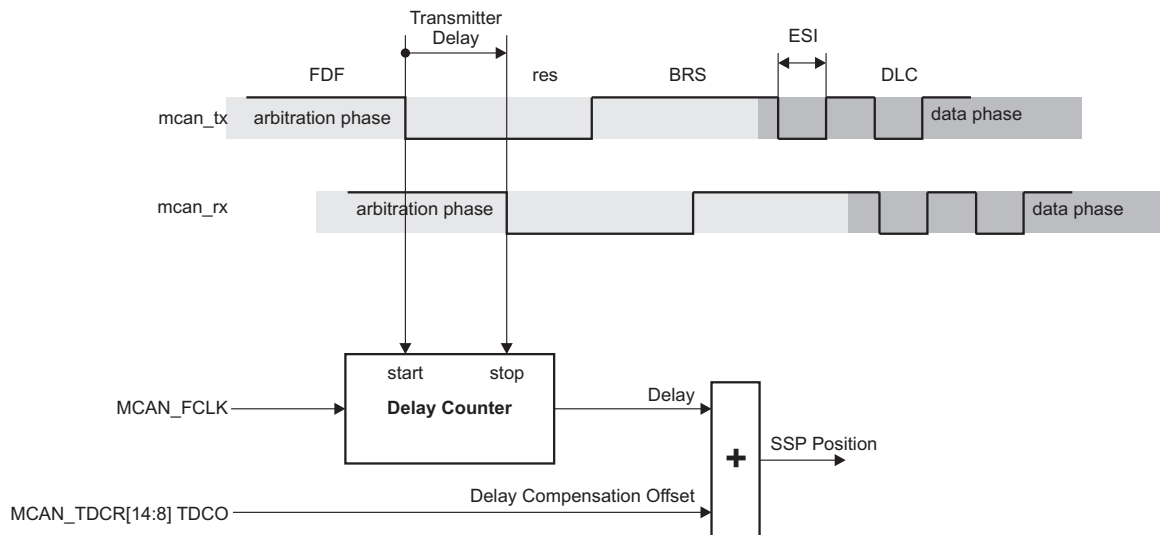

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the [MCAN_DBTP\[23\]](#) TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output MCAN_TX pin through the transceiver to the receive input MCAN_RX pin plus the transmitter delay compensation offset configured by the [MCAN_TDCR\[14:8\]](#) TDCO field (see [Figure 19-140](#)). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the [MCAN_PSR\[22:16\]](#) TDCV field. This field is cleared when the [MCAN_CCCR\[0\]](#) INIT bit is set and is updated at each transmission of CAN FD frame while the [MCAN_DBTP\[23\]](#) TDC bit is set.

Figure 19-140. Transmitter Delay Measurement

mcan-005

19.7.4.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming [MCAN_DBTP\[23\]](#) TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input MCAN_RX pin of the transmitter. The resolution of this measurement is one mtq (see [Figure 19-140](#)). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming [MCAN_TDCR\[6:0\]](#) TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the MCAN_RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least [MCAN_TDCR\[6:0\]](#) TDCF field and the MCAN_RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset ([MCAN_TDCR\[14:8\]](#) TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset ([MCAN_TDCR\[14:8\]](#) TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

19.7.4.4.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters ([MCAN_ECR\[14:8\]](#) REC and [MCAN_ECR\[7:0\]](#) TEC) are frozen while CAN error logging ([MCAN_ECR\[23:16\]](#) CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting [MCAN_CCCR\[2\]](#) ASM bit. The bit can only be set by the Host CPU at any time when both [MCAN_CCCR\[2\]](#) CCE and [MCAN_CCCR\[1\]](#) INIT bits are set to 1.

The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset [MCAN_CCCR\[2\]](#) ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

NOTE: The Restricted Operation Mode must not be combined with the Loop Back Mode.

19.7.4.4.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the [MCAN_CCCR\[5\]](#) MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the [MCAN_TXBRP](#) register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. [Figure 19-141](#) shows the connection of the MCAN_TX and MCAN_RX signals to the MCAN module in Bus Monitoring Mode.

Figure 19-141. Connection of Signals in Bus Monitoring Mode

19.7.4.4.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the [MCAN_CCCR\[6\]](#) DAR bit).

19.7.4.4.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending [MCAN_TXBRP\[xx\]](#) TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred [MCAN_TXBTO\[xx\]](#) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished [MCAN_TXBCF\[xx\]](#) CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred [MCAN_TXBTO\[xx\]](#) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished [MCAN_TXBCF\[xx\]](#) CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred [MCAN_TXBTO\[xx\]](#) TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished [MCAN_TXBCF\[xx\]](#) CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

19.7.4.4.8 Power Down (Sleep Mode)

Entering Power Down mode is controlled via the input clock stop request signal ([mcanss_clkstp_clkstop_req](#)) or [MCAN_CCCR\[4\]](#) CSR bit. As long as the clock stop request signal is active, the [MCAN_CCCR\[4\]](#) CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the [MCAN_CCCR\[1\]](#) INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal ([mcanss_clkstop_clkstop_ack](#)) to 1 and the [MCAN_CCCR\[3\]](#) CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the [MCAN_CCCR\[1\]](#) INIT bit will have no effect. Now the module clock inputs [MCAN_ICLK](#) and [MCAN_FCLK](#) may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the [MCAN_CCCR\[4\]](#) CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the [MCAN_CCCR\[3\]](#) CSA flag bit. Afterwards, the application can restart CAN communication by resetting [MCAN_CCCR\[1\]](#) INIT bit.

19.7.4.4.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The [MCAN_CCCR\[0\]](#) INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the [MCANSS_CTRL\[5\]](#) AUTOWAKEUP and [MCANSS_CTRL\[4\]](#) WAKEUPREQEN bits to 1 (for more information, see [Section 19.7.4.4.8.3, Wakeup request](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the [MCAN_CCCR\[0\]](#) INIT bit is performed to clear it.

19.7.4.4.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the [MCANSS_CTRL\[3\]](#) FREE and [MCANSS_CTRL\[2\]](#) SOFT bits), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the [MCAN_CCCR\[0\]](#) INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading [MCAN_CCCR\[0\]](#) INIT bit.

The automatic wakeup feature is enabled by setting the [MCANSS_CTRL\[5\]](#) AUTOWAKEUP and [MCANSS_CTRL\[4\]](#) WAKEUPREQEN bits to 1 (for more information, see [Section 19.7.4.4.8.3, Wakeup request](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the [MCAN_CCCR\[0\]](#) INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- [MCAN_ECR\[23:16\]](#) CEL
- [MCAN_PSR\[2:0\]](#) LEC
- [MCAN_PSR\[10:8\]](#) DLEC
- [MCAN_PSR\[11\]](#) RESI
- [MCAN_PSR\[12\]](#) RBRS
- [MCAN_PSR\[13\]](#) RFDF
- [MCAN_PSR\[14\]](#) PXE

19.7.4.4.8.3 Wakeup request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the [MCANSS_CTRL\[5\]](#) AUTOWAKEUP and [MCANSS_CTRL\[4\]](#) WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the [MCAN_CCCR\[0\]](#) INIT bit and the MCAN core will resume operation.

If the [MCANSS_CTRL\[4\]](#) WAKEUPREQEN bit is set, the MCAN module provides a wakeup request (SWakeup) on any of the following wakeup events:

- The receive MCAN_RX pin is dominant (logical 0)
- OCP access is performed

To clear the SWakeup in case any of these events is active, the [MCANSS_CTRL\[4\]](#) WAKEUPREQEN bit should be cleared. The MCAN module adds a third wakeup event source - interrupt line 0 (INT0). In this case the SWakeup is cleared by clearing the interrupt source.

19.7.4.4.9 Test Modes

The [MCAN_TEST](#) register write access is enabled by setting the test mode enable [MCAN_CCCR\[7\]](#) TEST bit to 1. The [MCAN_TEST](#) register allows the configuration of the test modes and test functions.

The CAN transmit MCAN_TX pin has four output functions. One of those functions can be selected by programming the [MCAN_TEST\[6:5\]](#) TX filed. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive MCAN_RX pin can be monitored from [MCAN_TEST\[7\]](#) RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (MCAN_FCLK) and Host clock (MCAN_ICLK) domain, there may be a delay of several Host clock periods between writing to the [MCAN_TEST\[6:5\]](#) TX filed until the new configuration is visible at the output MCAN_TX pin. This applies also when reading input MCAN_RX pin via the [MCAN_TEST\[7\]](#) RX bit.

NOTE: Test modes should be used for self test only. The software control for MCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

19.7.4.4.9.1 Internal Loop Back Mode

The MCAN module can be set into Internal Loop Back Mode by programming [MCAN_TEST\[4\]](#) LBCK and [MCAN_CCCR\[5\]](#) MON bits to 1. The Internal Loop Back Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the MCAN_TX and MCAN_RX pins. In this mode MCAN_RX pin is disconnected from the MCAN module and MCAN_TX pin is held recessive. [Figure 19-142](#) shows the connection of the MCAN_TX and MCAN_RX pins to the MCAN module in case of Internal Loop Back Mode.

Figure 19-142. Internal Loop Back Mode

19.7.4.5 Timestamp Generation

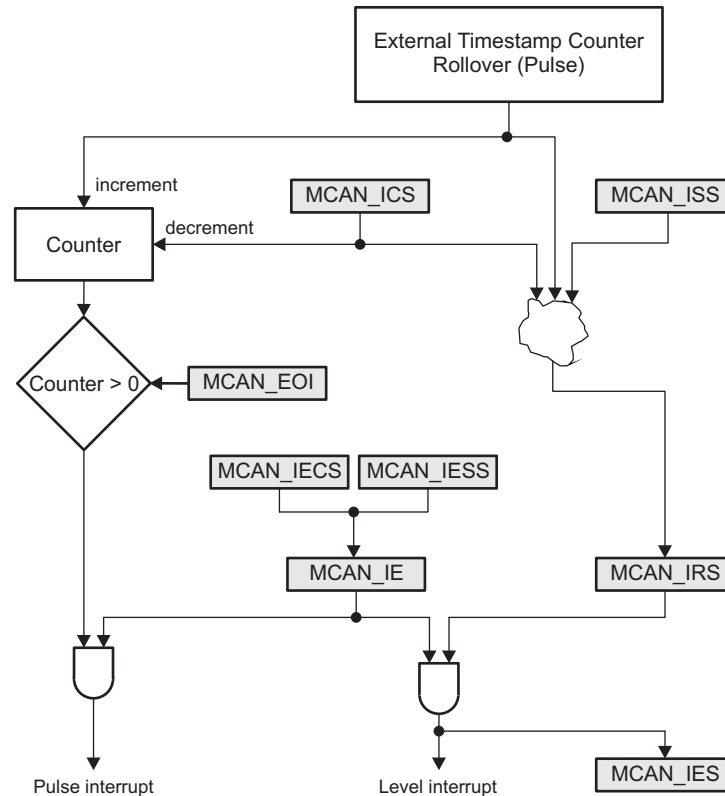

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler [MCAN_TSCC\[19:16\]](#) TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the [MCAN_TSCV\[15:0\]](#) TSC field. A write access to the [MCAN_TSCV](#) register resets the counter to zero. When the timestamp counter wraps around the interrupt [MCAN_IR\[16\]](#) TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see [Section 19.7.4.11, Message RAM](#).

19.7.4.5.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the [MCAN_TSCC\[1:0\]](#) TSS field.

The External Timestamp Counter uses the interface clock (MCAN_ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see [MCANSS_EXT_TS_PRESCALER\[23:0\]](#) PRESCALER field). When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the [MCAN_IRQ_TS](#) interrupt is generated. The MCAN module provides both pulse and level interrupt type for this interrupt.

When the timestamp rolls over the [MCANSS_IRS](#) register is set (see [Figure 19-143](#)). The [MCANSS_IE](#) register can be affected by writing to the [MCAN_IESS](#) register to set or to the [MCANSS_IECS](#) register to clear. The level interrupt is a reflection of both [MCANSS_IRS](#) and [MCANSS_IE](#) being set. The [MCANSS_IES](#) register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the [MCANSS_ICS](#) register to clear the [MCANSS_IRS](#) register will also decrement the interrupt counter. Writing to the [MCANSS_EOI](#) register will issue another pulse if the interrupt counter is not zero.

Figure 19-143. External Timestamp Counter Interrupt

mcan-021

19.7.4.6 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the [MCAN_TOCC](#) register. It is enabled via the [MCAN_TOCC\[0\]](#) ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the [MCAN_TSCC\[19:16\]](#) TCP field as the Timestamp Counter. The actual counter value can be monitored from the [MCAN_TOCV\[15:0\]](#) TOC field. The Timeout Counter can be started only when [MCAN_CCCR\[1\]](#) INIT = 0 and stopped when [MCAN_CCCR\[1\]](#) INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the [MCAN_TOCC\[2:1\]](#) TOS field. When Continuous Mode is selected, the counter starts when [MCAN_CCCR\[1\]](#) INIT = 0, a write to the [MCAN_TOCV](#) register presets the counter to the value configured by the [MCAN_TOCC\[31:16\]](#) TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the [MCAN_TOCC\[31:16\]](#) TOP field. Down-counting is started when the first FIFO element is stored. Writing to the [MCAN_TOCV](#) register has no effect. When the counter reaches zero, the interrupt [MCAN_IR\[18\]](#) TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the [MCAN_TOCC\[31:16\]](#) TOP field.

19.7.4.7 Safety

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC Aggregator.

19.7.4.7.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

19.7.4.7.2 ECC Aggregator

This section describes the functional details of the ECC Aggregator module.

19.7.4.7.2.1 ECC Aggregator Overview

The ECC Aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

19.7.4.7.2.2 ECC Aggregator Registers

There are 3 groups of registers in the ECC aggregator module:

- Global registers - Aggregator Revision Register ([MCANSS_ECC_AGGR_REVISION](#)), ECC Vector Register ([MCANSS_ECC_VECTOR](#)), Misc Status Register ([MCANSS_ECC_MISC_STATUS](#)), ECC Control Register ([MCANSS_ECC_CONTROL](#)), and ECC Wrapper Revision Register ([MCANSS_ECC_WRAP_REVISION](#)).
- Control and status registers - ECC Error Control Registers ([MCANSS_ECC_ERR_CTRL1](#) and [MCANSS_ECC_ERR_CTRL2](#)) and ECC Error Status Registers ([MCANSS_ECC_ERR_STAT1](#) and [MCANSS_ECC_ERR_STAT2](#)).
- Interrupt registers - interrupt status, interrupt enable set, interrupt enable clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
 - [MCANSS_ECC_SEC_EOI_REG](#)
 - [MCANSS_ECC_SEC_STATUS_REG0](#)
 - [MCANSS_ECC_SEC_ENABLE_SET_REG0](#)
 - [MCANSS_ECC_SEC_ENABLE_CLR_REG0](#)
 - [MCANSS_ECC_DED_EOI_REG](#)
 - [MCANSS_ECC_DED_STATUS_REG0](#)
 - [MCANSS_ECC_DED_ENABLE_SET_REG0](#)
 - [MCANSS_ECC_DED_ENABLE_CLR_REG0](#)

19.7.4.7.2.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as described below:

- Software writes value (the ECC RAM ID) to the [MCANSS_ECC_VECTOR](#)[10-0] ECC_VECTOR field to select the ECC RAM for control or status.

- Software writes 1 to the [MCANSS_ECC_VECTOR\[15\]](#) RD_SVBUS bit to trigger a read.
- Software writes read address to the [MCANSS_ECC_VECTOR\[23-16\]](#) RD_SVBUS_ADDRESS field.
- Software then polls the [MCANSS_ECC_VECTOR\[24\]](#) RD_SVBUS_DONE bit to check if it is 1. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

19.7.4.7.2.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM by writing to the [MCANSS_ECC_SEC_ENABLE_SET_REG0/MCANSS_ECC_DED_ENABLE_SET_REG0](#) register.
- Software writes the ECC RAM ID in the [MCANSS_ECC_VECTOR\[10-0\]](#) ECC_VECTOR.
- Software writes the [MCANSS_ECC_VECTOR\[15\]](#) RD_SVBUS bit to trigger the read.
- Software writes the [MCANSS_ECC_ERR_STAT1](#) register address to the [MCANSS_ECC_VECTOR\[23-16\]](#) RD_SVBUS_ADDRESS field. Software will need to load the 'read message' in the [MCANSS_ECC_VECTOR](#) register again if it needs to read the [MCANSS_ECC_ERR_STAT2](#) register.
- Software polls the [MCANSS_ECC_VECTOR\[24\]](#) RD_SVBUS_DONE bit. When this bit is set, a read of the [MCANSS_ECC_ERR_STAT1/MCANSS_ECC_ERR_STAT2](#) register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the [MCANSS_ECC_ERR_STAT1\[8\]](#) CLR_ECC_SEC or [MCANSS_ECC_ERR_STAT1\[9\]](#) CLR_ECC_DED bit depending on the type of the ECC error.
- Software has to poll the [MCANSS_ECC_ERR_STAT1](#) register to guarantee that the status bit has been cleared.
- Software will write to the [MCANSS_ECC_SEC_EOI_REG/MCANSS_ECC_DED_EOI_REG](#) register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the [MCANSS_ECC_EOI\[8\]](#) ECC_EOI bit.

19.7.4.8 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

19.7.4.8.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
 - Range Filter (from - to)
 - Filter for specific IDs (for one or two dedicated IDs)
 - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration ([MCAN_GFC](#)) register
- Standard ID Filter Configuration ([MCAN_SIDFC](#)) register
- Extended ID Filter Configuration ([MCAN_XIDFC](#)) register
- Extended ID AND Mask ([MCAN_XIDAM](#)) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 19.7.4.11](#), *Message RAM*) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse. For more information, see [Section 19.7.4.2.1](#), *DMA Requests*.
- Received frame is rejected
- Set High Priority Message interrupt flag [MCAN_IR\[8\]](#) HPM
- Set High Priority Message interrupt flag [MCAN_IR\[8\]](#) HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:
New Data flag ([MCAN_NDAT1/MCAN_NDAT2](#)) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see [MCAN_PSR\[2:0\]](#) LEC respectively [MCAN_PSR\[10:8\]](#) DLEC fields).
- Rx FIFO:
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see [MCAN_PSR\[2:0\]](#) LEC respectively [MCAN_PSR\[10:8\]](#) DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 19.7.4.8.2.2](#) have to be considered.

19.7.4.8.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 19.7.4.11.5](#), *Standard Message ID Filter Element* and [Section 19.7.4.11.6](#), *Extended Message ID Filter Element*.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask ([MCAN_XIDAM](#)) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask ([MCAN_XIDAM](#)) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask ([MCAN_XIDAM](#)) is not used for Range Filtering.

19.7.4.8.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see [Section 19.7.4.11.5](#), *Standard Message ID Filter Element* and [Section 19.7.4.11.6](#), *Extended Message ID Filter Element*.

19.7.4.8.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

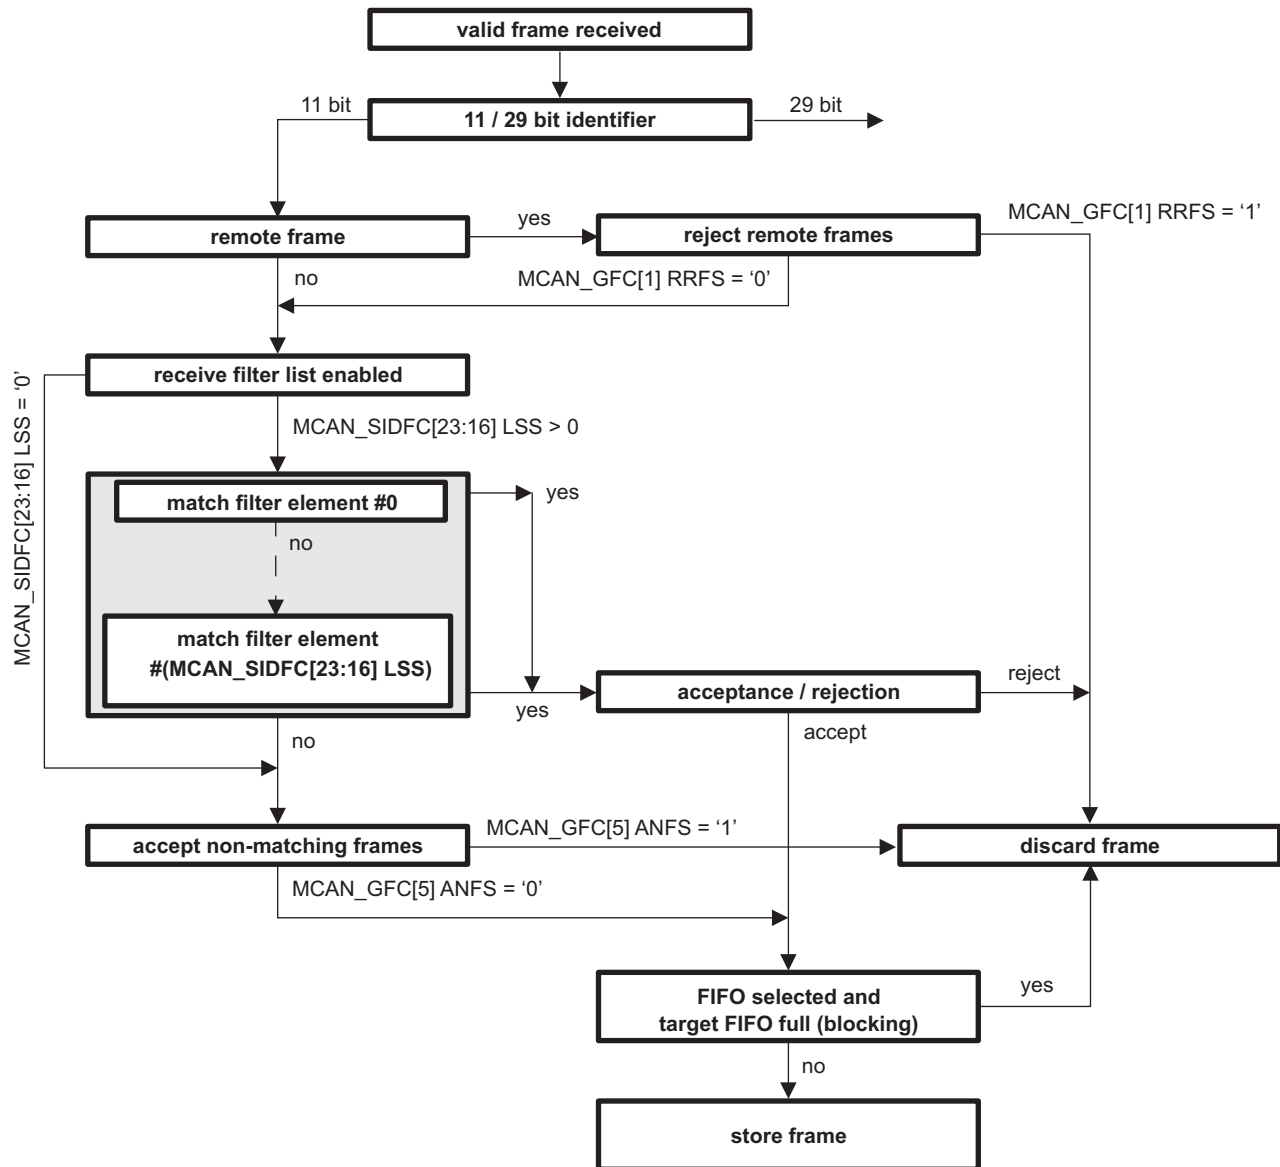

19.7.4.8.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in [Figure 19-144](#). [Section 19.7.4.11.5](#), *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration ([MCAN_GFC](#)) register
- Standard ID Filter Configuration ([MCAN_SIDFC](#)) register

Figure 19-144. Standard Message ID Filter Path

mcan-009

19.7.4.8.1.5 Extended Message ID Filtering

The extended Message ID (29-bit ID) filtering flow is shown in [Figure 19-145](#). [Section 19.7.4.11.6, Extended Message ID Filter Element](#) describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration ([MCAN_GFC](#)) register
- Extended ID Filter Configuration ([MCAN_XIDFC](#)) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask ([MCAN_XIDAM](#)).

Figure 19-145. Extended Message ID Filter Path

mcan-010

19.7.4.8.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the [MCAN_RXF0C](#) and [MCAN_RXF1C](#) registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in [Section 19.7.4.8.1, Acceptance Filtering](#). [Section 19.7.4.11.2, Rx Buffer and FIFO Element](#) describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the [MCAN_RXFnC\[30:24\] FnWM](#) field (where: n = 0 or 1) an interrupt flag [MCAN_IR\[1\] RF0W/MCAN_IR\[5\] RF1W](#) is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index ([MCAN_RXFnS\[21:16\] FnPI](#) = [MCAN_RXFnS\[13:8\] FnGI](#)) an Rx FIFO Full condition is signalled by the [MCAN_RXFnS\[24\] FnF](#) status bit and interrupt flag [MCAN_IR\[2\] RF0F/MCAN_IR\[6\] RF1F](#) is set. [Figure 19-146](#) shows Rx FIFO Status. The FIFOs fill level is presented in the [MCAN_RXFnS\[6:0\] FnFL](#) field (the number of elements stored in Rx FIFO).

Figure 19-146. Rx FIFO Status

mcan-011

Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 19-618 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 19-618. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC[10:8] RBDS MCAN_RXESC[2:0] F0DS/MCAN_RXESC[6:4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

19.7.4.8.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = 1 and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set.

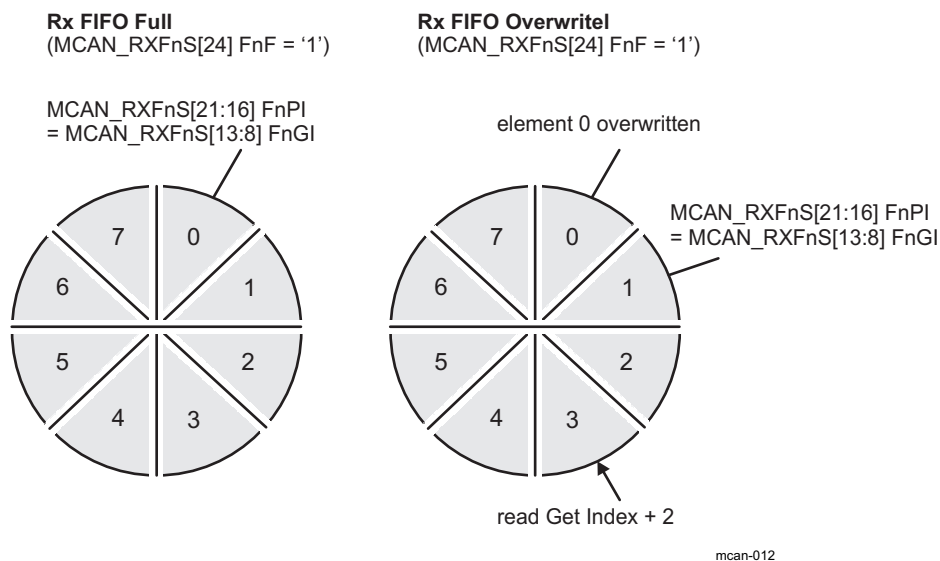

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = 1 and interrupt flag MCAN_IR[3] RFnL/MCAN_IR[25] RFnL is set.

19.7.4.8.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signalled by MCAN_RXFnS[24] FnF = 1, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 19-147 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 19-147. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = 0).

19.7.4.8.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15:2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see Section 19.7.4.11.5, Standard Message ID Filter Element and Section 19.7.4.11.6, Extended Message ID Filter Element).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

Table 19-619 shows Example Filter Configuration for Rx Buffers.

Table 19-619. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register [MCAN_NDAT1/MCAN_NDAT2](#) is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

19.7.4.8.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag [MCAN_IR\[19\]](#) DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

19.7.4.9 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 19.7.4.11.3](#) describes the Tx Buffer Element. [Table 19-620](#) shows the possible configurations for message transmission.

Table 19-620. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending [MCAN_TXBRP](#) register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

NOTE: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

19.7.4.9.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the [MCAN_CCCR\[14\]](#) TXP bit. By default this bit is disabled ([MCAN_CCCR\[14\]](#) TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

19.7.4.9.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the [MCAN_TXBAR\[x\]ARn](#) bit (where $x = 0 - 31$). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

[Table 19-621](#) shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 ([MCAN_TXFQS\[20:16\] TFQPI](#)) × Element Size to the Tx Buffer Start Address [MCAN_TXBC\[15:2\] TBSA](#) field.

Table 19-621. Tx Buffer/Tx FIFO/Tx Queue Element Size

MCAN_TXESC[2:0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

19.7.4.9.3 Tx FIFO

Tx FIFO mode is configured by setting bit [MCAN_TXBC\[30\] TFQM = 0](#). The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index [MCAN_TXFQS\[12:8\] TFGI](#) field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level [MCAN_TXFQS\[5:0\] TFFL](#) field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index [MCAN_TXFQS\[20:16\] TFQPI](#) field. After each Add Request ([MCAN_TXBAR\[x\] ARn = 1](#)) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index ([MCAN_TXFQS\[20:16\] TFQPI = MCAN_TXFQS\[12:8\] TFGI](#)), Tx FIFO Full condition is signalled by bit [MCAN_TXFQS\[21\] TFQF = 1](#). In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level [MCAN_TXFQS\[5:0\] TFFL](#) field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level [MCAN_TXFQS\[5:0\] TFFL](#) field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see [Table 19-621](#)). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index [MCAN_TXFQS\[20:16\] TFQPI](#) (from 0 to 31) × Element Size to the Tx Buffer Start Address [MCAN_TXBC\[15:2\] TBSA](#) field.

19.7.4.9.4 Tx Queue

Tx Queue mode is configured by setting bit [MCAN_TXBC\[30\]](#) TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index [MCAN_TXFQS\[20:16\]](#) TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition ([MCAN_TXFQS\[21\]](#) TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the [MCAN_TXBRP](#) register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see [Table 19-621](#)). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index [MCAN_TXFQS\[20:16\]](#) TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address [MCAN_TXBC\[15:2\]](#) TBSA field.

19.7.4.9.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the [MCAN_TXBC\[21:16\]](#) NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the [MCAN_TXBC\[29:24\]](#) TFQS field

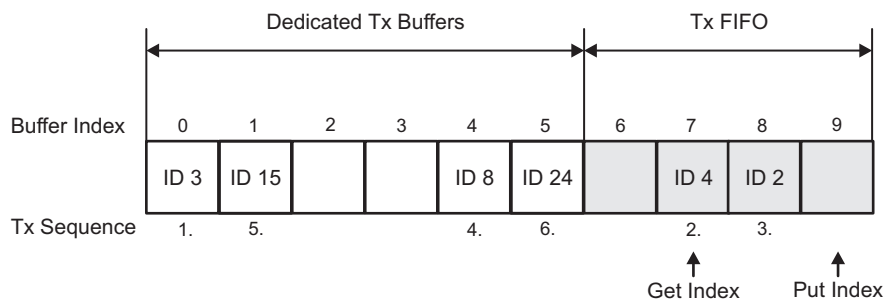

If the [MCAN_TXBC\[29:24\]](#) TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the [MCAN_TXFQS\[12:8\]](#) TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

[Figure 19-148](#) shows Mixed Dedicated Tx Buffers/Tx FIFO example.

Figure 19-148. Mixed Dedicated Tx Buffers /Tx FIFO (example)

mcan-013

19.7.4.9.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the [MCAN_TXBC\[21:16\]](#) NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the [MCAN_TXBC\[29:24\]](#) TFQS field

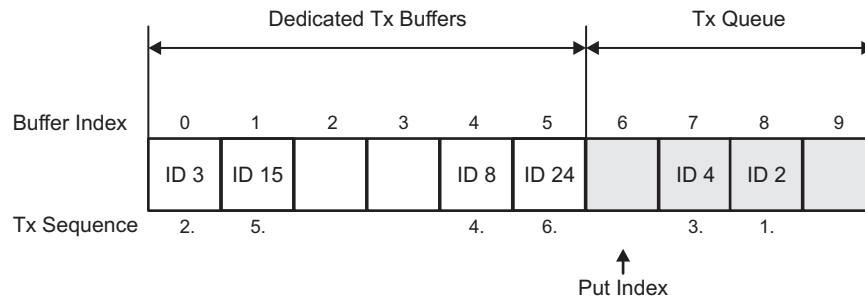

If [MCAN_TXBC\[29:24\]](#) TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 19-149 shows Mixed Dedicated Tx Buffers/Tx Queue example.

Figure 19-149. Mixed Dedicated Tx Buffers /Tx Queue (example)

mcan-014

19.7.4.9.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit [MCAN_TXBCR\[n\]](#) CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the [MCAN_TXBCF](#) register ([MCAN_TXBCF\[n\]](#) CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding [MCAN_TXBRP\[n\]](#) TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding [MCAN_TXBTO\[n\]](#) TOn and [MCAN_TXBCF\[n\]](#) CFn bits are set. If the transmission was not successful, only the corresponding bit [MCAN_TXBCF\[n\]](#) CFn = 1.

NOTE: If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

19.7.4.9.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. [Section 19.7.4.11.4](#) describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the [MCAN_IR\[14\]](#) TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented ([MCAN_TXEFS\[12:8\]](#) EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag [MCAN_IR\[15\]](#) TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the [MCAN_TXEFC\[29:24\]](#) EFWM field, interrupt flag [MCAN_IR\[13\]](#) TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index [MCAN_TXEFS\[12:8\]](#) EFGI field has to be added to the Tx Event FIFO start address [MCAN_TXEFC\[15:2\]](#) EFSA field.

19.7.4.10 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see [MCAN_RXF0A](#), [MCAN_RXF1A](#), and [MCAN_TXEFA](#)). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

NOTE: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

19.7.4.11 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

19.7.4.11.1 Message RAM Configuration

The MCAN module is configured to allocate 1600 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM is from 0x4848 0000 to 0x4848 18FC.

The Message RAM is capable to include each of the sections listed in [Figure 19-150](#). It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the [MCAN_RXESC\[2:0\]](#) F0DS field
- Rx FIFO 1 via the [MCAN_RXESC\[6:4\]](#) F1DS field
- Rx Buffers via the [MCAN_RXESC\[10:8\]](#) RBDS field
- Tx Buffers via the [MCAN_TXESC\[2:0\]](#) TBDS field

Figure 19-150. Message RAM Configuration

mcan-015

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

NOTE: The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

19.7.4.11.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the [MCAN_RXESC](#) register.

Figure 19-151 shows Rx Buffer/Rx FIFO element structure.

Figure 19-151. Rx Buffer/Rx FIFO Element Structure

mcan-016

Table 19-622 shows Rx Buffer/Rx FIFO element field descriptions.

Table 19-622. Rx Buffer/Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator <ul style="list-style-type: none"> 0x0: Transmitting node is error active 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. <ul style="list-style-type: none"> 0x0: 11-bit standard identifier 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. <ul style="list-style-type: none"> 0x0: Received frame is a data frame 0x1: Received frame is a remote frame Note: There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]).
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].
	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5:4] ANFS and MCAN_GFC[3:2] ANFE fields. <ul style="list-style-type: none"> 0x0: Received frame matching filter index FIDX field 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC[23:16] LSS - 1 respectively MCAN_XIDFC[22:16] LSE - 1.
R1	23:22	RES	Reserved

	19:16	DLC[3:0]	Data Length Code <ul style="list-style-type: none"> 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes 0x9-0xF (9-15): CAN: received frame has 8 data bytes 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
R2	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP.
	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 19-622. Rx Buffer/Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size ([MCAN_RXESC](#)), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

19.7.4.11.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the [MCAN_TXBC\[29:24\]](#) TFQS and [MCAN_TXBC\[21:16\]](#) NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the [MCAN_TXESC](#) register.

[Figure 19-152](#) shows Tx Buffer element structure.

Figure 19-152. Tx Buffer Element Structure

Word	Bits	Field Name	Description
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size ([MCAN_TXESC](#)), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

19.7.4.11.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the [MCAN_TXEFS](#) register.

[Figure 19-153](#) shows Tx Event FIFO element structure.

Figure 19-153. Tx Event FIFO Element Structure

	30	XTD	Extended Identifier <ul style="list-style-type: none"> 0x0: 11-bit standard identifier 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request <ul style="list-style-type: none"> 0x0: Data frame transmitted 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 19-624. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 19-623).
	23:22	ET[1:0]	Event Type <ul style="list-style-type: none"> • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format <ul style="list-style-type: none"> • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code <ul style="list-style-type: none"> • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP filed.

19.7.4.11.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address [MCAN_SIDFC\[15:2\]](#) FLSSA field plus the index of the filter element (0-127).

[Figure 19-154](#) shows Standard Message ID Filter element structure.

Figure 19-154. Standard Message ID Filter Element Structure

mcan-019

[Table 19-625](#) shows Standard Message ID Filter element field descriptions.

Table 19-625. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description	
S0	31:30	SFT[1:0]	Standard Filter Type <ul style="list-style-type: none"> 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) 0x1: Dual ID filter for SFID1 or SFID2 0x2: Classic filter: SFID1 = filter; SFID2 = mask 0x3: Filter element disabled Note: With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = 000)	
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. <ul style="list-style-type: none"> 0x0: Disable filter element 0x1: Store in Rx FIFO 0 if filter matches 0x2: Store in Rx FIFO 1 if filter matches 0x3: Reject ID if filter matches 0x4: Set priority if filter matches 0x5: Set priority and store in FIFO 0 if filter matches 0x6: Set priority and store in FIFO 1 if filter matches 0x7: Store into Rx Buffer, configuration of SFT[1:0] ignored 	
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.	
	15:11	RES	Reserved	
			SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: <ul style="list-style-type: none"> 1) SFEC = 001 - 110 Second ID of standard ID filter element 2) SFEC = 111 Filter for Rx Buffers
		10:0	SFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> 0x0: Store message into an Rx Buffer 0x1: Debug Message A 0x2: Debug Message B 0x3: Debug Message C Note: Debug feature is not supported.
			SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. Note: Only two filter event pins are supported.
			SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC [15:2] RBSA field for storage of a matching message.

19.7.4.11.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address [MCAN_XIDFC\[15:2\]](#) FLESA field plus two times the index of the filter element (0-63).

[Figure 19-155](#) shows Extended Message ID Filter element structure.

Figure 19-155. Extended Message ID Filter Element Structure

[Table 19-626](#) shows Extended Message ID Filter element field descriptions.

Table 19-626. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	<p>Extended Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	<p>Extended Filter ID 1</p> <p>First ID of extended ID filter element.</p> <p>When filtering for Rx Buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 19.7.4.8.1.5, Extended Message ID Filtering) is used.</p>

Table 19-626. Extended Message ID Filter Element Field Descriptions (continued)

	29	RES	Reserved
		EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: <ul style="list-style-type: none"> • 1) EFEC = 001 - 110 Second ID of extended ID filter element • 2) EFEC = 111 Filter for Rx Buffers
	28:0	EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C Note: Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. Note: Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC [15:2] RBSA field for storage of a matching message.

19.7.5 MCAN Register Manual

19.7.5.1 MCAN Instance Summary

Table 19-627. MCAN Instance Summary

Module Name	Base Address	Size
MCAN	0x4848 0000	8 KiB

19.7.5.2 MCAN Registers

NOTE: After hardware reset, the registers of the MCAN module hold the values shown in the register descriptions.

Additionally, the Bus_Off state is reset and the MCAN_TX pin is set to recessive (high). The [MCAN_CCCR\[0\] INIT](#) bit is set to enable the software initialization. The MCAN module will not influence the CAN bus until the software resets the [MCAN_CCCR\[0\] INIT](#) bit.

Table 19-657. MCAN_DBTP

Address Offset	0x0000 1A0C	Instance	MCAN
Physical Address	0x4848 1A0C		
Description	<p>Data Bit Timing & Prescaler Register Configuration of data phase bit timing, transmitter delay compensation enable.</p> <p>This register is only writable if the MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 MCAN_FCLK periods. $t_q = (\text{MCAN_DBTP}[20:16] \text{ DBRP} + 1) \text{ mtq}$ (minimum time quantum = CAN clock period (MCAN_FCLK)).</p> <p>The MCAN_DBTP[12:8] DTSEG1 field is the sum of Prop_Seg and Phase_Seg1. The MCAN_DBTP[7:4] DTSEG2 field is Phase_Seg2.</p> <p>Therefore the length of the bit time is (programmed values) [MCAN_DBTP[12:8] DTSEG1 + MCAN_DBTP[7:4] DTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q. The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.</p> <p>Note: With a CAN clock (MCAN_FCLK) of 8 MHz, the reset value of 0x0000 0A33 configures the MCAN module for a data phase bit rate of 500 kBit/s.</p> <p>Note: The bit rate configured for the CAN FD data phase via the MCAN_DBTP register must be higher or equal to the bit rate configured for the arbitration phase via the MCAN_NBTP register.</p>		
Type	RW

Address Offset	0x0000 1A1C	Instance	MCAN
Physical Address	0x4848 1A1C		
Description	<p>Nominal Bit Timing & Prescaler Register Configuration of arbitration phase bit timing. This register is only writable if the MCAN_CCCR[1] CCE and MCAN_CCCR[0] INIT bits are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 MCAN_FCLK periods. $t_q = (\text{MCAN_NBTP}[24:16] \text{ NBRP} + 1) \text{ mtq}$. The MCAN_NBTP[15:8] NTSEG1 field is the sum of Prop_Seg and Phase_Seg1. The MCAN_NBTP[6:0] NTSEG2 field is Phase_Seg2. Therefore the length of the bit time is (programmed values) [MCAN_NBTP[15:8] NTSEG1 + MCAN_NBTP[6:0] NTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q. The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.</p>		
Type	RW

NSJW								NBRP								NTSEG1								RESERVED	NTSEG2							

Bits	Field Name	Description	Type	Reset
31:25	NSJW	Nominal (Re)Synchronization Jump Width Valid values are 0 to 127 (0x00-0x7F). The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.	RW	0x3
24:16	NBRP	Nominal Baud Rate Prescaler The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 511 (0x000-0x1FF). The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.	RW	0x0
15:8	NTSEG1	Nominal Time segment before sample point Valid values are 1 to 255 (0x01-0xFF). The actual interpretation by the hardware of this value is such that one more than the programmed value is used.	RW	0xA
7	RESERVED	Reserved	R	0x0
6:0	NTSEG2	Nominal Time segment after sample point Valid values are 0 to 127 (0x00-0x7F). The actual interpretation by the hardware of this value is such that one more than the programmed value is used. Note: With a CAN clock (MCAN_FCLK) of 8 MHz, the reset value of 0x0600 0A03 configures the MCAN module for a bit rate of 500 kBit/s.	RW	0x3

Bits	Field Name	Description	Type	Reset
31:23	RESERVED	Reserved	R	0x0
22:16	TDCV	Transmitter Delay Compensation Value Position of the secondary sample point, defined by the sum of the measured delay from the MCAN_TX to MCAN_RX pins and the MCAN_TDCR [14:8] TDCO field. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq (0x00-0x7F).	R	0x0

Bits	Field Name	Description	Type	Reset
15	RESERVED	Reserved	R	0x0
14	PXE	Protocol Exception Event 0x0: No protocol exception event occurred since last read access 0x1: Protocol exception event occurred	R	0x0
13	RFDF	Received a CAN FD Message This bit is set independent of acceptance filtering. 0x0: Since this bit was reset by the Host CPU, no CAN FD message has been received 0x1: Message in CAN FD format with FDF flag set has been received	R	0x0
12	RBRS	BRS flag of last received CAN FD Message This bit is set together with the MCAN_PSR[13] RFDF bit, independent of acceptance filtering. 0x0: Last received CAN FD message did not have its BRS flag set 0x1: Last received CAN FD message had its BRS flag set	R	0x0
11	RESI	ESI flag of last received CAN FD Message This bit is set together with the MCAN_PSR[13] RFDF bit, independent of acceptance filtering. 0x0: Last received CAN FD message did not have its ESI flag set 0x1: Last received CAN FD message had its ESI flag set	R	0x0
10:8	DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for the MCAN_PSR[2:0] LEC field. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.	R	0x7
7	BO	Bus_Off Status 0x0: The MCAN module is not Bus_Off 0x1: The MCAN module is in Bus_Off state	R	0x0
6	EW	Warning Status 0x0: Both error counters are below the Error_Warning limit of 96 0x1: At least one of error counter has reached the Error_Warning limit of 96	R	0x0
5	EP	Error Passive 0x0: The MCAN module is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 0x1: The MCAN module is in the Error_Passive state	R	0x0
4:3	ACT	Activity Monitors the module's CAN communication state. 0x0: Synchronizing - node is synchronizing on CAN communication 0x1: Idle - node is neither receiver nor transmitter 0x2: Receiver - node is operating as receiver 0x3: Transmitter - node is operating as transmitter Note: ACT is set to 00 by a Protocol Exception Event.	R	0x0

Bits	Field Name	Description	Type	Reset
2:0	LEC	<p>Last Error Code</p> <p>The MCAN_PSR[2:0] LEC field indicates the type of the last error to occur on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error.</p> <p>0x0: No Error: No error occurred since the MCAN_PSR[2:0] LEC field has been reset by successful reception or transmission.</p> <p>0x1: Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.</p> <p>0x2: Form Error: A fixed format part of a received frame has the wrong format.</p> <p>0x3: AckError: The message transmitted by the MCAN module was not acknowledged by another node.</p> <p>0x4: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.</p> <p>0x5: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the Host CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>0x6: CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.</p> <p>0x7: NoChange: Any read access to the Protocol Status Register re-initializes the MCAN_PSR[2:0] LEC field to '0x7'. When the MCAN_PSR[2:0] LEC field shows the value '0x7', no CAN bus event was detected since the last Host CPU read access to the Protocol Status Register.</p> <p>Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in the MCAN_PSR[10:8] DLEC field instead of the MCAN_PSR[2:0] LEC field. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.</p> <p>Note: The Bus_Off recovery sequence (see ISO11898-1:2015) cannot be shortened by setting or resetting the MCAN_CCCR[0] INIT bit. If the device goes Bus_Off, it will set the MCAN_CCCR[0] INIT bit of its own accord, stopping all bus activities. Once the MCAN_CCCR[0] INIT bit has been cleared by the Host CPU, the device will then wait for 129 occurrences of Bus Idle (129 x 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of the MCAN_CCCR[0] INIT bit, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the MCAN_PSR[2:0] LEC field, enabling the Host CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. The MCAN_ECR[14:8] REC field is used to count these sequences.</p>	R	0x7

Table 19-699. MCAN_NDAT1

Address Offset	0x0000 1A98	Instance	MCAN
Physical Address	0x4848 1A98		
Description	New Data 1 NewDat flags of dedicated Rx buffers 0-31. The register holds the New Data flags of Rx Buffers 0 to 31. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host CPU clears them. Aflag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. Ahard reset will clear the register.

Table 19-701. MCAN_NDAT2

Address Offset	0x0000 1A9C	Instance	MCAN
Physical Address	0x4848 1A9C		
Description	New Data 2 NewDat flags of dedicated Rx buffers 32-63. The register holds the New Data flags of Rx Buffers 32 to 63. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host CPU clears them. Aflag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. Ahard reset will clear the register.

Table 19-725. MCAN_TXBRP

Address Offset	0x0000 1ACC	Instance	MCAN
Physical Address	0x4848 1ACC		
Description	<p>Tx Buffer Request Pending Tx buffers with pending transmission request.</p> <p>Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via the MCAN_TXBAR register. The bits are reset after a requested transmission has completed or has been cancelled via the MCAN_TXBCR register.</p> <p>The MCAN_TXBRP bits are set only for those Tx Buffers configured via the MCAN_TXBC register. After a MCAN_TXBRP bit has been set, a Tx scan (see Section 19.7.4.9, Tx Handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).</p> <p>A cancellation request resets the corresponding transmission request pending bit of register the MCAN_TXBRP register. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding MCAN_TXBRP bit has been reset.</p> <p>After a cancellation has been requested, a finished cancellation is signalled via the MCAN_TXBCF</p> <ul style="list-style-type: none"> • after successful transmission together with the corresponding MCAN_TXBTO bit • when the transmission has not yet been started at the point of cancellation • when the transmission has been aborted due to lost arbitration • when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding MCAN_TXBCF bit is set for all unsuccessful transmissions. <p>Note: The TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding MCAN_TXBRP bit is reset.</p>

Table 19-733. MCAN_TXBCF

Address Offset	0x0000 1ADC	Instance	MCAN
Physical Address	0x4848 1ADC		
Description	Tx Buffer Cancellation Finished Signals successful transmit cancellation, set when corresponding TXBRP flag is cleared after cancellation request. Each Tx Buffer has its own Cancellation Finished bit. The bits are set when the corresponding MCAN_TXBRP bit is cleared after a cancellation was requested via the MCAN_TXBCR register. In case the corresponding MCAN_TXBRP bit was not set at the point of cancellation, MCAN_TXBCF[n] CF bit is set immediately. The bits are reset when a new transmission is requested by writing a '1' to the corresponding bit of the MCAN_TXBAR register.

19.8 Gigabit Ethernet Switch (GMAC_SW)

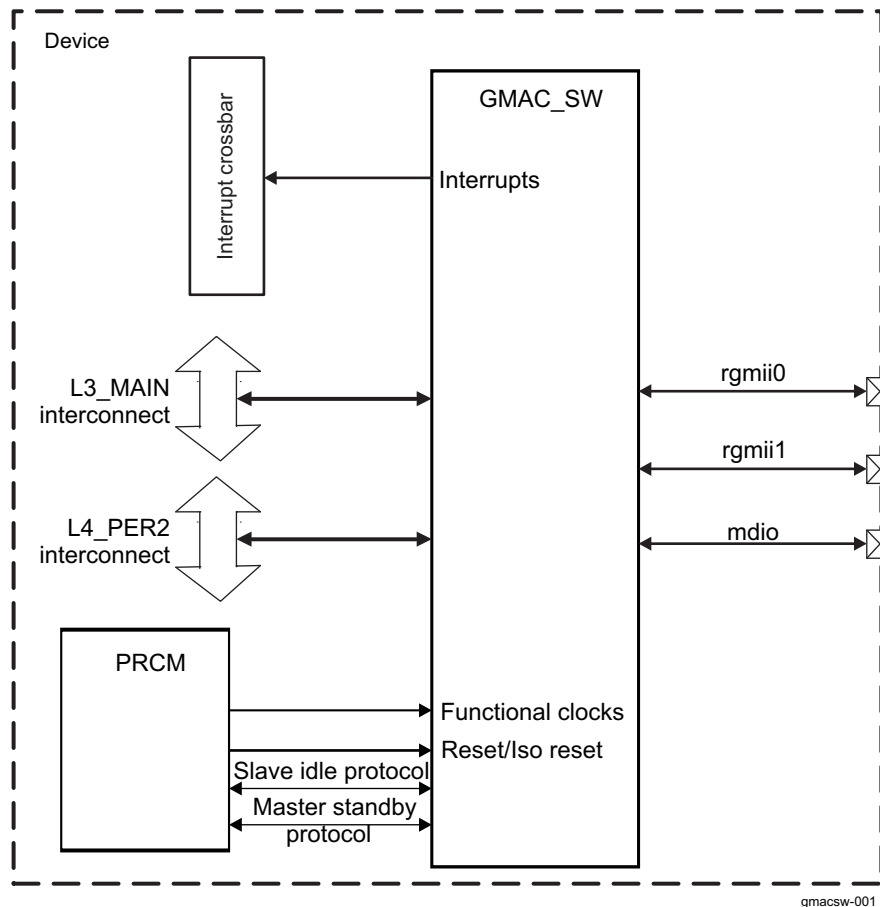

This chapter describes the three-port gigabit switch ethernet subsystem in the device.

19.8.1 GMAC_SW Overview

The three-port gigabit ethernet switch subsystem (GMAC_SW) provides ethernet packet communication and can be configured as an ethernet switch. It provides the reduced gigabit media independent interface (RGMII), and the management data input output (MDIO) for physical layer device (PHY) management.

Figure 19-156 shows the GMAC_SW subsystem overview.

Figure 19-156. GMAC_SW Overview

NOTE: The number of supported GMAC_SW Ethernet ports is device part number dependent. Refer to device Data Manual for more information.

19.8.1.1 Features

The GMAC_SW subsystem provides the following features:

- Two Ethernet ports (port 1 and port 2) with RGMII interfaces plus internal Communications Port Programming Interface (CPPI 3.1) on port 0
- Synchronous 10/100/1000 Mbit operation
- Wire rate switching (802.1d)
- Non-blocking switch fabric
- Flexible logical FIFO-based packet buffer structure

- Four priority level Quality Of Service (QOS) support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D and Annex F)
 - Timing FIFO and time stamping logic embedded in the subsystem
- Device Level Ring (DLR) Support
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Address Lookup Engine (ALE)
 - 1024 total address entries plus VLANs
 - Wire rate lookup
 - Host controlled time-based aging
 - Multiple spanning tree support (spanning tree per VLAN)
 - L2 address lock and L2 filtering support
 - MAC authentication (802.1x)
 - Receive-based or destination-based multicast and broadcast rate limits
 - MAC address blocking
 - Source port locking
 - OUI (Vendor ID) host accept/deny feature
 - Remapping of priority level of VLAN or ports
- VLAN support
 - 802.1Q compliant
 - Auto add port VLAN for untagged frames on ingress
 - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
 - EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (shared)
 - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- Flow Control Support (802.3x)
- Digital loopback and FIFO loopback modes supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 x 32) internal CPPI buffer descriptor memory
- Management Data Input/Output (MDIO) module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Programmable Transmit Inter Packet Gap (IPG)
- Reset isolation (switch function remains active even in case of all device resets except for POR pin reset and ICEPICK cold reset)
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps.
- IEEE 802.3 gigabit Ethernet conformant

19.8.2 GMAC_SW Environment

19.8.2.1 RGMII Interface

NOTE: The number of supported GMAC_SW Ethernet ports is device part number dependent. Refer to device Data Manual for more information.

Figure 19-157 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 19-779.

Figure 19-157. RGMII Interface Typical Application

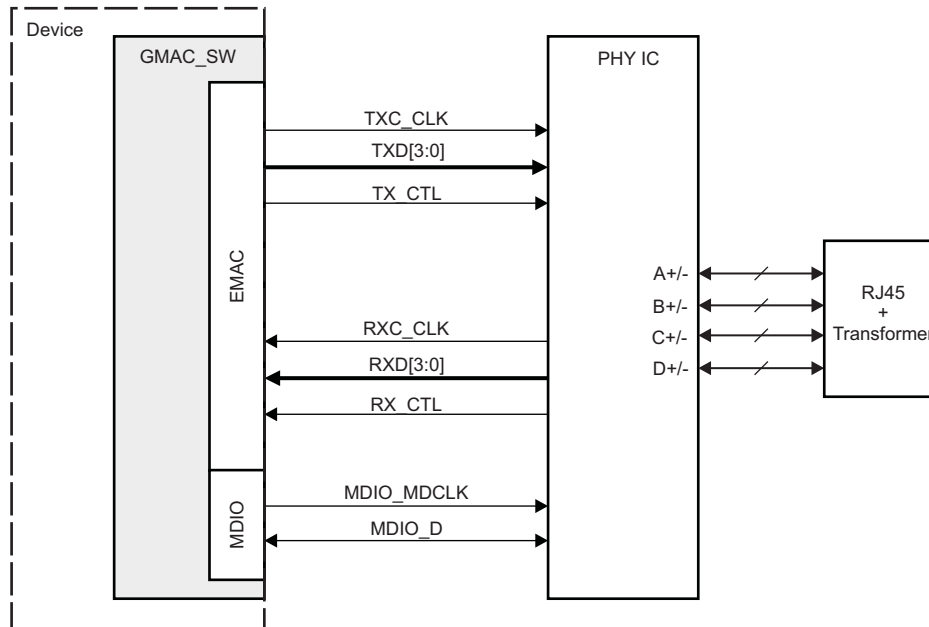

Table 19-779. RGMII I/O Description

Signal	Device Pin(s)	I/O ⁽¹⁾	Description
TXD[3:0]	rgmii0_txd[3:0] rgmii1_txd[3:0]	O	The transmit data pins are a collection of 4 bits of data. TXD0 is the least-significant bit (LSB). The signals are valid only when TX_CTL is asserted.
TX_CTL	rgmii0_rxctl rgmii1_rxctl	O	Transmit Control/enable. The transmit enable signal indicates that the TXD pins are generating data for use by the PHY.
TXC_CLK	rgmii0_txc rgmii1_txc	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RXD[3:0]	rgmii0_rxd[3:0] rgmii1_rxd[3:0]	I	The receive data pins are a collection of 4 bits of data. RXD0 is the least-significant bit (LSB). The signals are valid only when RX_CTL is asserted
RX_CTL	rgmii0_rxctl rgmii1_rxctl	I	The receive data valid/control signal indicates that the RXD pins are nibble data for use by the GMAC_SW.
RXC_CLK	rgmii0_rxc rgmii1_rxc	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.

⁽¹⁾ I = Input; O = Output

Table 19-779. RGMII I/O Description (continued)

Signal	Device Pin(s)	I/O ⁽¹⁾	Description
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 14.4.6.1, Pad Configuration Registers](#) in [Chapter 14, Control Module](#).

19.8.3 GMAC_SW Integration

[Figure 19-158](#) shows the integration of the GMAC_SW module in the device.

Figure 19-158. GMAC_SW Integration

gmacsw-005

Table 19-780 through Table 19-782 summarize the integration of the GMAC_SW module in the device.

Table 19-780. GMAC_SW Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GMAC_SW	PD_COREAON	Yes	L3_MAIN L4_PER2

Table 19-781. GMAC_SW Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GMAC_SW	MAIN_CLK	GMAC_MAIN_CLK	PRCM	Interface clock for the GMAC_SW module (125 MHz)
	MHZ_5_CLK	RGMII_5MHZ_CLK	PRCM	5-MHz RGMII clock
	MHZ_50_CLK	RMII_50MHZ_CLK	PRCM	50-MHz RGMII clock
	MHZ_250_CLK	GMII_250MHZ_CLK	PRCM	250-MHz RGMII clock
	CPTS_RFT_CLK	GMAC_RFT_CLK	PRCM	IEEE 1588 clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GMAC_SW	GMAC_SW_RST	L3INIT_RST/PRM_PWR_ON_RST	PRCM	GMAC_SW main reset
	GMAC_SW_ISO_RST	tied off/L3INIT_RST	PRCM	GMAC_SW isolate reset (must be enabled in Control module)

Table 19-782. GMAC_SW Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
GMAC_SW	RX_THRESH_PULSE	IRQ_CROSSBAR_334	-	Receive threshold interrupt
	RX_PULSE	IRQ_CROSSBAR_335	-	Receive packet completion interrupt
	TX_PULSE	IRQ_CROSSBAR_336	-	Transmit packet completion interrupt
	MISC_PULSE	IRQ_CROSSBAR_337	-	Miscellaneous interrupt (SPF2_PEND, SPF1_PEND, EVNT_PEND, STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT)

NOTE: GMAC_SW has no default IRQ mappings through the IRQ_CROSSBAR. For GMAC_SW, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).
For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For the description of the interrupt source, see [Section 19.8.4.5, Interrupt Functionality](#).

19.8.4 GMAC_SW Functional Description

The 3-port switch (GMAC_SW) Ethernet subsystem modules are compliant to the IEEE Std 802.3 Specification. GMAC_SW is shown in [Figure 19-159](#).

NOTE: The number of supported GMAC_SW Ethernet ports is device part number dependent. Refer to device Data Manual for more information.

19.8.4.1 Functional Block Diagram

The GMAC_SW subsystem consists of:

- CPSW_3G which contains two G/MII interfaces (not pinned out in this device, used to connect to CPRGMII0/1)
- Two RGMII interface modules
- Two RMII interface modules (RMII0/1 are not pinned out in this device)
- One MDIO interface module
- One Interrupt Controller module
- One CPPI interface
- Local CPPI memory of size 8 KiB
- Two Static Packet Filters

Figure 19-159. GMAC_SW Top Level Block Diagram

gmacsw-011

19.8.4.2 GMAC_SW Ports

Ethernet Subsystem has three Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to RGMII.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the RGMII0
- Port2 is referred to the RGMII1

The MII mode selection register bitfields (GMII1_SEL and GMII2_SEL) in the control module must be set to 0x2 (RGMII). See [Section 14.5](#), *Control Module Register Manual* for details.

19.8.4.3 Clocking

19.8.4.3.1 Subsystem Clocking

GMAC_SW clocking summary is shown in [Section 19.8.3](#), *GMAC_SW Integration*.

19.8.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

19.8.4.3.2.1 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

19.8.4.3.2.2 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (MAIN_CLK) clock, running at 125 MHz. The application software or driver must control the divide-down value.

See the [MDIO_CONTROL](#) register for configuring the Clock Divider (CLKDIV) value.

19.8.4.4 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The [CPSW_SOFT_IDLE\[0\]](#) SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW_SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

19.8.4.5 Interrupt Functionality

GMAC_SW Ethernet Subsystem has four Interrupt outputs:

- RX_PULSE - Receive Interrupt
- TX_PULSE - Transmit Interrupt
- RX_THRESH_PULSE - Receive Threshold Interrupt
- MISC_PULSE - Miscellaneous Interrupt.

19.8.4.5.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW RX_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the [CPDMA_RX_INTMASK_SET](#) register.
2. The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register ([WR_CO_RX_EN](#)). The masked interrupt status can be read in the address location of RX_STAT bit in the [WR_CO_RX_STAT](#) register.

When the GMAC_SW completes a packet reception, the subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the software processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX n_{CP}) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the [WR_CO_RX_STAT\[7:0\]](#) RX_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (RX n_{CP}). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the GMAC_SW has received more packets than the software has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the GMAC_SW is expecting is found by reading the receive channel n completion pointer register (RX n_{CP}).
4. Write the value 1h to the [CPDMA_EOI_VECTOR](#) register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the [CPDMA_RX_INTMASK_CLEAR](#) register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the [WR_CO_RX_EN](#) register.

The software could still poll for the [CPDMA_RX_INTSTAT_RAW](#) and [CPDMA_RX_INTSTAT_MASKED](#) registers if the corresponding interrupts are enabled.

19.8.4.5.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW TX_PEND[7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the [CPDMA_TX_INTMASK_SET](#) register.
2. The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register [WR_CO_TX_EN](#). The masked interrupt status can be read in the address location of TX_STAT bit in the [WR_CO_TX_STAT](#) register.

When the GMAC_SW completes the transmission of a packet, the GMAC_SW subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (TX n_{CP}). The data written by the host (buffer descriptor

address of the last processed buffer) is compared to the data in the register written by the GMAC_SW (address of last buffer descriptor used by the GMAC_SW). If the two values are not equal (which means that the GMAC_SW has transmitted more packets than the software has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the GMAC_SW is expecting is found by reading the transmit channel *n* completion pointer register (TX *n*_CP).

4. Write the 2h to the [CPDMA_EOI_VECTOR](#) register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the [CPDMA_TX_INTMASK_CLEAR](#) register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the [WR_C0_TX_EN](#) register.

The software could still poll for the [CPDMA_TX_INTSTAT_RAW](#) and [CPDMA_TX_INTSTAT_MASKED](#) registers, if the corresponding interrupts are enabled.

19.8.4.5.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the [CPDMA_RX_INTMASK_SET](#) register.
2. The receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register [WR_C0_RX_THRESH_EN](#). The masked interrupt status can be read in the address location of RX_THRESH_STAT bit in the [WR_C0_RX_THRESH_STAT](#) register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX *n*_FREEBUFFER is less than or equal to the corresponding RX *n*_PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.
3. Write the CPSW_3G completion pointer(s).
4. Write the value 0h to the [CPDMA_EOI_VECTOR](#) register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the [CPDMA_RX_INTMASK_CLEAR](#) register.
2. The receive threshold pulse interrupt could be disabled by clearing to 0 the corresponding bits in the [WR_C0_RX_THRESH_EN](#) register.

The software could still poll for the [CPDMA_RX_INTSTAT_RAW](#) and [CPDMA_RX_INTSTAT_MASKED](#) registers, if the corresponding interrupts are enabled.

19.8.4.5.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (SPF2_PEND, SPF1_PEND, EVNT_PEND, STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT).

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register ([WR_C0_MISC_EN](#)).

Upon reception of an interrupt, software should perform the following:

- Read the MISC_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the [CPDMA_EOI_VECTOR](#) register.

NOTE: The [WR_C0_MISC_STAT](#) register's [MDIO_LINKINT](#) and [MDIO_USERINT](#) bitfields represent the Port0/Phy0 status. [MDIO_LINKINT\[1\]](#) and [MDIO_USERINT\[1\]](#) are not provided in [WR_C0_MISC_STAT](#) register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the [MDIO_LINKINTMASKED](#) or [MDIO_USERINTMASKED](#) registers.

19.8.4.5.4.1 *EVNT_PEND(CPTS_PEND) Interrupt*

See [Section 19.8.4.10](#), *Common Platform Time Sync (CPTS)* for more details on this interrupt.

19.8.4.5.4.2 *Statistics Interrupt*

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the [CPDMA_TX_INTSTAT_RAW](#) and [CPDMA_TX_INTSTAT_MASKED](#) registers, respectively.

The Statistics interrupt is enabled by setting to 1 the [STAT_INT_MASK](#) bit in the [CPDMA_DMA_INTMASK_SET](#) register

19.8.4.5.4.3 *Host Error interrupt*

The host error interrupt (HOST_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked host interrupt status can be read by reading the [CPDMA_DMA_INTSTAT_RAW](#) and [CPDMA_DMA_INTSTAT_MASKED](#) registers, respectively.

The transmit host error conditions are:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0
- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The [HOST_PEND](#) is enabled by setting to 1 the [HOST_ERR_INTMASK](#) in the [CPDMA_DMA_INTMASK_SET](#) register. The host error interrupt is disabled by setting to 1 the appropriate bit in the [CPDMA_DMA_INTMASK_CLEAR](#) register.

19.8.4.5.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the **PHYADR_MON** field of the **MDIO_USERPHYSEL_n** register and the corresponding **LINKINT_ENABLE** bit is set. The **MDIO_LINKINT** event is also captured in the **MDIO_LINKINTMASKED** register. When the **GO** bit in the **MDIO_USERACCESS_n** register transitions from 1 to 0, indicating the completion of a user access, and the corresponding **USERINTMASKSET** bit in the **MDIO_USERINTMASKSET** register is set, the **MDIO_USERINT** signal is asserted. The **MDIO_USERINT** event is also captured in the **MDIO_USERINTMASKED** register.

19.8.4.5.5 Interrupt Pacing

RX_PULSE and **TX_PULSE** interrupts can be paced. The **RX_THRESH_PULSE** and **MISC_PULSE** interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the processor cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the processor instruction cache.

Each **RX_PULSE** and **TX_PULSE** interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 μs pulse that is created from a prescale counter whose value is set in the **INT_PRESCALE** field in the **WR_INT_CONTROL** register. The **INT_PRESCALE** value should be written with the number of **ICLK** periods in 4 μs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 μs. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
    pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The **WR_CO_RX_IMAX/WR_CO_TX_IMAX** register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

19.8.4.6 Reset Isolation

Reset isolation for the **GMAC_SW** allows the switch function to remain active in during all device resets except for **POR** pin reset and **ICEPICK COLD** reset. Packet traffic to/from the **GMAC_SW** host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related I/O and reference clocks needed by the **GMAC_SW** to be active is controlled by a protected control module bit.

19.8.4.6.1 Reset Isolation Functional Description

The device has two modes of operation concerning the reset of the GMAC_SW Ethernet switch. The mode is controlled by the GMAC_RESET_ISOLATION_ENABLE bit in the Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the GMAC_RESET_ISOLATION_ENABLE bit and to the lock register must all be supervisor mode writes.

GMAC_RESET_ISOLATION_ENABLE = 0 (disabled)

1. This is the default state of the bit after control module reset.
2. Upon any device level resets, the entire GMAC_SW, DPLL_GMAC_DSP, L3/L4 interconnect, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are immediately reset.

GMAC_RESET_ISOLATION_ENABLE = 1 (enabled)

1. This mode is selected when the GMAC_RESET_ISOLATION_ENABLE bit is set to 1 by software.
2. Upon any device reset source other than porz pin or ICEPICK cold (that is, this includes software global cold, any watchdog reset, warm resetn pin, ICEPICK warm, software global warm or security violation), the following is true:
 1. The CPSW_3GSS_R is put into "isolate" mode and non-switch related portions of the subsystem are reset.
 2. The 50 MHz and 125 MHz reference clocks to the GMAC_SW Ethernet Subsystem remain active throughout the entire reset condition.
 3. The control for pin multiplexing for all of the signals maintain their current configuration throughout the entire reset condition.
 4. The reset-isolated logic inside GMAC_SW Ethernet Subsystem maintains the switch functionality
3. Upon any cold reset sources, the entire GMAC_SW Ethernet Subsystem, DPLL_GMAC_DSP, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are reset.

For more details on the register configuration, see the Control Module CTRL_CORE_CONTROL_IO_2 register in [Section 14.5, Control Module Register Manual](#).

19.8.4.7 Software Reset

The CPSW_3G software reset register ([CPSW_SOFT_RESET](#)), CPSW_3GSS software reset register ([WR_SOFT_RESET](#)) and the three submodule software reset registers enable the CPSW_3GSS to be reset by software.

There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2 ([SL_SOFT_RESET](#)), and CPDMA ([CPDMA_SOFT_RESET](#))). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

19.8.4.8 CPSW_3G

The CPSW_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW_3G is shown in Figure 19-160.

Figure 19-160. CPSW_3G Block Diagram

19.8.4.8.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI compliant packet DMA transfer controller. The CPPI interface is port 0.

19.8.4.8.1.1 Functional Operation

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI protocol. For a detailed description of buffer descriptors, see Section 19.8.4.11, *CPPI Buffer Descriptors*.

19.8.4.8.1.2 Receive DMA Interface

The receive DMA is an eight channel CPPI compliant interface. Each channel has a single queue for frame reception.

19.8.4.8.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX_HDP registers to 0.
3. Enable the desired receive interrupts in the [CPDMA_RX_INTMASK_SET](#) register.
4. Write the [CPDMA_RX_BUFFER_OFFSET](#) register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI
6. Enable the RX DMA controller by setting the RX_EN bit in the [CPDMA_RX_CONTROL](#) register.

19.8.4.8.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the [CPDMA_RX_TEARDOWN](#) register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The `teardown_complete` bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

19.8.4.8.1.3 Transmit DMA Interface

The transmit DMA is an eight channel CPPI compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the `TX_PTYPE` bit in the [CPDMA_DMACONTROL](#) register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

19.8.4.8.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the `TX_HDP` registers to 0.
2. Enable the desired transmit interrupts in the [CPDMA_TX_INTMASK_SET](#) register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI.
4. Configure and enable the transmit operation as desired in the [CPDMA_TX_CONTROL](#) register.
5. Write the appropriate `TX_HDP` registers with the appropriate values to start transmit operations.

19.8.4.8.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the [CPDMA_TX_TEARDOWN](#) register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

19.8.4.8.1.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX_RLIM bit associated with that channel is set in the CPDMA_DMACONTROL register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX_PRI(0..7)_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)_SEND_CNT) and an idle count (PRI(0..7)_IDLE_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

$$\text{Priority Transfer rate in Mbit/s} = ((\text{PRI_IDLE_CNT}/(\text{PRI_IDLE_CNT} + \text{PRI_SEND_CNT})) \times \text{frequency} \times 32$$

Where *frequency* is the CPDMA interface clock (MAIN_CLK) frequency.

19.8.4.8.1.5 Command IDLE

The CMD_IDLE bit in the CPDMA_DMACONTROL register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

19.8.4.8.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should be forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the SL_MACCONTROL configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the P0_CPDMA_RX_CH_MAP register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

19.8.4.8.2.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 19-783. Learned Address Control Bits

Bit(s)	Value
unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

19.8.4.8.2.1.1 Free Table Entry

Table 19-784. Free (Unused) Address Table Entry Bit Values

71:62	61:60	59:0
Reserved	ENTRY_TYPE(00)	Reserved

19.8.4.8.2.1.2 Multicast Address Table Entry

Table 19-785. Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_S TATE	ENTRY_TYPE(01)	Reserved	MULTICAST_A DDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

19.8.4.8.2.1.3 VLAN/Multicast Address Table Entry

Table 19-786. VLAN/Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_S TATE	ENTRY_TYPE(11)	VLAN_ID	MULTICAST_A DDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

19.8.4.8.2.1.4 Unicast Address Table Entry

Table 19-787. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(01)	Reserved	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

19.8.4.8.2.1.5 OUI Unicast Address Table Entry
Table 19-788. OUI Unicast Address Table Entry Bit Values

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE(10)	ENTRY_TYPE(01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

19.8.4.8.2.1.6 VLAN/Unicast Address Table Entry
Table 19-789. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

19.8.4.8.2.1.7 VLAN Table Entry

Table 19-790. VLAN Table Entry

71:62	61:60	59:48	47:27	26:24	23:19	18:16	15:11	10:8	7:3	2:0
Reserved	ENTRY_TY PE(10)	VLAN_ID	Reserved	FORCE_UN TAGGED_E GRESS	Reserved	REG_MCAST_FLOOD_MASK	Reserved	UNREG_MCAST_FLOOD_MASK	Reserved	VLAN_MEMBER_LIST

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is found.

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is not found.

VLAN Member List (VLAN_MEMBER_LIST)

This 3-bit field indicates which port(s) are members of the associated VLAN.

19.8.4.8.2.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The `mcast_fwd_state` indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the `CPGMAC_SL` to the ALE. Packets with errors may be passed to the host (not aborted) by a `CPGMAC_SL` port, if the port has the `RX_CMF_EN`, `RX_CEF_EN`, or `RX_CSF_EN` bit(s) set. Error packets that are passed to the host by the `CPGMAC_SL` are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the [SL_MACCONTROL](#) register:

- [22] `RX_CEF_EN` - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] `RX_CSF_EN` - enables short frames to be forwarded
- [24] `RX_CMF_EN` - enables MAC control frames to be forwarded.

19.8.4.8.2.3 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

19.8.4.8.2.4 VLAN Aware Mode

The `CPSW_3G` is in VLAN aware mode when the `VLAN_AWARE` bit is set in the [CPSW_CONTROL](#) register. In VLAN aware mode, ports 0 receive packets (out of the `CPSW_3G`) may or may not be VLAN encapsulated depending on the `RX_VLAN_ENCAP` bit in the [CPSW_CONTROL](#) register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set `rx_vlan_encap` bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (`pkt_type`), packet priority (`pkt_pri`), and VLAN information.

19.8.4.8.2.5 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the VLAN_AWARE bit is cleared to 0 in the [CPSW_CONTROL](#) register. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the [CPSW_CONTROL](#) register. Port 0 transmit packets are never VLAN encapsulated.

19.8.4.8.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

19.8.4.8.4 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKs field in the FIFOs associated Px_MAX_BLKs register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX_MAX_BLKs field in the FIFO's associated Px_MAX_BLKs register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKs value plus the RX_MAX_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

19.8.4.8.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

19.8.4.8.5.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX_IN_SEL = 00 for all ports (default value in P0/1/2_TX_IN_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to [Section 19.8.4.8.3, Packet Priority Handling](#).

19.8.4.8.5.2 Dual MAC Mode

When operating in dual MAC mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual MAC mode is configured as described below:

- Set the ALE_VLAN_AWARE bit in the [ALE_CONTROL](#) register. This bit configures the ALE to process in VLAN aware mode. The CPSW_3G VLAN aware bit (VLAN_AWARE in [CPSW_CONTROL](#)) determines how packets VLAN's are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
 - Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
 - Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
 - Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
 - Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX_IN_SEL = 01 in [P0_TX_IN_CTL](#). The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

19.8.4.8.5.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX_IN_SEL = 10 in P1/2_TX_IN_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX_RATE_EN field in P1/2_TX_IN_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1_PRIN_SHAPE_EN and P2_PRIN_SHAPE_EN in the [CPSW_PTYPE](#) register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX_RATE_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on

a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).

4. [P0_TX_IN_CTL\[17:16\]](#) TX_IN_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX_RLIM field in the [CPDMA_DMACONTROL](#) register. If there are two rate-limited channels, then TX_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX_PTYPE bit in the [CPDMA_DMACONTROL](#) register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

19.8.4.8.6 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*." a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

Figure 19-161. The Network Stack with AVB

gmacsw-016

The following sections describe the media transport protocols that work within the AVB framework.

19.8.4.8.6.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

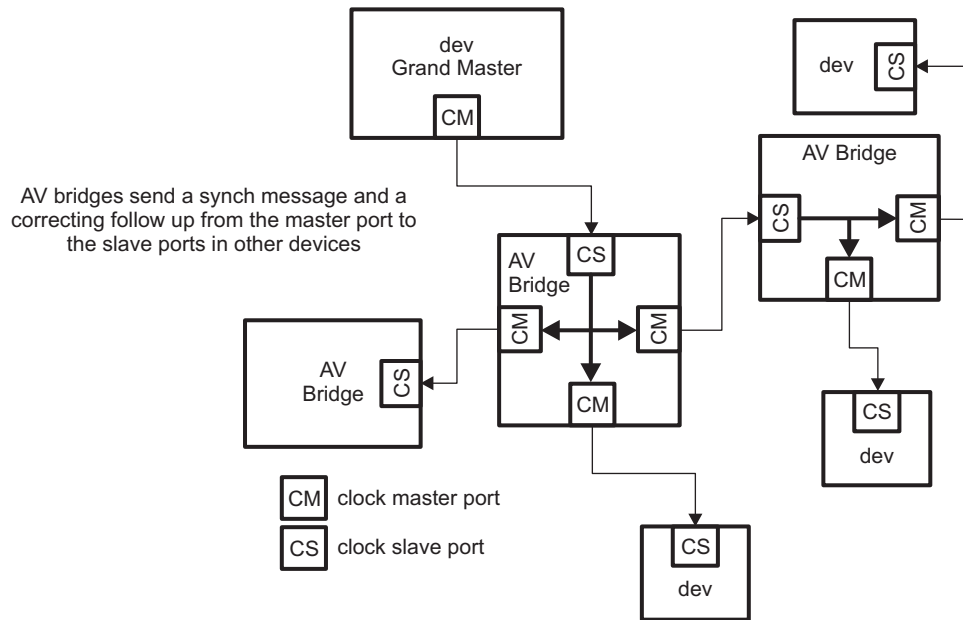

NOTE: The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002, PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2--in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1- μ s accuracy over seven network hops.

Figure 19-162. AVB Network & PTP Clock Entities

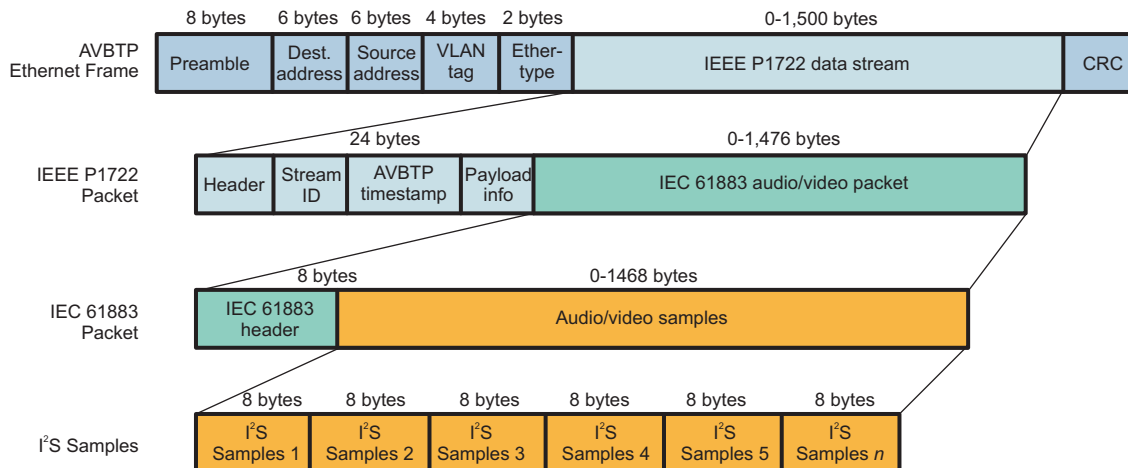

The media transport protocols that work within the AVB framework are:

19.8.4.8.6.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 19-163 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

Figure 19-163. IEEE 1722 Packets

IEEE 1722 Packet Construction

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

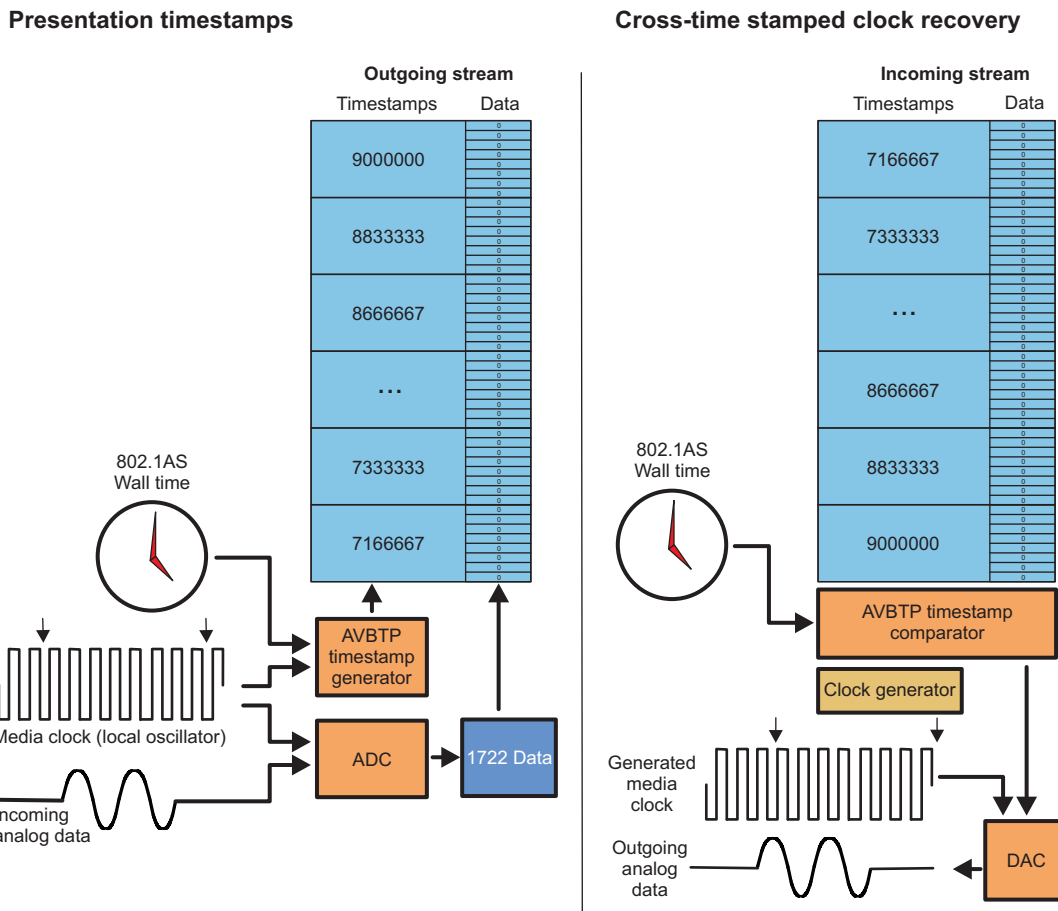

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 19-164 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

19.8.4.8.6.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

Figure 19-164. Cross Time Stamping and Presentation Timestamps

19.8.4.8.6.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-

"Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
 - Receive policing and
 - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 19-165](#).

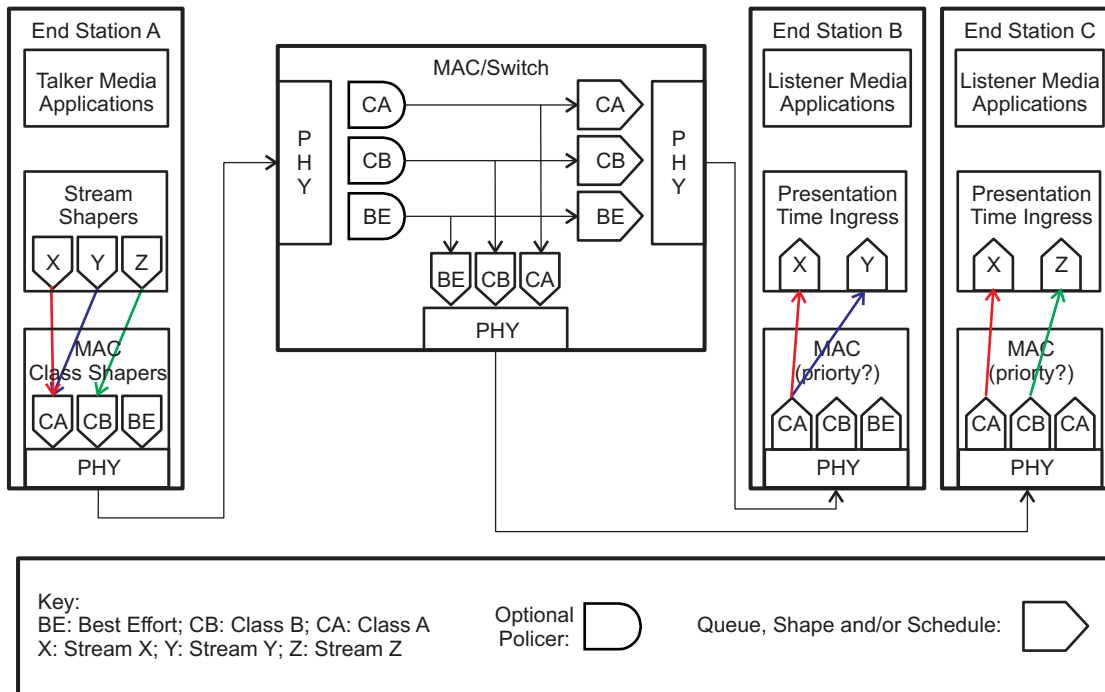

Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

Figure 19-165. AV Stream Queuing/Policing

19.8.4.8.6.2.1 Configuring the Device for 802.1Qav Operation:

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
 - CPPI TX and RX descriptors
 - VLAN and Priority tags

Table 19-791. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 19-792. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
 - ALE in VLAN-ware mode, Non-ALE in bypass mode.

Table 19-793. Example of Rate-limit Configurations

Register	Value	Description
CPSW_PTYPE	0x0006 0000	For Port1 -- 2 highest priority channels.
P1_TX_IN_CTL[23:20] TX_RATE_EN	0b1100	2 highest priority channels are rate limited
P1_TX_IN_CTL[17:16] TX_IN_SEL	0b10	Rate limit mode
P1_SEND_PERCENT	0x14 3E00	20% PRI7, 62% PRI5
CPDMA_DMACONTROL	0xC001	Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel.
CPDMA_TX_PRI7_RATE	0x1 0013	200 Mbps
CPDMA_TX_PRI6_RATE	0x1 0005	~600 Mbps

19.8.4.8.7 Ethernet MAC Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- G/MII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

19.8.4.8.7.1 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

19.8.4.8.7.1.1 RGMII Features

- Supports 1000/100/10 Mbps speed
- In SR1.0, Internal TXC delay on transmit is always enabled
- In SR2.x, Internal TXC delay on transmit can be enabled or disabled using bits [26] RGMII2_ID_MODE_N and [25] RGMII1_ID_MODE_N of the [CTRL_CORE_SMA_SW_1](#) register.
- MII mode is not supported

19.8.4.8.7.1.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

19.8.4.8.7.1.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the EXT_EN bit of the [SL_MACCONTROL](#) register is set to 1. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 19-794](#).

Table 19-794. In-Band Data

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0: half-duplex	00: 10-Mbps mode	2.5 MHz	0: Link is down
1: full-duplex	01: 100-Mbps mode	25 MHz	1: Link is up
	10: 1000-Mbps mode	125 MHz	
	11: reserved	reserved	

19.8.4.8.7.1.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the EXT_EN bit of the [SL_MACCONTROL](#) register is set to 0. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the [SL_MACCONTROL](#)[0] FULLDUPLEX and [7] GIG bits. If GIG = 1, then operation is gigabit mode. If the GIG is 0, the operation is 100 Mbps mode.

19.8.4.8.7.1.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

The TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

19.8.4.8.7.2 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the [SL_RX_MAXLEN](#) register. The [SL_RX_MAXLEN](#) register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.

- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

19.8.4.8.8 Embedded Memories

Table 19-795. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 2560 x 64 RAM	3	(Packet FIFO's)
Single-port 64-word x 1152-bit RAM	1	(ALE)
Single-port 2048-word x 32-bit RAM	1	(CPPI)

19.8.4.8.9 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

19.8.4.8.9.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0_FLOW_EN bit in the [CPSW_FLOW_CONTROL](#) register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

19.8.4.8.9.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in the associated CPGMAC_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

19.8.4.8.9.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the [SL_MACCONTROL](#) register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the FULLDUPLEX bit in the [SL_MACCONTROL](#) register.

19.8.4.8.9.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in [SL_MACCONTROL](#)). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

19.8.4.8.9.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in [SL_MACCONTROL](#)). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47:0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

19.8.4.8.9.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the SL_MACCONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the SL_MACCONTROL register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX_FLOW_EN is set in SL_MACCONTROL register, and
- the frame's length is 64 to SL_RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in SL_MACCONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
 - The reserved multicast destination address 01.80.C2.00.00.01
 - , or the CPGMAC_SL SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

19.8.4.8.10 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the [SL_MACCONTROL](#) register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The [CPSW_GAP_THRESH](#) register value determines the port 1 short gap threshold, and the [CPSW_GAP_THRESH](#) register value determines the port 2 short gap threshold.

19.8.4.8.11 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Table 19-796. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 μ s
10	6.5 μ s

19.8.4.8.12 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the [SL_EMCONTROL](#) register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CPDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the [CPDMA_EMCONTROL](#) register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

[Table 19-797](#) shows the operations of the emulation control input and register bits.

Table 19-797. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend

Table 19-797. Emulation Control Input (continued)

EMUSUSP	SOFT	FREE	Description
1	X	1	Normal Operation

19.8.4.8.13 FIFO Loopback

FIFO loopback mode is entered when the FIFO_LOOPBACK bit in the [CPSW_CONTROL](#) register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in full duplex mode only.

19.8.4.8.14 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the DLR_EN bit in the [CPSW_CONTROL](#) register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the P0_DLR_CPDMA_CH field in the [P0_CONTROL](#) register. The supervisor node MAC address feature is supported with the dlr_unicast bit in the unicast address table entry. When set, the dlr_unicast bit causes a packet with the matching destination address to be flooded to the vlan_member_list minus the receive port and minus the host port (the port_number field in the unicast address table entry is a don't care). Matching dlr_unicast packets are flooded regardless of whether the packet is a DLR packet or not. The EN_P0_UNI_FLOOD bit in the [ALE_CONTROL](#) register has no effect on DLR unicast packets. Packets are determined to be DLR packets as shown below:

1. DLR is enabled (DLR_EN is set in the [CPSW_CONTROL](#)).
2. One of the sequences below are true.
 1. The first packet ltype matches [CPSW_VLAN_LTYPE](#)[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches [CPSW_DLR_LTYPE](#)[15:0] DLR_LTYPE.
 2. The first packet ltype matches [CPSW_VLAN_LTYPE](#)[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the second packet ltype matches [CPSW_DLR_LTYPE](#)[15:0] DLR_LTYPE.
 3. The first packet ltype matches [CPSW_VLAN_LTYPE](#)[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches [CPSW_VLAN_LTYPE](#)[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the third packet ltype matches [CPSW_DLR_LTYPE](#)[15:0] DLR_LTYPE.

19.8.4.8.15 Energy Efficient Ethernet Support (802.3az)

NOTE: CM_GMAC_CLKSTCTRL[1:0]CLKTRCTRL bit field must not be programmed for SW_SLEEP or HW_AUTO.

Energy Efficient Ethernet (EEE) allows the PRCM to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. EEE operations are configured as shown below:

1. The 10-bit EEE clock pre-scale value is written to the [CPSW_EEE_PRESCALE](#) register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (Px_IDLE2LPI) are written with the desired values
3. The port LPI to Wake count values (Px_LPI2WAKE) are written with the desired values
4. The EEE_EN bit is set in the switch [CPSW_CONTROL](#) register
5. Set the [WR_CONTROL](#)[8] SS_EEE_EN bit to enable energy efficient operations at subsystem level.

EEE operation can begin after configuration. The host allows (through PRCM) the CPSW_3G to enter a low power state by asserting the CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert CLKSTOP_REQ to the CPSW_3G.

Each ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the CPSW_3G GMII interface. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the Px_IDLE2LPI value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPDMA LPI state includes transmit and receive. The CPDMA LPI state is entered when the CPDMA transmit and receive have both been idle for the Idle to LPI time ([PO_IDLE2LPI](#)). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

NOTE: The procedure above is described for the GMII interfaces at the CPSW_3G boundary. External PHY signaling has the following conditions:

- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC_CLK edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC_CLK edges, respectively
-

When all transmit and receive ports are in the LPI state (CPSW LPI state), the CLKSTOP_ACK signal is asserted, and the PRCM is allowed to stop the module clock. When CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW_3G memory address space, and then turn off the clock again while CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting CLKSTOP_REQ. The host may queue transmit packets at any time including without regard to the CPSW_3G LPI state (the clock must be restarted in order to write the CPSW_3G slave address space as described above). Host writes to transmit head descriptor pointers will cause the CLKSTOP_WAKEUP signal to be asserted if the CPSW_3G is in the low power state (if CLKSTOP_ACK is asserted).

The external Ethernet PHY's can also wakeup the PRCM by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with CLKSTOP_ACK asserted and the receive LPI indication is removed, the CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the PRCM restarts the clock and de-asserts the CLKSTOP_REQ signal. The CLKSTOP_WAKEUP signal will be synchronously deasserted with CLKSTOP_ACK. Upon the deassertion of CLKSTOP_REQ, the Ethernet ports will count the Px_LPI2WAKE time for each port at which time the port is available for transmit. Upon the de-assertion of CLKSTOP_REQ, the CPDMA transmit will count the [PO_LPI2WAKE](#) count at which time the CPDMA will begin to send any packets that the host has queued (switch ingress). The wait time on CPDMA transmit is included to preclude the host from filling up the Ethernet port transmit FIFO's while the Ethernet ports are in the LPI to wake time. There is no LPI to wake time on CPDMA receive (switch egress).

19.8.4.8.16 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of GMAC_RST. When one or more port enable (Pn_STAT_EN) bits in the [CPSW_STAT_PORT_EN](#) register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set Pn_STAT_EN bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

See [Section 19.8.6.5](#), *STATS Registers* for description of every network statistic.

[Table 19-798](#) and [Table 19-799](#) summarize network statistics.

Table 19-798. Rx Statistics Summary

Rx Statistic	Frame /Oct	Rx/Rx +Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data ⁽¹⁾			<64	64	65-127	128-255	256-511	512-1023	1024-rx_maxlen	>rx_maxlen	Flow Coll. ⁽²⁾	CRC Error	Align/Code	Overrun	Addr. Disc.
			Pause frame	Non-pause ⁽³⁾	Multicast	Broadcast	Unicast													
Good Rx Frames	F	R	(y ⁽⁴⁾	y	y	y	y)	n	(y	y	y	y	y	y)	n	- ⁽⁵⁾	n	n	-	n
Broadcast Rx Frames	F	R	(% ⁽⁶⁾	%	n	y)	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Multicast Rx Frames	F	R	(%	%	y)	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Pause Rx Frames	F	R	y	n	n	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	-
Rx CRC Errors	F	R	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	y	n	-	n

(1) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
(2) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
(3) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
(4) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
(5) "-" indicates conditions which are ignored in the formations of the statistic.
(6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
(7) "y^" Frame fragments are not counted if less than 8 bytes.
(8) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.
(9) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

Table 19-799. Tx Statistics Summary

Tx Statistic ⁽¹⁾	Frame/Octet	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control ⁽²⁾		Data			64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Collision Type					No Carrier	Queued	Deferred	Underrun

Single Collision Tx Frames	F	T	n	(y	y	y	y	(y	y	y	y	y	y	-	-	y	n	n	n	n	-	-	-	
Multiple Collision Tx Frames	F	T	n	(y	y	y	y	(y	y	y	y	y	y	-	-	n	y	n	n	n	-	-	-	
Excessive Collisions	F	T	n	(y	y	y	y	(y	y	y	y	y	y	-	-	n	n	y	n	n	-	-	-	
Late Collisions	F	T	n	(y	y	y	y	n	(y	y	y	y	y	-	-	-	-	-	y	-	-	-	-	
Deferred Tx Frames	F	T	n	(y	y	y	y	(y	y	y	y	y	y	-	-	n	n	n	n	n	-	y	n	
Carrier Sense Errors	F	T	(y	y	y	y	y	(y	y	y	y	y	y	-	-	-	-	-	-	y	-	-	-	
64octet Frames	F	R+T ⁽⁸⁾	(y	y	y	y	y	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-	
65-127octet Frames	F	R+T	(y	y	y	y	y	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-	
128-255octet Frames	F	R+T	(y	y	y	y	y	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-	

⁽¹⁾ When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

⁽²⁾ Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.

⁽³⁾ The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 19-798](#).)

⁽⁴⁾ "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.

⁽⁵⁾ "-" indicates conditions which are ignored in the formations of the statistic.

⁽⁶⁾ "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

⁽⁷⁾ "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.

⁽⁸⁾ Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

Table 19-799. Tx Statistics Summary (continued)

19.8.4.9 Static Packet Filter (SPF)

19.8.4.9.1 SPF Overview

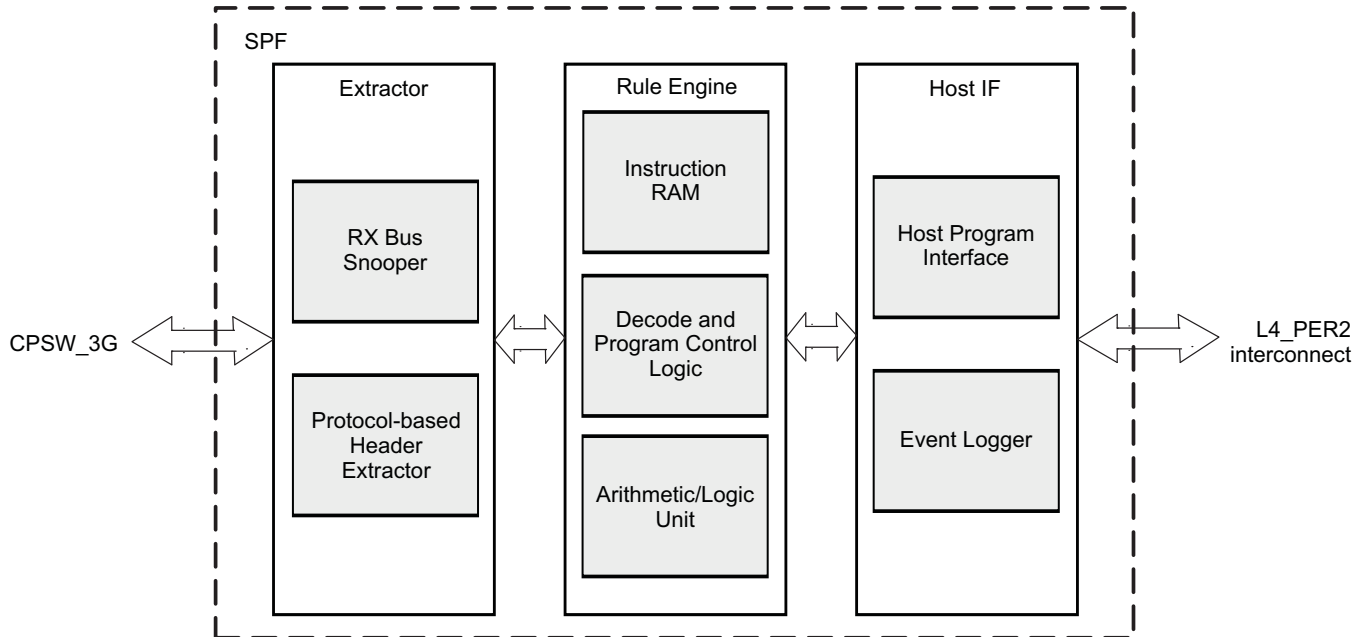

The Static Packet Filter (SPF) provides protection against some of the most common forms of Denial of Service (DoS) attacks that exploit the Layer 3 and Layer 4 functions of the network stack running on a system. The DoS attacks that are mitigated by the SPF module are:

- ARP Flood
- Fraggle
- Illegal Fragment Offset
- Illegal TCP Options
- Jolt2
- Jolt
- Land
- Micro Fragment
- Null Scan
- Ping Flood
- Short ICMP Packet
- Smurf
- SSPing
- SYN Fragment
- TCP SYN Flood
- Xmas Scan

19.8.4.9.2 SPF Functional Description

19.8.4.9.2.1 SPF Block Diagram

[Figure 19-166](#) shows the block diagram of the Static Packet Filter module. There are three main components of the static packet filter – packet header extractor to decode packet formats, rule engine to check for malformed protocol header fields and a host interface to provide control and configuration access to a host processor and to keep a log of filtered packets in system memory.

Figure 19-166. SPF Block Diagram

gmacsw-024

The packet parser interfaces to the three-port Ethernet switch (CPSW_3G). The CPSW_3G signals are snooped for receive traffic and the packet contents are provided to the packet header extractor. The parser can decode various network packet formats and determine the location of the header corresponding to each of the specified protocols and store the values in internal registers. The packet parser can decode VLAN, PPPoE, IP, TCP, UDP and ICMP frame formats and determine the location of each protocol header in a frame. The location of each of these headers is used by the rule engine for performing checks against preprogrammed conditions.

The rule engine monitors information in the header fields and upon detection of an abnormal combination of values in these packet header fields, issues an instruction to drop the packet to the external RFIFO interface. The rule engine can also monitor the receive rate of a particular class of packets and can limit the number of packets that actually pass through the system. The operation of rule engine is programmable and that gives flexibility to perform a range of different checks on the contents of packet to determine whether or not it should be accepted.

The event logger captures the activity in the packet filter. In addition, based upon the settings programmed by the host software, the event logger writes detailed information about any frames that have been dropped thus far. This information is written to a part of the system memory as configured by the host software.

19.8.4.9.2.2 Interrupts

The Static Packet Filter has one interrupt that is used to inform the host about excessive number of logged packet drops. The addresses of the instructions (or drop codes) in the instruction memory that cause packet to be dropped are associated with a threshold. When the threshold is met, the packet drop is logged. Each time a packet drop is logged, it is counted. When the number of logged records reaches the value specified by the `SPF_INTCNT` register, the host is interrupted. The threshold settings can be controlled by host software to limit the frequency of interrupts. Writing a zero to `SPF_INTCNT` disables the interrupt in this scenario. Whenever interrupt is enabled and is triggered, it can be cleared by writing one to either Raw register or Masked register.

Interrupts are controlled by the following registers:

1. Raw register `SPF_INT_RAW`: Holds the Raw state of interrupt, that is, without mask. The hardware interrupt is latched in this register and is only cleared when a one is written to either Raw register or Masked register. Writing a zero has no effect on this register.
2. Masked register `SPF_INT_MASKED`: This is the actual interrupt given to the system. It is the result of

bitwise AND operation of Raw and Mask registers. Once the interrupt is sensed by the system, this register should be cleared by writing one to this register or to Raw register during ISR execution. Writing zero has no effect on this register

3. Mask set register [SPF_MASK_SET](#): Writing one to this register enables the interrupt. By default, the interrupt is disabled and needs to be enabled by writing a one to this register. Writing a zero has no effect on this register. Writing to this register also set clear register.
4. Mask clear register [SPF_MASK_CLR](#): Writing one to this register disables interrupt. Writing a zero has no effect on this register.

19.8.4.9.2.3 Protocol Header Extractor

The extractor module has a protocol aware state machine. It decodes the header field in the current protocol header to determine the encapsulating protocol type and extracts various parameters used for software logging. The extractor module also provides the offset to octets in the packet, where Layer 3 and Layer 4 protocol headers start, to the rule engine. These protocol headers correspond to the location of IP and TCP/UDP/ICMP headers from the beginning of the packet.

Ethernet packets with VLAN, PPPoE, IP, IP Options, and ICMP/TCP/UDP protocol are supported by the extractor. When unknown protocols are detected, the extractor skips any additional packet processing. Some examples of how packet parsing is done by the Extractor are given below.

- Ethernet – VLAN - PPPoE – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – IP options – Unknown – Payload
- Ethernet – VLAN – PPPoE – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – Unknown – Payload
- Ethernet – VLAN – PPPoE – Fragmented IP – Unknown – Payload
- Ethernet – VLAN – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – IP options – Unknown – Payload
- Ethernet – VLAN – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – Unknown – Payload
- Ethernet – VLAN – Fragmented IP – Unknown – Payload
- Ethernet – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – IP – IP options – Unknown – Payload
- Ethernet – IP – TCP/UDP/ICMP – Payload
- Ethernet – IP – Unknown – Payload
- Ethernet – Fragmented IP – Unknown – Payload
- Ethernet – Unknown

The flow of Extractor state machine flow is as follows.

1. Wait for start of packet and proceed to step 2 if start of packet detected.
2. Read Ethernet header Length/Type field (at offset 13). Go to step 3 if next header is VLAN, to step 4 if it is PPP header, to step 5 if it is IP header and to step 8 otherwise.
3. Allow VLAN header to pass and read the Length/Type field. Go to step 4 if next header is PPP, to step 5 if it is IP header and to step 8 otherwise.
4. Read the protocol type in PPP header. Go to step 5 if protocol is IP and to step 8 for unknown protocol
5. Extract source IP address and destination IP address from the IP header. Determine if the packet has IP options or if the packet is fragmented. Go to step 6 if the packet has IP options and to step 8 if the packet is fragmented. If there are no options and the next protocol header is TCP/UDP, go to step 7. Otherwise, skip processing and go to step 8 because the packet has unrecognized protocol header
6. Skip IP options and determines the next protocol header. Go to step 7 if next header is TCP/UDP/ICMP. In case the packet contains an IP fragment or if the protocol in the next header is unknown, skip processing and go to step 8.
7. The packet has TCP/UDP/ICMP header. Extract TCP/UDP source and destination port numbers for logging or ICMP type and code fields and go to step 8.

8. Wait for end of frame and go to step 1 at end of frame.

In case the packet is aborted (indicated by address 0x10 on VBUSP with request and write ready asserted), the extractor state machine flushes its current state, goes back to the idle state and waits for next packet.

The Extractor provides information to rule engine about location of Layer 3 and Layer 4 protocols. When this information is provided to rule engine, the Base Register 1 and Base register 2 are loaded with Layer 3 start offset and Layer 4 start offset respectively. Until the extractor completes decoding of these protocol headers and sends the offset values to rule engine, the rule engine does not execute any instruction that operates on fields in these protocol headers.

Extractor module extracts IP protocol, Source IP address, Destination IP address, TCP/UDP source port, TCP/UDP destination port and ICMP type/code from incoming packet and provides this information to the Host logger module for software reporting. In case IP header or TCP/UDP header does not contain the extractable fields then the corresponding field is logged as zero.

In case packet has unknown Layer 4 protocol or IP packet is fragmented such that the packet does not contain TCP/UDP/ICMP header then TCP/UDP source/destination ports or ICMP type/code fields are logged as zeros.

19.8.4.9.2.4 Programmable Rule Engine

The rule engine is a micro-coded machine that is programmed by the host software. The rule engine is programmed to evaluate various expressions involving the header fields of different protocols that the incoming packet belongs to. These expressions are coded into the instructions that are stored in an internal RAM and are used to check whether a packet is mal-formed or is potentially a DoS attack packet. The rule engine executes the instructions for each incoming packet and makes a decision about accepting or rejecting the packet.

Since each packet can have multiple distinct protocol headers, the location of the headers can be different from packet to packet. The rule engine gets information about the location of the protocol headers from the packet header extractor. The packet header extractor can decode several different protocol types. The octet number at which a particular protocol header is stored is loaded into SPF Base Registers. An application may require SPF to filter packets based on protocols that are not decoded by the extractor. In such cases, SPF allows bypassing the header extractor and then the rule engine can be programmed to analyze packets and figure out the location of each header.

The Rule Engine instructions are programmed before the SPF module is enabled. The instructions cannot be overwritten while the rule engine is processing packets. To modify the contents of code RAM during operation, SPF must be disabled temporarily and then new instructions can be loaded.

Once SPF is enabled, the rule engine starts to fetch instructions one at a time. For each instruction, the operands are obtained from either the packet octets that are being received, from internal registers or from the immediate values inside the instruction itself. If the octet that is needed for execution has not yet been received, then the execution stalls until the required octet is received. In case the operand specified in the instruction refers to a packet octet that has already gone by and is not available in the packet buffer, then the execution stalls until the end of packet. An instruction is executed only when all the required operands are available. Based on the instruction execution results, the packet may immediately be dropped or the results of the evaluated expressions may be stored for future use. In addition, the current instruction can also cause the rule engine to skip a specified number of instructions (immediately following the current instruction) and resume from another location in the instruction RAM.

The rule engine operates on multiple operands and performs multiple tasks in each clock cycle. In each cycle, it can perform one arithmetic and/or logical operation on two pairs of operands. The operands are masked with a 32-bit mask that is generated from the information provided in the instruction. The mask allows for operations that involve variable sized operands. Each operation generates a 32-bit number and a flag bit. The 32-bit number is typically either the sum or the output of bit-wise logical operation. The flag is a single bit result of a comparison operation. The result of each operation can be saved in the internal registers if a specified condition is satisfied. Similarly, depending on the result of the operation, the rule

engine can jump to another location in the instruction memory. The program can instruct the rule engine to either perform two save operations, two conditional jumps or one jump and one save. The conditions must be mutually exclusive to prevent unspecified operation. In addition to providing an alternate path for execution, the instruction can cause the rule engine to accept or reject the current packet and exit from the program until the next packet is received.

When the execution of an instruction does not result in a decision to accept or reject the packet, the rule engine progresses to the next instruction. Instructions are executed until a final decision is made. If a packet is aborted in the middle at the network interface, the rule engine aborts execution and clears all base registers, program counter, octet counter and packet buffer. It is then ready to process next packet.

From a hardware perspective, the rule engine contains a buffer to store packet octets, several internal registers for temporary storage, instruction decoding logic and control circuitry. A description of each of the hardware resources in the rule engine follows.

19.8.4.9.2.4.1 Internal Registers

Several different types of registers are provided in the rule engine. The description of each of these is provided below.

- **Base Registers (B0-B4):** There are four hardware base registers (B1-B4) that store the location of various protocol headers. The B0 register is not a hardware register and it always means a reference to the first octet in a packet. Each base register is eight bits wide and is used to reference octets in a packet. The base registers can point to any octet in the packet upto 255 octets. These registers are readable and writable by the rule engine. In addition, base registers B1 and B2 are loaded with data provided by the extractor when the rule engine is not running in extractor bypass mode (`SPF_CONTROL[2] SPF_EXT_BYPASS`). The rule engine can write to base registers irrespective of whether extractor bypass is enabled. When an operand needs to use contents of B1-B4 registers, the instruction only executes if the specified base register was loaded at least once after the beginning of current packet. If the specified base register was not loaded during the current packet, then the operand referenced by this base register cannot be extracted from the packet and will cause the rule engine to stall.
- **Constant Registers (C0-C7):** The rule engine can refer to any of eight 32-bit constant values. These are programmed by the host (`SPF_CONSTj`, $j = 0$ to 7) and the rule engine only has read access to these registers. Each of these registers can be changed at any time by the host software. However, changing the value of these registers is not recommended as unpredictable behavior may occur if contents are changed while the rule engine is executing instructions that use the C0-C7 values.
- **General Purpose 32-bit registers (R0-R7):** There are eight 32-bit registers that can be read/written by the rule engine. These are general purpose registers and can be used as temporary storage. In addition, when the rule engine is required to provide logging information, R4-R7 are used to store information that will be written to memory.
- **Rate limit registers (L0-L3):** Four 8-bit rate limit registers are used by rule engine to count specific types of packets that are to be rate limited. These registers are counters that are loaded with programmed threshold values (`SPF_RATELIMIi`, $i = 0$ to 3) at the end of time interval determined by the clock pre-scaler (`SPF_PRESCALE`).
- **General Purpose 1-bit registers (T0-T3):** Four 1-bit registers are provided to store comparison results by the rule engine. These registers can be used to store 1-bit output from ALUs. In addition, the logical OR and logical AND of the flags can also be stored in T0-T3 registers. The 32-bit ALU results may also be stored in T0-T3 registers but only the LSB will be stored.

The rule engine instructions refer to these internal registers during execution. More details about instruction encoding are in subsequent sections.

19.8.4.9.2.4.2 Packet Buffer

When the rule engine is processing a packet, it stored a snapshot of latest 32 octets in an internal buffer. This buffer allows evaluation of expressions on packet octets even after the packet octets have gone by on the external receive VBUSP network interface.

At the start of packet, the first eight octets received are loaded into the first eight locations of the packet buffer. When the next eight octets arrive, these are loaded into the first eight locations and the existing octets are moved to the following eight locations. This process is continued until the packet buffer is full. When packet buffer is full and additional octets arrive, the oldest eight octets are shifted out and are no longer available to the rule engine. Thus, the packet buffer provides a snapshot of most recent octets received.

When the rule engine encounters instructions that reference packet octets which have not yet been received then the rule engine stalls until the required octets are available. Similarly, instructions which require octets that have already been shifted out of the packet buffer will cause rule engine to stall. And since these octets will never be available, the rule engine will not execute any further instructions for the current packet. It will return to the first instruction when the packet ends.

Figure 19-167. Packet Octets as Stored in the Packet Buffer

	24	23	22	21	20	19	18	17

gmacsw-025

The contents of a packet, when used as one or more operands in an instruction, are always fetched from the packet buffer. The Base registers (B0-B4) in conjunction with an offset and bits are used to specify which octets are to be used as operands.

19.8.4.9.2.5 Intrusion Event Logger

The activity of the static packet filter is logged by the intrusion event logger. Based on the configuration, the event logger writes specific fields of the incoming packet that violate a particular rule to the system memory for software diagnostics.

The logging module allows controlling the frequency at which events are logged to the memory. A set of nine counters are provided and, of these, eight can be mapped to any address of the rule engine's instruction RAM using map registers. This mapping logically associates the log information with the instruction that caused the packet to be dropped. The 9th counter is not associated with any particular instruction and it can be used to count the packets that were dropped at instructions not mapped to any of the other eight counters.

For each of the nine counters, there is a register to store the minimum number of attacks that must be detected before any information is logged to memory. Only when this threshold is met and logging is enabled, the host interface module writes log data in system memory. The memory area used to log is specified by the host in the [SPF_LOG_BEGIN](#) address and [SPF_LOG_END](#) address registers.

The event logger continues to write data to memory until it runs out of space and the log overwrite is disabled. With each update of the log, the [SPF_LOG_HWPTR](#) is updated. This information can be used by the host to determine how much data has been logged. The software in turn keeps the [SPF_LOG_SWPTR](#) updated to inform the SPF about the next address from where information will be read by the host software. It is required that software program correct value of [SPF_LOG_END](#) address to enable hardware to determine roll-over location. The SPF considers all space before the [SPF_LOG_SWPTR](#) as available for logging. In case [SPF_CONTROL](#)[9] [SPF_LOGOW_EN](#) control bit is set, SPF ignores [SPF_LOG_SWPTR](#) and logs data irrespective of software read log status. Note that the memory space allocated for logging is a multiple of four 32-bit words and end address [SPF_LOG_END](#) should be loaded with byte address of the next byte following the last log entry. For example if 16 bytes space is allocated for SPF logging from address 0x1400_0000, then [SPF_LOG_BEGIN](#) should be 0x1400_0000 and [SPF_LOG_END](#) should be 0x1400_0010.

The host software must set [SPF_CONTROL](#)[8] [SPF_LOG_EN](#) bit to activate logging. The setting of [SPF_LOG_EN](#) bit has no effect on the threshold based counters and they are always active. In addition to the log counters, SPF has one master drop count register ([SPF_DROPCNT](#)) which tracks the total number of packets dropped thus far. This counter does not roll over and must be cleared for re-run by the host processor once it reaches the maximum value.

The format in which packet information is written in the memory by the event logger is shown in [Table 19-800](#) and [Table 19-801](#).

Table 19-800. Format for TCP/UDP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Source TCP/UDP Port		Destination TCP/UDP Port	

Table 19-801. Format for ICMP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Type	Code	Checksum	

Each entry logged to memory has a drop code associated with it. The drop code is the address in instruction memory that actually triggered the drop. Up to eight drop codes can be monitored in this manner. In addition to drop code, the protocol, IP addresses and source/destination ports associated with the dropped packet are recorded.

Log data can be supplied by either Extractor module or by Rule engine. The [SPF_CONTROL](#)[3] [SPF_RULE_LOG](#) bit must be set to use log data from Rule Engine and cleared to use data supplied by the Extractor.

When logging is done through the Rule Engine, contents of internal registers R4-R7 are written to memory. The format of packet information stored can be programmed in the rule engine except for the drop code field which is static and cannot be changed. The format in which rule engine information is written in the memory by the event logger is shown in [Table 19-802](#).

Table 19-802. Rule Engine Format

Drop Code	Register 4[23:0]
	Register 5[31:0]
	Register 6[31:0]

Table 19-802. Rule Engine Format (continued)

Register 7[31:0]

The rule engine programming must ensure that these registers contain all required information that is to be recorded before the packet drop instruction is executed. As soon as the drop instruction is executed, the logging module starts to send data from the registers R4, R5, R6 and R7 to the system memory and is not possible to modify the contents of these registers.

19.8.4.9.2.6 Rate Limiter

The static packet filter provides a way to limit the rate of specific types of incoming packets. The SPF module provides four rate limit registers (L0-L3) that are used in conjunction with a clock prescaler (SPF_PRESCALE) and rule engine instructions. The clock prescaler is a clock divider and every count down to zero and the subsequent roll-over indicates end of a time interval. At every such event, each of the four rate limit registers is loaded with a preset value (SPF_RATELIM_i, i = 0 to 3) that is programmable by the host processor. When packets are received, the rule engine can identify packets of particular types and execute a limit operation. The limit operation specifies a condition (described in Table 19-820) and a limit register. If the condition evaluates to true, the packet is dropped if the rate limit register is zero. If it is non-zero, then the rate limit register is decremented by one.

Thus, by using the prescaler and the limit registers, it is possible to control the rate of specific type of packets. By controlling the value of prescale counter (common to all rate limit registers) and the rate limit thresholds, the granularity of the rate can be modified. A lower value of prescale counter will cause frequent reloads of the rate limit registers and will allow rate control over small time intervals. Keeping the prescale counter at extremely small values may cause the rate limiter to be ineffective because the limit registers will be reloaded too frequently to count down to zero. Conversely, a higher value of prescale counter will cause less frequent reloads of the rate limit registers and the rate control will be over longer time intervals. The reload value of each 8-bit rate limit register and the prescale register are programmed by the host processor before SPF is enabled. A reload value of 0xFF can be used to disable any of the rate limiters at run-time without changing the firmware. Both the prescale and limit registers can be modified during run-time.

19.8.4.9.2.7 Rule Engine Instruction Set Architecture

19.8.4.9.2.7.1 Instruction Format

The design supports 64 deep instruction memory. Each of the instructions is 78 bit wide and is stored in a RAM internal to the SPF module. Each instruction can have up to four operands, two arithmetic/logical operations and two conditional jump/save actions based on the outcome of the operations.

The operand field is 52 bits wide and it can have up to four operands. The arithmetic and logical operation codes are four bits each. The operation codes are nine bits each.

Table 19-803. Instruction Format

Bits	Field Name	Description
77:26	OPERAND	Up to four operands are specified in this field. The source of the operands can be the packet that is being received at the network interface, one of the internal register values or an 8/16/32 bit operand specified within the instruction.
25:22	FUNCTION0	This field specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of first two operands specified in the instruction.
21:18	FUNCTION1	This field also specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of the third and fourth operands specified in the instruction.

Table 19-803. Instruction Format (continued)

Bits	Field Name	Description
17:9	OPERATION0	<p>A Save/Jump/Limit/Nop operation is specified in this function.</p> <p>Save operation code includes the source and destination information. The save source is the output of functions and the destination is one of the internal registers where data should be saved.</p> <p>Jump operation code has information about a condition and a destination. The jump occurs when the condition, which is based on the result of function0 and function1, is true. The Jump destination controls the flow of instruction execution.</p> <p>Jump to location 1 results in the packet being dropped. Rule engine goes back to initial instruction and waits for next packet. The event logger writes information to memory.</p> <p>Jump to location zero results in the packet being accepted. The rule engine goes back to initial instruction and waits for next packet.</p> <p>Limit operation code has information about a condition and a rate limit register. The Limit operation either causes the packet to be dropped or results in the specified rate limit register to be decremented by one.</p>
8:0	OPERATION1	This field specifies a second save/jump operation. The format for this field is same as for Operation0.

19.8.4.9.2.7.2 Operand Field

The operand field specifies up to four operands. Each operand is obtained from the incoming packet data, from an internal register or as an immediate value specified in the instruction itself. In addition, there is a bit mask associated with each operand. The mask values are encoded in the instruction itself and the mask for each operand is applied before it is used by the Arithmetic and Logic Unit.

The operands are input to the two 32-bit Arithmetic and Logic units. For all calculations, a mask is used with each operand. The mask is a 32-bit number that is generated from a 5-bit code provided in the instruction or from an immediate value in the instruction. The 5-bit mask code specifies how many bits (from the LSB side) will be input to the ALU. An immediate mask must be used when the mask is not a continuous sequence of 1's. Whenever an immediate mask value is specified, the mask value specified by the 'Bits' fields is ignored.

Each operand is at least 13-bits long and the encoding for each operand types is shown in [Table 19-804](#) to [Table 19-811](#).

Table 19-804. Packet Data Operand

Description	This type of operand is derived from the packet itself. The encoding specifies a number of bits (up to 32) to be extracted from a location in the packet indicated by the selected base register and offset. The format of 13-bit operand code is shown below. Internally, a 32-bit number is obtained from the packet. Then, a mask is created from the bits[4:0] field and bitwise ANDed with the 32- bits extracted from the packet.												
	12	11	10	9	8	7	6	5	4	3	2	1	0
	Base[2:0]			Offset[4:0]					Bits[4:0]				
Bits	Field Name	Description											
12:10	Base[2:0]	The Base field selects one of the Base registers B0, B1, B2, B3 or B4. The operand comprises of (Bits+1) bits extracted from the packet. The offset from where the operand octets are extracted is determined by the sum of the value of specified base register (Base 0 to Base 4) and the specified offset. Base 0 is start of packet.											
9:5	Offset[4:0]	The value of the selected base register plus the specified offset is the octet location in the packet from where the specified number of bits will be picked.											
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, only one bit is used as operand. When Bits[4:0] is 31, then 32 bits are used as operand.											

Table 19-805. Constant Operand

Description		One of the eight constants programmed by the host software can be used as operand. The bits field specifies the mask to be applied to the selected 32-bit constant.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	0	0	C[2:0]			Bits[4:0]					
Bits	Field Name	Description											
7:5	C[2:0]	This field selects one of the constants (C0-C7).											
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.											

Table 19-806. 32-bit Register Operand

Description		One of eight 32-bit registers is used as operand and bits[4:0] field specifies the bitmask to be applied to that register.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	0	1	R[2:0]			Bits[4:0]					
Bits	Field Name	Description											
7:5	R[2:0]	This field selects one of the 32-bits registers (R0-R7).											
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.											

Table 19-807. 1-bit Register Operand

Description		One of the four 1-bit registers is used as operand.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	1	0	0	T[1:0]		0	0	0	0	0	
Bits	Field Name	Description											
6:5	T[1:0]	This field selects one of the four 1-bits registers (T0-T3).											

Table 19-808. Base Register Operand

Description		One of the base registers is used. The 2-bit codes are 00, 01, 10 and 11 for B1 to B4 respectively.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	1	1	1	B[1:0]		0	0	Bits[2:0]			
Bits	Field Name	Description											
6:5	B[1:0]	This field selects one of the four base registers (B1-B4). Note that B0 is a virtual register which is always zero and specifies the start of packet.											
2:0	Bits[2:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.											

Table 19-809. End of Packet Operand

Description	The End-of-Packet (EOP) operand can be used to detect the end of current packet. Use of this operand will stall the CPU until the end of packet is reached. The end of packet operand will always be equal to one when the CPU detects end of packet. It will be zero until packet data is being received and will also stall the CPU. The recommended use of this operand is in the last instruction where a check may be made for size of current packet. Note that this operand only tracks the end of a complete successfully received packet by the RFIFO. The EOP operand does not detect abort of a packet.
--------------------	--

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	1	0	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask. However, these bits are inconsequential for EOP operand. Irrespective of the mask specified by bits[4:0], the EOP operand is always equal to 0x1 in the execution cycle of the instruction it is used.

Table 19-810. Octet Count Operand

Description	The Octet count operand is used to determine the number of bytes that have been received by rule engine.
--------------------	--

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	0	1	1	1	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask that is applied to octet counter value. The recommend value for this field is 0x1F.

Table 19-811. Immediate Data Operands

Description	The immediate data operands can be bigger than 13 bits as shown in the codes below. Each of such operands is directly sent to the ALU without applying any addition bit mask. The immediate data operands can be 8, 16 or 32 bits wide.
--------------------	---

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	0	Data[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	Data[15:0]															

3	3	3	3	3	3	3	2	2	2	2	2	2	2	2	2	2	2	1	1	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0			
6	5	4	3	2	1	0	9	8	7	6	5	4	3	2	1	0	5	4	3	2	1	0																
1	1	1	1	1	0	Data[31:0]																																

Table 19-812. Immediate Operand Masks

Description	The operand fields can also be used to specify bit masks. These are used when only specific bits from an operand are to be extracted. There is provision for 8-bit and 16-bit masks that can be encoded into an instruction's operand field.
--------------------	--

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	Mask[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	1	Mask[15:0]															

When the operand field is all-ones it does not specify any operand and is considered zero.

The tables below list the combinations in which operands may be programmed in an instruction. In this list, Pkt/Reg operand is an operand consisting of octets from the packet or the contents of one of the internal registers; mask specifies the value that is used as a mask instead of the mask generated from the Bits field in the instruction; immediate operand (immediate[7:0], immediate[15:0] and immediate[31:0]) is an 8/16/32 bit number that is used as an operand. The format of Pkt/Reg operand is as shown previously. The decoding of operands for each ALU is dependent upon the type of operation specified in the ALU and the format of the operand field. When there are four operands in the operand field, the first and second operands are used in ALU0 and the rest by ALU1. When ALU0 needs only one operand, then the remaining operands are fed to ALU1. The order of decoding operands is designed to first provide operands to ALU0 from the more significant side of operand field and then to ALU1. If the number of operands specified in instruction does not match with the number of operands required by the ALUs, unspecified behavior can occur. For an instruction to execute, both ALUs must have valid data. If any of the ALUs uses a packet data operand which is not yet available then the rule engine stalls until data is available. During the stall phase, the instruction is decoded every cycle and all required operands must be available simultaneously for the instruction to be executed. In addition, if an instruction refers to packet octets that are no longer available, the rule engine stalls until the end of packet.

-----------------------	-----------------	---------------------------------------	----------

Pkt/Reg Operand[12:0]	11000 Mask[7:0]	Pkt/Reg Operand[12:0]	11000 Mask[7:0]
11101 Immediate[15:0] 11111		Pkt/Reg Operand[12:0]	11000 Mask[7:0]
Pkt / Reg / Imm[7:0] Operand[12:0]	11101 Immediate[15:0] 11111		Reserved
Pkt/Reg Operand[12:0]	11000 Mask[7:0]	11101 Immediate[15:0] 11111	
11101 Immediate[15:0] 11111		11101 Immediate[15:0] 11111	
11101 Immediate[15:0] 11111		Pkt / Reg / Imm[7:0] Operand[12:0]	Reserved
Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111		Pkt / Reg / Imm[7:0] Operand[12:0]
Pkt / Reg / Imm[7:0] Operand[12:0]	Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111	
Pkt/Reg Operand[12:0]	1101 Mask[15:0] 01 Immediate[15:0]		
Pkt / Reg / Imm[7:0] Operand[12:0]	11110 Immediate[31:0] 11		
11110 Immediate[31:0] 11			Pkt / Reg / Imm[7:0] Operand[12:0]

Table 19-816. Operand Field With One Operand

Pkt / Reg / Imm[7:0] Operand[12:0]	Reserved	Reserved	Reserved
Pkt/Reg Operand[12:0]	11000 Mask[7:0]	Reserved	Reserved
Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111		Reserved
11101 Immediate[15:0] 11111		Reserved	Reserved
11110 Immediate[31:0] 11			Reserved

The formats in which operands are specified in the operand field have certain restrictions:

- a mask cannot follow an immediate value
- a mask cannot follow a previous mask
- a reserved field should have all following fields reserved as well
- the first field cannot be a mask

19.8.4.9.2.7.3 Arithmetic/Logical Function Field

There can be two codes for arithmetic and logical functions in each instruction. Each of the operations can involve one or two operands.

The location of each function field in an instruction is listed in [Table 19-817](#).

Table 19-817. Arithmetic/Logical Instruction Field

Bits	Description
23:20	Single or Dual operand Arithmetic/Logic Function (function 0)
19:16	Single or Dual operand Arithmetic/Logic Function (function 1)

The bit codes for each arithmetic/logic function that can be performed on the operands of an instruction are listed in [Table 19-818](#).

Table 19-818. Arithmetic/Logical Operation Codes

Code	Description	Operands Required	32-bit result	1-bit flag result
0x0	Less Than	2	0	Set if true
0x1	Less Than Equal To	2	0	Set if true
0x2	Greater Than	2	0	Set if true
0x3	Greater Than Equal To	2	0	Set if true
0x4	Equal to Zero	1	0	Set if true
0x5	Not Equal to Zero	1	0	Set if true
0x6	Equal to One	1	0	Set if true
0x7	Not Equal to One	1	0	Set if true
0x8	Equal	2	0	Set if true
0x9	Not Equal	2	0	Set if true
0xA	Add	2	Sum	Set if overflow
0xB	Subtract	2	Difference	Set if output is negative
0xC	Bitwise AND	2	Bitwise AND	0
0xD	Bitwise OR	2	Bitwise OR	0
0xE	Result is same as Operand	1	Same as operand	0
0xF	No Function (NOF)	0	0	0

The ALU0 and ALU1 are assigned function0 and function1 respectively. In case only one function is to be performed in an instruction, function0 field should be used to do that. An instruction with no function for ALU0 and a valid function for ALU1 will result in unspecified behavior.

The output of each function is in the form of a 32-bit number and a single bit value. The single bit value is either the carry bit from an add/subtract operation or the Boolean result from a comparison function. The single bit output from each function is referred as the flag0 or flag1 result. The 32-bit number is the outcome of arithmetic or a bitwise logical operation and it is referred to as the word0 or word1 result.

19.8.4.9.2.7.4 Operation Field

The operation field specifies a limit, save or a jump operation. All of these operations involve two arguments that are specified within the instruction.

In case of limit operation, one of the arguments is a condition and the other argument is a limit register. In case of save operation, one of the arguments is source data and the other argument is a destination where the data will be saved. In jump operation, the first argument is a condition that must be true for the jump to occur and the second argument is a destination to which the program control will be moved to. The destination argument in a jump operation also specifies specific destinations that lead to the current packet being immediately rejected or accepted.

The location of operation field in an instruction is shown in [Table 19-819](#).

Table 19-819. Operation Fields

Bits	Description
17:9	Limit/Save/Jump Operation (operation 0) For limit operation, [17:16] is the operation field, [15:13] is the condition field and [12:9] is a limit register. For save operation, [17:16] is the operation field, [15:13] is the source field, and [12:9] is the destination field. For jump operation, [17:16] is the operation field, [15:13] is the condition field, and [12:9] is the destination field
8:0	Limit/Save/Jump Operation (operation 1) For limit operation, [8:7] is the operation field, [6:4] is the condition field and [3:0] is a limit register. For save operation, [8:7] is the operation field, [6:4] is the source field, and [3:0] is the destination field. For jump operation, [8:7] is the operation field, [6:4] is the condition field, and [3:0] is the destination field.

Table 19-820. Limit Operation

Description	In a limit operation, the condition argument specifies a condition that must be true for the specified limit register to be decremented if non-zero or the packet to be dropped if the limit register is zero.
--------------------	--

8	7	6	5	4	3	2	1	0
0	0	Condition Code			Limit Register			

Bits	Field Name	Description
6:4	Condition Code	It is a 3-bit code that specifies the condition that must be true for the operation to be executed. 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 flag1) 0x3: Logical NOR of flags (!(flag0 flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Decrement/Limit
3:0	Limit Register	It is a 4-bit code that specifies the limit register that is to be decremented or checked for zero value. 0x0: Rate limit register L0 0x1: Rate limit register L1 0x2: Rate limit register L2 0x3: Rate limit register L3 0x4-0xF: Reserved

Table 19-821. Save Operation

Description	The arguments for a save operation include a code for source data and a code for the destination. The source is either a single bit data or a 32-bit word. The single bit data is either a flag from the functions or a logical OR/AND of the flags. The 32-bit word is the result of the ALU arithmetic/logical functions.
--------------------	---

8	7	6	5	4	3	2	1	0
0	1	Source Data Code			Destination Register Code			

Bits	Field Name	Description
6:4	Source Data Code	It is a 3-bit code that specifies the source data which is to be save in another register 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 flag1) 0x3: Logical AND of flags (flag0 & flag1) 0x4: Output of function (word0) 0x5: Output of function (word1) 0x6-0x7: Reserved
3:0	Destination Register Code	It is a 4-bit code that specified the register in which source data is to be stored 0x0-0x3: Single Bit register (T0-T3) 0x4-0x7: Base Register (B1-B3) 0x8-0xF: 32-bit Register (R0-R7)

For some instructions, the rule engine extracts the operand from the current packet. To determine the packet bits to be used as operands, it refers to one or more base registers. Whenever an instruction causes a change in value of any of the base registers, it cause the rule engine to wait for one clock cycle before executing the next instruction. The rule engine is a pipelined processor and change in the value of a base register causes the prefetched operand values to become stale and these need to be fetched again. The clock cycle inserted allows rule-engine to fetch the data again before the instruction using this data is executed. Only the instructions that use packet data will be delayed by a clock cycle if the previous instruction caused a change in the base register that is referenced in the current instruction.

Table 19-822. Jump Operation

Description	For jump operation, one of the operands is a condition that must evaluate to true for the jump operation to occur. The other operand is the destination to which the program counter will move to if the jump operation is executed. The condition in a jump operation is either one of the flags from the output of the arithmetic/logic unit or a logical AND/OR of the flags.							
8	7	6	5	4	3	2	1	0
1	0	Condition Code			Destination Code			

Bits	Field Name	Description
6:4	Condition Code	Condition Code 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 flag1) 0x3: Logical NOR of flags (!(flag0 flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Jump
3:0	Destination Code	Destination Code 0x0: Accept packet, return to instruction zero and wait for the next packet. 0x1: Reject packet and return to instruction zero. 0x2-0xF: Go to instruction at offset +2 ...+15

The jump operation results in a change of program execution flow. The jump destination determines the next instruction that will be executed by the rule engine. The destination is only specified as a positive offset to the current value of the program counter. The program counter can result in the rule engine skipping a given number of instructions instead of executing the next instruction. In addition, the destination field can instruct the rule engine to immediately reject or accept the current packet without any further checks. The rule engine then goes back to the first instruction and waits for a new packet to arrive before it executes any further instructions.

The rule engine is a pipelined processor. When it executes a jump operation, there is a delay of one clock cycle before the next instruction is executed.

The operations specified in the two operation fields are independent of each other. However, it is possible that conflicting operations are specified in the operation fields of an instruction. When conflicting operations are specified and conditions of both operations evaluate to true; then the execution flow is determined as described below:

1. If one of the ALUs has a limit/jump operation that will cause the packet to be dropped, then the packet will be dropped irrespective of what the other ALU indicates.
2. If case 1 above is false and one of the ALUs has a jump operation that will cause the packet to be accepted, then the packet will be accepted and the rule engine will return to idle state.
3. If case 1 and 2 above are false and one of the ALUs has a jump to offset with the respective condition true, the jump will be executed. If there is conflicting jump to offset information in the two ALUs, ALU0 is given priority.

Table 19-823. No Operation

Description		If there is no Save, Jump or Limit operation specified in the operation field, it is interpreted as a no operation. There is no change in execution flow, no change in any register values or rate limit registers when a no operation is encountered.							
8	7	6	5	4	3	2	1	0	
1	1	Reserved			Reserved				

It is expected that the rule engine will be programmed such that a decision to accept or discard the current packet is made before all instructions have executed. If the rule engine reaches the last instruction and it does not result in a decision to accept/reject the packet, then the execution flow does not stop and all instructions from the first instruction are executed again until the end of packet is reached.

19.8.4.9.3 Programming Guide

19.8.4.9.3.1 Initialization Routine

The packet filter must be initialized in order for it to operate as specified. A typical order in which the module can be initialized is shown below:

1. Initialize the firmware by programming the internal memory and verify it (SPF_INSTR_W2, SPF_INSTR_W1, SPF_INSTR_W0, [SPF_INSTR_CTL](#))
2. Allocate memory for logs written by SPF and initialized the log space parameters ([SPF_LOG_BEGIN](#), [SPF_LOG_END](#), SPF_SW_PTR)
3. Program the log map registers to associate drop codes with the log thresholds. ([SPF_LOG_MAP0](#), [SPF_LOG_MAP1](#))
4. Program log thresholds ([SPF_LOG_THRESHk](#), where k = 0 to 8)
5. Program constant registers if required by the firmware ([SPF_CONSTj](#), where j = 0 to 7)
6. Program clock prescale counters and rate limit registers if required by the firmware ([SPF_PRESCALE](#), [SPF_RATELIMI](#), where i = 0 to 3)
7. Program the interrupt frequency control register and interrupt mask register to setup interrupts ([SPF_INTCNT](#), [SPF_MASK_SET](#))
8. Program the control registers to enable SPF filter and logger ([SPF_CONTROL](#)).

19.8.4.9.3.2 Interrupt Service Routine

The interrupt service routine in SPF should be designed to process the data logs generated by SPF. It should trigger a higher layer application software that can analyze the data logs and determine if any remedial measures are required based on the information in the logs. At the minimum, the interrupt service routine must reprogram the software pointer for the logging machine to be able to continue logging.

The typical tasks performed following an interrupt are listed in the pseudo code below.

```
SPF_ISR {
  read log hardware pointer
  read log software pointer
  determine how many log entries are to be read
  read each log entry starting with the software pointer
  update software pointer to reflect the next unread entry
  clear interrupt
}
```

19.8.4.9.3.3 Rule Engine Example Program

Here is an example of how the rule engine can be programmed to detect packets that resemble Denial of Service traffic. The pseudo code is shown below.

```
IDLE:
  jump to ICMP if start_of_packet
```

```

ICMP:
if (protocol==ICMP)
limit_ICMP
if (fragmented packet)
drop and jump to IDLE
accept and jump to IDLE
else
jump to IP
IP:
if (source_ip==dest_ip)
drop and jump to IDLE
if (fragmented and (fragment_offset+ip_size)>2^16)
drop and jump to IDLE
accept the packet and jump to IDLE
    
```

19.8.4.10 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

19.8.4.10.1 CPTS Architecture

Figure 19-168 shows the architecture of the CPTS module inside the GMAC_SW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the GMAC_SW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value through the Event FIFO

Figure 19-168. CPTS Block Diagram

The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources. See [Chapter 3, PRCM](#) for more details.

19.8.4.10.2 CPTS Initialization

The CPTS module should be configured as:

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the [CPTS_CONTROL](#) register.
3. Write the CLKSEL_RFT value in the CM_GMAC_GMAC_CLKCTRL register in the PRCM with the desired reference clock selection.
4. Set the CPTS_EN bit in the [CPTS_CONTROL](#) register.

5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the [CPTS_INT_ENABLE](#) register.

19.8.4.10.3 Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function ([CPTS_TS_LOAD_VAL](#) and [CPTS_TS_LOAD_EN](#) registers).

19.8.4.10.4 Event FIFO

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

19.8.4.10.5 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. Two 32-bit registers, [CPTS_EVENT_HIGH](#) and [CPTS_EVENT_LOW](#) hold the data of a time sync event. There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

19.8.4.10.5.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the [CPTS_TS_PUSH](#) register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

19.8.4.10.5.2 Time Stamp Counter Rollover Event

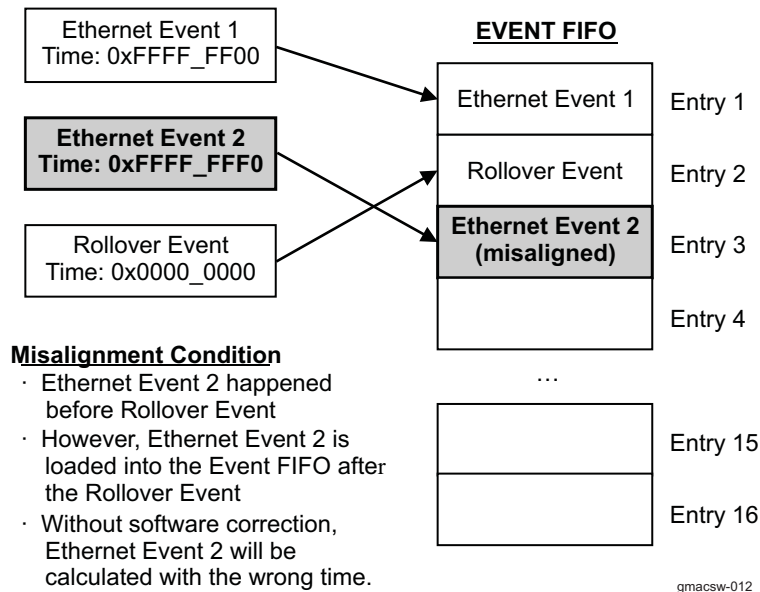

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

19.8.4.10.5.3 Time Stamp Counter Half-rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 19-169](#) shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

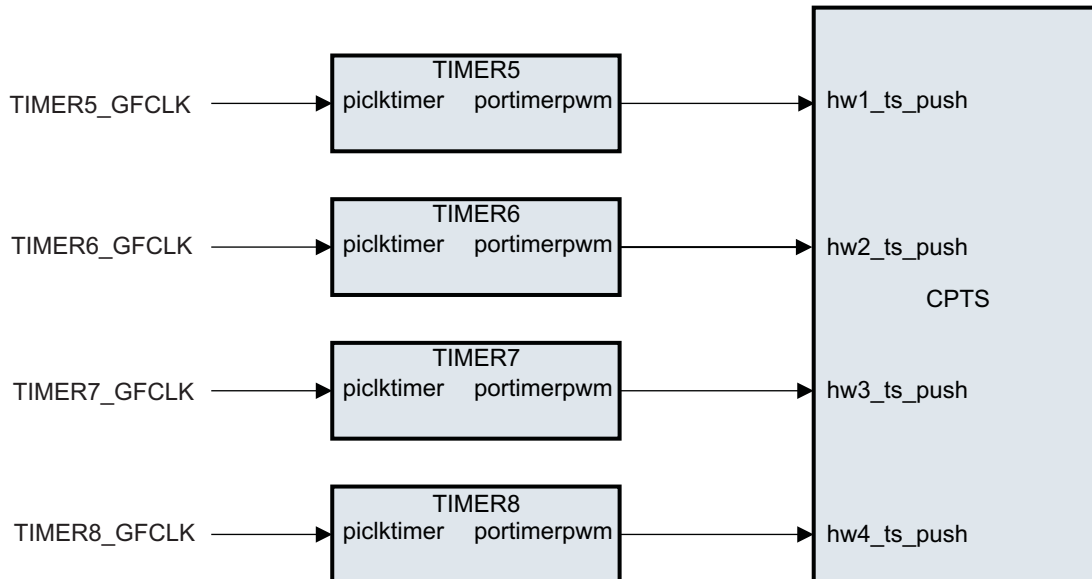

Figure 19-169. Event FIFO Misalignment Condition

19.8.4.10.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in [Figure 19-170](#).

Figure 19-170. HW1/4_TSP_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the [CPTS_EVENT_HIGH](#) register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the [CPTS_CONTROL](#) register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

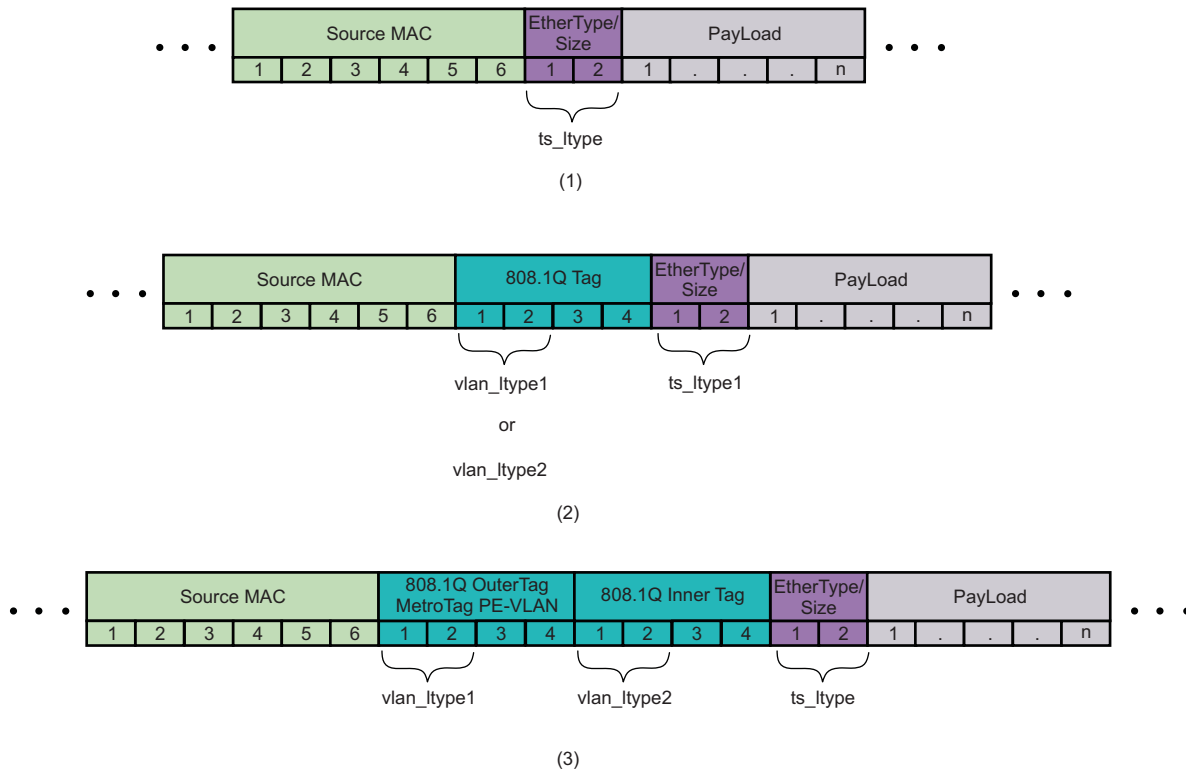

19.8.4.10.5.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the Payload field, as shown in [Figure 19-171](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field or the TS_LTYPE2 field (depending on which enable bit was set) in the [CPSW_TS_LTYPE](#) register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 19-171](#). To indicate to the CPTS hardware that a virtual LAN is in use, the Pn_TS_VLAN_LTYPE1_EN (or Pn_TS_VLAN_LTYPE2_EN) enable bit must be set in the Pn_CONTROL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the VLAN_LTYPE1 (or VLAN_LTYPE2 depending on which enable bit was set) field in the [CPSW_VLAN_LTYPE](#) register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in [Figure 19-171](#). In this case, both VLAN_LTYPE1 and VLAN_LTYPE2 must be enabled. The outer tag must match the value of the VLAN_LTYPE1 field, and the inner tag must match the value of the VLAN_LTYPE2 field.

Figure 19-171. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where *n* is the port number:

1. Set the [1] `Pn_TS_TX_EN` or the [0] `Pn_TS_RX_EN` bit in the `Pn_CONTROL` register to enable transmit/receive event packets
2. Configure the register fields as follows:
 1. Set the `Pn_CONTROL[2] Pn_TS_LTYPE1_EN` or [3] `Pn_TS_LTYPE2_EN` bit to 1
 2. Set the `CPSW_TS_LTYPE[15:0] TS_LTYPE1` or [31:16] `TS_LTYPE2` (depending on which enable bit was set in 2(a)) field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
 3. Set the `Pn_TS_SEQ_MTYPE[21:16] Pn_TS_SEQ_ID_OFFSET` field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
 1. Set the [20] `Pn_TS_VLAN_LTYPE1_EN` or [21] `Pn_TS_VLAN_LTYPE2_EN` bit in the `Pn_CONTROL` register.
 2. Set the `CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1` or [31:16] `VLAN_LTYPE2` field (matching what was used in step 3a) to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
 1. Set the `Pn_TS_VLAN_LTYPE1_EN` and `Pn_TS_VLAN_LTYPE2_EN` bits in the `Pn_CONTROL` register.
 2. Set the `VLAN_LTYPE1` field in the `CPSW_VLAN_LTYPE` register to match the EtherType of the outer tag.
 3. Set the `VLAN_LTYPE2` field in the `CPSW_VLAN_LTYPE` register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the `Pn_TS_SEQ_MTYPE[15:0] Pn_TS_MSG_TYPE_EN` field to choose which types of time stamp messages will push events onto the Event FIFO. Table 9-20 lists the message types defined in the

IEEE 1588-2008 specification. [Table 19-824](#) lists the message types defined in the IEEE 1588-2008 specification.

Table 19-824. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The [CPTS_EVENT_HIGH](#) register contains the Message Type and Sequence ID values from the original time sync packet. The [CPTS_EVENT_LOW](#) register contains the time stamp value when the packet arrived at the corresponding port.

19.8.4.10.6 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the [CPTS_INT_ENABLE](#) register.
2. Upon interrupt, read the [CPTS_EVENT_LOW](#) and [CPTS_EVENT_HIGH](#) registers values.
3. Set the EVENT_POP field (bit 0) of the [CPTS_EVENT_POP](#) register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the [CPTS_INT_ENABLE](#) register.
2. Upon interrupt, read the [CPTS_EVENT_LOW](#) and [CPTS_EVENT_HIGH](#) registers values.
3. Set the EVENT_POP bit of the [CPTS_EVENT_POP](#) register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four CPTS_RFT_CLK periods plus four MAIN_CLK periods.
5. Read the TS_PEND_RAW bit in the [CPTS_INTSTAT_RAW](#) register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the [CPTS_INTSTAT_RAW](#) register to determine if a valid event is on the event FIFO.

19.8.4.11 CPPI Buffer Descriptors

The buffer descriptor is a central part of the GMAC_SW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Host Software sends and receives network frames via the CPPI compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

NOTE: The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 0x4848 6000 and end at 0x4848 7FFF from the GMAC_SW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use this address range.

19.8.4.11.1 TX Buffer Descriptors

A TX buffer descriptor (Table 19-825) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 19-825. TX Buffer Descriptor Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

19.8.4.11.1.1 CPPI TX Data Word 0

Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

19.8.4.11.1.2 CPPI TX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the `buffer_pointer`. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

19.8.4.11.1.3 CPPI TX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the `Buffer_Offset` value (which may be zero to the buffer length minus 1). Valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the `Buffer_Length` field. The host sets the `Buffer_Length`. The `Buffer_Length` must be greater than zero.

19.8.4.11.1.4 CPPI TX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the `Buffer_Length` fields should equal the `Packet_Length`. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

Ownership (OWNER) Flag

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

TO_PORT

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

1 - Send the packet to port 1 if TO_PORT_EN is asserted.

2 - Send the packet to port 2 if TO_PORT_EN is asserted.

TO_PORT_ENABLE

Indicates when set that the packet is a directed packet to be sent to the TO_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

0 - not a directed packet

1 - directed packet

19.8.4.11.2 RX Buffer Descriptors

A RX buffer descriptor ([Table 19-826](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 19-826. RX Buffer Descriptor Format

19.8.4.11.2.1 CPPI RX Data Word 0

Next Descriptor Pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next_Descriptor_Pointer.

19.8.4.11.2.2 CPPI RX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer_Pointer.

19.8.4.11.2.3 CPPI RX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer_Offset with the value from the CPDMA_RX_BUFFER_OFFSET register value. The host initializes the Buffer_Offset to zero for free buffers. The Buffer_Length must be greater than the CPDMARX_BUFFER_OFFSET register value. The buffer offset is valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer_Length must be greater than zero.

19.8.4.11.2.4 CPPI RX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL). The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the [SL_MACCONTROL](#) register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the [SL_MACCONTROL](#) register.

Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the [SL_MACCONTROL](#) register.

Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

Packet Error (PKT_ERR) Flag

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

VLAN Encapsulated Packet (RX_VLAN_ENCAP)

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the [CPSW_CONTROL](#) register RX_VLAN_ENCAP bit.

FROM_PORT

Indicates the port number that the packet was received on (ingress to the switch).

19.8.4.12 MDIO

The MII Management interface module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers ([MDIO_USERACCESS0/MDIO_USERACCESS1](#)) control and monitor up to two PHYs simultaneously.

19.8.4.12.1 MDIO Frame Formats

[Table 19-827](#) shows the read format and [Table 19-828](#) shows the write format of the 32-bit MII Management interface frames.

Table 19-827. MDIO Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 19-828. MDIO Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

19.8.4.12.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the [MDIO_CONTROL](#) register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the [MDIO_LINK](#) register. The LINKSEL bit in the [MDIO_USERPHYSEL0/1](#) register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the [MDIO_LINKINTRAW](#) register and the [MDIO_LINKINTMASKED](#) register, if enabled by the LINKINT_ENABLE bit in the [MDIO_USERPHYSEL0/1](#) register.

The [MDIO_ALIVE](#) register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the [MDIO_ALIVE](#) register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a [MDIO_USERACCESS0/1](#) register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the [MDIO_USERINTRAW](#) register corresponding to the [MDIO_USERACCESS0/1](#) register being used. The corresponding bit in the [MDIO_USERINTMASKED](#) register may also be set depending on the mask setting in the [MDIO_USERINTMASKSET](#) and [MDIO_USERINTMASKCLR](#) registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different [MDIO_USERACCESS0/1](#) registers. The host should check the status of the GO bit in the [MDIO_USERACCESS0/1](#) register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the [MDIO_USERACCESS0/1](#) register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the [SL_MACCONTROL](#) register in the corresponding MAC.

19.8.5 GMAC_SW Programming Guide

19.8.5.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

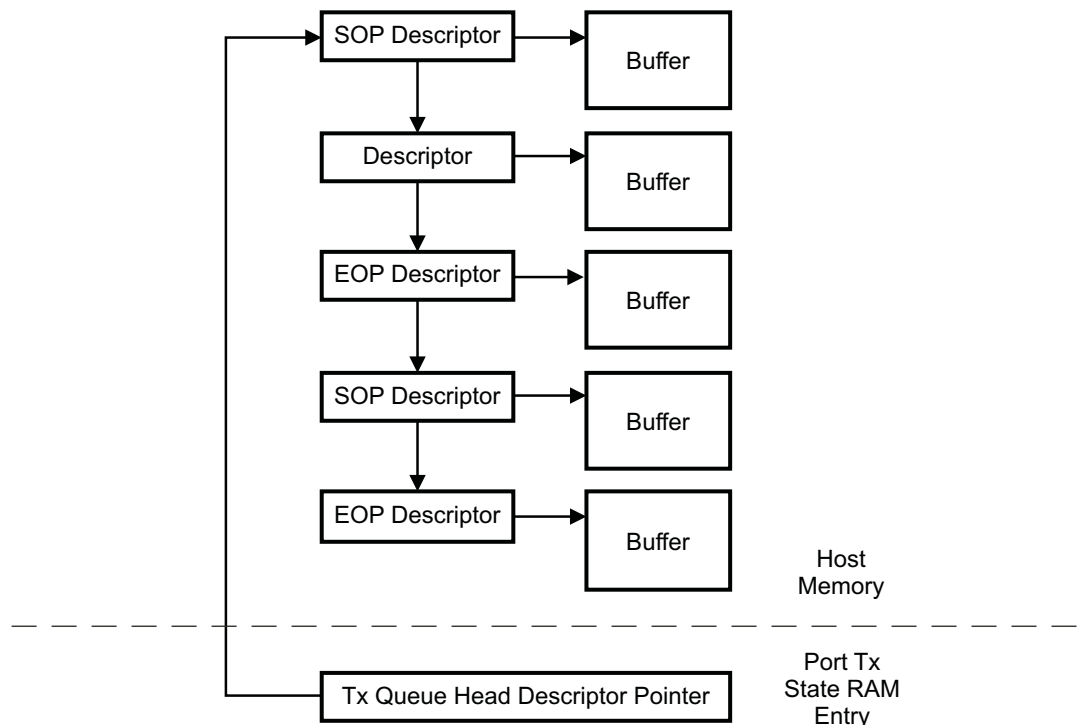

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (RAM). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

Figure 19-172. TX Queue Head Descriptor

19.8.5.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

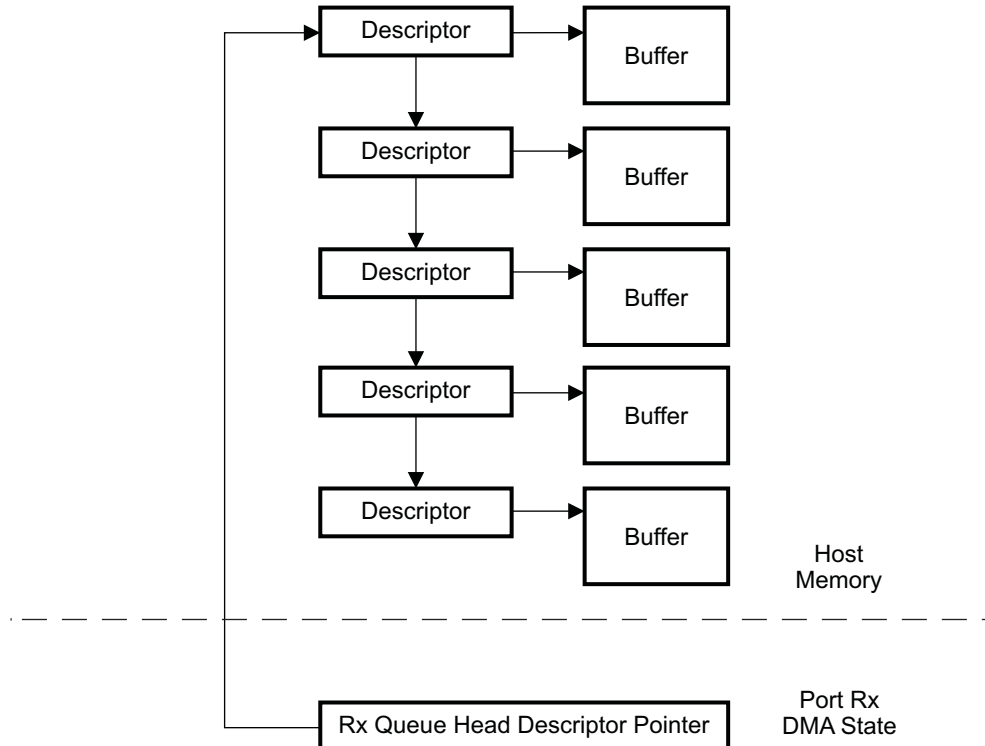

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value

will be less than or equal to the host initialized value.

2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.
5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

Figure 19-173. RX Queue Head Descriptor

19.8.5.3 MDIO Software Interface

19.8.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register ([MDIO_CONTROL](#)).
2. Enable the MDIO module by setting the ENABLE bit in [MDIO_CONTROL](#).
3. The MDIO PHY alive status register ([MDIO_ALIVE](#)) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register ([MDIO_LINK](#)) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register ([MDIO_USERPHYSEL0/1](#)), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register ([MDIO_USERINTMASKSET](#)) to use the MDIO user access register ([MDIO_USERACCESS0/1](#)). Since only one PHY is used in this device, the application software can use one [MDIO_USERACCESS0/1](#) to trigger a completion interrupt; the other [MDIO_USERACCESS0/1](#) is not setup.

19.8.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register ([MDIO_USERACCESS0/1](#)) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register ([MDIO_USERACCESS0/1](#)) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in [MDIO_USERACCESS0/1](#) corresponding to the PHY and PHY register you want to write.

3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in [MDIO_USERACCESS0/1](#) for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register ([MDIO_USERINTRAW](#)) corresponding to [MDIO_USERACCESS0/1](#) used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register ([MDIO_USERINTMASKSET](#)), then the bit is also set in the MDIO user command complete interrupt register ([MDIO_USERINTMASKED](#)) and an interrupt is triggered on the host processor.

19.8.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register ([MDIO_USERACCESS0/1](#)) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register ([MDIO_USERACCESSn](#)) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in [MDIO_USERACCESS0/1](#) corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in [MDIO_USERACCESS0/1](#) after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in [MDIO_USERACCESS0/1](#). After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register ([MDIO_USERINTRAW](#)) corresponding to [MDIO_USERACCESS0/1](#) used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register ([MDIO_USERINTMASKSET](#)), then the bit is also set in the MDIO user command complete interrupt register ([MDIO_USERINTMASKED](#)) and an interrupt is triggered on the host processor.

19.8.5.4 Initialization and Configuration of CPSW

To configure the GMAC_SW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RGMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the GMAC_SW Ethernet Subsystem Clocks
4. Configure the PRCM registers [CM_GMAC_CLKSTCTRL](#) and [CM_GMAC_GMAC_CLKCTRL](#) to enable power and clocks to GMAC_SW Ethernet Subsystem.
5. Apply Soft Reset to GMAC_SW Subsystem, [CPSW_3G](#), [CPGMAC_SL1/2](#), and [CPDMA](#)
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the [CPSW_CONTROL](#) register
9. Configure the [CPSW_STAT_PORT_EN](#) register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure [CPGMAC_SL1](#) and [CPGMAC_SL2](#), as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

Table 19-938. P2_MAX_BLKs

Address Offset	0x0000 0208		
Physical Address	0x4848 4308	Instance	PORT
Description	CPSW PORT 2 maximum FIFO blocks register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																P2_TX_MAX_BLKs				P2_RX_MAX_BLKs											

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x0
8:4	P2_TX_MAX_BLKs	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of P2_TX_MAX_BLKs unless the port is in fullduplex flow control mode. In flow control mode, the P2_RX_MAX_BLKs will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P2_RX_MAX_BLKs. 0xE is the minimum value P2_TX_MAX_BLKs.	RW	0x11
3:0	P2_RX_MAX_BLKs	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The P2_TX_MAX_BLKs value must be decreased by the amount of increase in P2_RX_MAX_BLKs. 0x3 is the minimum value P2_RX_MAX_BLKs and 0x6 is the maximum value.	RW	0x3

RESERVED																SOFT_RESET															

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SOFT_RESET	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.	RW	0x0

RESERVED																TX_RLIM												RESERVED	RX_CEF	CMD_IDLE	RX_OFFLEN_BLOCK	RX_OWNERSHIP	TX_PTYPE

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:8	TX_RLIM	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set MSB towards LSB. TX_PTYPE must be set if any TX_RLIM bit is set for fixed priority.	RW	0x0
7:5	RESERVED		R	0x0
4	RX_CEF	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 - Frames containing overrun errors are filtered. 1 - Frames containing overrun errors are transferred to memory.	RW	0x0
3	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in CPDMA_DMASTATUS)	RW	0x0
2	RX_OFFLEN_BLOCK	Receive Offset/Length word write block. 0 - Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1 - Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.	RW	0x0
1	RX_OWNERSHIP	Receive Ownership Write Bit Value. 0 - The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. 1 - The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.	RW	0x0
0	TX_PTYPE	Transmit Queue Priority Type 0 - The queue uses a round robin scheme to select the next channel for transmission. 1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission	RW	0x0

Description	CPDMA_REGS CPDMA status register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
RESERVED								TX_HOST_ERR_CODE				RESERVED		TX_ERR_CH				RX_HOST_ERR_CODE				RESERVED		RX_ERR_CH				RESERVED							

Bits	Field Name	Description	Type	Reset
31	IDLE	Idle Status Bit - Indicates when set that the CPDMA is not transferring a packet on transmit or receive.	R	0x0
30:24	RESERVED		R	0x0
23:20	TX_HOST_ERR_CODE	TX Host Error Code - This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected. 0x0 - No error 0x1 - SOP error. 0x2 - Ownership bit not set in SOP buffer. 0x3 - Zero Next Buffer Descriptor Pointer Without EOP 0x4 - Zero Buffer Pointer. 0x5 - Zero Buffer Length 0x6 - Packet Length Error (sum of buffers is less than packet length) 0x7 - 1xF - reserved	R	0x0
19	RESERVED		R	0x0
18:16	TX_ERR_CH	TX Host Error Channel - This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read.	R	0x0
15:12	RX_HOST_ERR_CODE	RX Host Error Code - This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. 0x0 - No error 0x1 - reserved 0x2 - Ownership bit not set in input buffer. 0x3 - reserved 0x4 - Zero Buffer Pointer. 0x5 - Zero buffer length on non-SOP descriptor 0x6 - SOP buffer length not greater than offset 0x7 - 1xF - reserved	R	0x0
11	RESERVED		R	0x0
10:8	RX_ERR_CH	RX Host Error Channel - This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read.	R	0x0
7:0	RESERVED		R	0x0

Table 19-995. CPDMA_RX_BUFFER_OFFSET

Address Offset	0x0000 0028	Instance	CPDMA
Physical Address	0x4848 4828		
Description	CPDMA_REGS receive buffer offset		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RX_BUFFER_OFFSET															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_BUFFER_OFFSET	Receive Buffer Offset Value - The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_FREEBUFFER	Rx Free Buffer Count - This field contains the count of free buffers available. The CPDMA_RX0_PENDTHRESH[7:0] RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.	W	0x0

Table 19-1104. PAUSE_TX_FRAMES

Address Offset	0x0000 0040	Instance	STATS
Physical Address	0x4848 4940		
Description	This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count. Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic. Transmitted pause frames are always 64 byte multicast frames so will appear in the MULTICAST_TX_FRAMES and RX_TX_64_OCTET_FRAMES statistics.

Table 19-1138. RX_START_OF_FRAME_OVERRUNS

Address Offset	0x0000 0084
Physical Address	0x4848 4984
Description	<p>The total number of frames received on the port that had a CPDMA start of frame (SOF) overrun or were dropped by due to FIFO resource limitations, or were dropped by the SPF. SOF overrun frame is defined to be:</p> <ul style="list-style-type: none"> - Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Any length (including less than 64 bytes and greater than SL_RX_MAXLEN[13:0] RX_MAXLEN bytes) - The CPDMA had a start of frame overrun or the packet was dropped due to FIFO resource limitations

RESERVED																	TS_PUSH														

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	TS_PUSH	Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.	W	0x0

RESERVED																															EVENT_POP

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	EVENT_POP	Event Pop - When a logic high is written to this bit an event is popped off the event FIFO. The event FIFO pop occurs as part of the interrupt process after the event has been read in the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers. Popping an event discards the event and causes the next event, if any, to be moved to the top of the FIFO ready to be read by software on interrupt.	W	0x0

Table 19-1235. ALE_CONTROL

Address Offset	0x0000 0008	Instance	ALE
Physical Address	0x4848 4D08		
Description	Address lookup engine control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENABLE_ALE	CLEAR_TABLE	AGE_OUT_NOW	RESERVED													EN_P0_UNI_FLOOD	LEARN_NO_VID	EN_VID0_MODE	ENABLE_OUI_DENY	BYPASS	RATE_LIMIT_TX	VLAN_AWARE	ENABLE_AUTH_MODE	ENABLE_RATE_LIMIT							

Bits	Field Name	Description	Type	Reset
31	ENABLE_ALE	Enable ALE - 0 - Drop all packets 1 - Enable ALE packet processing	RW	0x0
30	CLEAR_TABLE	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.	RW	0x0
29	AGE_OUT_NOW	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.	RW	0x0

Bits	Field Name	Description	Type	Reset
28:9	RESERVED		R	0x0
8	EN_P0_UNI_FLOOD	Enable Port 0 (Host Port) unicast flood 0 - do not flood unknown unicast packets to host port (p0) 1 - flood unknown unicast packets to host port (p0)	RW	0x0
7	LEARN_NO_VID	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID).	RW	0x0
6	EN_VID0_MODE	Enable VLAN ID = 0 Mode 0 - Process the packet with VID = PORT_VLAN[11:0]. 1 - Process the packet with VID = 0.	RW	0x0
5	ENABLE_OUI_DENY	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.	RW	0x0
4	BYPASS	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).	RW	0x0
3	RATE_LIMIT_TX	Rate Limit Transmit mode - 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based.	RW	0x0
2	VLAN_AWARE	ALE VLAN Aware - Determines what is done if VLAN not found. 0 - Flood if VLAN not found 1 - Drop packet if VLAN not found	RW	0x0
1	ENABLE_AUTH_MODE	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode	RW	0x0
0	ENABLE_RATE_LIMIT	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.	RW	0x0

Address Offset	0x0000 0004	
Physical Address	0x4848 4D84 0x4848 4DC4	Instance SL1 SL2
Description	CPGMAC_SL MAC control register	
Type	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RX_CMF_EN	RX_CSF_EN	RX_CEF_EN	TX_SHORT_GAP_LIM_EN	RESERVED	EXT_EN	GIG_FORCE	IFCTL_B	IFCTL_A	RESERVED	CMD_IDLE	TX_SHORT_GAP_EN	RESERVED	GIG	TX_PACE	GMII_EN	TX_FLOW_EN	RX_FLOW_EN	MTEST	LOOPBACK	FULLDUPLEX			

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x0
24	RX_CMF_EN	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the SL_MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the control bit set in their EOP buffer descriptor. 0 - MAC control frames are filtered (but acted upon if enabled). 1 - MAC control frames are transferred to memory.	RW	0x0

Bits	Field Name	Description	Type	Reset
23	RX_CSF_EN	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 - Short frames are filtered 1 - Short frames are transferred to memory.	RW	0x0
22	RX_CEF_EN	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF_EN is not set. 0 - Frames containing errors are filtered. 1 - Frames containing errors are transferred to memory.	RW	0x0
21	TX_SHORT_GAP_LIM_EN	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.	RW	0x0
20:19	RESERVED		R	0x0
18	EXT_EN	Control Enable - Enables the full duplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the FULLDUPLEX and GIG bits in this register. The FULLDUPLEX_MODE bit reflects the actual full duplex mode selected 0 - Use this setting for RMII/GMII mode . 1 - Use this setting for RGMII mode	RW	0x0
17	GIG_FORCE	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.	RW	0x0
16	IFCTL_B	Interface Control B (NOT FUNCTIONAL) 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
15	IFCTL_A	Interface Control A 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
14:12	RESERVED		R	0x0
11	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in SL_MACSTATUS)	RW	0x0
10	TX_SHORT_GAP_EN	Transmit Short Gap Enable 0 - Transmit with a short IPG is disabled 1 - Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.	RW	0x0
9:8	RESERVED		R	0x0
7	GIG	Gigabit Mode - 0 - 10/100 mode 1 - Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.	RW	0x0
6	TX_PACE	Transmit Pacing Enable 0 - Transmit Pacing Disabled 1 - Transmit Pacing Enabled	RW	0x0
5	GMII_EN	GMII Enable - 0 - GMII RX and TX held in reset. 1 - GMII RX and TX released from reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
4	TX_FLOW_EN	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0 - Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1 - Transmit Flow Control Enabled . Full-duplex mode - Incoming pause frames are acted upon.	RW	0x0
3	RX_FLOW_EN	Receive Flow Control Enable - 0 - Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1 - Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.	RW	0x0
2	MTEST	Manufacturing Test mode - This bit must be set to allow writes to the SL_BOFFTEST and SL_RX_PAUSE/SL_TX_PAUSE registers.	RW	0x0
1	LOOPBACK	Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. 0 - Not looped back 1 - Loop Back Mode enabled	RW	0x0
0	FULLDUPLEX	Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 - half duplex mode 1 - full duplex mode	RW	0x0

Address Offset	0x0000 0014			
Physical Address	0x4848 4D94 0x4848 4DD4	Instance	SL1 SL2	
Description	CPGMAC_SL backoff test register			
Type	RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	PACEVAL							RNDNUM							COLL_COUNT				RESERVED	TX_BACKOFF											

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30:26	PACEVAL	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce 'capture' effects improving overall network bandwidth.	RW	0x0
25:16	RNDNUM	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.	RW	0x0
15:12	COLL_COUNT	Collision Count - The number of collisions the current frame has experienced.	R	0x0
11:10	RESERVED		R	0x0
9:0	TX_BACKOFF	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.	R	0x0

Table 19-1287. MDIO_CONTROL

Address Offset	0x0000 0004	Instance	MDIO
Physical Address	0x4848 5004		
Description	MDIO Control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDLE	ENABLE	RESERVED	HIGHEST_USER_CHANNEL				RESERVED	PREAMBLE	FAULT	FAULTENB	INTTESTENB	RESERVED	CLKDIV																		

Bits	Field Name	Description	Type	Reset
31	IDLE	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state. 0: State machine is not in idle state. 1: State machine is in idle state.	R	0x0
30	ENABLE	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the IDLE bit. If using byte access, the ENABLE bit has to be the last bit written in this register. 0: Disables the MDIO state machine. 1: Enable the MDIO state machine.	RW	0x0
29	RESERVED		R	0x0
28:24	HIGHEST_USER_CHANNEL	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that the MDIO_USERACCESS1 register is the highest available user access channel.	R	0x0

Bits	Field Name	Description	Type	Reset
23:21	RESERVED		R	0x0
20	PREAMBLE	Preamble disable. 0: Standard MDIO preamble is used. 1: Disables this device from sending MDIO frame preambles.	RW	0x0
19	FAULT	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. 0: No failure. 1: Physical layer fault; the MDIO state machine is reset.	RW	0x0
18	FAULTENB	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. 0: Disables the physical layer fault detection. 1: Enables the physical layer fault detection.	RW	0x0
17	INTTESTENB	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. 0: Interrupt bits are not set. 1: Enables the host to set the USERINT and LINKINT bits for test purposes.	RW	0x0
16	RESERVED		R	0x0
15:0	CLKDIV	Clock divider. This field specifies the division ratio between ICLK and the frequency of MDCLK. MDCLK is disabled when CLKDIV is set to 0. MDCLK frequency = ICLK frequency/(CLKDIV+1).	RW	0x0

ALIVE																																																																																															
Bits	Field Name	Description	Type	Reset																																																																																											
31:0	ALIVE	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.	RW	0x0

LINK																															

Bits	Field Name	Description	Type	Reset
31:0	LINK	MDIO link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the MDIO_USERPHYSEL registers can be determined using the MLINK input pins (NOT PINNED OUT). This is determined by the LINKSEL bit in the MDIO_USERPHYSEL register.	R	0x0

RESERVED																LINKINTMASKED															

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0
1:0	LINKINTMASKED	MDIO link change interrupt, masked value. When asserted 1, a bit indicates that there was an MDIO link change event (i.e. change in the MDIO Link register) corresponding to the PHY address in the MDIO_USERPHYSEL register and the corresponding LINKINTENB bit was set. LINKINTMASKED[0] and LINKINTMASKED[1] correspond to MDIO_USERPHYSEL0 and MDIO_USERPHYSEL1 , respectively. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIO_CONTROL register is set, the host may set the LINKINT bits to a 1. This mode may be used for test purposes.	RW	0x0

RESERVED																SPF_LOGOW_EN	SPF_LOG_EN	RESERVED				SPF_RULE_LOG	SPF_EXT_BYPASS	SPF_DROP	SPF_ENABLE						

Bits	Field Name	Description	Type	Reset
31:10	RESERVED		R	0x0
9	SPF_LOGOW_EN	SPF Log Overwrite Enable. Setting this bit will cause SPF to overwrite previously logged data whether or not software has updated the software_working_pointer. Overwriting only occurs if there is new data but no space to write it in the space indicated by log_start_address and log_end_address.	RW	0x0
8	SPF_LOG_EN	SPF Log Enable. Setting this bit will allow SPF to log information about dropped packets to memory.	RW	0x0
7:4	RESERVED		R	0x0
3	SPF_RULE_LOG	SPF Rule Engine Log Enable. Setting this bit will allow SPF to log data from rule engine. The default is log data from extractor.	RW	0x0
2	SPF_EXT_BYPASS	SPF Extractor Bypass Enable. The extractor will not provide any offset information to rule engine if this bit is set. The rule engine must load each of the base registers it intends to use to determine if the packet should be discarded.	RW	0x0
1	SPF_DROP	SPF Drop Enable. This bit must be set to activate packet drops.	RW	0x0
0	SPF_ENABLE	SPF Enable. This bit must be set to enable any operation in SPF. The SPF instruction memory can only be accessed by host processor when the spf_enable is deasserted. Once spf_enable is set, writing a zero to this bit will only take effect when spf_busy signal is low. This ensures that spf stops only on packet boundaries.	RW	0x0

SDIO Controller

This chapter describes the features and functions of the SDIO interface of the device.

Topic	Page
20.1 SDIO Overview	6167
20.2 SDIO Environment	6169
20.3 SDIO Integration	6173
20.4 SDIO Functional Description	6176
20.5 SDIO Programming Guide	6197
20.6 SDIO Register Manual	6213

20.1 SDIO Overview

The SDIO host controller provides an interface between a local host (LH) such as a microprocessor unit or digital signal processor and SDIO cards. It handles SDIO transactions with minimal LH intervention.

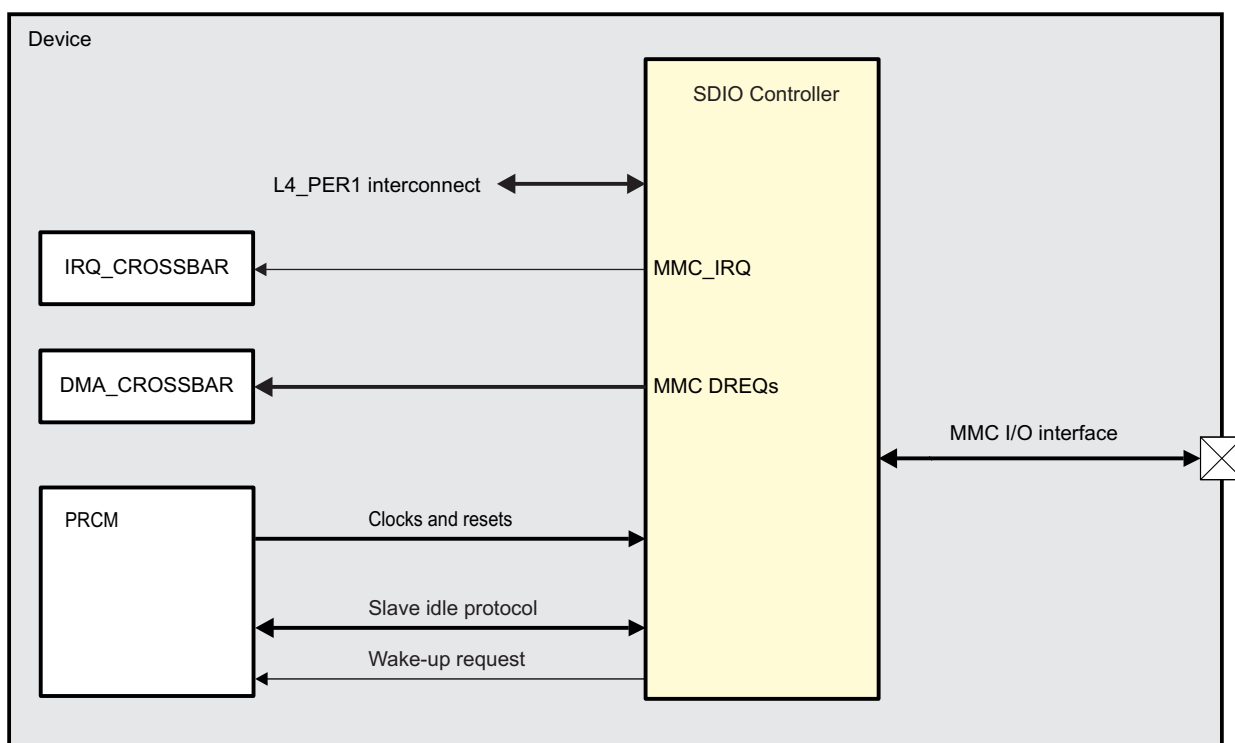

The SDIO host controller deals with SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The SDIO host controller also supports two slave DMA channels.

The SDIO controller is also referred to as MMC. [Figure 20-1](#) shows an overview of the SDIO controller.

Figure 20-1. SDIO Overview

mmchs-001

20.1.1 SDIO Features

This section describes the features supplied by the SDIO controller.

Compliance with standards:

- SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v3.00
- SD command/response sets as defined in the SD Physical Layer specification v3.01
- SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v3.00

Main features of the SDIO host controller:

- Flexible architecture allowing support for new command structure
- 32-bit wide access bus to maximize bus throughput
- Designed for low power
- Programmable clock generation

- L4 slave interface supports:
 - 32-bit data bus width
 - 8/16/32 bit access supported
 - 9-bit address bus width
 - Streaming burst supported only with burst length up to 7
 - WNP supported
- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Supported data transfer rates up to SDR25 mode
- The SDIO controller is connected to 1,8V/3.3V compatible I/Os to support 1,8V/3.3V signaling

The differences between the SDIO host controller and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v3.00* are:

- The clock divider in the SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications, v3.0*. The SDIO host controller supports odd and even clock ratios.
- The SDIO host controller supports configurable busy time-out.
- There is no external LED control.

20.2 SDIO Environment

Figure 20-2 shows the SDIO host controller environment.

Figure 20-2. SDIO Controller Environment

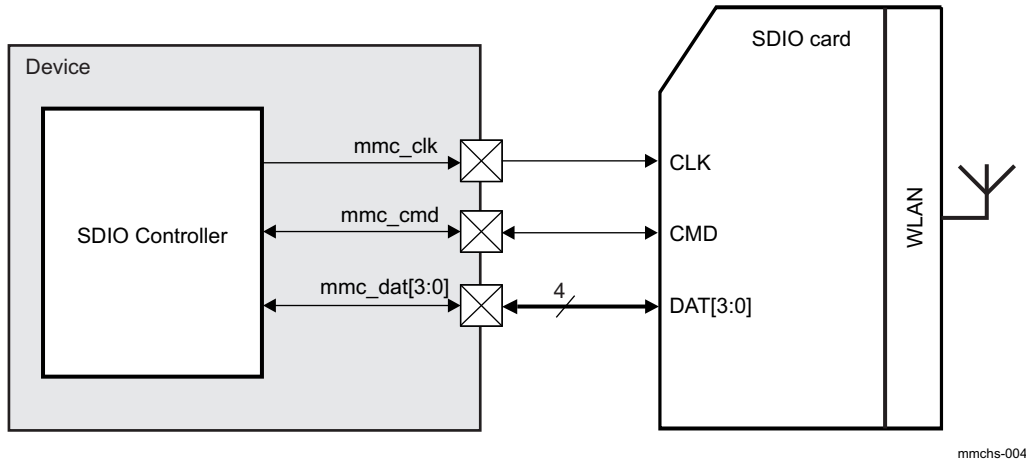

Table 20-1 describes the SDIO host controller I/O's.

Table 20-1. Description of SDIO host controller I/O's

Instance	Signal name	Direction	Description
MMC	mmc_clk	O	External clock for SDIO card
	mmc_cmd	I/O	Command line
	mmc_dat[3:0]	I/O	Data signals

NOTE: For the mmc_clk signal to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 by software. This is because the SDIO controller uses the input from the pad as loopback clock, which the controller can use for read capture.

20.2.1 Protocol and Data Format

The bus protocol between the SDIO host controller and the card is message-based. Each message is represented by one of the following parts:

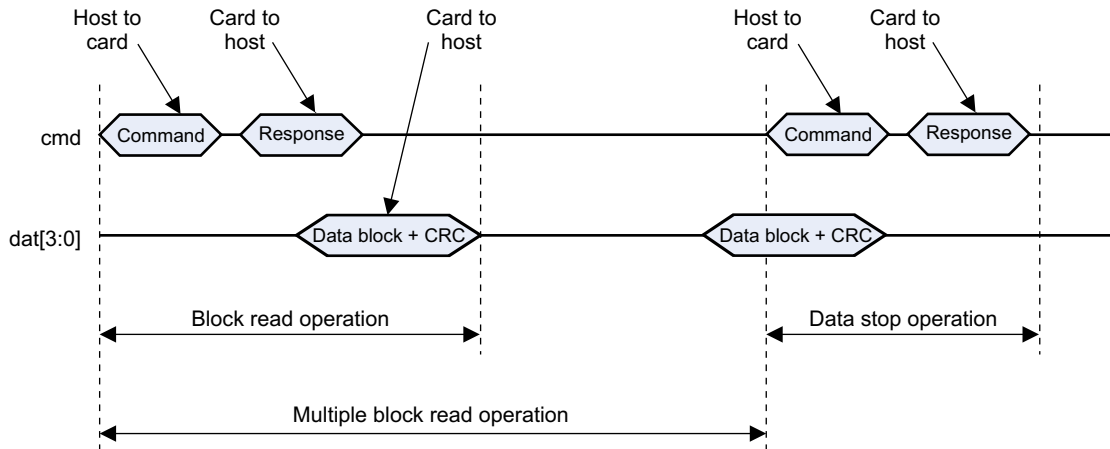

- **Command:** A command starts an operation. The command is transferred serially from the SDIO host controller to the card on the CMD line.
- **Response:** A response is an answer to a command. The response is sent from the card to the SDIO host controller. It is transferred serially on the CMD line.
- **Data:** Data are transferred from the SDIO host controller to the card or from a card to the SDIO host controller using the data lines.
- **Busy:** The DAT[0] signal is maintained low by the card as far as it is programming the data received.
- **CRC status:** The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

20.2.1.1 Protocol

There are specific commands for block-oriented operation. For information about commands and programming sequences, see the *SDIO Card Specification (Part E1)*.

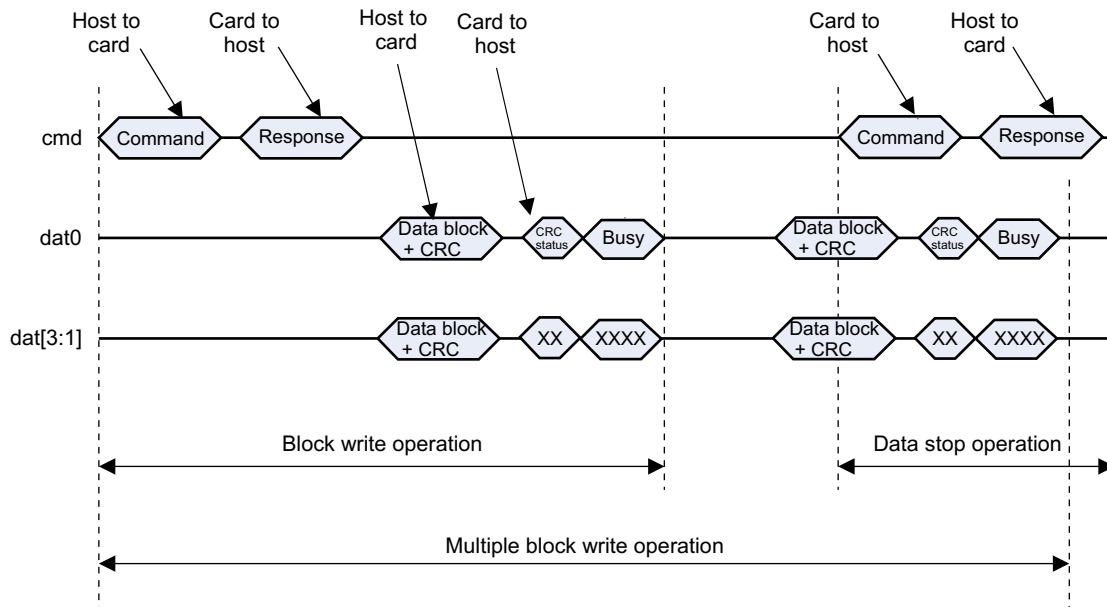

Figure 20-3 and Figure 20-4 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmc_cmd line.

Figure 20-3. Multiple Block Read Operation

mmchs-008

Figure 20-4. Multiple Block Write Operation With Card Busy Signal

mmchs-009

NOTE:

- The card busy signal is not always generated by the card; refer to Figure 20-3 and Figure 20-4, that show a particular case.
- Software must perform a software reset (set the MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure that CLK is stopped.

20.2.1.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 20-5](#)).

Figure 20-5. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7) and the content is protected by 7-bit CRC checksum (see [Figure 20-6](#) and [Figure 20-7](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 20-2](#)). For more information about response types, see the *SD Memory Card Specifications*, and *SDIO Card Specification*.

Figure 20-6. Response Token Format (R1, R3, R4, R5, R6, R7)

Figure 20-7. Response Token Format (R2)

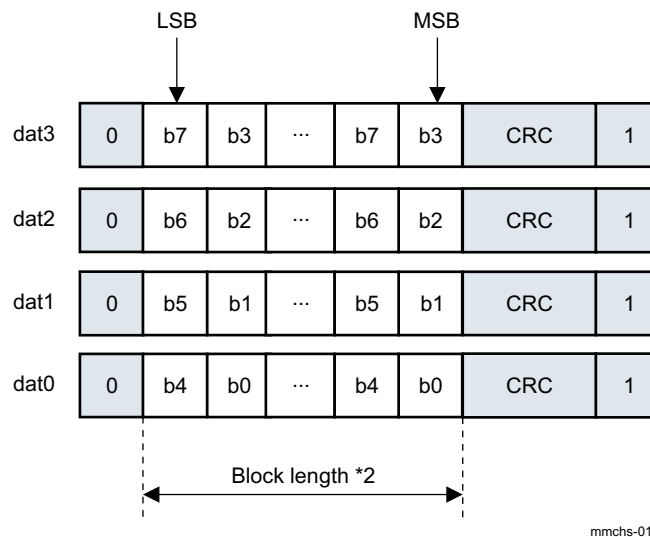

Table 20-2. Relationship Between Configuration and Name of Response Type

Response Type MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCHS_CMD[20] CICE	CRC Check Enable MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 20-8](#) and [Figure 20-9](#)).

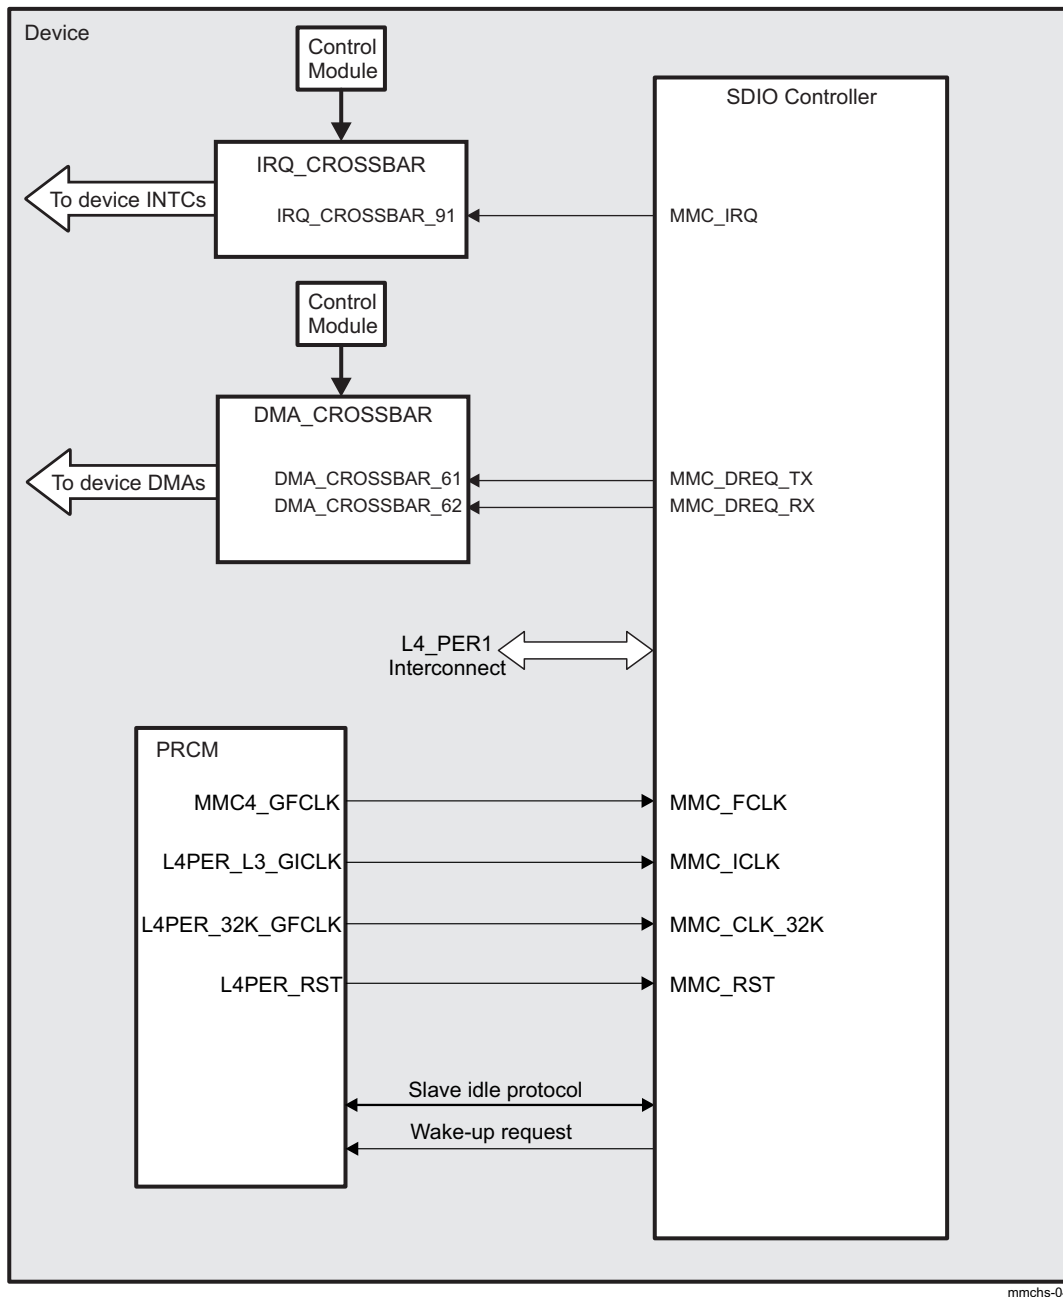

Figure 20-8. Data Token Format for 1-Bit Transfers

Figure 20-9. Data Token Format for 4-Bit Transfers

20.3 SDIO Integration

This section describes the integration of the SDIO controller in the device, including information about clocks, resets, and hardware requests.

Figure 20-10 shows the integration of the SDIO controller which is connected to the L4_PER1 interconnect and act as a slave only.

Figure 20-10. SDIO Integration

mmchs-045

NOTE: For more information about the slave idle protocol and the wake-up request, see [Section 3.1.1, Device Power-Management Architecture Building Blocks](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 20-3 through Table 20-5 summarize the integration of the module in the device.

Table 20-3. SDIO Controller Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
MMC	PD_COREAON	L4_PER1

Table 20-4. SDIO Controller Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MMC	MMC_ICLK	L4PER_L3_GICLK	PRCM	SDIO controller interface clock
	MMC_FCLK	MMC4_GFCLK	PRCM	SDIO controller functional clock
	MMC_CLK_32K	L4PER_32K_GFCLK	PRCM	SDIO controller debounce clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MMC4	MMC_RST	L4PER_RST	PRCM	Reset to the SDIO controller

Table 20-5. SDIO Controller Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
MMC	MMC_IRQ	IRQ_CROSSBAR_91	-	SDIO controller interrupt request. This IRQ source signal is not mapped by default to any device INTC.
DMA Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
MMC	MMC_DREQ_TX	DMA_CROSSBAR_61	DMA_EDMA_DREQ_6 0	SDIO Controller DMA transmit request
	MMC_DREQ_RX	DMA_CROSSBAR_62	DMA_EDMA_DREQ_6 1	SDIO Controller DMA receive request

NOTE: The “Default Mapping” column in [Table 20-5 SDIO Controller Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controller, see [Chapter 13, Interrupt controller](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

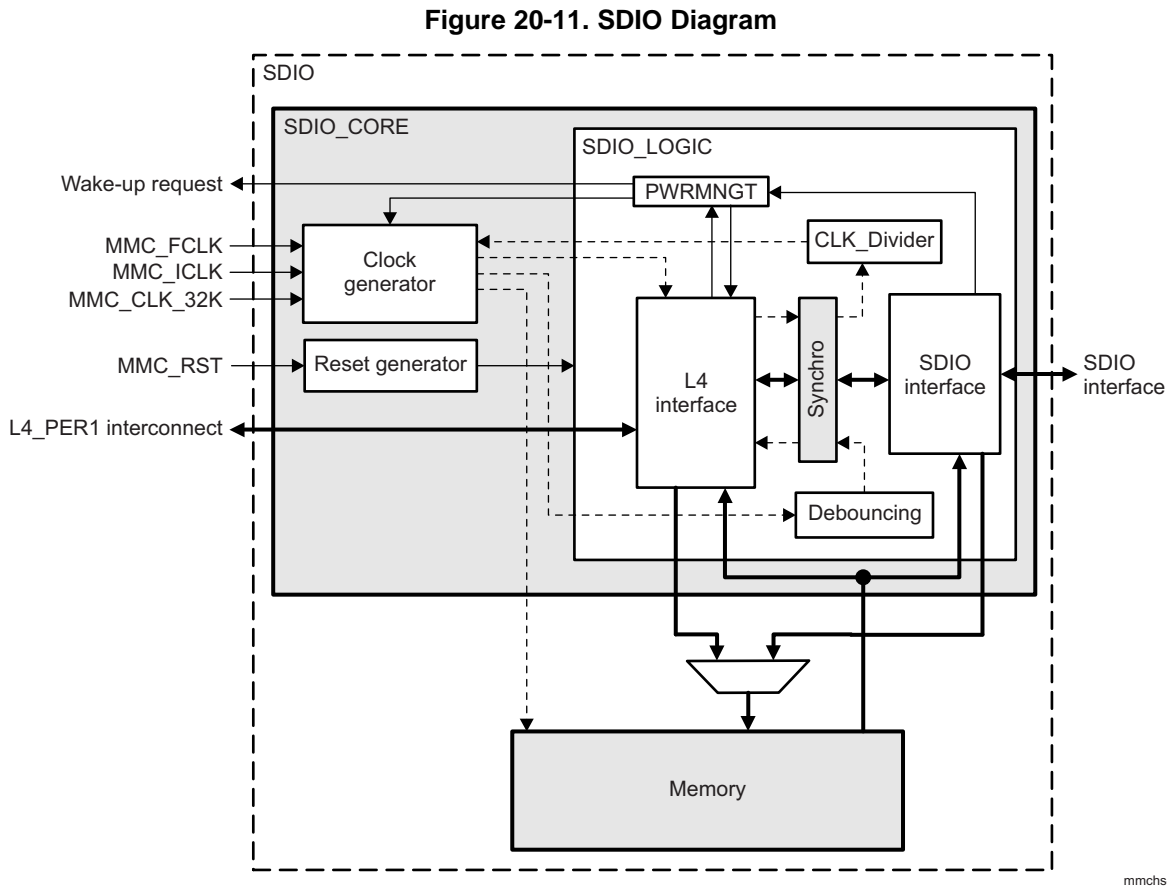

NOTE:

- For a description of the interrupt source, see [Section 20.4.4, Interrupt Requests](#).
- For a description of the DMA source, see [Section 20.4.5, DMA Modes](#).

20.4 SDIO Functional Description

20.4.1 Block Diagram

Figure 20-11 is a block diagram of the SDIO host controller.

mmchs-017

20.4.2 Resets

20.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see [Table 20-4](#) for more information about reset signals).

The `MMCHS_SYSSTATUS[0] RESETDONE` bit can be monitored by software to check whether the module is ready to use after a hardware reset.

NOTE: The functional clock (`MMC_FCLK`) and interface clock (`MMC_ICLK`) must be provided to the module to allow the `RESETDONE` status bit to be set.

The debounce clock (`MMC_CLK_32K`) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

20.4.2.2 Software Reset

The module is reinitialized by software through the `MMCHS_SYSCONFIG[1] SOFTRESET` bit. This bit has the same effect on the module logic as the hardware signal (`MMC_RST`), with the following exceptions:

- Debounce logic

- [MMCHS_PSTATE](#), [MMCHS_CAPA](#), and [MMCHS_CUR_CAPA](#) registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The [MMCHS_SYSCTL\[24\]](#) SRA bit has the same action on the design as the SOFTRESET bit.

The [MMCHS_SYSSTATUS\[0\]](#) RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- [MMCHS_SYSCTL\[26\]](#) SRD
- [MMCHS_SYSCTL\[25\]](#) SRC

These two reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The [MMCHS_SYSCTL\[26\]](#) SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The [MMCHS_SYSCTL\[25\]](#) SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

20.4.3 Power Management

The SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The SDIO host controller is compliant with the handshake protocol of the power, reset, and clock management (PRCM) module.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The [MMCHS_SYSCONFIG\[0\]](#) AUTOIDLE bit is set to 1.
- There is no transaction on the SDIO interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from SDIO card).
- A transaction on the SDIO interface starts.

Idle Mode

The MMC_ICLK and MMC_FCLK clocks provided to the SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The SDIO host controller complies with the handshaking protocol of the PRCM module:

- IDLE request from the system power manager
- Idle acknowledgment from the SDIO host controller
- Wake-up request from the SDIO host controller

The idle acknowledgment varies according to the [MMCHS_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field:

- 0x0: Force-idle mode. The SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events

when it is in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the SDIO host controller acknowledges that the MMC_ICLK and MMC_FCLK clocks may be switched off, regardless of the value set in the [MMCHS_SYSCONFIG\[9:8\] CLOCKACTIVITY](#) bit field.

The debounce clock must never be switched off by the system power manager in order to detect wake-up in idle mode.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the [MMCHS_SYSCONFIG\[4:3\] SIDLEMODE](#) bit field is set to 0x2 or 0x3.

The SDIO host controller goes into idle mode when the PRCM issues an IDLE request, according to its internal activity.

The SDIO host controller acknowledges the IDLE request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the DATA[1] signal.

As long as the SDIO controller does not acknowledge the IDLE request, if an event occurs, the SDIO host controller can still generate an interrupt or a DMA request. In this case, the module ignores the IDLE request from the PRCM module.

As soon as the SDIO controller acknowledges the IDLE request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when both the [MMCHS_SYSCONFIG\[2\] ENAWAKEUP](#) bit and [MMCHS_HCTL\[24\] IWE](#) bits are set to 0x1.

The [MMCHS_IE\[8\] CIRQ_ENABLE](#) bit must also be set to 0x1 before going in idle mode. Setting it to 0x1 enables the wakeup event detection. The source of wakeup can be identified after idle mode exiting by reading register [MMCHS_STAT](#)

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

[Table 20-6](#) lists the supported cases in smart-idle mode.

Table 20-6. Smart-Idle Mode and Wake-Up Capabilities

Mode	MMC_ICLK Clock	MMC_FCLK Clock	Wake-Up Event
Card interrupt	May be switched off ⁽¹⁾	May be switched off ⁽¹⁾	The module sends an asynchronous wake-up request when a card interrupt on the DATA[1] signal is detected.

⁽¹⁾ The SDIO host controller assumes that both clocks may be switched off, regardless of the value set in the [MMCHS_SYSCONFIG\[9:8\] CLOCKACTIVITY](#) bit field.

Transition From Smart-Idle Mode to Normal Mode

The SDIO host controller detects the end of the idle period when the PRCM module deasserts the IDLE request.

For the wake-up event, there is a corresponding interrupt status in the [MMCHS_STAT](#) register. The SDIO host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the [MMCHS_ISE](#) register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the [MMCHS_HCTL](#) and [MMCHS_ISE](#) registers. The overall consistency must be ensured by software.

The [MMCHS_STAT](#)[8] CIRQ bit is updated with the event that caused the wake-up when the [MMCHS_IE](#)[8] CIRQ_ENABLE bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into an interrupt or DMA request. (The [MMCHS_STAT](#) register is updated and the status of the interrupt signal is changed.)

When the IDLE request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the [MMCHS_SYSCONFIG](#)[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the SDIO host controller responds unconditionally to the IDLE request from the PRCM module. Moreover, in this mode, the SDIO host controller unconditionally deasserts interrupts and DMA request lines if they are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the [MMCHS_STAT](#) register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMC_ICLK and MMC_FCLK can be switched off.

CAUTION

In force-idle mode, an IDLE request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMC_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the IDLE request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Power Pad Control

The SDIO host controller has the ability to reduce the pad power leakage when no transfer is sent through the pad. According to the [MMCHS_CON](#)[15] PADEN there are two different pad power management modes: automatic and manual.

If [MMCHS_CON](#)[15] PADEN is set to 1, pads mmc_clk, mmc_cmd, mmc_dat[0], mmc_dat[2] and mmc_dat[3] are always powered on.

If [MMCHS_CON](#)[15] PADEN is set to 0, the power for pads mmc_clk, mmc_cmd, mmc_dat[0], mmc_dat[2] and mmc_dat[3] is "ON" only when there is a transfer on going. This is automatically managed by an internal state machine of the SDIO host controller.

The DAT[1] pad active state is controlled through [MMCHS_CON](#)[11] CTPL in order to detect SDIO asynchronous interrupt when there is no transaction.

The delay between pad power "ON" and the command transmission is controlled through the [MMCHS_PWCNT](#) register which act as a programmable counter. It is also used to delay the pad power "OFF" after the end of transmission. By default this counter is reset which means that no additional delay is added. But there is approximately 6-7 clock cycles margin between pad power "ON" and real start of the command due to an internal state machine of the SDIO host controller.

NOTE: The [MMCHS_PWCNT](#) register is considered as static. No dynamic configuration during the transfer is supported. This results in an unpredictable behavior.

Local Power Management

[Table 20-7](#) describes the power-management features available for the SDIO controller.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 20-7. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG [0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMC_ICLK clock upon the interface activity, or gating the MMC_FCLK clock upon the internal activity.
Slave-idle modes	MMCHS_SYSCONFIG [3:4] SIDLEMODE	Force-idle, No-idle, Smart-idle and Smart-idle wake-up-capable modes are available.
Clock activity	MMCHS_SYSCONFIG [8:9] CLOCKACTIVITY	For configuration details, see Table 20-8 .
Global wake-up enable	MMCHS_SYSCONFIG [2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

Table 20-8. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMC_ICLK	MMC_FCLK		
00	OFF	OFF	None	Card interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and SDIO clock PRCM control bits. For a description of the Clock activity feature, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

20.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the [MMCHS_STAT](#) register; it indicates which service is required.
- The interrupt status enable bits of the [MMCHS_IE](#) register enable or disable the automatic update of the [MMCHS_STAT](#) register on an event-by-event basis.
- The interrupt signal enable bits of the [MMCHS_ISE](#) register enable or disable the transmission of an interrupt request on the interrupt line MMC_IRQ on an event-by-event basis.

If an interrupt status is disabled in the [MMCHS_IE](#) register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the [MMCHS_ISE](#) register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the SDIO host controller updates the status bit) in the [MMCHS_STAT](#) register. If a mask is later applied on the interrupt in the [MMCHS_ISE](#) register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the **MMCHS_STAT** register and the corresponding mask is removed from the **MMCHS_ISE** register, the interrupt status is not asserted again in the **MMCHS_STAT** register and the SDIO host controller does not transmit an interrupt request.

NOTE: If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the **MMCHS_STAT** register, and the corresponding mask is removed, then the SDIO host controller waits for the service of the interrupt without updating the status **MMCHS_STAT** register or transmitting an interrupt request.

Table 20-9 lists the event flags, and their mask, that can cause module interrupts.

Table 20-9. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT [29] BADA	MMCHS_IE [29] BADA_ENABLE	MMC_IRQ	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE [11] BRE = 0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE [10] BWE = 0).
MMCHS_STAT [28] CERR	MMCHS_IE [28] CERR_ENABLE	MMC_IRQ	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.
MMCHS_STAT [24] ACE	MMCHS_IE [24] ACE_ENABLE	MMC_IRQ	Auto CMD12 error. This bit is set automatically when one of the bits MMCHS_AC12 [4:0] changes from 0 to 1.
MMCHS_STAT [22] DEB	MMCHS_IE [22] DEB_ENABLE	MMC_IRQ	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT [21] DCRC	MMCHS_IE [21] DCRC_ENABLE	MMC_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.
MMCHS_STAT [20] DTO	MMCHS_IE [20] DTO_ENABLE	MMC_IRQ	Data time-out error. This bit is set automatically according to the following conditions: <ul style="list-style-type: none"> • Busy time-out for R1b, R5b response type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out
MMCHS_STAT [19] CIE	MMCHS_IE [19] CIE_ENABLE	MMC_IRQ	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD [20] CICE bit.
MMCHS_STAT [18] CEB	MMCHS_IE [18] CEB_ENABLE	MMC_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.

Table 20-9. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMC_IRQ	Command CRC error. This bit is set automatically when a CRC7 error occurs in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMC_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMC_IRQ	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[31:16]) are set, this bit is set to 1.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMC_IRQ	Card interrupt. The interrupt source is sampled during the interrupt cycle.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMC_IRQ	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH must empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMC_IRQ	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMC_IRQ	Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMC_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). <ul style="list-style-type: none"> In read mode: This bit is automatically set when a read transfer completes (MMCHS_PSTATE[9] RTA). In write mode: This bit is automatically set when the DAT line use completes (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMC_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

NOTE: To send an interrupt request to the MMC_IRQ line, the mask/unmask bit must be set in the [MMCHS_IE](#) and [MMCHS_ISE](#) registers.

The SDIO host controller supports interrupt-driven operation and polling.

20.4.4.1 Interrupt-Driven Operation

An interrupt-enable bit must be set in the [MMCHS_IE](#) register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the [MMCHS_STAT](#) register to identify which event occurred.
2. Write 1 into the corresponding bit of the [MMCHS_STAT](#) register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

NOTE: In the [MMCHS_STAT](#) register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The [MMCHS_STAT](#)[8] CIRQ status bit must be masked by disabling the [MMCHS_IE](#)[8] CIRQ_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The [MMCHS_STAT](#)[15] ERRI bit is automatically cleared when all status bits in the [MMCHS_STAT](#) register (bits 31 through 16) are cleared.

20.4.4.2 Polling

When the interrupt capability of an event is disabled in the [MMCHS_ISE](#) register, the interrupt line is not asserted:

- Software can poll the status bit in the [MMCHS_STAT](#) register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the [MMCHS_STAT](#) register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the previous note concerning clearing of the CIRQ and ERRI bits.

20.4.4.3 Asynchronous Interrupt

Asynchronous interrupt is defined in *SDIO Card Specification version 3.00, part E*. This interrupt is effective in 4-bit mode and is generated without SD clock. Asynchronous interrupt period is defined in the synchronous interrupt period after the last data block and until a next command is received.

Asynchronous interrupt period in a multiple block write operation.

If [MMCHS_CAPA](#)[29] AIS is set to 0, writing to [MMCHS_AC12](#)[30] AI_ENABLE is ignored. This bit is set to 0. A synchronous interrupt period starts two clocks after the last data block. If [MMCHS_AC12](#)[30] AI_ENABLE is set to 1, the asynchronous interrupt period starts four clocks after the start of the synchronous interrupt period. Four clocks after the start bit of the next command, the asynchronous interrupt period ends and goes back to the synchronous interrupt period.

20.4.5 DMA Modes

The SDIO controller supports DMA slave mode. It is selected by setting the [MMCHS_CON](#)[20] DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMC_DMA_TX and MMC_DMA_RX).

20.4.5.1 Slave DMA Operations

The SDIO host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers.

The DMA request is issued if the following conditions are met:

- The [MMCHS_CMD](#)[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the CMD line.
- There is enough space in the buffer of the SDIO host controller to write an entire block (BLEN writes).

20.4.5.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal `MMC_DMA_RX` is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the [MMCHS_BLK](#)[10:0] BLEN bit field.

`MMC_DMA_RX` is deasserted to its inactive level when the a certain device DMA module reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of DMA reads is $\text{Integer}(\text{BLEN} / 4) + 1$.

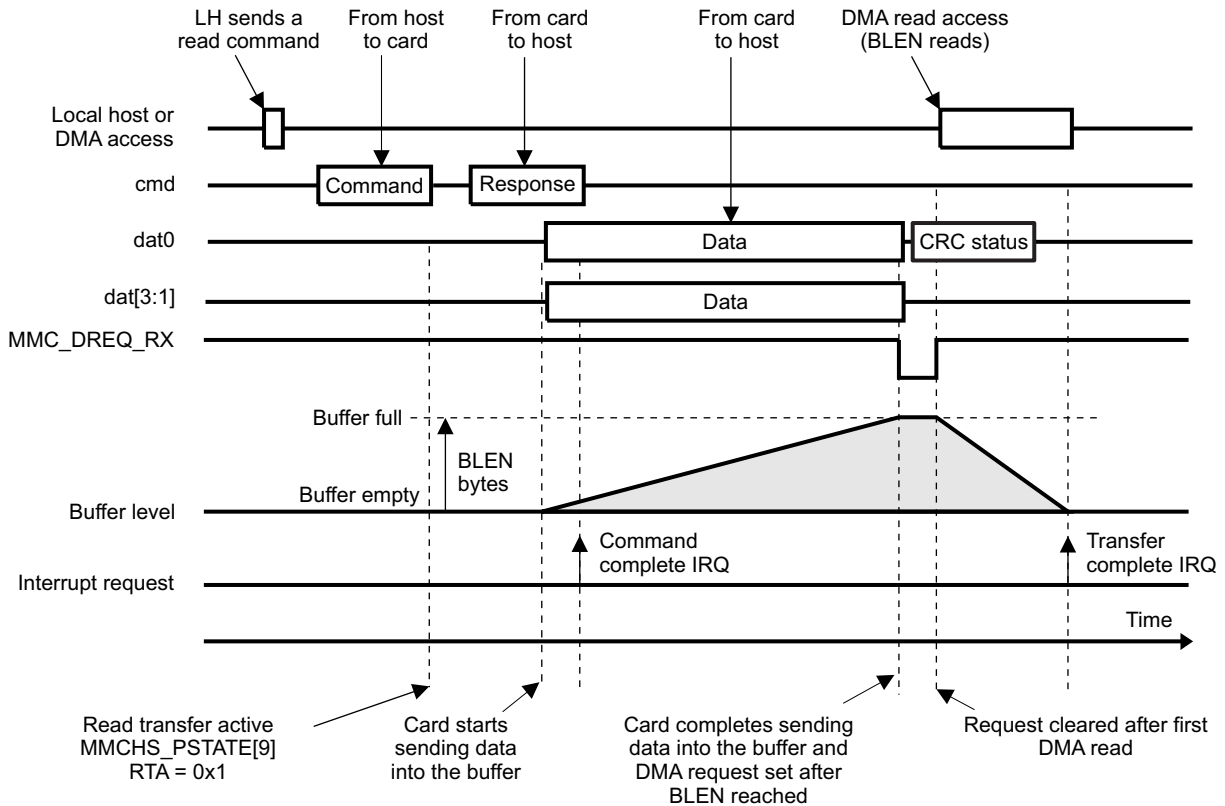

The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the `mmc_clk` clock signal (provided to the card) is momentarily stopped until a certain device DMA or another initiator performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

[Figure 20-12](#) shows DMA receive mode.

Figure 20-12. DMA Receive Mode

mmchs-020

20.4.5.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMC_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCHS_BLK[10:0] BLEN bit field.

MMC_DMA_TX is deasserted to its inactive level when a certain device DMA writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

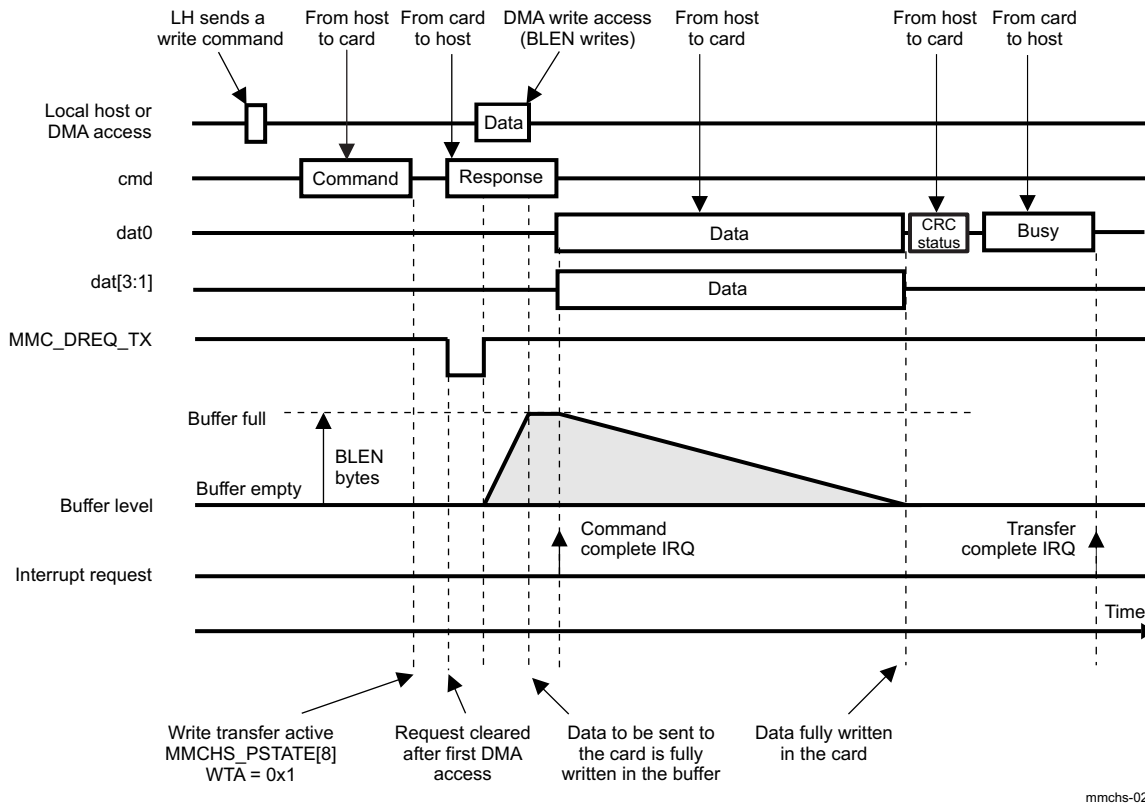

New DMA requests are internally masked if the DMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of DMA reads is $\text{Integer}(\text{BLEN} / 4) + 1$) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 20-13 shows DMA transmit mode.

Figure 20-13. DMA Transmit Mode

mmchs-021

20.4.6 Mode Selection

The SDIO host controller has been designed to be the most transparent with the type of the card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *SD Memory Card Specifications* and *SDIO Card Specification, Part E1*.

20.4.7 Buffer Management

20.4.7.1 Data Buffer

The SDIO host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SDIO bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the prefetch buffer and the post-write buffer is the 32-bit [MMCHS_DATA](#) register. A write access to the [MMCHS_DATA](#) register followed by a read access from the [MMCHS_DATA](#) register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the [MMCHS_DATA](#) register and the data of the read access to the [MMCHS_DATA](#) register are different.

The number of 32-bit accesses to the [MMCHS_DATA](#) register that are needed to read (or write) a data block with a size of the [MMCHS_BLK\[11:0\]](#) BLEN bit field is equal to the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the [MMCHS_CAPA\[17:16\]](#) MBL bit field and cannot be changed.

A read access to the [MMCHS_DATA](#) register is allowed only when the buffer read-enable status is set to 1 (the [MMCHS_PSTATE\[11\]](#) BRE bit); otherwise, a bad access (the [MMCHS_STAT\[29\]](#) BADA bit) is signaled.

A write access to the [MMCHS_DATA](#) register is allowed only when the buffer write-enable status is set to 1 (the [MMCHS_PSTATE\[10\]](#) BWE bit); otherwise, a bad access (the [MMCHS_STAT\[29\]](#) BADA bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The SDIO host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time. In this way, data can be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 0x200 (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

CAUTION

The [MMCHS_CMD\[4\]](#) DDIR bit must be configured before a transfer to indicate the direction of the transfer.

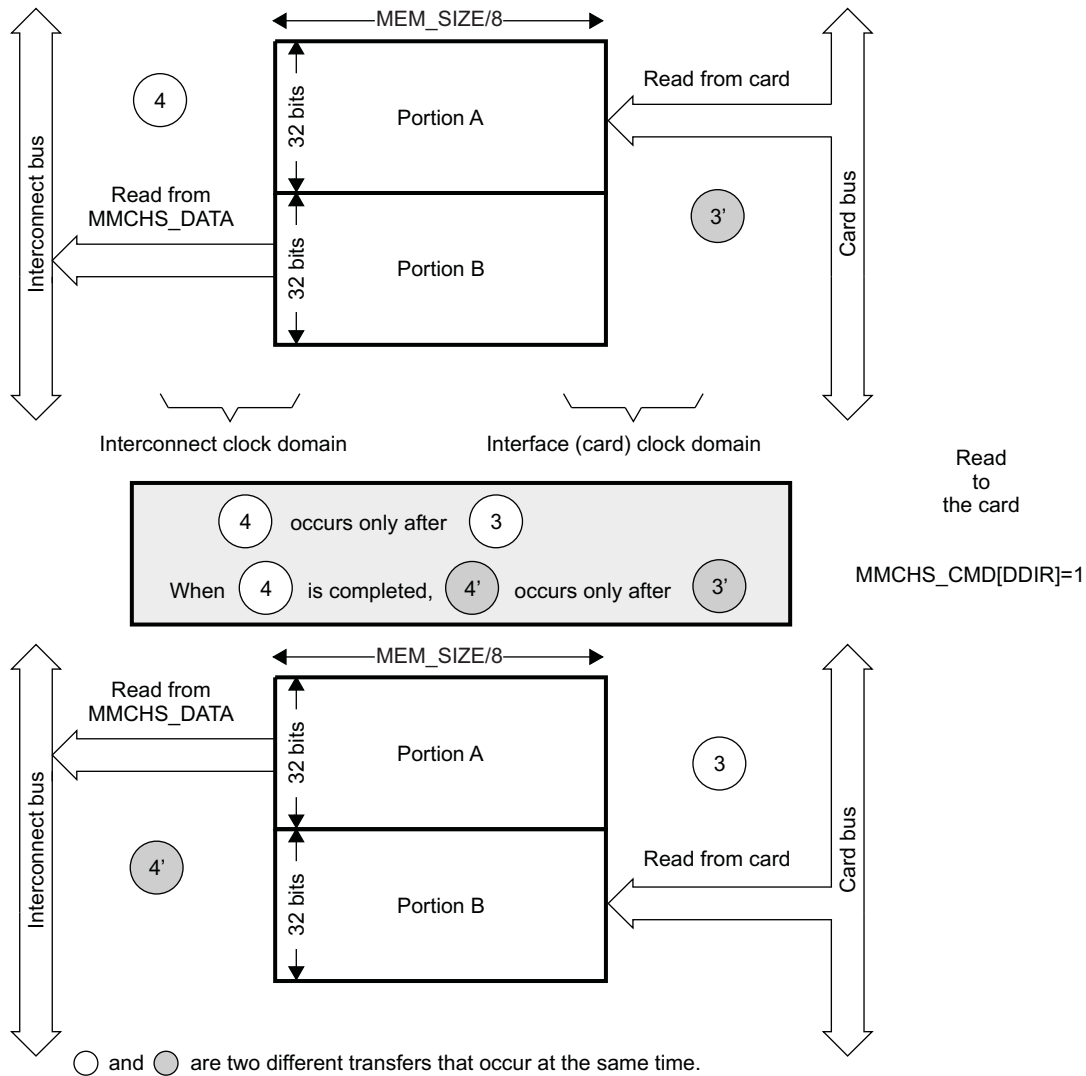

[Figure 20-14](#) and [Figure 20-15](#) show the buffer management for a write and a read, respectively.

Figure 20-14. Buffer Management for a Write

mmchs-022

Figure 20-15. Buffer Management for a Read

- When the size of the data block to transfer is larger than $MEM_SIZE / 2$, only one data transfer at a time can occur from one data bus to the other data bus. The SDIO host controller uses the entire data buffer as a single portion.

In this mode, a bad access (the `MMCHS_STAT[29]` BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

20.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see [Table 20-10](#)).

NOTE: Double-buffering is always the buffer management for large memory depth.

Table 20-10. Memory Size, BLEN, and Buffer Relationship

Memory Size (<code>MMCHS_HL_HWINFO[5:2]</code> MEM_SIZE in bytes)	512	1024
Maximum block length supported	512	1024

Table 20-10. Memory Size, BLEN, and Buffer Relationship (continued)

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN <= 512
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024

NOTE: For single-buffering management, throughput on the SDIO bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the SDIO bus. The clock is maintained on write SDIO transfers (the MMCHS_CMD[4] DDIR bit is 0) and halted on read SDIO transfers (the MMCHS_CMD[4] DDIR bit is 1).

20.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
 - MMCHS_STAT[29] BADA: Bad access to data space
 - MMCHS_STAT[5] BRR: Buffer read ready
 - MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
 - MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCHS_PSTATE[10] BWE: Buffer write enable

20.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

20.4.8.1 Different Types of Commands

Different types of commands are specific for the SD and SDIO cards. For more information, see the *SD Memory Card Specifications* and *SDIO Card Specification, Part E1*.

20.4.8.2 Different Types of Responses

Different types of responses are specific for the SD and SDIO cards. For more information, see the *SD Memory Card Specifications* and *SDIO Card Specification, Part E1*.

Table 20-11 describes how the SD/SDIO responses are stored in the MMCHS_RSPxx registers.

Table 20-11. SD/SDIO Responses in the MMCHS_RSPxx Registers

Type of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8] ⁽¹⁾	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response), R1	RESP[39:8] ⁽¹⁾	MMCHS_RSP76[31:0]
R2	RESP[127:0] ⁽¹⁾	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the host controller may execute multiple block data transfers on the data line concurrently with a command. This allows the host controller to avoid overwriting the response of Auto CMD12 with the command response stored in the MMCHS_RSP10 register, and vice versa.

20.4.9 Transfer or Command Status and Errors Reporting

Flags in the SDIO host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see [Table 20-12](#) and the register description.

Table 20-12. CC and TC Values Upon Error Detected

Error Hold in MMCHS_STAT	CC	TC	Comments
29 BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.
21 DCRC		1	TC is set upon DCRC.
20 DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19 CIE	1		CC is set upon CIE.
18 CEB	1		CC is set upon CEB.
17 CCRC	1		CC can be set upon CCRC. See CTO comment.
16 CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

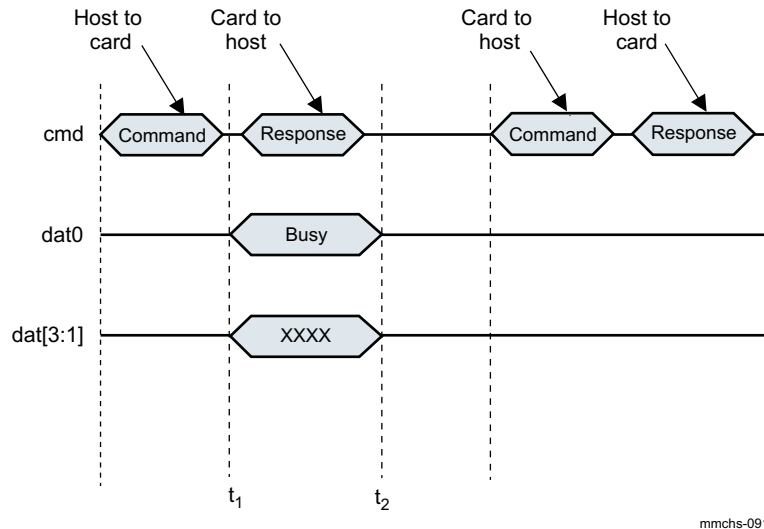

A MMCHS_STAT[20] DTO event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out

20.4.9.1 Busy Time-Out for R1b, R5b Response Type

Figure 20-16 shows the DTO event condition asserted when there is a busy time-out for Rb1, R5b response.

Figure 20-16. Busy Time-Out for R1b, R5b Response Type

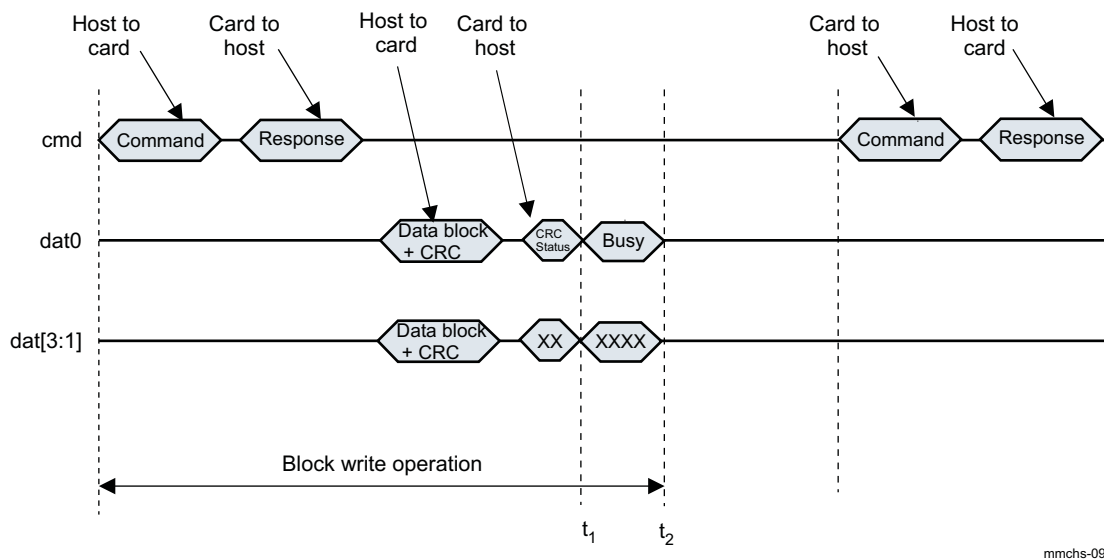

t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[20\]](#) DTO bit is generated.

20.4.9.2 Busy Time-Out After Write CRC Status

Figure 20-17 shows the DTO event condition asserted when there is a busy time-out after write CRC status.

Figure 20-17. Busy Time-Out After Write CRC Status

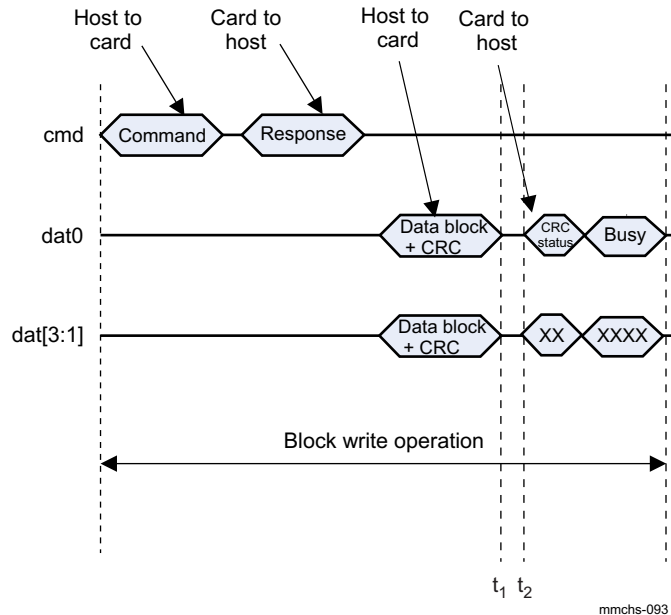

t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[20\]](#) DTO bit is generated.

20.4.9.3 Write CRC Status Time-Out

Figure 20-18 shows the DTO event condition asserted when there is a write CRC status time-out.

Figure 20-18. Write CRC Status Time-Out

- t₁ – Data time-out counter is loaded and starts after data block + CRC.
- t₂ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[20\]](#) DTO bit is generated.

20.4.9.4 Read Data Time-Out

Figure 20-19 shows the DTO event condition asserted when there is a read data time-out.

Figure 20-19. Read Data Time-Out

- t₁ – Data time-out counter is loaded and starts after command transmission.
- t₂ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[20\]](#) DTO bit is generated.
- t₃ – Data time-out counter is loaded and starts after data block + CRC transmission.
- t₄ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[20\]](#) DTO bit is generated.

20.4.10 Transfer Stop

Whenever a transfer is initiated, the transmission can be stopped before it finishes. This could happen in case of multiple-block-oriented transfers (transfer length is known).

NOTE: Because the SDIO controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The SDIO controller includes two features that make a transfer stop more convenient and easier to manage:

- Auto CMD12 (for SD cards only):
Auto CMD12 feature is enabled by setting the [MMCHS_CMD\[3:2\]](#) ACEN bit field to 0x1 (this setting is relevant for a SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the SDIO controller automatically issues a CMD12 command when the expected number of blocks is exchanged.
- Stop at block gap:
This feature is enabled by setting the [MMCHS_HCTL\[16\]](#) SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

NOTE: For SD cards, the stop-at-block-gap feature is not supported in read mode.
For SDIO cards, this setting can be supported in read mode if the card has read-wait capability.

[Table 20-13](#) shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 20-13. SDIO Controller Transfer Stop Command Summary

		Write Transfer		Read Transfer	
		SD	SDIO	SD	SDIO
Single block		Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.
Multiblocks	Before the programmed block boundary	Send CMD12. Wait TC.	Send CMD52. Wait TC.	Send CMD12. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer	Auto CMD12 active. Transfer ends automatically. Wait TC.	Set MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC.	Auto CMD12 active. Transfer ends automatically. Wait TC.	If READ_WAIT supported Stop at block gap. Wait TC. <hr/> If READ_WAIT not supported Send CMD52. Wait TC.

NOTE: The SDIO controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

20.4.11 Output Signals Generation

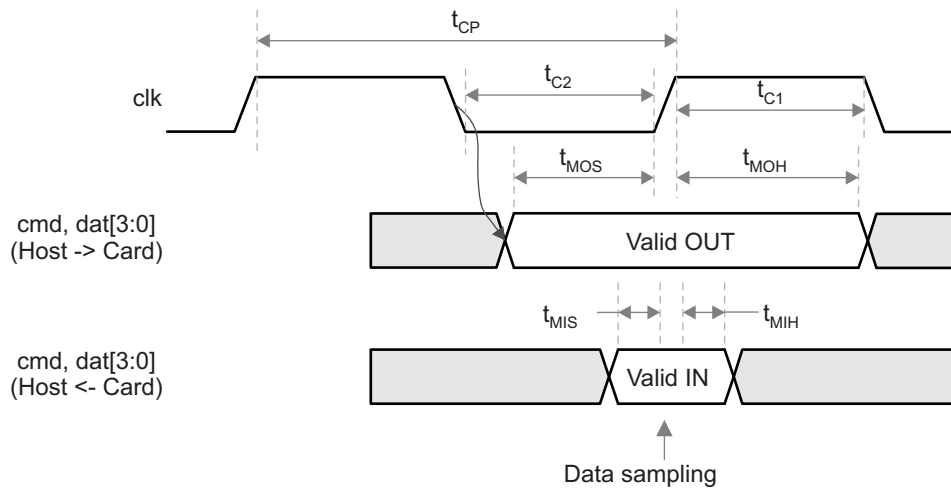

The SDIO output signals can be driven on the falling edge or rising edge, depending on the [MMCHS_HCTL\[2\]](#) HSPE bit.

20.4.11.1 Generation on Falling Edge of SDIO clock

The controller defaults to this mode to maximize hold timings. In this case, the [MMCHS_HCTL\[2\]](#) HSPE bit is set to 0.

[Figure 20-20](#) shows the output signals of the module when generating from the falling edge of the SDIO clock.

Figure 20-20. Output Driven on Falling Edge

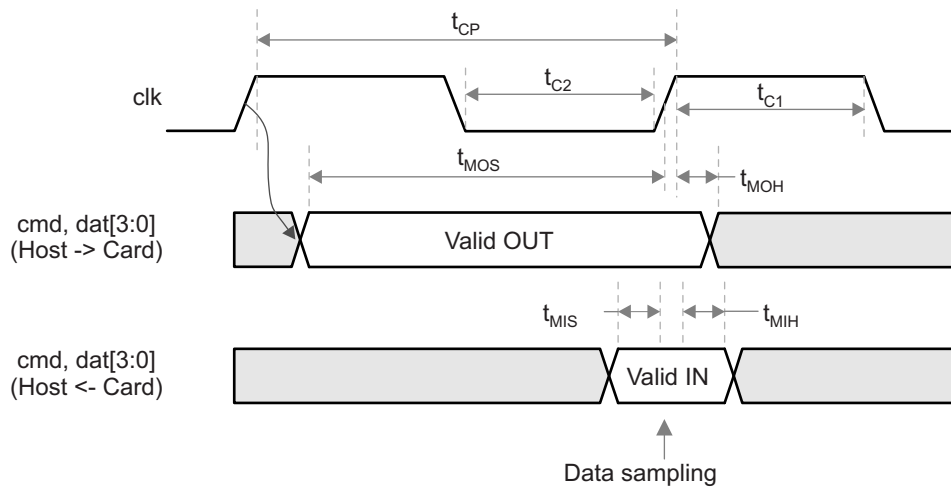

mmchs-024

20.4.11.2 Generation on Rising Edge of SDIO clock

This mode is intended to increase setup timings. This feature is activated by setting the [MMCHS_HCTL\[2\]](#) HSPE bit to 1.

[Figure 20-21](#) shows the output signals of the module when generating from the rising edge of the SDIO clock.

Figure 20-21. Output Driven on Rising Edge

mmchs-025

20.4.12 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register ([MMCHS_FE](#)) is used to control the error status and error interrupt status for Auto CMD12.

The system test register ([MMCHS_SYSTEST](#)) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the [MMCHS_CON\[4\]](#) MODE bit = 1) for boundary connectivity verification.

20.4.13 SDIO Hardware Status Features

[Table 20-14](#) describes the SDIO hardware status features.

Table 20-14. SDIO Hardware Status Features

Feature	Type	Register/Bit Field	Description
Interrupt flags		See Section 20.4.4, Interrupt Requests .	
CMD line signal level	Status	MMCHS_PSTATE[24] CLEV	Indicates the level of the command line
DAT lines signal level	Status	MMCHS_PSTATE[23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	MMCHS_PSTATE[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	MMCHS_PSTATE[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	MMCHS_PSTATE[9] RTA	Used to detect completion of a read transfer.
Write transfer active	Status	MMCHS_PSTATE[8] WTA	Indicates a write transfer active
Data line active	Status	MMCHS_PSTATE[2] DLA	Indicates whether the data lines are active
Command Inhibit (DAT lines)	Status	MMCHS_PSTATE[1] DATI	Indicates whether issuing of command using data lines is allowed. For example, commands with busy mechanism (that is, R1b response), data transfer commands.
Command inhibit (CMD line)	Status	MMCHS_PSTATE[0] CMDI	Indicates whether issuing of command using command line is allowed

[Table 20-15](#) describes the SDIO preset value features.

Table 20-15. SDIO Preset Value Registers

Feature	Type	Register	Description
Preset value register	Status	MMCHS_PVINITSD	Preset Values for Initialization and Default Speed modes
Preset value register	Status	MMCHS_PVHSSDR12	Preset Values for High Speed and SDR12 speed modes
Preset value register	Status	MMCHS_PVSDR25SDR50	Preset Values for SDR25 speed mode

20.5 SDIO Programming Guide

20.5.1 Low-Level Programming Models

20.5.1.1 Global Initialization

20.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SDIO controller. For more information, see [Section 20.3, SDIO Integration](#), and [Section 20.2, SDIO Environment](#). [Table 20-16](#) shows the global initialization of the surrounding modules.

Table 20-16. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management .
Control module	Module-specific pad muxing and configuration must be set in the control module. See Chapter 14, Control Module .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 14.4.6.5, DMA_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
Device DMAs	Device DMAs configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 13 Interrupt controller .

20.5.1.1.2 SDIO Host Controller Initialization Flow

[Table 20-17](#) shows the SDIO controller general initialization steps.

Table 20-17. SDIO Controller Meta Initialization Steps

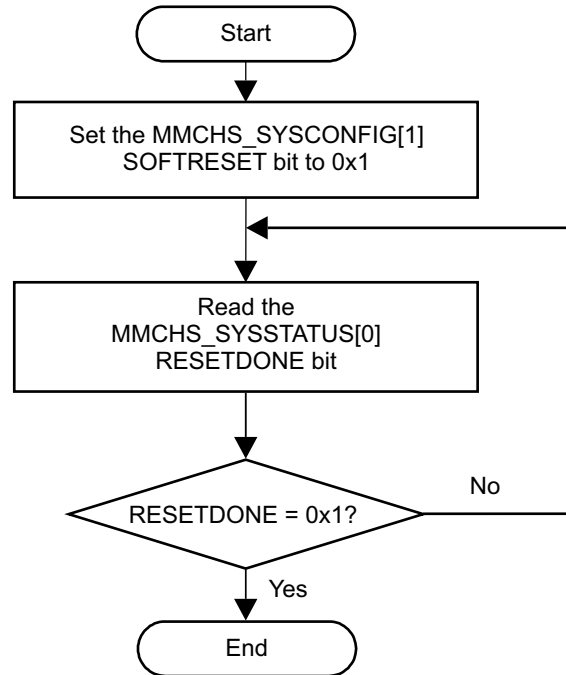

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See Section 20.5.1.1.2.1, Enable Interface and Functional Clock for the SDIO Controller .	
Software reset of the controller.		See Section 20.5.1.1.2.2, SDIO Soft Reset Flow .	
Set module hardware capabilities.		See Section 20.5.1.1.2.3, Set SDIO Default Capabilities .	
Set module idle and wake-up modes.		See Section 20.5.1.1.2.4, Wake-Up Configuration .	

20.5.1.1.2.1 Enable Interface and Functional Clock for the SDIO Controller

Before any access to the registers of the SDIO controller, its interface and functional clocks in the PRCM module registers must be enabled. See [Section 3.6.4.1.4, Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#).

20.5.1.1.2.2 SDIO Soft Reset Flow

[Figure 20-22](#) shows the soft reset process of the SDIO controller.

Figure 20-22. SDIO Controller Software Reset Flow

mmchs-028

Table 20-18. Register Call Summary for Main Sequence – Software Reset Flow

Register Name	Register Name
MMCHS_SYSCONFIG	MMCHS_SYSSTATUS

20.5.1.1.2.3 Set SDIO Default Capabilities

Software must read capabilities and set (write) the [MMCHS_CAPA\[26:24\]](#) and [MMCHS_CUR_CAPA\[23:0\]](#) bit fields before the SDIO host driver is started.

20.5.1.1.2.4 Wake-Up Configuration

[Table 20-19](#) describes the SDIO controller wake-up configuration.

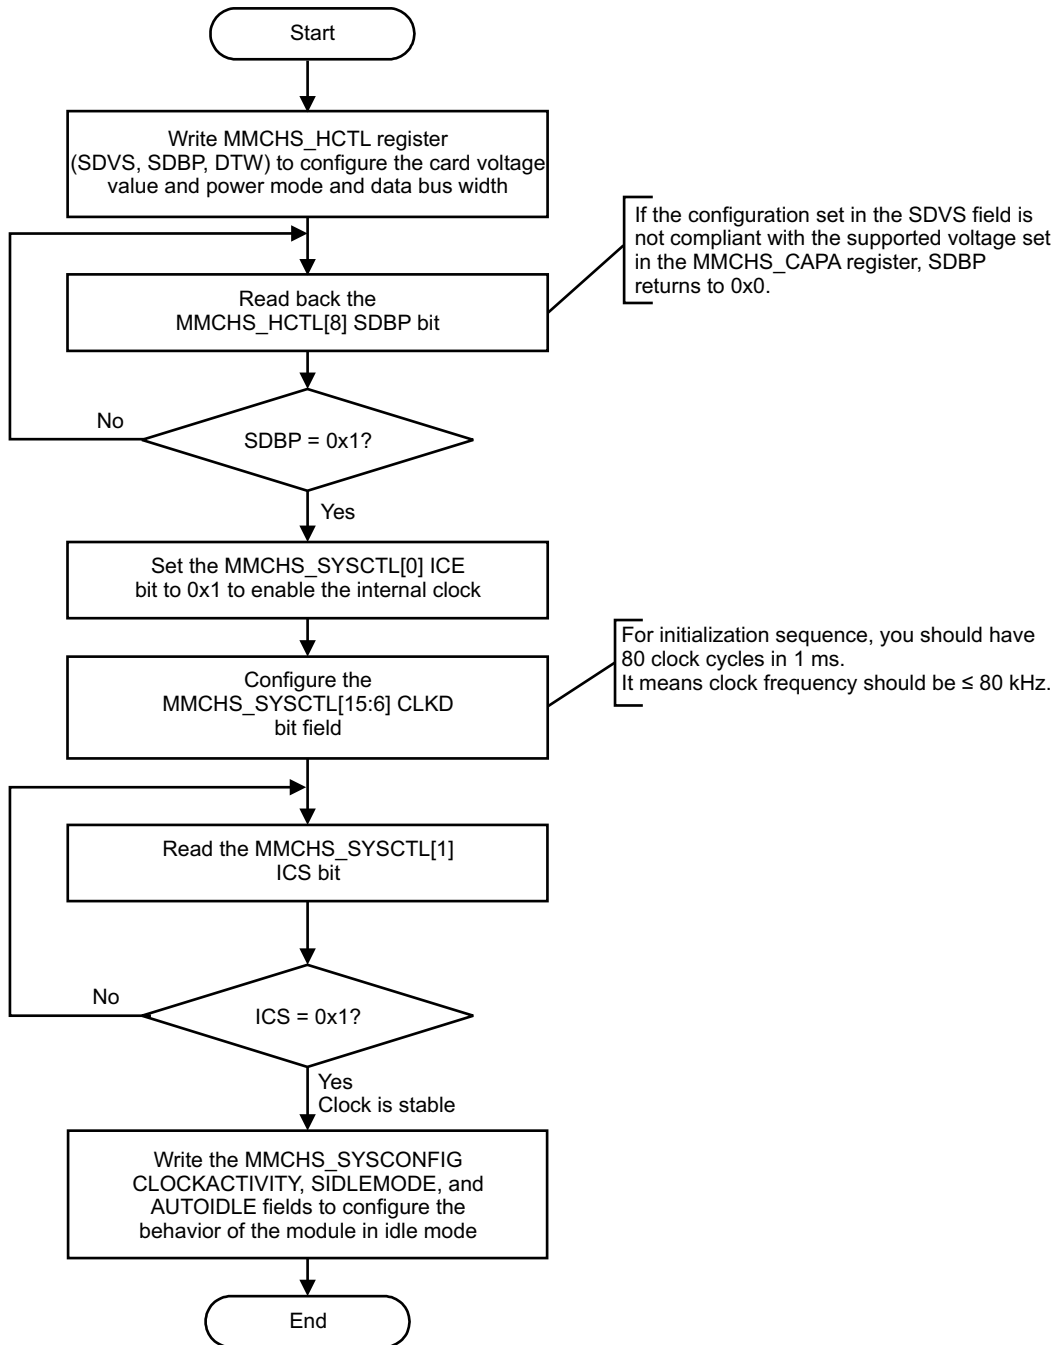

Table 20-19. SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCHS_SYSCONFIG[2] ENAWAKEUP	0x1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCHS_HCTL[24] IWE	0x1
SDIO card only: Enable card interrupt (if necessary).	W	MMCHS_IE[8] CIRQ_ENABLE	0x1

20.5.1.1.2.5 SDIO Host and Bus Configuration

Figure 20-23 shows the SDIO bus configuration process.

Figure 20-23. SDIO Controller Bus Configuration

mmchs-029

Table 20-20. Register Call Summary for Main Sequence – Bus Configuration

Register Name	Register Name
MMCHS_CON	MMCHS_HCTL
MMCHS_SYSCONFIG	MMCHS_SYSCTL

20.5.1.2 Operational Modes Configuration

20.5.1.2.1 Basic Operations for SDIO Host Controller

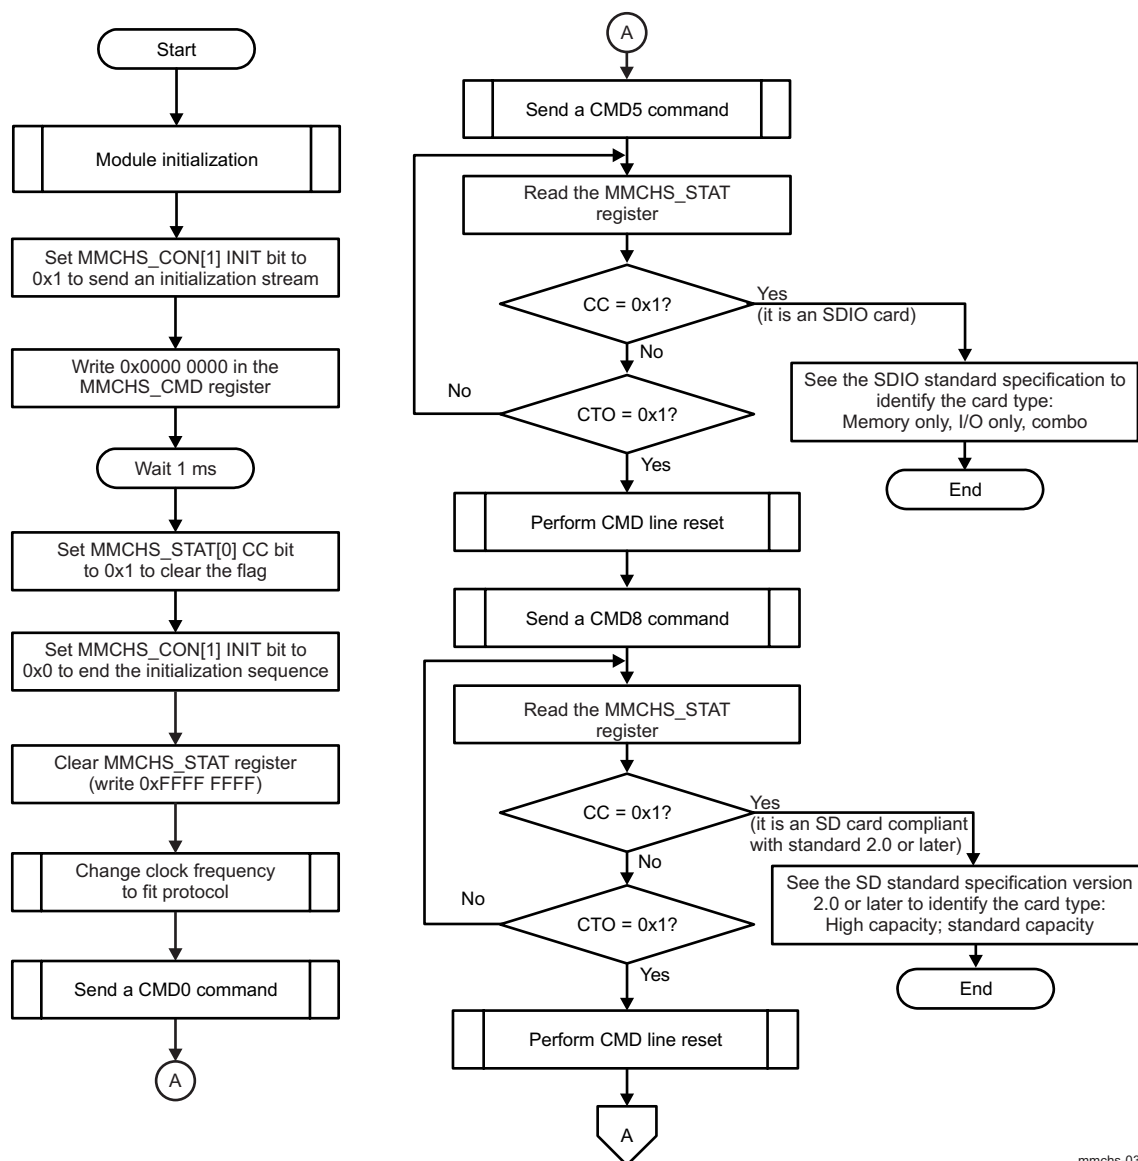

The SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

20.5.1.2.1.1 Card Identification and Selection

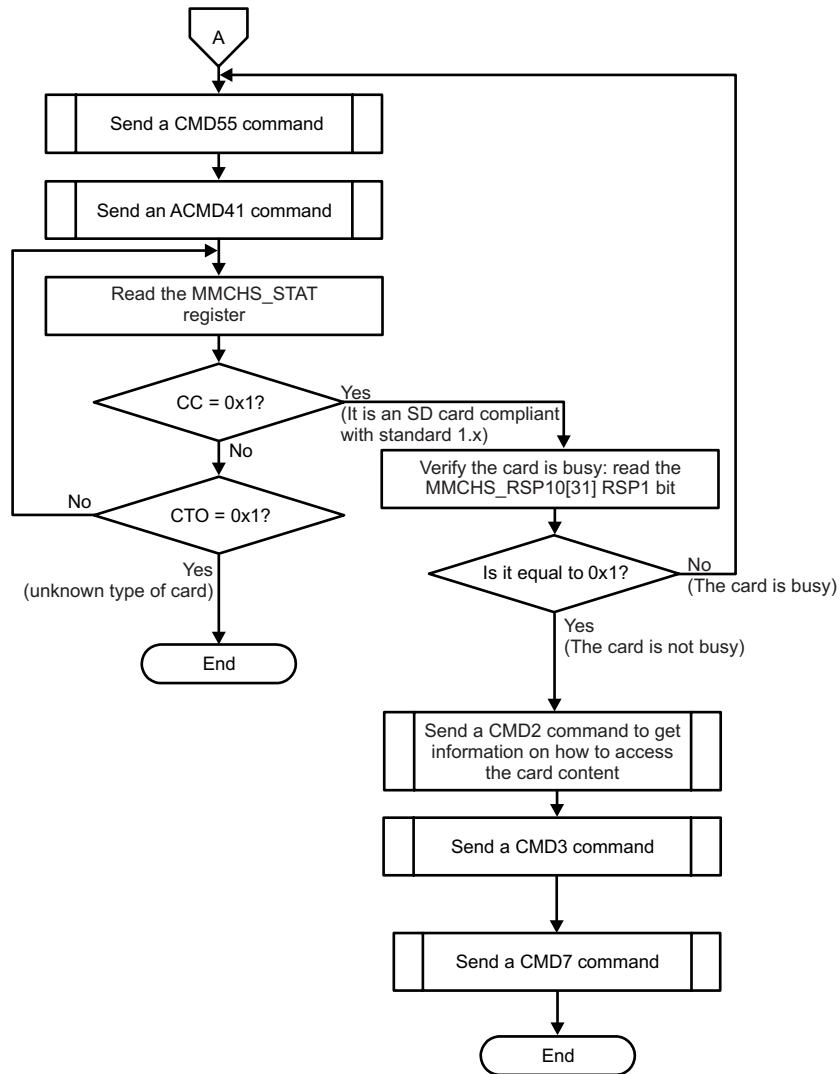

Figure 20-24 and Figure 20-25 show the card identification and selection process.

Figure 20-24. SDIO Controller Card Identification and Selection – Part 1

Table 20-52. MMCHS_CSRE

Address Offset	0x0000 0124	Instance	MMC
Physical Address	0x480D 1124		
Description	Card Status Response Error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP0[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP10). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RSP76) for possible card errors.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 20-54. MMCHS_SYSTEST

Address Offset	0x0000 0128	Instance	MMC
Physical Address	0x480D 1128		
Description	System Test Register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[BLN]) and the Blocks count for current transfer (MMCHS_BLK[NBLK]) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[BWR]) or a Buffer read ready interrupt (MMCHS_STAT[BRR]) and DMA requests if enabled.		
Type	RW

Table 20-56. MMCHS_CON

Address Offset	0x0000 012C	Instance	MMC
Physical Address	0x480D 112C		
Description	Configuration Register This register is used: - to select the functional mode or the SYSTEST mode for any card. - to send an initialization sequence to any card. - to enable the detection on DAT[1] of a card interrupt for SDIO cards only.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SDMA_LINE	DMA_MNS	DDR	RESERVED	CLKEXTFREE	PADEN	RESERVED	CTPL	RESERVED							DW8	MODE	RESERVED	INIT	RESERVED				

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000
21	SDMA_LNE	<p>Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA.</p> <p>0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion</p>	RW	0
20	DMA_MNS	<p>DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory).This option is only available if generic parameter MADMA_EN is asserted to '1'.</p> <p>0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA. NOTE: The SDIO Controller does NOT support Master DMA operations. This bit must be kept to value of 0x0.</p>	RW	0
19	DDR	<p>Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting.</p> <p>0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTRL[HSPE]. 0x1: Data Bytes and CRC are transmitted on both edge.NOTE: The SDIO Controller does NOT support DDR mode. This bit must be kept to value of 0x0.</p>	RW	0
18:17	RESERVED		R	0x0
16	CLKEXTFREE	<p>External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[CEN] is set.</p> <p>0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[CEN] is set.</p>	RW	0
15	PADEN	<p>Control Power for SDIO Lines: This register is only useful when SDIO PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[CTPL] bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the SDIO controller FSMs. 0x1: ADPIDLE module pin is forced to active state.</p>	RW	0
14:12	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
11	CTPL	Control Power for DAT[1] line SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.	RW	0
10:6	RESERVED			0x18
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. 0x0: 1-bit or 4-bit Data width (DAT[0] used, SD cards) 0x1: 8-bit Data width. NOTE: Not supported on this device.	RW	0
4	MODE	Mode select This bit select between Functional mode and SYSTEST mode. 0x0: Functional mode. Transfers to SD/SDIO cards follow the card protocol. SDIO clock is enabled. SD transfers are operated under the control of the CMD register. 0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3:2	RESERVED		R	0x0
1	INIT	Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[CLKD]) should be set to ensure that 80 clock periods are greater than 1ms. (section 6.4 in the SD card specification). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.	RW	0
0	RESERVED		R	0

SDMA_ARG2																															

Bits	Field Name	Description	Type	Reset
31:0	SDMA_ARG2	<p>This register contains the system memory address for a DMA transfer. When the Host Controller stops the DMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value.</p> <p>The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the next system address of the next contiguous data position can be read from this register.</p> <p>The DMA transfer waits at the every boundary specified by the Host DMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the DMA transfer.</p> <p>When restarting DMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the DMA System Address register.</p>	RW	0x0000 0000

23:22	CMD_TYPE	Command type This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR	RW	0x0
21	DP	Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[CIE] set to 1). Note: The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[CCRC] set to 1). Note: The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	RESERVED		R	0
17:16	RSP_TYPE	Response type This bits defines the response type of the command 0x0: No response	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x1: Response Length 136 bits 0x3: Response Length 48 bits with busy after response 0x2: Response Length 48 bits		
15:6	RESERVED		R	0x000
5	MSBS	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[NBLK] . 0x1: Multi block. When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3:2	ACEN	Auto CMD Enable - SD card only. This field determines use of auto command functions. There are two methods to stop Multiple-block read and write operation Auto CMD12 Enable When this field is set to 01b, the Host Controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register (MMCHS_AC12). The Host Driver shall not set this bit if the command does not require CMD12. In particular, secure commands defined in the Part 3 File Security specification do not require CMD12. 0x0: Auto Command Disabled 0x1: Auto CMD12 enable or CCS detection enabled. 0x2: Reserved 0x3: Reserved	RW	0x0
1	BCE	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[NBLK]). When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Table 20-76. MMCHS_DATA

Address Offset	0x0000 0220	Instance	MMC																																																																
Physical Address	0x480D 1220																																																																		
Description	<p>Data Register</p> <p>This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.</p> <p>Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.</p> <p>Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad</p>

RESERVED								CLEV	DLEV				RESERVED								BRE	BWE	RTA	WTA	RESERVED				DLA	DATI	CMDI

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x00
24	CLEV	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x1: The CMD line level is 1. Read 0x0: The CMD line level is 0.	R	-
23:20	DLEV	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.	R	0x-
19:12	RESERVED		R	0x-
11	BRE	Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[BLLEN] has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[BRR]). Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer. Read 0x0: Read BLEN bytes disable	R	0
10	BWE	Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data.	R	0
9	RTA	Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x1: read data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0

Bits	Field Name	Description	Type	Reset
8	WTA	<p>Write transfer active</p> <p>This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x1: Write data transfer on going.</p> <p>Read 0x0: No valid data on the DAT lines.</p>	R	0
7:3	RESERVED		R	0x0
2	DLA	<p>DAT line active</p> <p>This status bit indicates whether one of the DAT line is in use.</p> <p>In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode.</p> <p>In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x1: DAT Line active</p> <p>Read 0x0: DAT Line inactive</p>	R	0
1	DATI	<p>Command inhibit(DAT)</p> <p>This status bit is generated if either DAT line is active (MMCHS_PSTATE[DLA]) or Read transfer is active (MMCHS_PSTATE[RTA]) or when a command with busy is issued. This bit prevents the local host to issue a command.</p> <p>A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[TC]).</p> <p>Read 0x1: Issuing of command using DAT lines is not allowed</p> <p>Read 0x0: Issuing of command using the DAT lines is allowed</p>	R	0
0	CMDI	<p>Command inhibit(CMD)</p> <p>This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted.</p> <p>This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[CCRC]) or MMCHS_STAT[CEB] set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[ACNE]). - After the end bit of the command without response (MMCHS_CMD[RSP_TYPE] set to "00") <p>In case of a command data error is detected (MMCHS_STAT[CTO] set to 1), this register is not automatically cleared.</p> <p>Read 0x1: Issuing of command using CMD line is not allowed</p> <p>Read 0x0: Issuing of command using CMD line is allowed</p>	R	0

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x0
24	IWE	Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	RESERVED		R	0x0
19	IBG	Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For SD cards this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0

Bits	Field Name	Description	Type	Reset
18	RWC	<p>Read wait control</p> <p>The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[SBGR]) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line.</p> <p>0x0: Disable Read Wait Control. Suspend/Resume cannot be supported.</p> <p>0x1: Enable Read Wait Control</p>	RW	0
17	CR	<p>Continue request</p> <p>This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[SBGR]). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[DLA]) or transferring data (MMCHS_PSTATE[WTA]).</p> <p>The Stop at block gap request must be disabled (MMCHS_HCTL[SBGR]=0) before setting this bit.</p> <p>0x0: No affect</p> <p>0x1: transfer restart</p>	RW	0
16	SBGR	<p>Stop at block gap request</p> <p>This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[CR]) or during a suspend/resume sequence.</p> <p>In case of read transfer, the card must support read wait control.</p> <p>In case of write transfer, the host driver shall set this bit after all block data written.</p> <p>Until the transfer completion (MMCHS_STAT[TC] set to 1), the host driver shall leave this bit set to 1.</p> <p>If this bit is set, the local host shall not write to the data register (MMCHS_DATA).</p> <p>0x0: Transfer mode</p> <p>0x1: Stop at block gap</p>	RW	0
15:12	RESERVED		R	0x0
11:9	SDVS	<p>SD bus voltage select</p> <p>All cards.</p> <p>The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[VS18,VS30,VS33]) before starting a transfer.</p> <p>0x6: 3.0V (Typical)</p> <p>0x7: 3.3V (Typical)</p> <p>0x5: 1.8V (Typical)</p>	RW	0x0
8	SDBP	<p>SD bus power</p> <p>Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[SDVS]). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage MMCHS_HCTL[SDVS] is not supported according to capability register (MMCHS_CAPA[VS*]).</p> <p>0x0: Power off</p> <p>0x1: Power on</p>	RW	0
7:3	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
2	HSPE	Before setting this bit, the Host Driver shall check the MMCHS_CAPA [21] HSS. This bit shall not be set when dual data rate mode is activated in MMCHS_CON [DDR]. 0x0: The Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock 0x1: The Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock NOTE: Do not set this bit to 0x1 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.	RW	0
1	DTW	Data transfer width For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)	RW	0
0	RESERVED		R	0

Table 20-90. MMCHS_AC12

Address Offset	0x0000 023C	Instance	MMC
Physical Address	0x480D 123C		
Description	Host Control 2 Register and Auto CMD Error Status Register This register is used to indicate CMD12 response error of Auto CMD12. The Host driver can determine what kind of Auto CMD12 errors occur by this register. Bits[7:0] are valid only when the MMCHS_CMD[3:2] ACEN bitfield is configured to enable Auto CMD and the Auto CMD Error bit (MMCHS_STAT[24] ACE) is set.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PV_ENABLE	AI_ENABLE	RESERVED						DS_SEL	V1V8_SIGEN	UHSMS			RESERVED						CNI	RESERVED	ACIE	ACEB	ACCE	ACTO	ACNE						

Bits	Field Name	Description	Type	Reset
31	PV_ENABLE	Preset Value Enable Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers, see, Table 20-15 . If this bit is set to 0, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Driver. If this bit is set to 1, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Controller as specified in the Preset Value registers, see, Table 20-15 . 0x0: SDCLK and Driver Strength (DS_SEL) are controlled by Host Driver. 0x1: Automatic Selection by Preset Value are Enabled.	RW	0
30	AI_ENABLE	Asynchronous Interrupt Enable This bit can be set to 1 if a card supports asynchronous interrupts and MMCHS_CAPA[29] AIS is set to 1. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card. 0x0: Disabled 0x1: Enabled	RW	0
29:22	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
21:20	DS_SEL	<p>Driver Strength Select</p> <p>Host Controller output driver in 1.8V signaling is selected by this bit. In 3.3V signaling, this field is not effective. This field can be set depending on Driver Type A, C and D support bits (DTA, DTC and DTD respectively) in the MMCHS_CAPA2 register.</p> <p>This bit depends on setting of Preset Value Enable. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers, see, Table 20-15.</p> <p>0x0: Driver Type B is selected (Default)</p> <p>0x1: Driver Type A is selected</p> <p>0x3: Driver Type D is selected</p> <p>0x2: Driver Type C is selected</p>	RW	0x0
19	V1V8_SIGEN	<p>1.8V Signaling Enable</p> <p>This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage. Setting this bit from 0 to 1 starts changing signal voltage from 3.3V to 1.8V. 1.8V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8V signaling fails.</p> <p>Clearing this bit from 1 to 0 starts changing signal voltage from 1.8V to 3.3V. 3.3V regulator output shall be stable within 5ms.</p> <p>Host Driver can set this bit to 1 when Host Controller supports 1.8V signaling (One of support bits is set to 1: SDR50, SDR104 or DDR50 in MMCHS_CAPA2 register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x).</p> <p>0x0: 3.3V Signaling</p> <p>0x1: 1.8V Signaling</p>	RW	0
18:16	UHSMS	<p>UHS Mode Select</p> <p>This field is used to select one of UHS-I modes and effective when 1.8V Signaling Enable is set to 1. If MMCHS_AC12[31] PV_ENABLE is set to 1, Host Controller sets MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL according to Preset Value registers, see, Table 20-15. In this case, one of preset value registers is selected by this field. Host Driver needs to reset MMCHS_SYSCTL[2] CEN before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets MMCHS_SYSCTL[2] CEN again.</p> <p>0x0: SDR12</p> <p>0x1: SDR25</p> <p>0x2 to 0x7: Reserved</p>	RW	0x0
15:8	RESERVED		R	0x00
7	CNI	<p>Command Not Issued By Auto CMD12 Error</p> <p>Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register.</p> <p>Read 0x1: Command not issued</p> <p>Read 0x0: No error</p>	R	0
6:5	RESERVED		R	0x0
4	ACIE	<p>Auto CMD Index Error for Auto CMD12</p> <p>This bit is set if the Command Index error occurs in response to a command.</p> <p>Read 0x1: Error</p> <p>Read 0x0: No error</p>	R	0

Bits	Field Name	Description	Type	Reset
3	ACEB	Auto CMD End Bit Error for Auto CMD12 This bit is set when detecting that the end bit of command response is 0. Read 0x1: End bit Error Generated Read 0x0: No error	R	0
2	ACCE	Auto CMD CRC Error for Auto CMD12 This bit is set when detecting a CRC error in the command response. Read 0x1: CRC Error Generated Read 0x0: No error	R	0
1	ACTO	Auto CMD Timeout Error for Auto CMD12 This bit is set if no response is returned within 64 SDCLK cycles from the end bit of command. If this bit is set to 1, the other error status bits (D04-D02) are meaningless. Read 0x1: Auto CMD Time Out Read 0x0: No error	R	0
0	ACNE	Auto CMD12 Not Executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the Host Controller cannot issue Auto CMD12 to stop memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (D04-D01) are meaningless. Read 0x1: Auto CMD12 Not Executed Read 0x0: Auto CMD12 Executed	R	0

28	BIT64	64 Bit System Bus Support Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. Read 0x1: 64 bit System bus address Read 0x0: 32 bit System bus address	R	0
27	RESERVED		R	0
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 1.8V Not supported Write 0x1: 1.8V Supported Read 0x1: 1.8V Supported Read 0x0: 1.8V Not Supported	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.0V Not supported Write 0x1: 3.0V Supported Read 0x1: 3.0V Supported Read 0x0: 3.0V Not Supported	RW	0
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.3V Not supported Write 0x1: 3.3V Supported Read 0x1: 3.3V Supported Read 0x0: 3.3V Not Supported	RW	0
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality.	R	1
22	DS	DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x1: DMA Supported Read 0x0: DMA Not Supported	R	1

Bits	Field Name	Description	Type	Reset
21	HSS	<p>High speed support This bit indicates that the host controller supports high speed operations and can supply an up-to maximum card frequency.</p> <p>Read 0x1: High Speed Supported Read 0x0: High Speed Not Supported</p> <p>NOTE: High Speed modes are supported, but MMCHS_HCTL[HSPE] bit must always be set to 0x0 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.</p>	R	1
20	RESERVED		R	0
19	AD2S	<p>ADMA2 Support This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN</p> <p>Read 0x1: ADMA2 Supported Read 0x0: ADMA2 not Supported</p>	R	0
18	RESERVED		R	0
17:16	MBL	<p>Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512 bytes and 1024 bytes block transfers.</p> <p>Read 0x2: 2048 bytes Read 0x1: 1024 bytes Read 0x0: 512 bytes</p>	R	0x1
15:8	BCF	<p>Base Clock Frequency For SD Clock This value indicates the base (maximum) clock frequency for the SD Clock. 8-bit Base Clock Frequency This mode is supported by the Host Controller Version 3.00. Unit values are 1MHz. The supported clock range is 10MHz to 255MHz. FFh : 255MHz : 02h : 2MHz 01h : 1MHz 00h : Get information via another method If the real frequency is 16.5MHz, the lager value shall be set 0001 0001b (17MHz) because the Host Driver use this value to calculate the clock divider value (Refer to MMCHS_SYSCTL[15:6] CLKD) and it shall not exceed upper limit of the SD Clock frequency. If these bits are all 0, the Host System has to get information via another method.</p> <p>Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method.</p>	R	0x00
7	TCU	<p>Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[DTO]).</p> <p>Read 0x1: MHz Read 0x0: KHz</p>	R	1
6	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
5:0	TCF	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.	R	0x00

23:16	CM	Clock Multiplier This field indicates clock multiplier value of programmable clock generator. Refer to MMCHS_SYSCTL [15:0] . Setting 00h means that Host Controller does not support programmable clock generator. 00h : Clock Multiplier is Not Supported 01h : Clock Multiplier M = 2 02h : Clock Multiplier M = 3 : FFh : Clock Multiplier M = 256	R	0x00

Bits	Field Name	Description	Type	Reset
15:14	RTM	<p>Re-Tuning Modes</p> <p>This field selects re-tuning method and limits the maximum data length.</p> <p>Bit47-46 Re-Tuning Mode Re-Tuning Method Data Length</p> <p>There are two re-tuning timings: Re-Tuning Request controlled by the Host Controller and expiration of a Re-Tuning Timer controlled by the Host Driver. By receiving either timing, the Host Driver executes the re-tuning procedure just before a next command issue. The maximum data length per read/write command is restricted so that re-tuning procedures can be inserted during data transfers.</p> <p>(1) Re-Tuning Mode 1</p> <p>The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MiB.</p> <p>(2) Re-Tuning Mode 2</p> <p>The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MiB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled.</p> <p>(3) Re-Tuning Mode 3</p> <p>The host controller has the capability to take care of the re-tuning during data transfer (Auto Re-Tuning). Re-Tuning Request shall not be generated during data transfers and there is no limitation to data length per read/write command. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled.</p> <p>Re-Tuning Timer Control Example for Re-Tuning Mode 1</p> <p>The initial value of re-tuning timer is provided by Timer Count for Re-Tuning field in this register. The timer starts counting by loading the initial value. When the timer expires, the Host Driver marks an expiration flag. On receiving a command request, the Host driver checks the expiration flag. If the expiration flag is set, then the Host Driver should perform the re-tuning procedure before issuing a command. If the expiration flag is not set, then the Host Driver issues a command without performing the re-tuning procedure. Every time the re-tuning procedure is performed, the timer loads the new initial value and the expiration flag is cleared.</p> <p>Re-Tuning Timer Control Example for Re-Tuning Mode 2 and Mode 3</p> <p>The timer control is almost the same as Re-Tuning Mode 1 except the timer loads the new initial value after data transfer (when receiving Transfer Complete). In case of Mode 3, Timer Count for Re-Tuning is set either smaller value: Tuning effective time after re-tuning procedure or after data transfer. If a Host System goes into power down mode, the Host Driver should stop the re-tuning timer and set the expiration flag to 1 when the Host System resumes from power down mode.</p> <p>Read 0x3: Reserved</p> <p>Read 0x2: Auto Re-Tuning (for transfer) - Timer and Re-Tuning Request</p> <p>Read 0x1: Timer and Re-Tuning Request - Max data length 4 MiB</p> <p>Read 0x0: Timer - Max data length 4 MiB</p>	R	0x0

General-Purpose Interface

This chapter describes the general-purpose interface for the device.

Topic	Page
21.1 General-Purpose Interface Overview	6265
21.2 General-Purpose Interface Environment	6268
21.3 General-Purpose Interface Integration	6271
21.4 General-Purpose Interface Functional Description	6275
21.5 General-Purpose Interface Programming Guide.....	6290
21.6 General-Purpose Interface Register Manual	6292

21.1 General-Purpose Interface Overview

The general-purpose interface combines four general-purpose input/output (GPIO) banks.

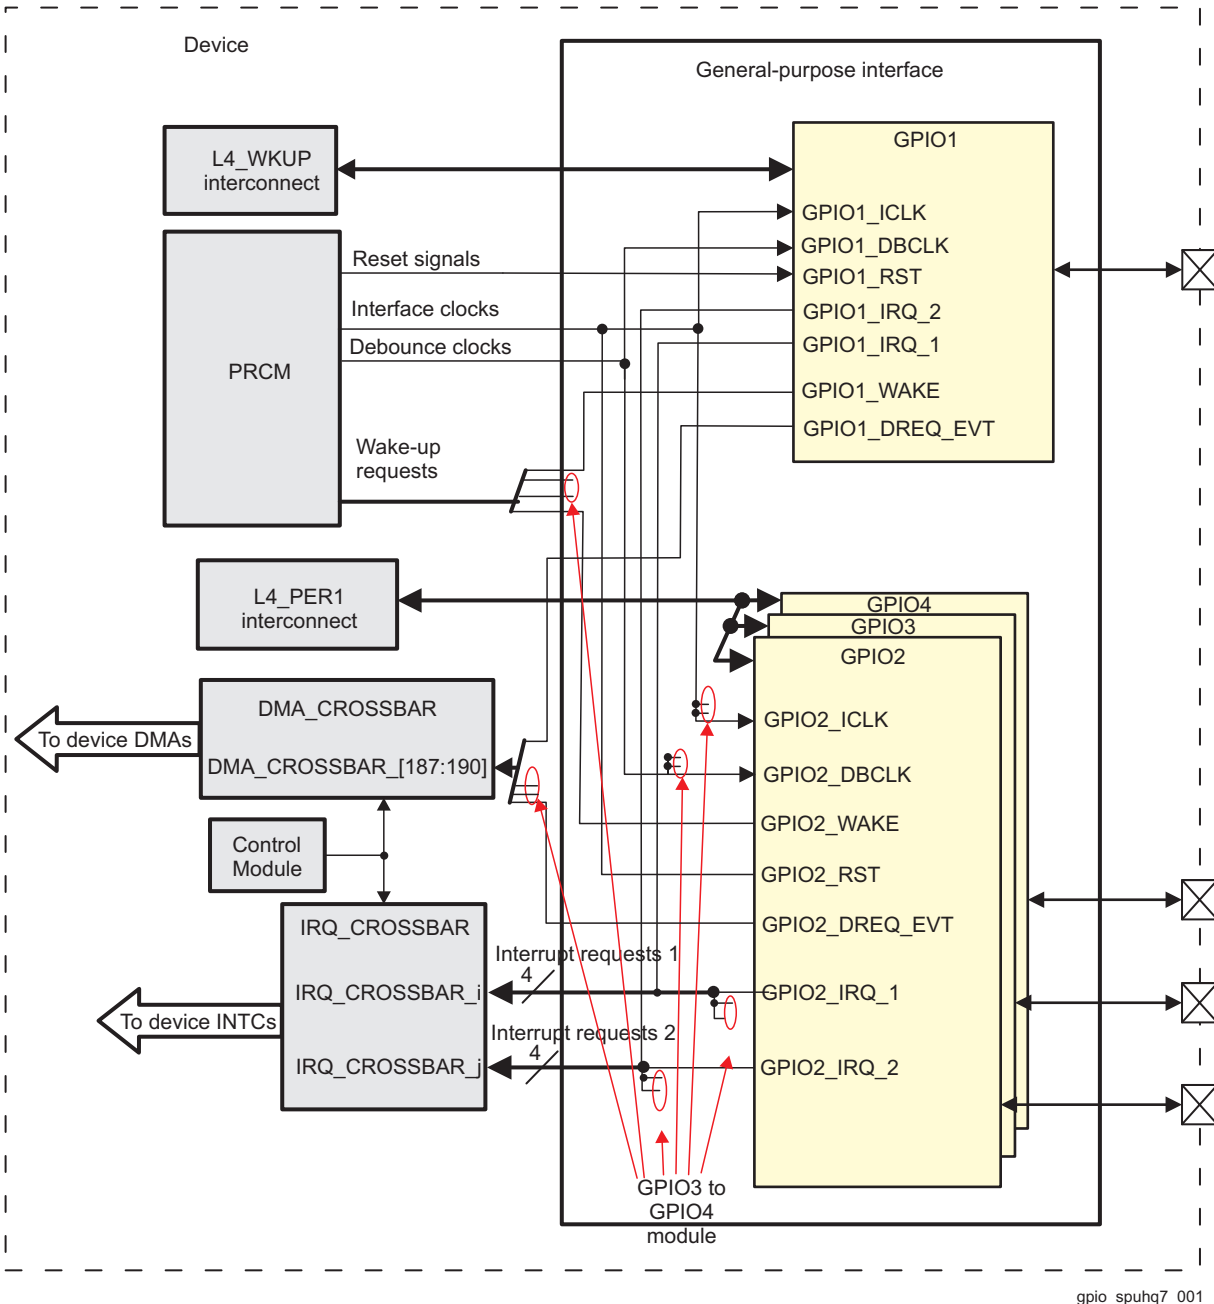

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 128 (4 x 32) pins. Some of the pins may be reserved in this Device. For more information of the supported number of GPIO pins, see the device Data Manual.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/down control, open-drain feature). For more information, see [Section 14.4.6.1](#), *Pad Configuration Registers*, in [Chapter 14](#), *Control Module*.

[Figure 21-1](#) is an overview of the general-purpose interface.

Figure 21-1. General-Purpose Interface Overview

gpio_spuhq7_001

The GPIO modules include the following global features:

- Two identical submodules can process synchronous interrupt requests from each channel to be used independently in a biprocessor environment. Each submodule controls its own synchronous interrupt request line. Each submodule also has its own interrupt-enable and interrupt status registers. The interrupt-enable register (GPIO_IRQSTATUS_SET_x [where x = 0 or 1]) selects the channel considered for the interrupt request generation. The interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel has activated the interrupt request. Event detection on GPIO channels is reflected into GPIO_IRQSTATUS_RAW independently from the content of the interrupt-enable registers.
- Wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)

- Power-management support

The general-purpose interface has 8 interrupt lines (two interrupt lines on GPIO1 through GPIO4 modules).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the level 4 (L4_WKUP and L4_PER1) interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO module, up to five different debouncing time values are possible.)
- The value of the input line is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 (L4_WKUP and L4_PER1) interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the data-output register (GPIO_DATAOUT). For this register, the module implements the set-and-clear protocol register update (see [Section 21.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

All module registers are 8-, 16-, or 32-bit accessible through the OCP-compatible interface (little-endian encoding)

21.2 General-Purpose Interface Environment

The general-purpose interface combines four GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 21-2 shows a typical application using the general-purpose interface.

Figure 21-2. General-Purpose Interface Typical Application

gpio-002

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

21.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix (r × c). Figure 21-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 21-3. General-Purpose Interface Used as a Keyboard Interface

gpio-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 21.4.6, *Interrupt and Wake-up Requests*).

When the keyboard interrupt is received, the processor (digital signal processor [DSP] subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

21.2.2 General-Purpose Interface Signals

Table 21-1 describes the module signals.

Table 21-1. I/O Description

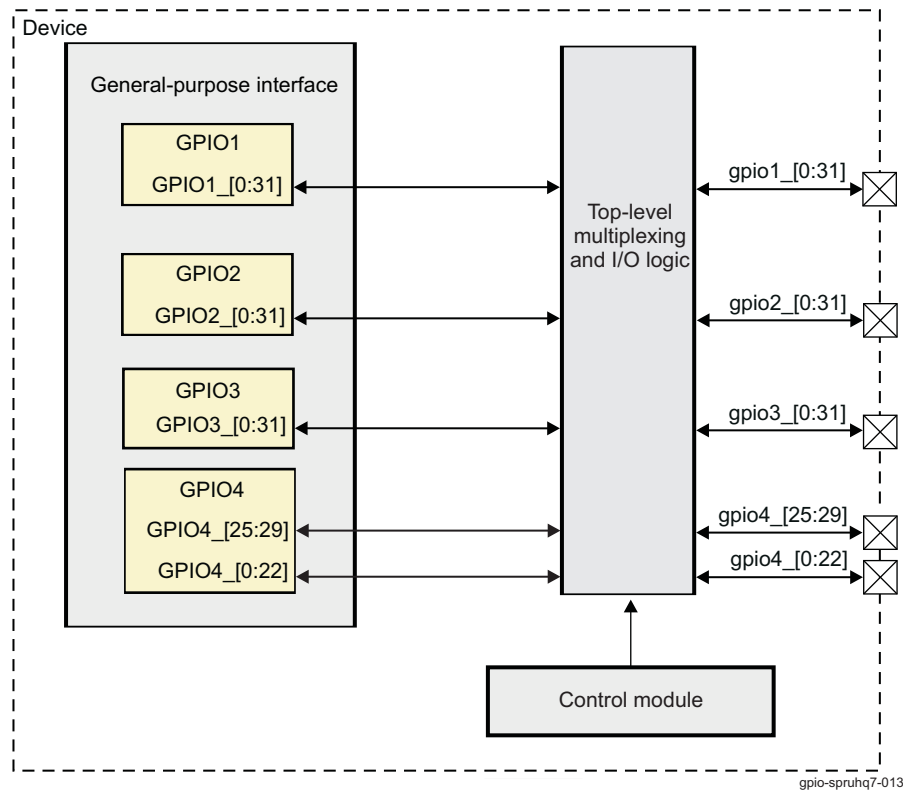

Signal	I/O ⁽¹⁾	Description	Reset Value ⁽²⁾
gpio1_[0:31]	I/O	GPIO	Hi-Z
gpio2_[0:31]	I/O	GPIO	Hi-Z
gpio3_[0:31]	I/O	GPIO	Hi-Z
gpio4_[0:22]	I/O	GPIO	Hi-Z
gpio4_[25:29]	I/O	GPIO	Hi-Z

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ Hi-Z = High Impedance

Figure 21-4 shows the signal connections of GPIO1 through GPIO4.

Figure 21-4. GPIO1 Through GPIO4 Signal Connections

NOTE: For more information about the GPIO1 through GPIO4 signals and channel description, see [Section 21.4.7, General-Purpose Interface Channels Description](#).

NOTE: For more information about GPIO signal multiplexing, see [Section 14.4.6.1, Pad Configuration Registers](#), and in [Chapter 14, Control Module](#).

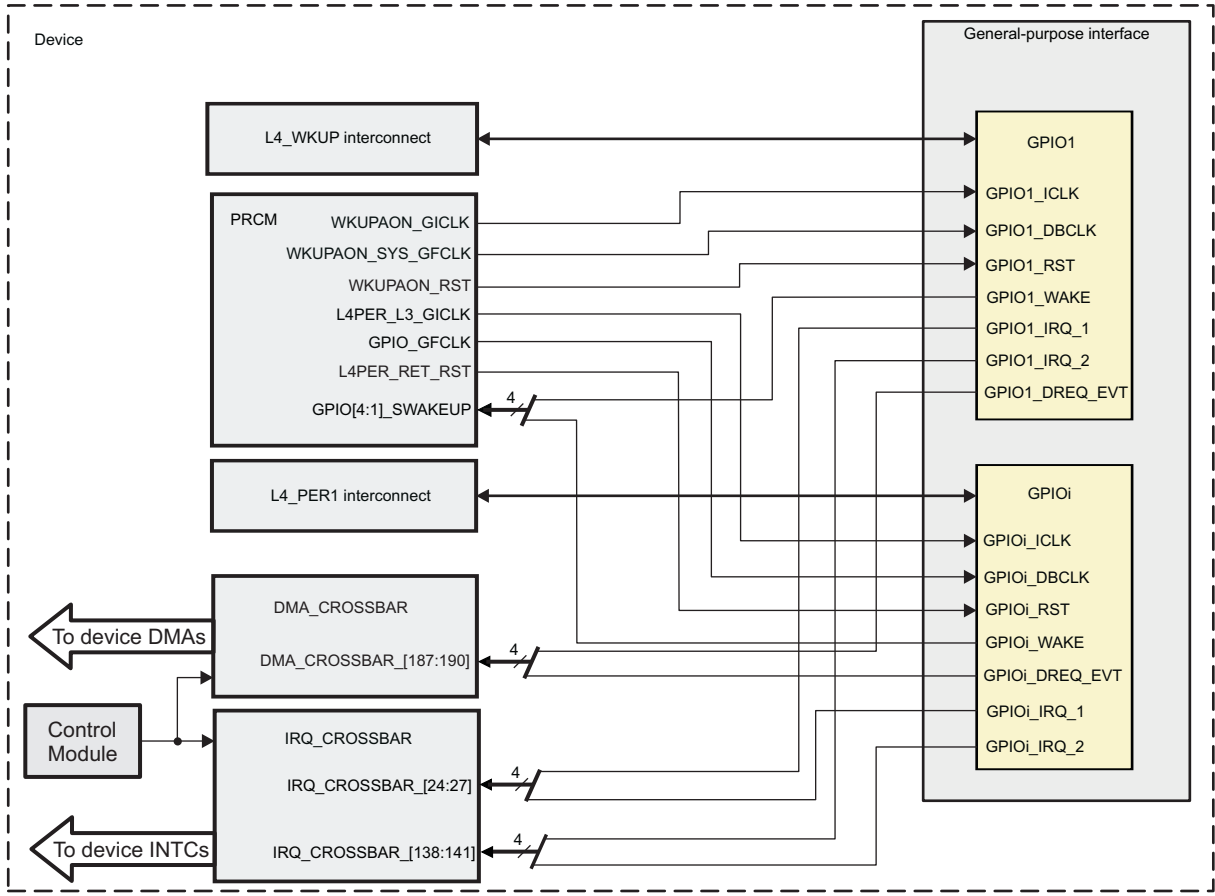

NOTE: GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

21.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 21-5 shows this module integration.

Figure 21-5. GPIO Integration

GPIO4	GPIO4_RST	L4PER_RET_RST	PRCM	GPIO reset signal

Table 21-4. GPIO Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
GPIO1	GPIO1_IRQ_2	IRQ_CROSSBAR_138	N/A	GPIO1 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC.
	GPIO1_IRQ_1	IRQ_CROSSBAR_24		GPIO1 interrupt request (first interrupt line)
			DSP1_IRQ_55	GPIO1 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_55	GPIO1 interrupt request to DSP2 (first interrupt line)
			IPU_IRQ_51	GPIO1 interrupt request to IPU1 (first interrupt line)
GPIO2	GPIO2_IRQ_2	IRQ_CROSSBAR_139	N/A	GPIO2 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO2_IRQ_1	IRQ_CROSSBAR_25		GPIO2 interrupt request (first interrupt line)
			DSP1_IRQ_56	GPIO2 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_56	GPIO2 interrupt request to DSP2 (first interrupt line)
			IPU_IRQ_52	GPIO2 interrupt request to IPU1 (first interrupt line)
GPIO3	GPIO3_IRQ_2	IRQ_CROSSBAR_140	N/A	GPIO3 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO3_IRQ_1	IRQ_CROSSBAR_26		GPIO3 interrupt request (first interrupt line)
			DSP1_IRQ_57	GPIO3 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_57	GPIO3 interrupt request to DSP2 (first interrupt line)
GPIO4	GPIO4_IRQ_2	IRQ_CROSSBAR_141	N/A	GPIO4 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO4_IRQ_1	IRQ_CROSSBAR_27		GPIO4 interrupt request (first interrupt line)
			DSP1_IRQ_58	GPIO4 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_58	GPIO4 interrupt request to DSP2 (first interrupt line)
DMA Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description

Table 21-4. GPIO Hardware Requests (continued)

GPIO1	GPIO1_DREQ_EVT	DMA_CROSSBAR_187	N/A	GPIO1 module - event/interrupt1. This DREQ source signal is not mapped by default to any device DMA controller.
GPIO2	GPIO2_DREQ_EVT	DMA_CROSSBAR_188	N/A	GPIO2 module - event/interrupt1. This DREQ source signal is not mapped by default to any device DMA controller.
GPIO3	GPIO3_DREQ_EVT	DMA_CROSSBAR_189	N/A	GPIO3 module - event/interrupt1. This DREQ source signal is not mapped by default to any device DMA controller.
GPIO4	GPIO4_DREQ_EVT	DMA_CROSSBAR_190	N/A	GPIO4 module - event/interrupt1. This DREQ source signal is not mapped by default to any device DMA controller.

NOTE: The “**Default Mapping**” column in [Table 21-4 GPIO Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

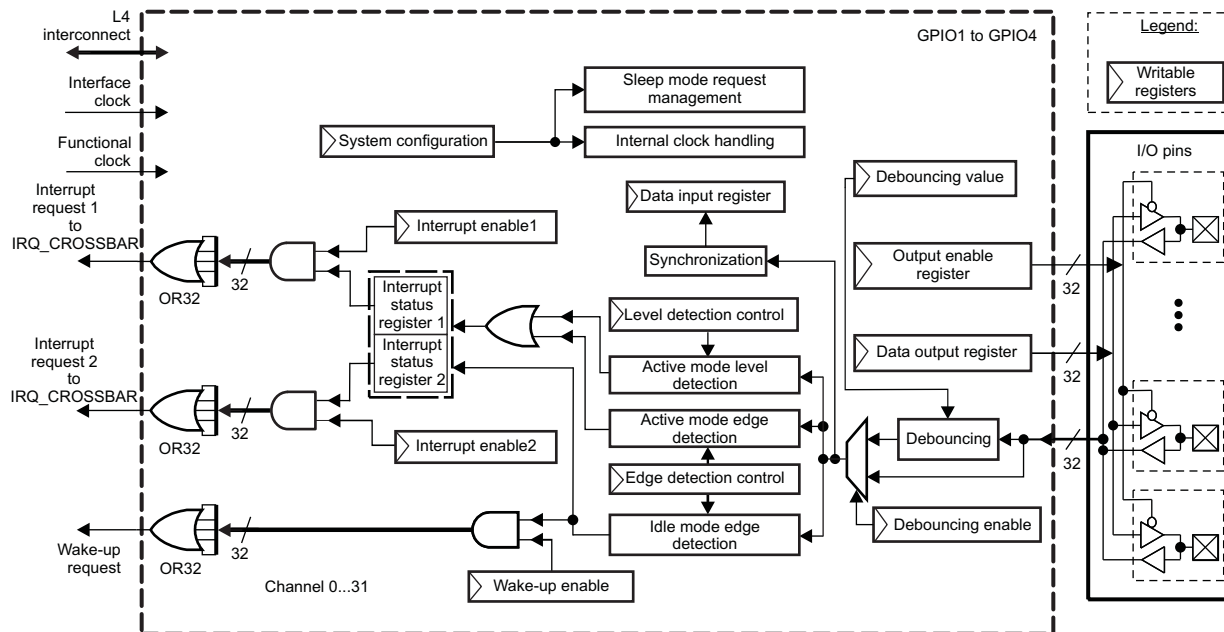

NOTE: For the description of the interrupt source, see [Section 21.4.6, Interrupt and Wake-Up Requests](#).

21.4 General-Purpose Interface Functional Description

21.4.1 General-Purpose Interface Block Diagram

Figure 21-6 shows the general-purpose interface block diagram.

Figure 21-6. General-Purpose Interface Block Diagram

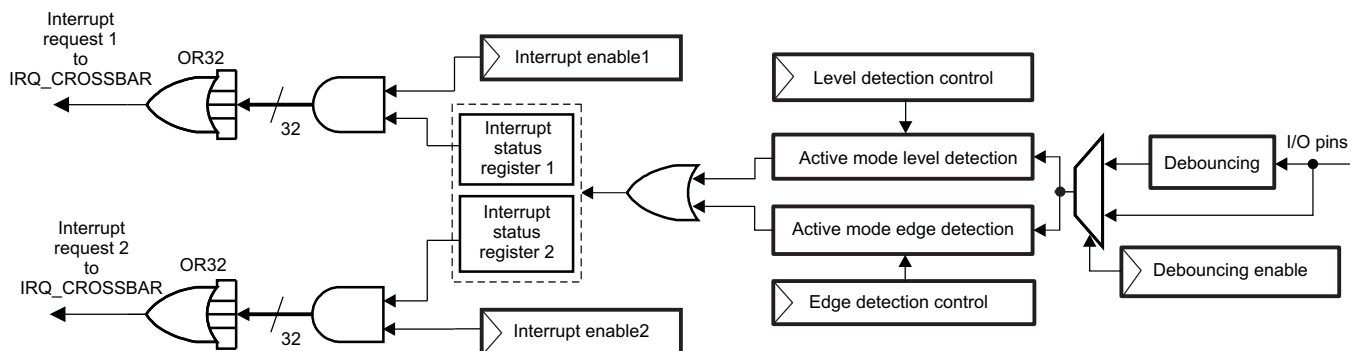

gpio-spruhq7-005

Figure 21-6 shows the details of the GPIO modules in the general-purpose interface block diagram, including their configuration registers and main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt-enable1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1). See Figure 21-7.

Figure 21-7. Synchronous Path

gpio-006

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 21-8.

Figure 21-8. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

21.4.2 General-Purpose Interface Interrupt and Wake-Up Features

21.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 8 interrupt lines (two interrupt lines per GPIO module instance for biprocessor operation for GPIO1 through GPIO4). The 8 interrupt signals are GPIOi_IRQ_1 (used by the DSP and IPU subsystems) and GPIOi_IRQ_2 (used by the CROSSBAR), where $i = 1$ to 4.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the CROSSBAR subsystem on one side and by the IPU, and DSP subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1) and interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1). The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see [Section 21.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see [Section 21.4.5.2.4, Module Power Saving](#)). When an event matches the programmed settings (see [Section 21.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), the corresponding bit in the interrupt status register (GPIO_IRQSTATUS_RAW_x [where $x = 0$ or 1]) is set to 1, and on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers GPIO_IRQSTATUS_SET_x [where $x = 0$ or 1]).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (that is, N times the interface clock period; see [Section 21.4.5.2.4, Module Power Saving](#)). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed three internally gated interface clock cycles plus two interface clock cycles when the debounce feature is not used.

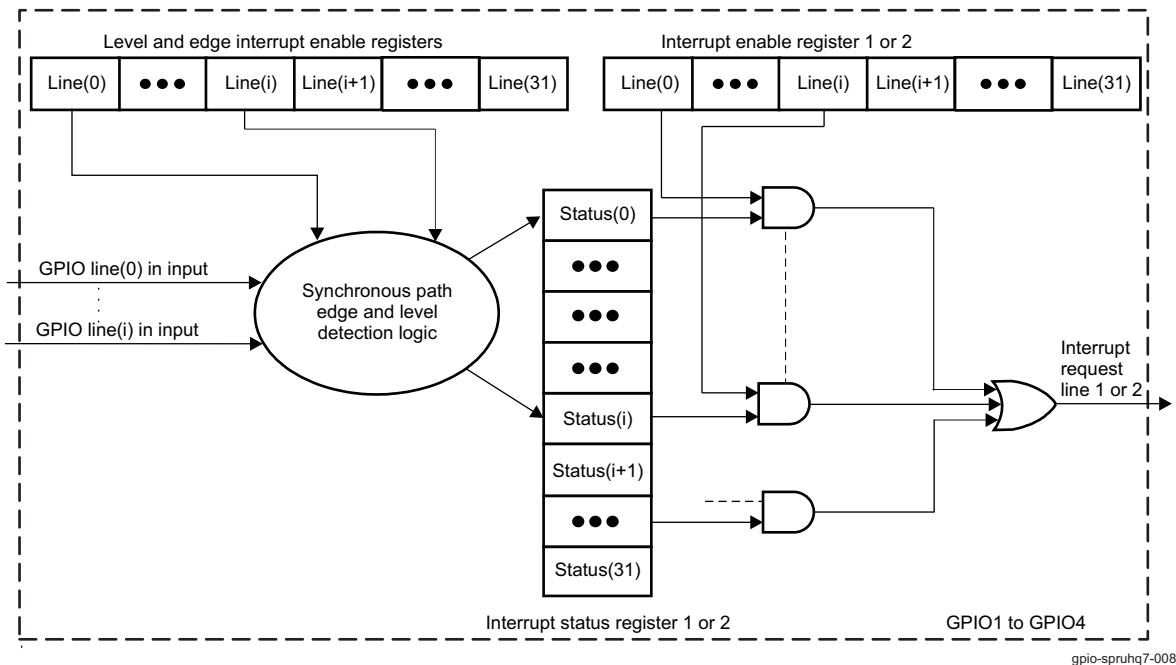

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see Section 21.4.3, *General-Purpose Interface Clock Configuration*) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is default mapped on the IPU, DSP subsystems.

Synchronous interrupt request line 2 is mapped on the CROSSBAR.

Figure 21-9 is an overview of the interrupt request generation.

Figure 21-9. Interrupt Request Generation

21.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has four wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 21.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP [where i = 1 to 4]), if the wake-up-enable register is set.

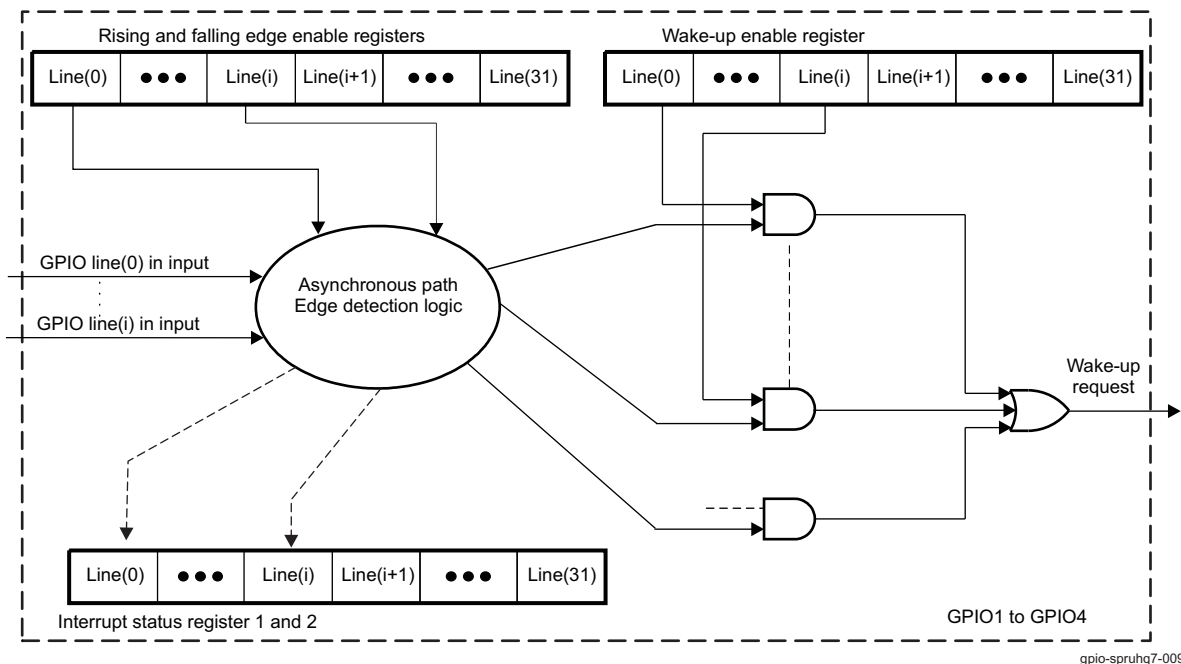

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active high) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

NOTE:

- If the debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request, because there is no sampling operation.
- If the debouncing is used, the minimum pulse width is set by the debouncing specified time.
- The ENAWAKEUP bit of the `GPIO_SYSCONFIG` register allows the enabling or disabling of the GPIO wake-up feature globally: if this bit is set to 0, `GPIO_IRQWAKEN_x` has no effect

Figure 21-10 is an overview of the wake-up request generation.

Figure 21-10. Wake-Up Request Generation

21.4.2.3 Wake-Up Event Conditions During Transition To/From IDLE State

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see Section 21.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of SLEEPTRANS state. During this period a synchronous interrupt request (see Section 21.4.2.1, *Synchronous Path: Interrupt Request Generation*) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see Section 21.4.2.2, *Asynchronous Path: Wake-Up Request Generation*) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight open-core protocol (OCP) clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see Section 21.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see Section 21.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

Figure 21-11 shows the wake-up event conditions.

Figure 21-11. Wake-Up Event Conditions

gpio-014

21.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the DSP subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the software resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

21.4.3 General-Purpose Interface Clock Configuration

21.4.3.1 Clocking

Each GPIO module uses two clocks:

- **Debounce clock:** The 32-kHz debounce clock, GPIOi_DBCLK (where i = 1 to 4 with one debounce clock per module), comes from the PRCM module and is used to debounce the submodule logic (without the corresponding configuration registers). This module can sample the input line and filter the input level using a programmed delay.

The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. Because the value is global for all the ports of one GPIO module, up to eight different debouncing values are possible. The debounce cell runs with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field + 1) × 31,

where the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field is from 0 to 255.

For more information, see [Section 3.6.4.5, CD_L4_PER1 Clock Domain](#), and [Section 3.6.4.1, CD_WKUPAON Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Interface clock:** The interface clock, GPIOi_ICLK (where i = 1 to 4), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). GPIOi_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For more information, see [Section 3.6.4.5, CD_L4_PER1 Clock Domain](#), and [Section 3.6.4.1, CD_WKUPAON Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 21-3](#) describes the clocks in the GPIO modules.

[Table 21-5](#) summarizes the functional clock configuration.

Table 21-5. Functional Clock Configuration

Interface Clock	GPIO_CTRL[2:1]GATINGRATIO	Functional Clock
GPIOi_ICLK (where i = 1 to 4)	00	GPIOi_ICLK /1
GPIOi_ICLK (where i = 1 to 4)	01	GPIOi_ICLK /2
GPIOi_ICLK (where i = 1 to 4)	10	GPIOi_ICLK /4
GPIOi_ICLK (where i = 1 to 4)	11	GPIOi_ICLK /8

21.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- **Hardware reset:** The GPIO2 to GPIO4 modules are attached to the L4PER_RET_RST reset domain. GPIO1 is attached to the WKUPAON_RST reset domain.

The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see [Section 3.5.5, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Software reset:** Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit. The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

Setting the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit to 1 resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the

GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. RESETDONE is set to 1 when the software reset completes.

21.4.5 General-Purpose Interface Power Management

21.4.5.1 Power Domain

GPIO1 is attached to the PD_WKUPAON power domain (see [Section 3.1.1.2, Power Management, in Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUPAON power domain is continuously active. The GPIO2 to GPIO4 modules are attached to the PD_L4PER power domain (see [Section 3.1.1.2, Power Management, in Chapter 3, Power, Reset, and Clock Management](#)). The PD_L4PER power domain is not active continuously.

21.4.5.2 Power Management

21.4.5.2.1 Idle Scheme

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- Efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_WAKEUP) are sideband signals between the PRCM module and the general-purpose interface (see [Section 21.4.6.2, Wake-Up Requests Generation](#)).

21.4.5.2.2 Operating Modes

Three operating modes are defined for the module:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.
If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle mode is configured within the module and activated on request by the host processor through sideband signals (see [Section 21.4.5.2.3, System Power Management and Wakeup](#)).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the system interface. When setting the GPIO_CTRL[0] DISABLEMODULE bit (enabling or disabling the GPIO module), it is important to switch the debouncing clock on or off in the following order:

- The GPIO optional debouncing clock must be enabled before the GPIO module is set (GPIO_CTRL[0]DISABLEMODULE = 0x0).
- The GPIO optional debouncing clock must be disabled after the GPIO module is disabled (GPIO_CTRL[0]DISABLEMODULE = 0x1).

21.4.5.2.3 System Power Management and Wakeup

The PRCM module can require the GPIO modules to be idled for power-saving purposes.

The general-purpose interface has eight identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Section 21.4.6.2, Wake-Up Requests Generation](#)): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode

When the GPIO module is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no write access to the GPIO.GPIO_DEBOUNCINGTIME register, which is waiting to be synchronized.

Idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs.

- Smart-idle wake-up mode

If the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to have the interface clock switched off. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO_DEBOUNCINGTIME register pending to be synchronized), the idle acknowledge is asserted and the GPIO enters into Idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see). When the system is awake, the IDLE request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the wake-up in the system) signals are immediately deasserted, and the asynchronous wake-up request (if it exists) is reflected into the synchronous interrupt status registers.

- Force-idle mode

When the GPIO module is configured in force-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x0) and receives an IDLE request from the PRCM module, the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO module is configured in no-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x1) and receives an IDLE request from the PRCM module, the GPIO module does not go into idle mode and the idle acknowledge is never sent.

NOTE: For more information about the idle modes, see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

21.4.5.2.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the system interface logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO_DATAIN register is not accessed.

- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no detection, the corresponding clock is gated off.
All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field and can take the values 1, 2, 4, and 8. The interface clock is enabled for this logic one cycle every N cycles. When N is 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at the equivalent frequency of interface clock frequency divided by N.
- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. Setting this bit to 1 forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

Table 21-6 describes the power-management features available for the general-purpose interface module.

NOTE: For information about source clock gating and sleep/wake-up transitions, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 21-6. Local Power-Management Features

Feature	Register Bits/Bit Fields	Description
Clock autogating	GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE	It sets the clock-gating strategy for the OCP interface block.
Slave-idle modes	GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle wake-up-capable modes are available.
Clock activity	GPIOi.GPIO_CTRL[0] DISABLEMODULE	Enable and disable the module.
Debouncing enable	GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE	Debouncing mode is available.
Global wake-up enable	GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE	This register enables or disables a specific IRQ request source to generate a wake-up signal.

Table 21-7 describes the clock activity settings.

Table 21-7. Clock Activity Settings

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
00	Force-idle	The GPIO module goes into inactive mode independently of the internal module state, and the IDLE acknowledge is never sent.	No
01	No-idle	The GPIO module does not go into Idle mode and the IDLE acknowledge is never sent.	No

Table 21-7. Clock Activity Settings (continued)

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
10	Smart-idle	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	No
11	Smart-idle wake-up	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	Yes

21.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

21.4.6.1 Interrupt Requests Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 8 interrupt lines (two interrupt lines per GPIO module instance).

- Synchronous interrupt request line 1 is default mapped on the DSP and IPU INTC subsystem.
- Synchronous interrupt request line 2 is mapped on the CROSSBAR.

Table 21-8 lists the event flags, and their mask, that can cause module interrupts.

Table 21-8. Events

Event Flag	Event Mask	Synchronou s	Sensitivity	Description
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/ level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE	Yes	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE	Yes	Edge/ level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_0 [31:0] INTLINE	No	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_1 [31:0] INTLINE	No	Edge/ level	Corresponding to the second line of interrupt

NOTE: For more information about interrupt mapping, see [Table 21-4, GPIO Hardware Request](#).

Synchronous interrupt request line 1 and line 2 are active depending on their respective interrupt-enable1 and interrupt-enable 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

- interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1)
The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line 1 (or line 2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or by using the alternate set-and-

clear protocol feature for register update. This feature allows setting or clearing explicit bits of these registers with a single write access (see [Section 21.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1)
The interrupt status 1 (or interrupt status 2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line 2) request (or the wake-up line).
When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, set the appropriate bit to 1. However, an interrupt cannot be generated by writing 1 to the interrupt status 1 (or interrupt status 2) register.
If 0 is written to a bit in this register, the value in the corresponding bit in the interrupt status 1 and remains unchanged. The interrupt status 1 (or interrupt status 2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and interrupt status 2 registers are set when the GPIO module is awoken.

CAUTION

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset and the interrupt line released (by setting the corresponding bit of the interrupt status register to 1).

Before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQSTATUS_SET_0 or GPIOi.GPIO_IRQSTATUS_SET_1) the corresponding status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

21.4.6.2 Wake-Up Requests Generation

The GPIO1 module of the general-purpose interface is attached to the WKUPAON power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#), and can wake up the system.

NOTE: The GPIO2 to GPIO4 modules belong to the PD_L4PER power domain and thus their wake-up capabilities are operational only when the PD_L4PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio1_[3:0] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_IRQWAKEN_0 and GPIO_IRQWAKEN_1 wake-up-enable registers (where i = 1 to 4).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

This register can be accessed with direct read/write operations.

NOTE: There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future IDLE request.

Table 21-9 lists the mapping of the wake-up signals.

Table 21-9. Wake-Up Signals

Name	Mapping	Comments
GPIOI_WAKE	GPIOi_SWAKEUP	Where i = 1 to 4. The destination is the PRCM module.

21.4.7 General-Purpose Interface Channels Description

Table 21-10 describes the GPIO channels.

Table 21-10. GPIO Channels Description

Channel Number	Type ⁽¹⁾	Mapping	Wake-Up Feature	Comments
GPIO1				
[31:0]	I/O	gpio1_[31:0]	Yes	GPIO. Wake-up path.
GPIO2				
[31:0]	I/O	gpio2_[31:0]	Yes	GPIO
GPIO3				
[31:0]	I/O	gpio3_[31:0]	Yes	GPIO
GPIO4				
[22:0]	I/O	gpio4_[22:0]	Yes	GPIO
[24:23]	-	Reserved	Reserved	Not pinned-out
[29:25]	I/O	gpio4_[29:25]	Yes	GPIO
[31:30]	-	Reserved	Reserved	Not pinned-out

⁽¹⁾ I = Input; O = Output; I/O = bidirectional

NOTE: For more information about pin configuration, see [Section 14.4.6.1, Pad Configuration Registers](#), in [Chapter 14, Control Module](#).

NOTE: GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

21.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO_OE) controls the I/O capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register

(GPIOi.GPIO_CLEARDATAOUT) address (see [Section 21.4.9, General-Purpose Interface Set-and-Clear Protocol](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1) registers to the interrupt and wake-up feature as needed. For using the alternate set-and-clear protocol, see [Section 21.4.9, General-Purpose Interface Set-and-Clear Protocol](#).

21.4.9 General-Purpose Interface Set-and-Clear Protocol

21.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

21.4.9.2 Clear Instruction

21.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

A write operation in the [GPIO_IRQSTATUS_CLR_0](#) (or [GPIO_IRQSTATUS_CLR_1](#)) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt enable0 (or enable1) register returns the value of the [GPIO_IRQSTATUS_CLR_0](#) (or [GPIO_IRQSTATUS_CLR_1](#)) register.

- Clear data-output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data-output register returns the value of the data-output register.

21.4.9.2.2 Clear Instruction Example

Assume the data-output register (or one of the interrupt or wake-up-enable registers) contains the binary value 0b0000 0001 0000 0001 and bit 0 is to be cleared.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt or wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt or wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the 16 least-significant bits (LSBs) are represented in this example.

Figure 21-12 is an example of a clear instruction.

Figure 21-12. GPIO_CLEARDATAOUT Register Example

21.4.9.3 Set Instruction

21.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).

A write operation in the GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt-enable 0 (or enable1) register returns the value of the interrupt GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register.

- Set data-output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data-output register returns the value of the data-output register.

21.4.9.3.2 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data-output register) contains the binary value 0b0000 0001 0000 0000 and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, the user has only to write 0b1000 0000 0000 1110 at the address of the GPIO_SETDATAOUT register. After this write operation, a reading of the GPIO_SETDATAOUT register returns 0b1000 0001 0000 1110: bits 15, 3, 2, and 1 have been set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the 16 LSBs are represented in this example.

Figure 21-13 is an example of a set instruction.

Figure 21-13. Write in GPIO_IRQSTATUS_SET_0 Register Example

The set wake-up-enable register offers the same feature with the wake-up-enable register.

21.5 General-Purpose Interface Programming Guide

21.5.1 General-Purpose Interface Low-Level Programming Models

21.5.1.1 Global Initialization

21.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see [Section 21.2, General-Purpose Interface Environment](#), and [Section 21.3, General-Purpose Interface Integration](#).

Table 21-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1, Clock Management , in Chapter 3, Power, Reset, and Clock Management .
Control module	Module specific pad muxing must be set in the control module. For more information about the module configuration, see Section 14.4.6.1, Pad Configuration Registers , in Chapter 14, Control Module .
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 13, Interrupt Controllers .
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

21.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

Table 21-12. General-Purpose Interface Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	GPIO_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset completed?	GPIO_SYSSTATUS[0] RESETDONE	= 0x1
Configure idle mode.	GPIO_SYSCONFIG[4:3] IDLEMODE	0x-
Configure interface clock gating.	GPIO_SYSCONFIG[0] AUTOIDLE	0x-
Set clock-gating ratio.	GPIO_CTRL [2:1] GATINGRATIO	0x-
Configure GPIO channels as input or output.	GPIO_OE[31:0] OUTPUTEN	0x-
Set debounce time value.	GPIO_DEBOUNCINGTIME[7:0] DEBOUNCINGTIME	0x-
Enable/disable debouncing for desired input line. (For example, when used with a push-button)	GPIO_DEBOUNCENABLE[31:0] DEBOUNCENABLE	0x-
Interrupt and wake-up requests configuration		
(Optional) Enable/disable wake-up for desired input lines.	GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE	0x-
(Optional) Enable wake-up generation.	GPIO_SYSCONFIG[2] ENAWAKEUP	0x1

Table 21-12. General-Purpose Interface Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Configure detection events. NOTE: Simultaneous enabling of high-level and low-level detection for one given pin creates a constant-interrupt generator.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and/or GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and/or GPIO_RISINGDETECT[31:0] RISINGDETECT and/or GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x-
Clear interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0xFFFF FFFF
Enable interrupts for desired input lines. If wakeup is enabled, it is mandatory to enable the corresponding interrupt.	GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE	0x-

NOTE: Detection of events requires a functional clock running for every group of 8 bits. If detection of events is enabled only within one octet (for example, 0x0012 0000), power saving can be achieved. Else (for example, 0x0102 0000), using two octets requires one more clock to be run by the module.

21.5.1.2 General-Purpose Interface Operational Modes Configuration

21.5.1.2.1 General-Purpose Interface Read Input Register

Table 21-13. General-Purpose Interface Read Input Register

Step	Register/Bit Field/Programming Model	Value
Read interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0x-
Read input register value.	GPIO_DATAIN[31:0] DATAIN	0x-
Clear interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0xFFFF FFFF

21.5.1.2.2 General-Purpose Interface Set Bit Function

Table 21-14. General-Purpose Interface Set Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to set desired bit(s) in DATAOUT register.	GPIO_SETDATAOUT [31:0] INTLINE	0x-

21.5.1.2.3 General-Purpose Interface Clear Bit Function

Table 21-15. General-Purpose Interface Clear Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to clear desired bit(s) in DATAOUT register.	GPIO_CLEARDATAOUT [31:0] INTLINE	0x-

21.6 General-Purpose Interface Register Manual

21.6.1 General-Purpose Interface Instance Summary

Table 21-16 summarizes the general-purpose interface instance.

Table 21-16. Instance Summary

Module Name	Module Base Address	Size
GPIO2	0x4805 5000	408 Bytes
GPIO3	0x4805 7000	408 Bytes
GPIO4	0x4805 9000	408 Bytes

21.6.2.2 General-Purpose Interface Register Description

through describe the individual general-purpose interface registers.

Table 21-19. GPIO_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4805 5000 0x4805 7000 0x4805 9000 0x4AE1 0000	Instance	GPIO2 GPIO3 GPIO4 GPIO1
Description	IP revision identifier (X.Y.R)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	See ⁽¹⁾

⁽¹⁾ TI Internal Data

Table 21-20. Register Call Summary for Register GPIO_REVISION

- General-Purpose Interface Register Manual
- [General-Purpose Interface Register Summary: \[1\]\[4\]](#)

Table 21-21. GPIO_SYSCONFIG

Address Offset	0x0000 0010	Instance	GPIO2
Physical Address	0x4805 5010 0x4805 7010 0x4805 9010 0x4AE1 0010		GPIO3 GPIO4 GPIO1
Description	System configuration register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IDLEMODE		ENAWAKEUP		SOFTRESET		AUTOIDLE									

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	R	0x00000000
4:3	IDLEMODE	0x0: Force-idle: An IDLE request is acknowledged unconditionally. 0x1: No-idle: An IDLE request is never acknowledged. 0x2: Smart-idle: The acknowledgment to an IDLE request is given based on the internal activity (see Section 21.4.5.2.3, System Power Management and Wakeup). 0x3: Smart-idle wakeup	RW	0x0
2	ENAWAKEUP	Wake-up control. 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	OCP clock gating control. 0x0: Internal interface OCP clock is free-running. 0x1: Automatic internal OCP clock gating, based on the OCP interface activity	RW	0

Pulse-Width Modulation Subsystem

This chapter describes the Pulse-Width Modulation (PWM) subsystem in the device.

Topic	Page
22.1 PWM Subsystem Resources	6311
22.2 Enhanced PWM (ePWM) Module	6325
22.3 Enhanced Capture (eCAP) Module	6413
22.4 Enhanced Quadrature Encoder Pulse (eQEP) Module	6434

22.1 PWM Subsystem Resources

22.1.1 PWMSS Overview

The device has an embedded Pulse Width Modulation Subsystem (PWMSS), which includes one instance of:

- Enhanced High Resolution Pulse Width Modulator (eHRPWM)
- Enhanced Capture (eCAP)
- Enhanced Quadrature Encoded Pulse (eQEP)

Figure 22-1 shows an overview of the device PWMSS.

Figure 22-1. PWMSS Block Diagram

22.1.1.1 PWMSS Key Features

The supported features by the device PWMSS are:

eHRPWM

- Dedicated 16 bit time-base with Period / Frequency control
- Can support 2 independent PWM outputs with Single edge operation
- Can support 2 independent PWM outputs with Dual edge symmetric operation
- Can support 1 independent PWM output with Dual edge asymmetric operation
- Supports Dead-band generation with independent Rising and Falling edge delay control
- Provides asynchronous over-ride control of PWM signals during fault conditions
- Supports “trip zone” allocation of both latched and un-latched fault conditions
- Allows events to trigger both CPU interrupts and start of ADC conversions
- Support PWM chopping by high frequency carrier signal, used for pulse transformer gate drives.

- High-resolution module with programmable delay line:
 - Programmable on a per PWM period basis
 - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all

eCAP

- Dedicated input Capture pin
- 32 bit Time Base (counter)
- 4 x 32 bit Time-stamp Capture registers ([PWMSS_ECAP_CAP1](#) - [PWMSS_ECAP_CAP4](#))
- 4 stage sequencer (Mod4 counter) which is synchronized to external events (ECAP pin edges)
- Independent Edge polarity (Rising / Falling edge) selection for all 4 events
- Input Capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 Time-stamp events
- Control for continuous Time-stamp captures using a 4 deep circular buffer ([PWMSS_ECAP_CAP1](#) - [PWMSS_ECAP_CAP4](#)) scheme
- Interrupt capabilities on any of the 4 capture events

eQEP

- Input Synchronization
- Three Stage/Six Stage Digital Noise Filter
- Quadrature Decoder Unit
- Position Counter and Control unit for position measurement
- Quadrature Edge Capture unit for low speed measurement
- Unit Time base for speed/frequency measurement
- Watchdog Timer for detecting stalls

At a PWMSS system level :

- the PWMSS generates 2 x eHRPWM, 1x eCAP and 1 x eQEP event mapped to the device IRQ_CROSSBAR.
- Three of the interrupt events (excluding ePWM tripzone event) are also mapped as DMA requests to the device DMA_CROSSBAR.

22.1.1.2 PWMSS Unsupported Features

The PWMSS limitations in the device are :

- No ePWM inputs are pinned-out (available at the off-chip boundary)
- Only one ePWM tripzone input is pinned-out
- No ePWM digital comparator inputs are pinned-out
- No signals of QEP are pinned-out.

Table 22-1. PWMSS Unsupported Features

Feature	Reason
ePWM inputs	Not pinned out
ePWM tripzone 1-5 inputs	Only Tripzone0 is pinned out
ePWM digital comparators	Inputs not connected
eQEP signals	No signals are connected

22.1.2 PWMSS Environment

22.1.2.1 PWMSS I/O Interface

[Table 22-2](#) shows the device integrated PWMSS interface signals to external devices.

Table 22-2. PWM Subsystem I/O Signals

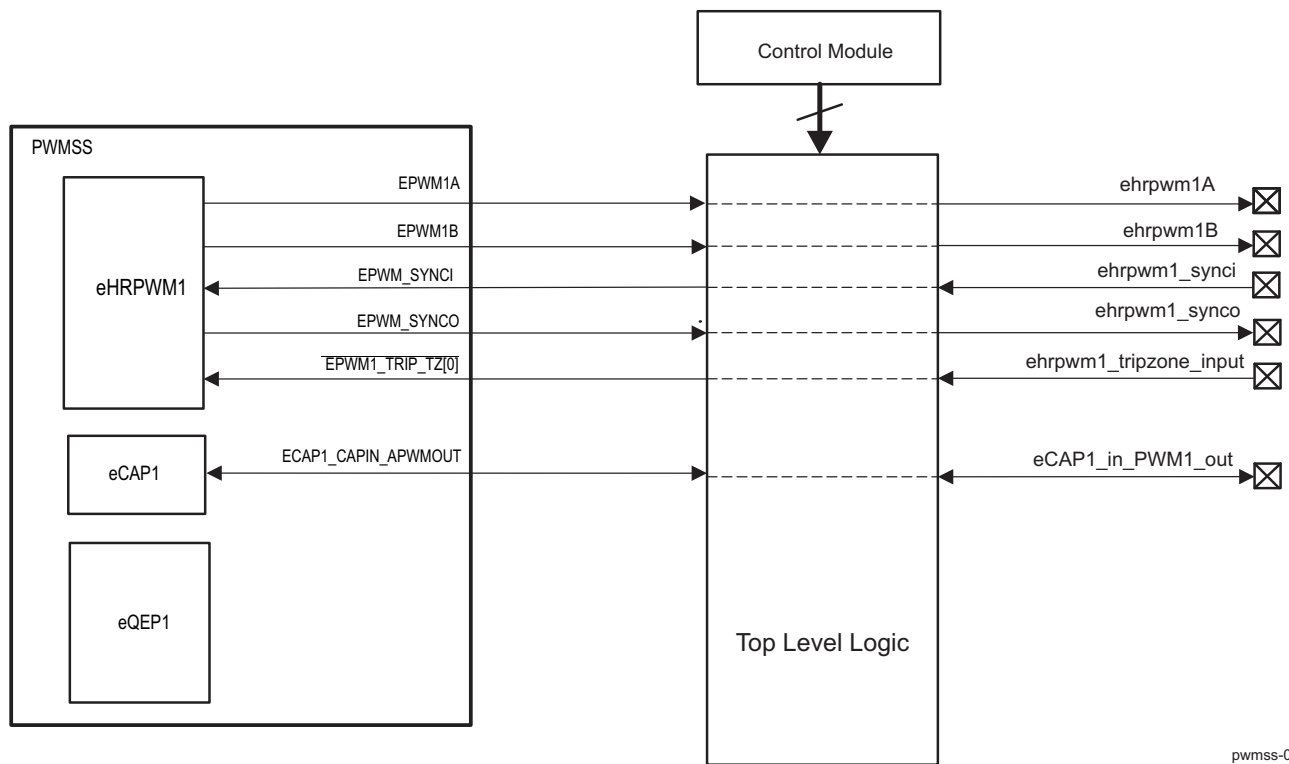

PWMSS Module Signal Names	Device Level Signal Names	I/O Type ⁽¹⁾	Description	Module Pin Reset Value
PWMSS				
EPWM1A	ehrpwm1A	O	PWM1 output A	0
EPWM1B	ehrpwm1B	O	PWM1 output B	0
EPWM_SYNCI	ehrpwm1_synci	I	PWM1 Sync input	HiZ
EPWM_SYNCO	ehrpwm1_synco	O	PWM1 Sync output	0
EPWM1_TRIP_TZ[0]	ehrpwm1_tripzone_input	I	PWM1 TripZone input	HiZ
ECAP1_CAPIN_APWMOUT	eCAP1_in_PWM1_out	I/O	eCAP1 Capture input / PWM1 output	HiZ

⁽¹⁾ I = Input; O = Output

Figure 22-2 shows the external interface I/Os for the integrated modules in the PWMSS.

Figure 22-2. PWMSS External Interface I/Os

Device

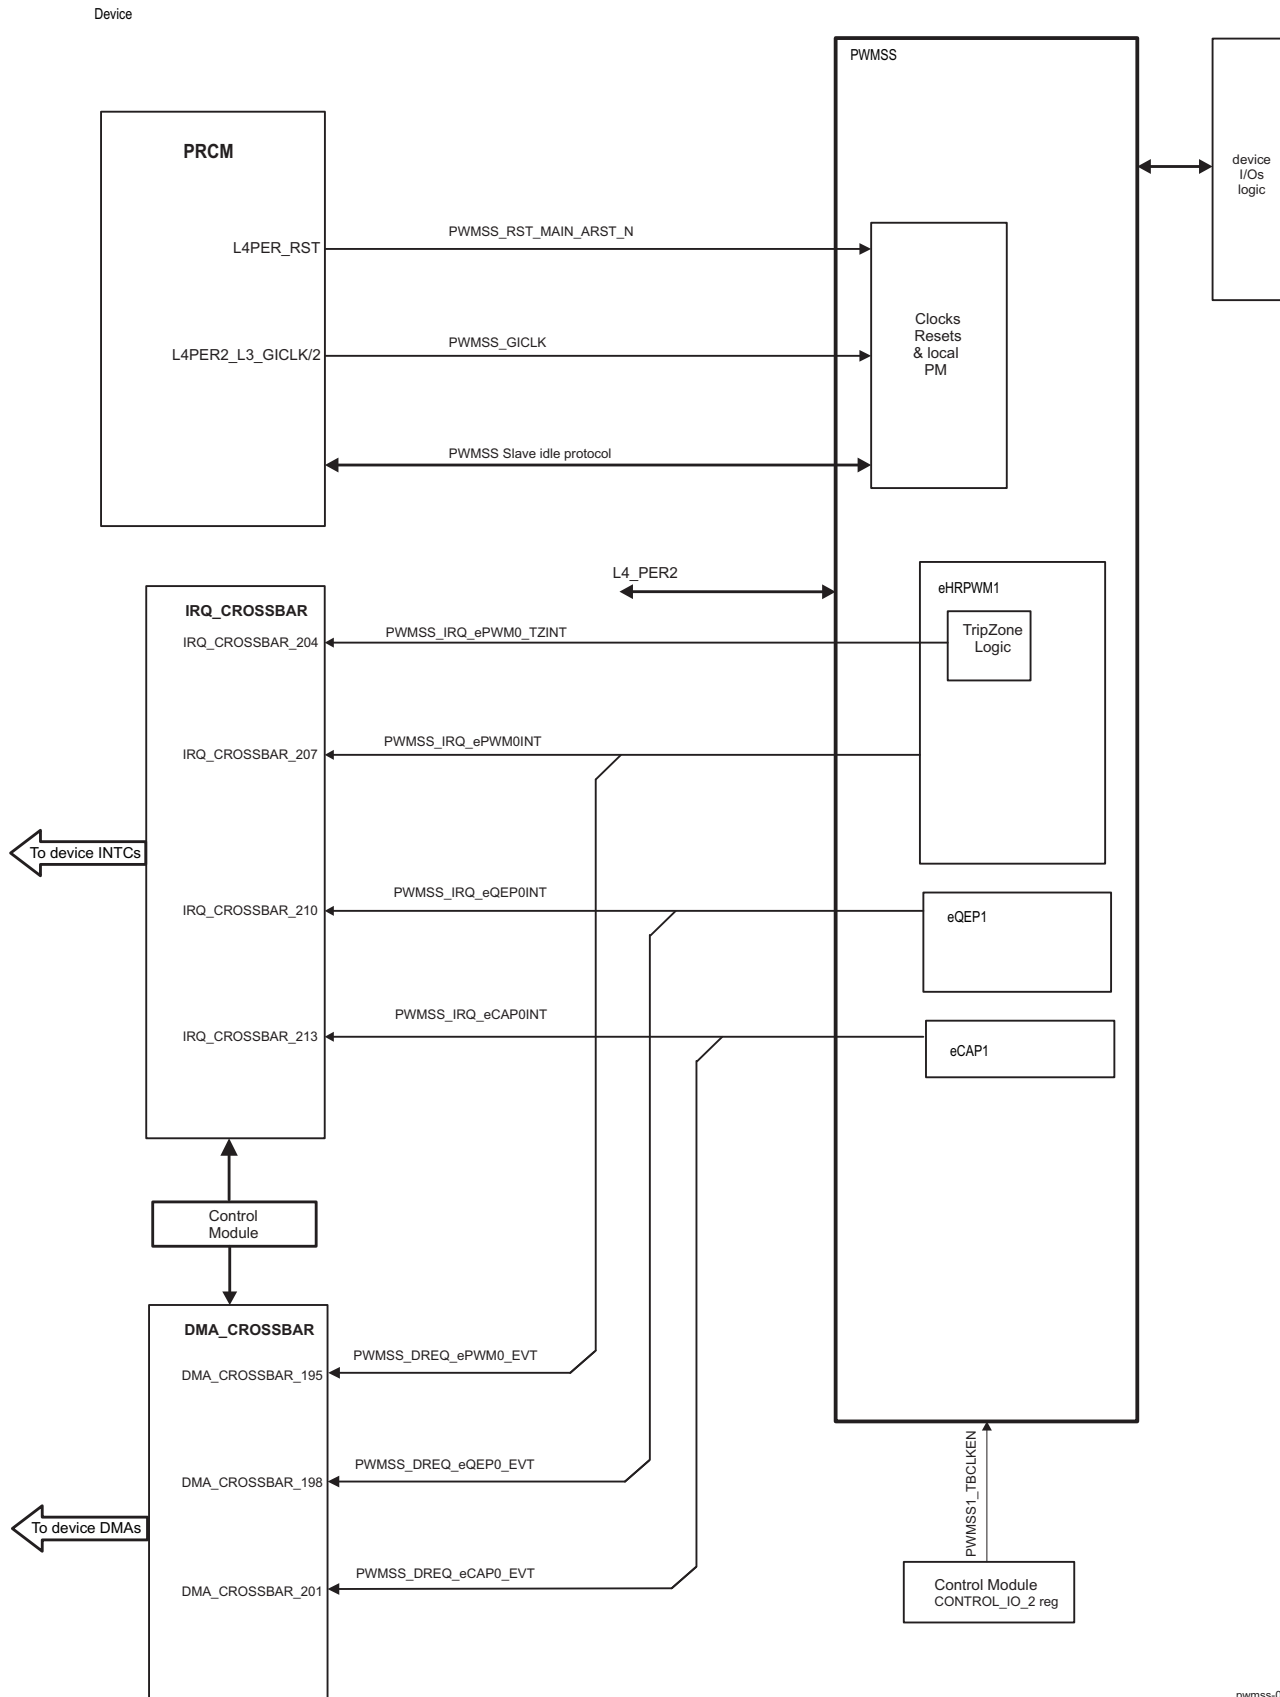

pwms-002

NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to [Section 14.4.6.1, Pad Configuration Registers](#), in chapter, *Control Module*.

22.1.3 PWMSS Integration

The Pulse Width Modulation Subsystem (PWMSS) includes a single instance of one pulse width modulator (ePWM) including an Enhanced High Resolution Modulator (eHRPWM), one Enhanced Capture (eCAP), and one Enhanced Quadrature Encoded Pulse (eQEP) modules.

Figure 22-3. PWMSS Integration

pwmss-003

At system level the PWMSS integration features:

- A 32-bit slave configuration port on the L4_PER2 interconnect.
- A single gateable interface and functional clock from PRCM to the PWMSS.
- A slave idle protocol with the device PRCM
- A "non-wakeup capable Smart Idle" mode supported

NOTE: For more information about the slave idle protocol, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

- A non-retention hardware reset from PRCM to the PWMSS
- A PWMSS global level software reset which impacts all registers of the PWMSS at the same time
- 4 hardware events. From these events the PWMSS :
 - generates 4 interrupts to the device IRQ_CROSSBAR
 - generates 3 DMA requests, mapped to the device DMA_CROSSBAR

[Table 22-3](#) through [Table 22-5](#) summarize the integration of the module in the device.

Table 22-3. PWMSS Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PWMSS	PD_COREAON	L4_PER2

Table 22-4. PWMSS Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
PWMSS	PWMSS_GICLK	L4PER2_L3_GICLK/2	PRCM	PWMSS gated interface and functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
PWMSS	PWMSS_RST_MAIN_ARST_N	L4PER_RST	PRCM	A nonretention hardware main reset to the PWMSS

Table 22-5. PWMSS Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
PWMSS	PWMSS_IRQ_ePWM0_TZINT	IRQ_CROSSBAR_204	N/A	eHRPWM1 tripzone event / interrupt. This IRQ source signal is not mapped by default to any device INTC.
	PWMSS_IRQ_ePWM0INT	IRQ_CROSSBAR_207	N/A	eHRPWM1 event / interrupt. This IRQ source signal is not mapped by default to any device INTC.
	PWMSS_IRQ_eQEP0INT	IRQ_CROSSBAR_210	N/A	eQEP1 event / interrupt. This IRQ source signal is not mapped by default to any device INTC.
	PWMSS_IRQ_eCAP0INT	IRQ_CROSSBAR_213	N/A	eCAP1 event / interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 22-5. PWMSS Hardware Requests (continued)

Module Instance	Source Signal Name	DMA Requests		Description
		Destination DMA_CROSSBAR Input	Default Mapping	
PWMSS	PWMSS_DREQ_ePWM0_EVT	DMA_CROSSBAR_195	N/A	eHRPWM1 event DMA request. This DMA req source signal is not mapped by default to any device DMA controller.
	PWMSS_DREQ_eQEP0_EVT	DMA_CROSSBAR_198	N/A	eQEP1 event DMA request. This DMA req source signal is not mapped by default to any device DMA controller.
	PWMSS_DREQ_eCAP0_EVT	DMA_CROSSBAR_201	N/A	eCAP1 event DMA request. This DMA req source signal is not mapped by default to any device DMA controller.

NOTE: The “Default Mapping” column in [Table 22-5, PWMSS Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

22.1.3.1 PWMSS Module Interfaces Implementation

This section describes how the PWMSS submodules - ePWM / eHRPWM, eQEP and eCAP can be used in terms of their functional interfaces considering PWMSS device specific integration.

22.1.3.1.1 Device Specific PWMSS Features

A High-Resolution PWM (HRPWM) modulator is added to the ePWM module, hence the ePWM is signified as eHRPWM.

While the eCAP functionalities are fully implemented in the device, the eHRPWM and eQEP module interface have some restrictions in functionality. The eHRPWM and eQEP restrictions are as follows:

- **For ePWM comparators - only the outputs (ehrpwm1A and ehripwm1B) are available at chip level**
- **Only one tripzone input pin - EPWM_TRIP_TZ[0] of ePWM / eHRPWM is available to the user at chip level**
- **No eQEP input signals are available to the user at chip level**

The eHRPWM and eQEP functional interface signals which are NOT available to user for the PWMSS are summarized in [Table 22-6](#).

Table 22-6. Device Limitations for the eHRPWM and eQEP Functional Interfaces of the PWMSS

Module Interface	Signal	Description	Comment
PWMSS eHRPWM	EPWM_COMP_EPWMDCMAH	ePWM Comparator A input (HIGH)	Not available at chip boundary (can not be used)
	EPWM_COMP_EPWMDCMAL	ePWM Comparator A input (LOW)	
	EPWM_COMP_EPWMDCMBH	ePWM Comparator B input (HIGH)	
	EPWM_COMP_EPWMDCMBL	ePWM Comparator B input (LOW)	
	EPWM_EPWMA_i	ePWM A input	
	EPWM_EPWMB_i	ePWM B input	
	EPWM_TRIP_TZ[5:1]	ePWM Tripzone inputs [5:1]	
	EPWM_ADC_SOCA	ePWM Start of ADC conversion A output	
	EPWM_ADC_SOCB	ePWM Start of ADC conversion B output	
	EPWM_TRIP_TZ_O[5:0]	ePWM Tripzone outputs	
PWMSS eQEP	EQEP_ERR_PHASE_ERR	eQEP phase error output	Not available at chip boundary (can not be used)
	EQEP_EQEPA_O	eQEP quadrature A output	
	EQEP_EQEPB_O	eQEP quadrature B output	
	EQEP1_A	eQEP1 Quadrature input	
	EQEP1_B	eQEP1 Quadrature input	
	EQEP1_INDEX	eQEP1 Index input/output	
	EQEP1_STROBE	eQEP1 Strobe input/output	

22.1.3.1.2 eHRPWM Module Time Base Clock Gating

PWMSS ePWM / eHRPWM module has an EPWMTBCLKEN module input used to individually **enable / disable its ePWM time-base clock**. This is done through the CTRL_CORE_CONTROL_IO_2[20] PWMSS1_TBCLKEN bit coming from the device control module.

To hold the TBCLK generation counter in its reset state the PWMSS1_TBCLKEN bit should be set to 0b0. When PWMSS1_TBCLKEN is set to 0b1, then the TBCLK generation counter is allowed to count.

For more details on the CTRL_CORE_CONTROL_IO_2, refer to the [Section 14.5, Control Module Register Manual](#), in the chapter, *Control Module*.

22.1.4 PWMSS Subsystem Power, Reset and Clock Configuration

22.1.4.1 PWMSS Local Clock Management

The system configuration register - [PWMSS_SYSCONFIG](#) is used to configure the local clock management of the PWMSS slave configuration port on the device L4_PER2 interconnect. Note that this register impacts the behaviour of the root interface and functional clock PWMSS_GICLK inside PWMSS shared between the ePWM/eHRPWM, eQEP and eCAP modules. An idle handshaking protocol is supported between PWMSS and the device PRCM.

NOTE: For more information about the slave idle protocol, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Table 22-7. Local IDLE Clock Management Features

Feature	Register bitfield	Description
Slave idle mode	PWMSS_SYSCONFIG IDLEMODE	[3:2] The available modes are: Force-idle, no-idle, and smart-idle (non-wakeup capable) modes.

NOTE: The device PWM subsystem is part of the CD_L4_PER2 clock domain. For more details on the PWM subsystem top level clock-management modes and control, refer to the [Section 3.6.4.1.4, Clock Domain Module Attributes](#), in the [Chapter 3, Power, Reset, and Clock Management](#).

22.1.4.2 PWMSS Module Local Clock Gating

NOTE: PWMSS Module Local Clock Gating feature is not supported in this family of devices.

In addition to PWMSS level IDLE clock management, described above, a clock configuration register - [PWMSS_CLKCONFIG](#) is used to individually gate (stop) or enable interface and functional clock to the ePWM / eHRPWM, eCAP and eQEP modules. By default, the interface/functional clock is enabled.

The clock status register - [PWMSS_CLKSTATUS](#) is used in the PWMSS submodule to indicated acknowledgement of a clock stop or clock enable request.

The [PWMSS_CLKCONFIG](#) and [PWMSS_CLKSTATUS](#) role is described in [Table 22-8](#).

Table 22-8. Local Module Clock Control and Status Features

Clock Control / Status Feature	PWMSS Submodule	Register bit
Request "stop interface and functional clock" to module	ePWM / eHRPWM	PWMSS_CLKCONFIG [9] EPWM_CLKSTOP_REQ
	eQEP	PWMSS_CLKCONFIG [5] EQEP_CLKSTOP_REQ
	eCAP	PWMSS_CLKCONFIG [1] ECAP_CLKSTOP_REQ
"Stop module interface and functional clock" acknowledged status	ePWM / eHRPWM	PWMSS_CLKSTATUS [9] EPWM_CLKSTOP_ACK
	eQEP	PWMSS_CLKSTATUS [5] EQEP_CLKSTOP_ACK
	eCAP	PWMSS_CLKSTATUS [1] ECAP_CLKSTOP_ACK
Request "enable interface and functional clock" to module	ePWM / eHRPWM	PWMSS_CLKCONFIG [8] EPWM_CLK_EN
	eQEP	PWMSS_CLKCONFIG [4] EQEP_CLK_EN
	eCAP	PWMSS_CLKCONFIG [0] ECAP_CLK_EN
"Enable module Interface and functional clock" acknowledged status	ePWM / eHRPWM	PWMSS_CLKSTATUS [8] EPWM_CLK_EN_ACK
	eQEP	PWMSS_CLKSTATUS [4] EQEP_CLK_EN_ACK
	eCAP	PWMSS_CLKSTATUS [0] ECAP_CLK_EN_ACK

NOTE: In order for the PWMSS to enter "Idle state", all PWMSS submodules must have acknowledged a stop clock request, i.e. the [PWMSS_CLKSTATUS](#) bits EPWM_CLKSTOP_ACK, ECAP_CLKSTOP_ACK and EQEP_CLKSTOP_ACK must be raised 'HIGH'.

22.1.4.3 PWMSS Software Reset

The [PWMSS_SYSCONFIG](#)[0] SOFTRESET bit can be used to exert a "PWMSS" software reset impacting ePWM / eHRPWM, eCAP and eQEP modules at the same time. The software has to poll the same bit until it is deasserted by HW, to insure software reset of all modules is completed.

22.1.5 PWMSS_CFG Register Manual

This section provides description of the PWM subsystem (top) level functional registers.

22.2 Enhanced PWM (ePWM) Module

22.2.1 ePWM Overview

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWM1A and EPWM1B. The ePWM functionality can be extended with the so called **High-Resolution Pulse Width modulator**. The HRPWM functionality is described in [Section 22.2.2.10](#).

The ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWM1A and EPWM1B) that can be used in the following configurations:
 - Two independent PWM outputs with single-edge operation
 - Two independent PWM outputs with dual-edge symmetric operation
 - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

The ePWM module consists of seven submodules and is connected within a system via the signals as shown in [Figure 22-4](#).

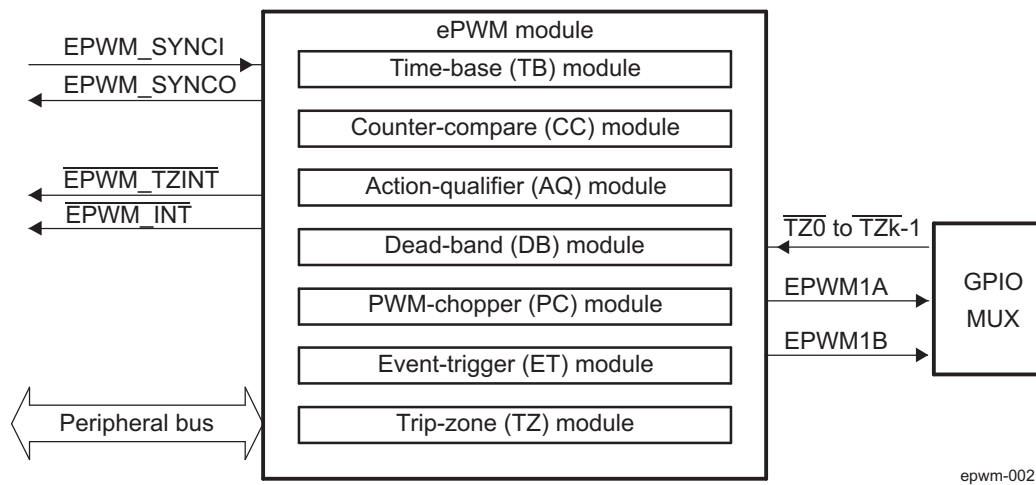

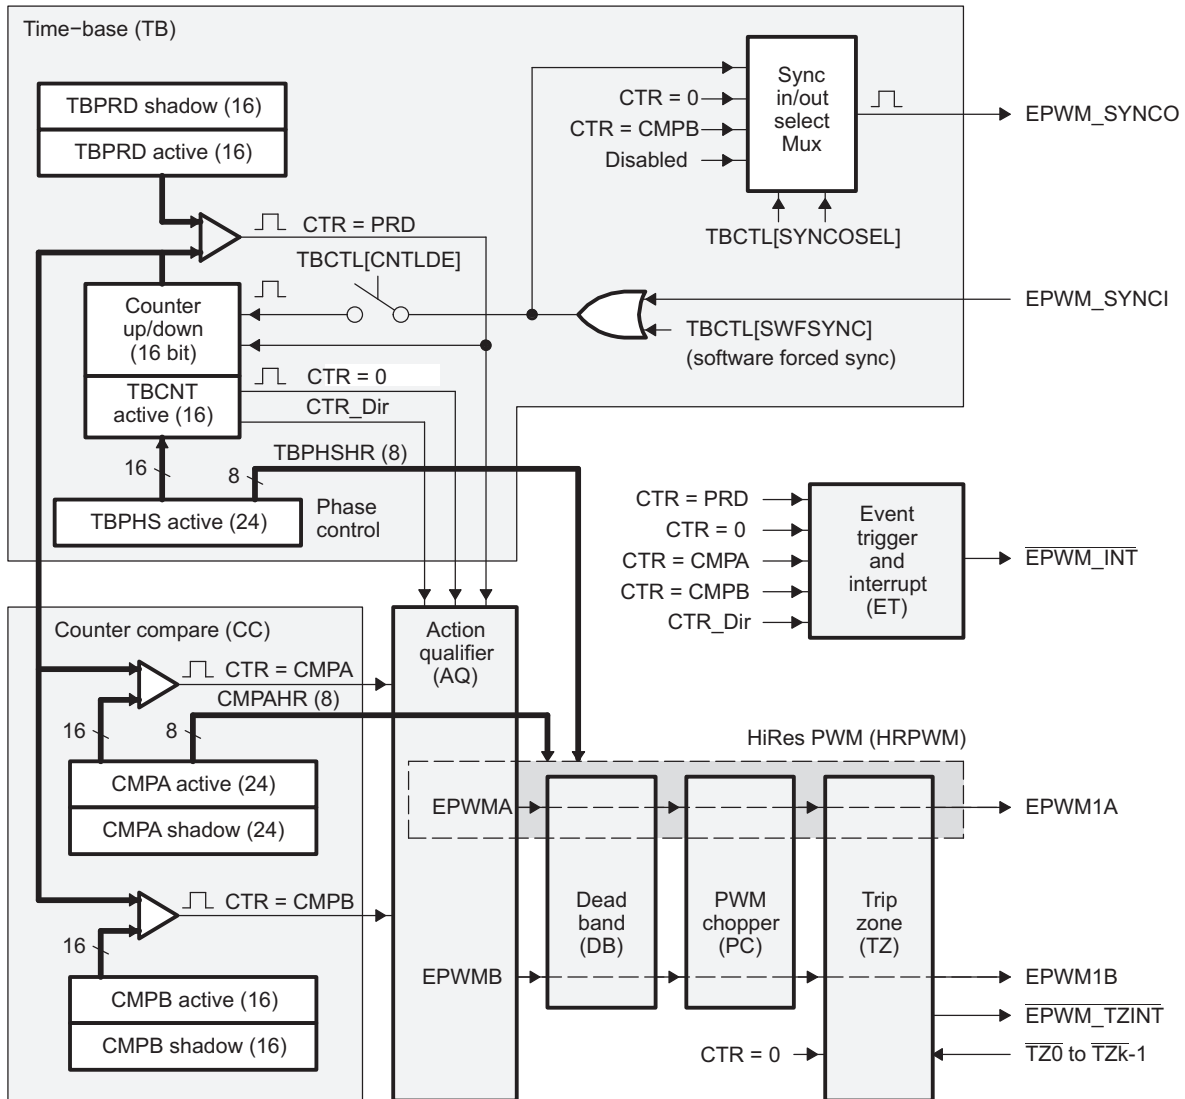

Figure 22-4. Submodules and Signal Connections for the ePWM Module

Figure 22-5 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWM1A and EPWM1B).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for your device.
- **Trip-zone signals ($\overline{TZ0}$ to $\overline{TZk-1}$).** These k input signals alert the ePWM module of an external fault condition. The ePWM module can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- Time-base synchronization input (EPWM_SYNCI) and output (EPWM_SYNCO) signals.
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 22-5 also shows the key internal submodule interconnect signals. Each submodule is described in Section 22.2.2.

Figure 22-5. ePWM Submodules and Critical Internal Signal Interconnects

epwm-003

22.2.2 ePWM Functional Description

Seven submodules are included in the ePWM peripheral. It also includes a high-resolution submodule that allows more precise control of the PWM outputs.

22.2.2.1 ePWM Submodule Features

Table 22-19 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 22.2.2.4 for relevant details.

Table 22-19. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> • Scale the time-base clock (TBCLK) relative to the system clock (SYSCLKOUT). • Configure the PWM time-base counter (TBCNT) frequency or period. • Set the mode for the time-base counter: <ul style="list-style-type: none"> – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: <ul style="list-style-type: none"> – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	<ul style="list-style-type: none"> • Specify the PWM duty cycle for output EPWM1A and/or output EPWM1B • Specify the time at which switching events occur on the EPWM1A or EPWM1B output
Action-qualifier (AQ)	<ul style="list-style-type: none"> • Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> – No action taken – Output EPWM1A and/or EPWM1B switched high – Output EPWM1A and/or EPWM1B switched low – Output EPWM1A and/or EPWM1B toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	<ul style="list-style-type: none"> • Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.
PWM-chopper (PC)	<ul style="list-style-type: none"> • Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.

Table 22-19. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	<ul style="list-style-type: none"> • Configure the ePWM module to react to one, all, or none of the trip-zone pins. • Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> – Force EPWM1A and/or EPWM1B high – Force EPWM1A and/or EPWM1B low – Force EPWM1A and/or EPWM1B to a high-impedance state – Configure EPWM1A and/or EPWM1B to ignore any trip condition. • Configure how often the ePWM will react to the trip-zone pin: <ul style="list-style-type: none"> – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	<ul style="list-style-type: none"> • Enable the ePWM events that will trigger an interrupt. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
High-Resolution PWM (HRPWM)	<ul style="list-style-type: none"> • Enable extended time resolution capabilities • Configure finer time granularity control or edge positioning

NOTE: The system clock - SYSCLKOUT is the ePWM functional clock derived from the PWMSS gateable interface and functional clock PWMSS_GICLK, described in [Section 22.1.3](#).

Code examples are provided in the remainder of this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions shown in [Example 22-1](#).

```

22.2.2.2 Proper ePWM Interrupt Initialization Procedure

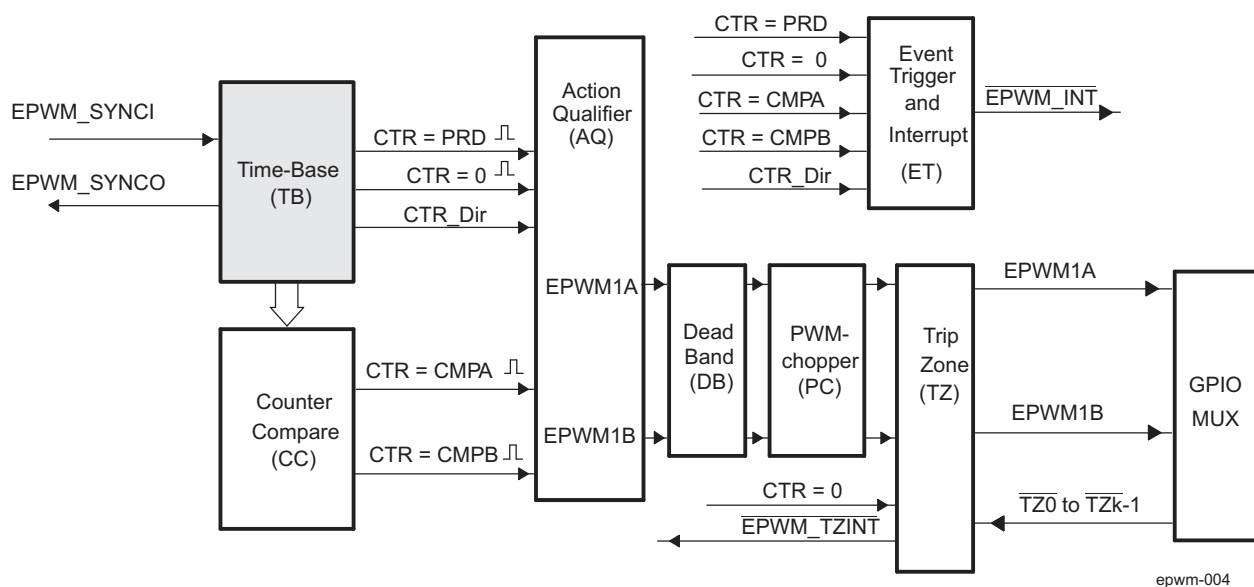

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Initialize peripheral registers
4. Clear any spurious ePWM flags
5. Enable ePWM interrupts
6. Enable global interrupts

22.2.2.3 ePWM Time-Base (TB) Submodule

The ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Figure 22-6 illustrates the time-base module's place within the ePWM.

Figure 22-6. ePWM Time-Base Submodule Block Diagram

epwm-004

22.2.2.3.1 Purpose of the ePWM Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM1 time-base counter (TBCNT) frequency or period in the [EPWM_TBCNT](#) register to control how often events occur.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
 - TBCNT = PRD: Time-base counter ([EPWM_TBCNT](#) register) equal to the specified period in [EPWM_TBPRD](#) register (i.e. TBCNT = TBPRD) .
 - TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (SYSCLKOUT). This allows the time-base counter to increment/decrement at a slower rate.

22.2.2.3.2 Controlling and Monitoring the ePWM Time-Base Submodule

Table 22-20 lists the registers used to control and monitor the time-base submodule.

Table 22-20. ePWM Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

Figure 22-7 shows the critical signals and registers of the time-base submodule. Table 22-21 provides descriptions of the key signals associated with the time-base submodule.

Figure 22-7. ePWM Time-Base Submodule Signals and Registers

epwm-005

Table 22-21. ePWM Key Time-Base Signals

Signal	Description
EPWM_SYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module. The ePWM peripheral can be configured to use or ignore this signal. This signal comes from a device pad. See Section 22.2.2.3.3.2 for information on the synchronization.

Table 22-21. ePWM Key Time-Base Signals (continued)

Signal	Description
EPWM_SYNCO	Time-base synchronization output. The ePWM module generates this signal from one of three event sources: <ol style="list-style-type: none"> 1. EPWM_SYNCI (Synchronization input pulse) 2. TBCNT = 0: The time-base counter (register EPWM_TBCNT) equal to zero (TBCNT = 0000h). 3. TBCNT = CMPB: The time-base counter (register EPWM_TBCNT) equal to the counter-compare B register - EPWM_CMPB (i.e. bitfield TBCNT = bitfield CMPB) .
TBCNT = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
TBCNT = 0	Time-base counter equal to zero. This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
TBCNT = CMPB	Time-base counter equal to active counter-compare B register (TBCNT = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic.
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCNT = FFFFh) Generated event when the EPWM_TBCNT value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock. This is a prescaled version of the system clock - SYSCLKOUT ⁽¹⁾ and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

⁽¹⁾ The system clock - SYSCLKOUT is the ePWM functional clock derived from the PWMSS gateable interface and functional clock PWMSS_GICLK, described in Section 22.1.3.

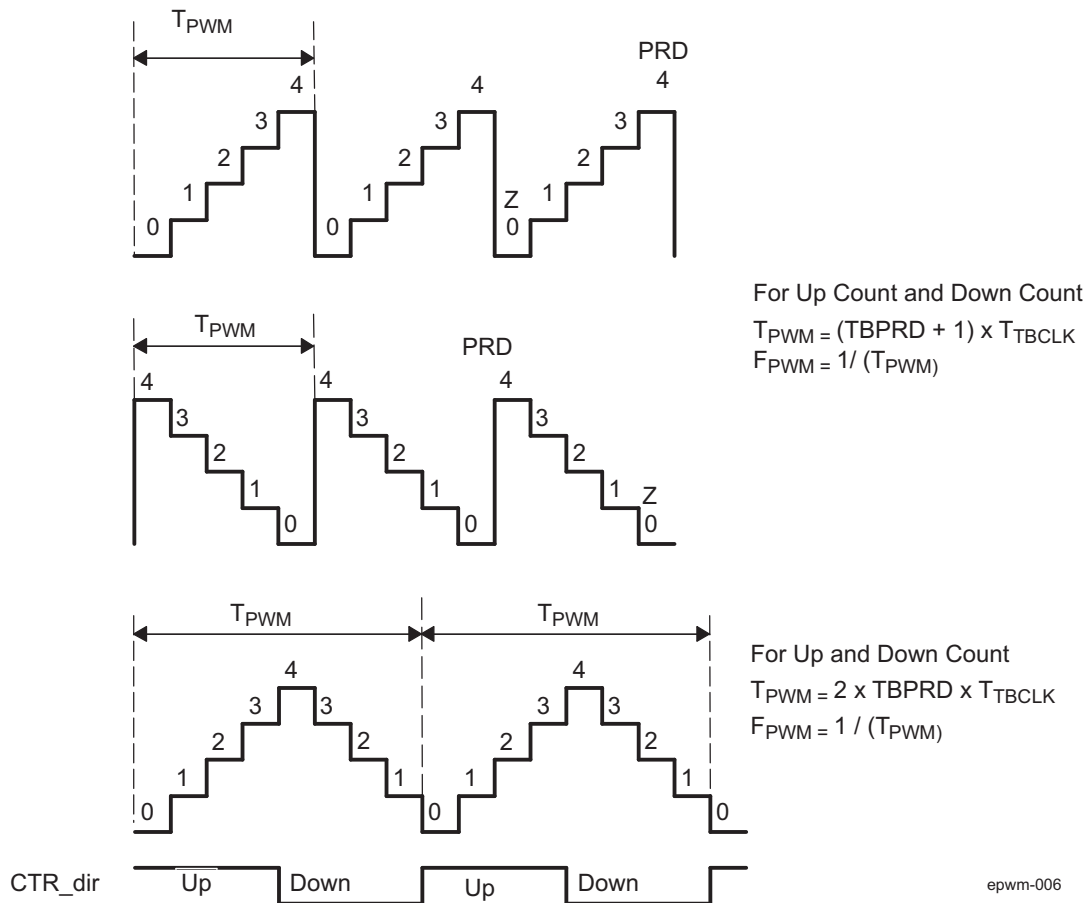

22.2.2.3.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (EPWM_TBPRD) register and the mode of the time-base counter. Figure 22-8 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (EPWM_TBPRD register bitfield TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (SYSCLKOUT).

The time-base counter has three modes of operation selected by the time-base control register (EPWM_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

Figure 22-8. ePWM Time-Base Frequency and Period

22.2.2.3.3.1 ePWM Time-Base Period Shadow Register

The time-base period register ([EPWM_TBPRD](#)) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the [EPWM_TBCTL\[3\]](#) PRDL bit. This bit enables and disables the [EPWM_TBPRD](#) shadow register as follows:

- **Time-Base Period Shadow Mode:** The [EPWM_TBPRD](#) shadow register is enabled when [EPWM_TBCTL\[3\]](#) PRDL = 0. Reads from and writes to the [EPWM_TBPRD](#) memory address go to the shadow register. The shadow register contents are transferred to the active register ([EPWM_TBPRD](#) (Active) ← [EPWM_TBPRD](#) (shadow)) when the time-base counter (register [EPWM_TBCNT](#)) equals zero (TBCNT = 0000h). By default the [EPWM_TBPRD](#) shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected ([EPWM_TBCTL\[3\]](#) PRDL = 1), then a read from or a write to the TBPRD memory address goes directly to the active

register.

22.2.2.3.3.2 ePWM Time-Base Counter Synchronization

The ePWM module can be configured to use or ignore the synchronization input. If the [EPWM_TBCTL\[2\]](#) PHSEN bit is set, then the time-base counter (TBCNT) of the ePWM module (register [EPWM_TBCNT](#)) will be automatically loaded with the phase register ([EPWM_TBPHS](#)) contents when one of the following conditions occur:

- **EPWM_SYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected ([EPWM_TBPHS](#) → [EPWM_TBCNT](#)). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the [EPWM_TBCTL\[6\]](#) SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWM_SYNCI.

Clearing the [EPWM_TBCTL\[2\]](#) PHSEN bit configures the ePWM to ignore the synchronization input pulse.

22.2.2.3.4 ePWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, [Figure 22-9](#) to [Figure 22-12](#) show when events are generated and how the time-base responds to an EPWM_SYNCI signal.

Figure 22-9. ePWM Time-Base Up-Count Mode Waveforms

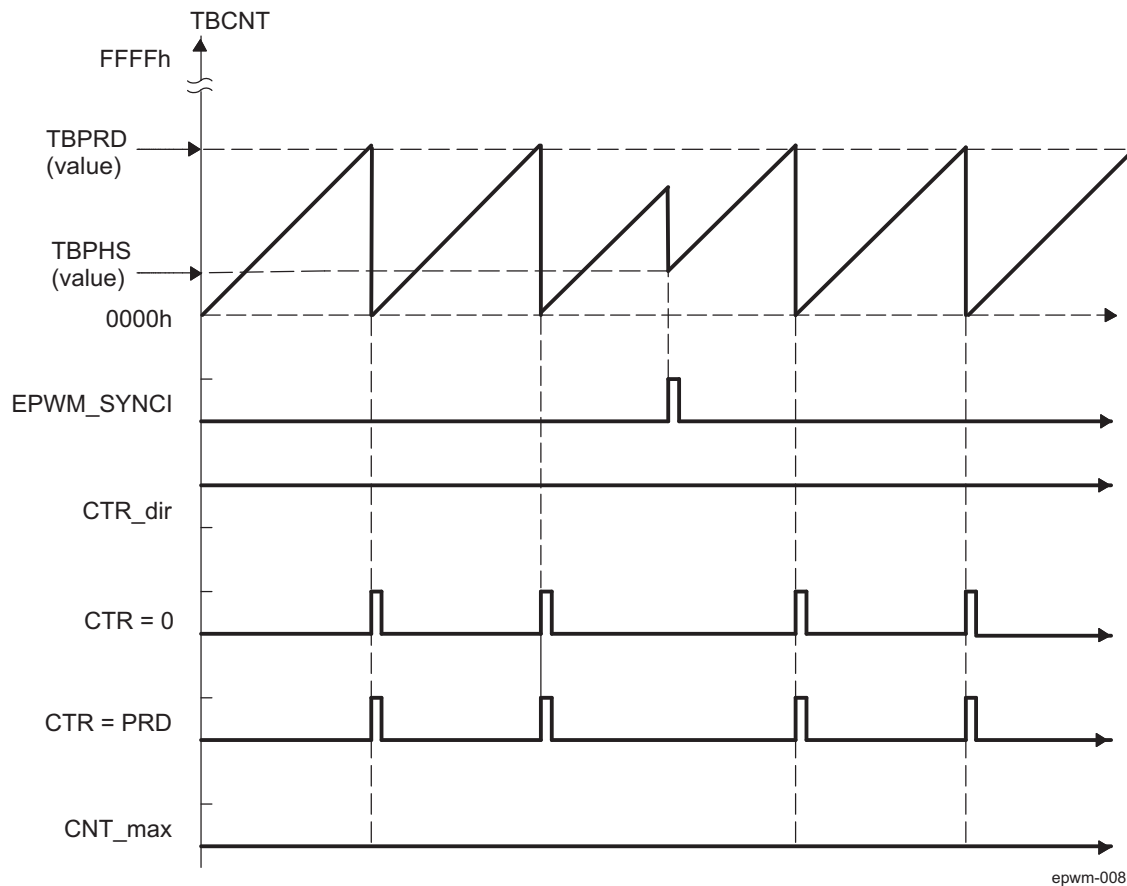

Figure 22-10. ePWM Time-Base Down-Count Mode Waveforms

Figure 22-11. ePWM Time-Base Up-Down-Count Waveforms, EPWM_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event

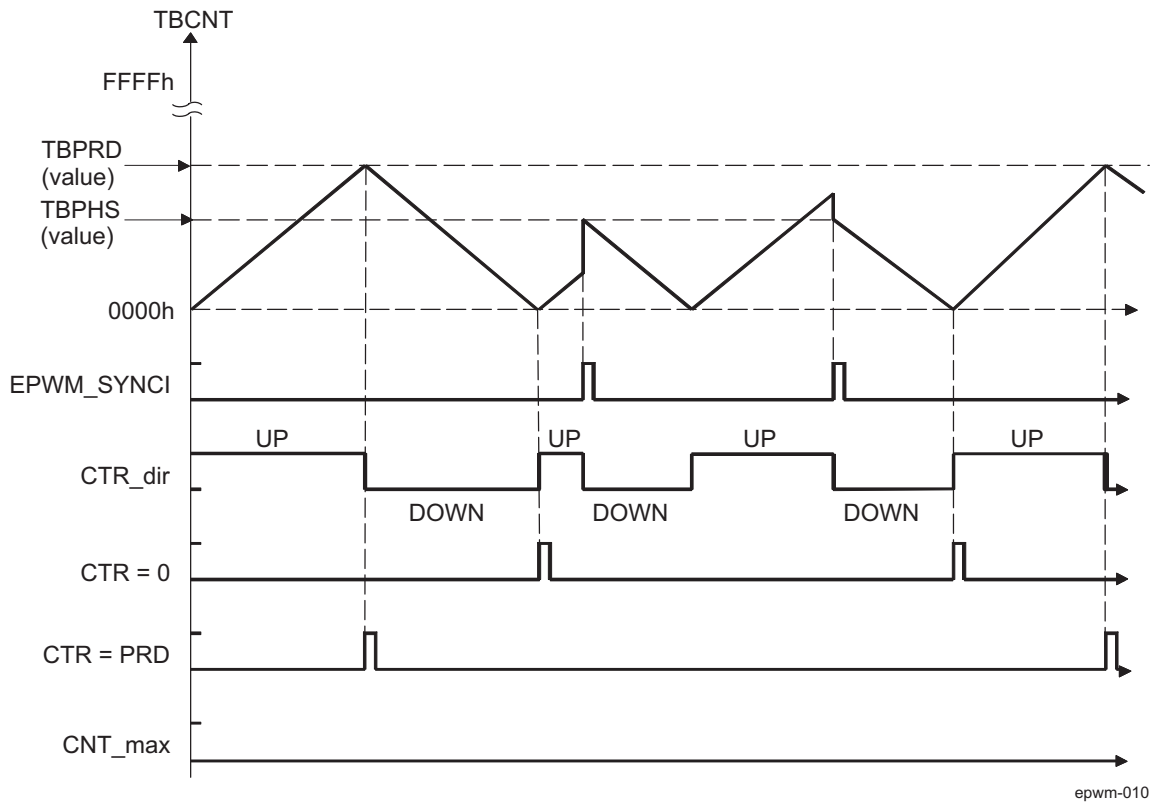

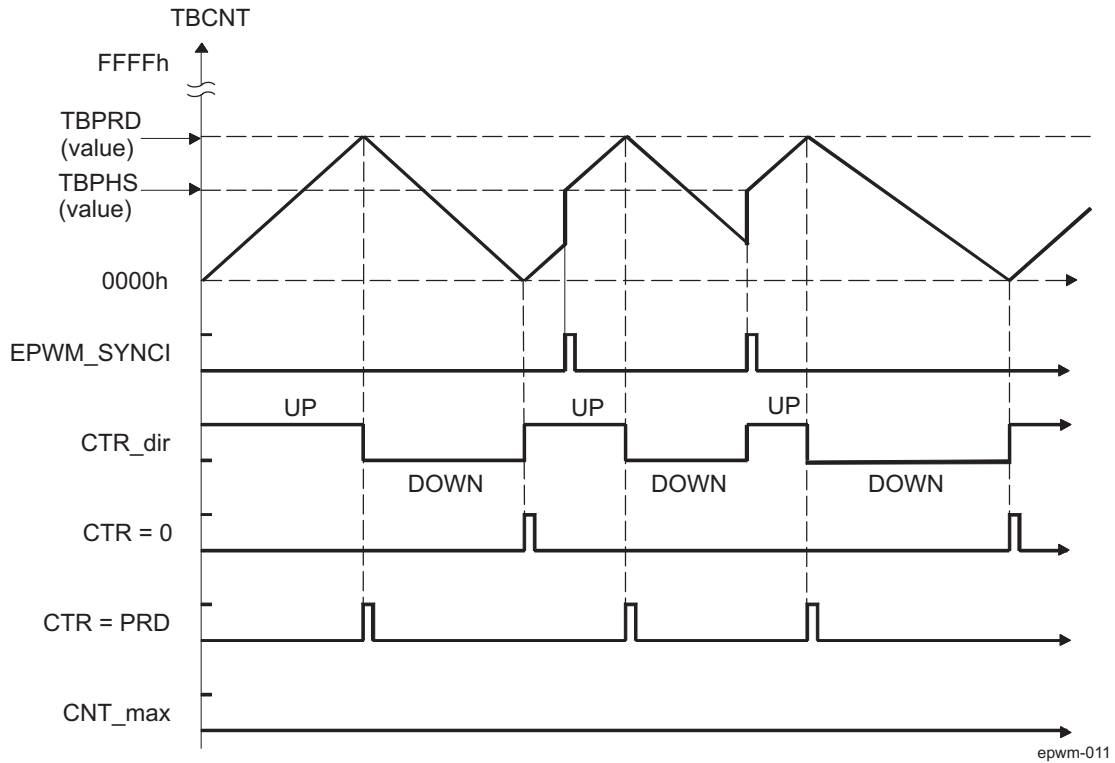

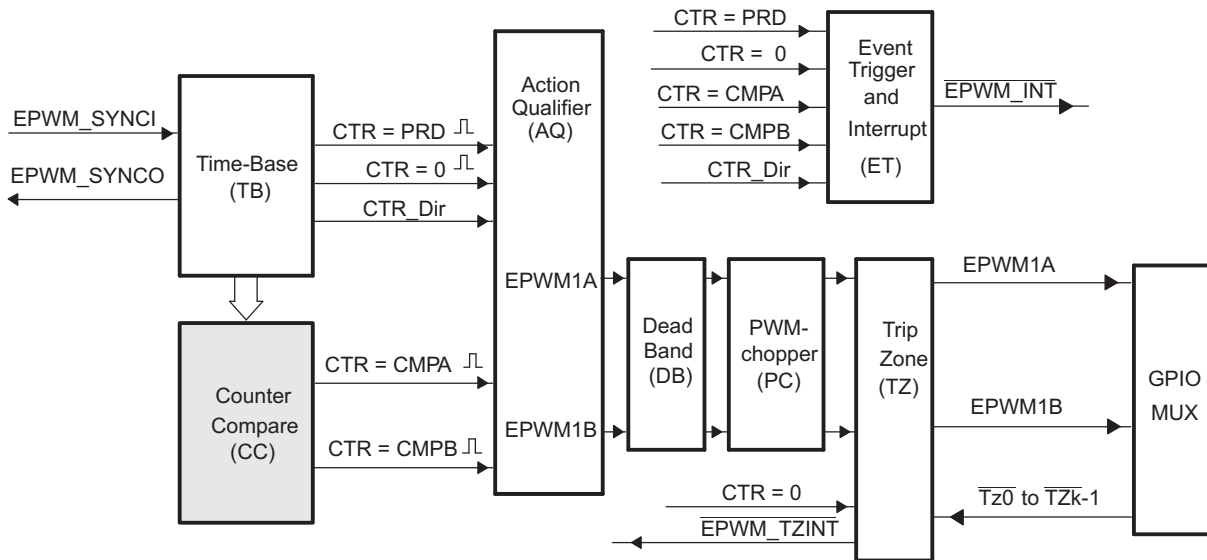

Figure 22-12. ePWM Time-Base Up-Down Count Waveforms, EPWM_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event

22.2.2.4 ePWM Counter-Compare (CC) Submodule

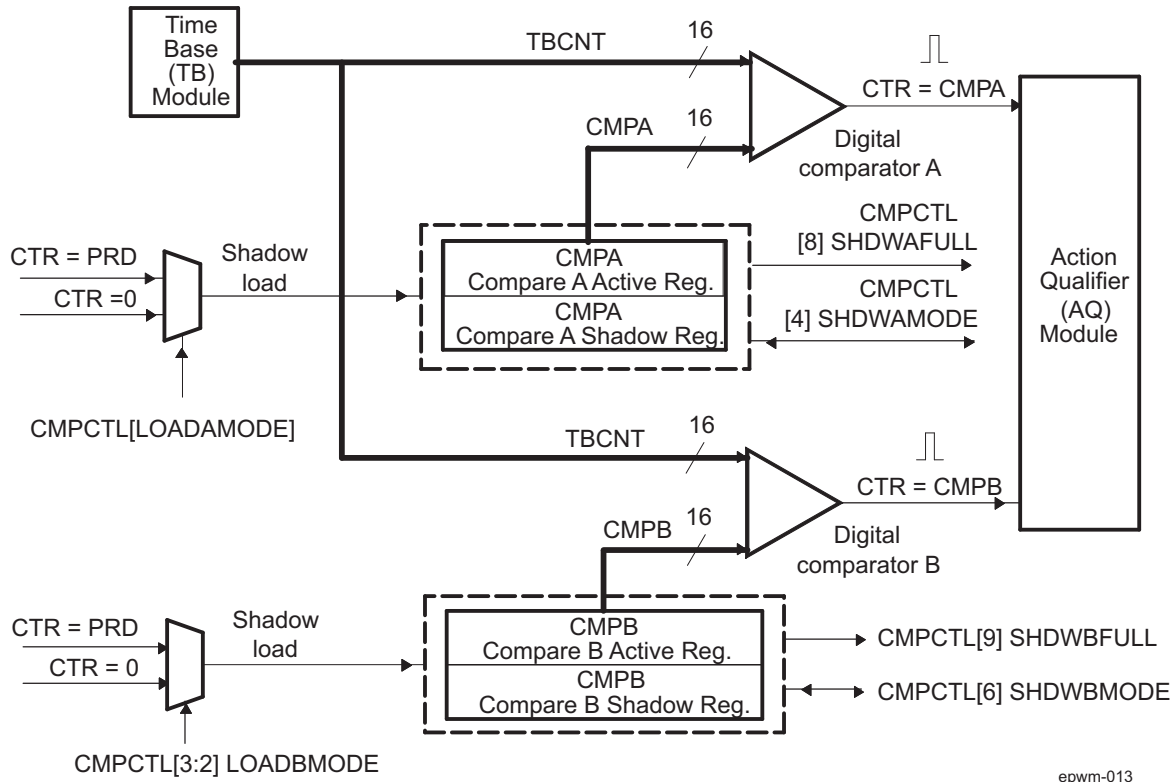

Figure 22-13 illustrates the counter-compare submodule within the ePWM. Figure 22-14 shows the basic structure of the counter-compare submodule.

Figure 22-13. ePWM Counter-Compare Submodule

epwm-012

Figure 22-14. ePWM Counter-Compare Submodule Signals and Registers

epwm-013

22.2.2.4.1 Purpose of the ePWM Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A ([EPWM_CMPA](#)) and counter-compare B ([EPWM_CMPB](#)) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare submodule:

- Generates events based on programmable time stamps using the [EPWM_CMPA](#) and [EPWM_CMPB](#) registers
 - TBCNT = CMPA: Time-base counter equals counter-compare A register (TBCNT = CMPA).
 - TBCNT = CMPB: Time-base counter equals counter-compare B register (TBCNT = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

22.2.2.4.2 Controlling and Monitoring the ePWM Counter-Compare Submodule

[Table 22-22](#) lists the registers used to control and monitor the counter-compare submodule. [Table 22-23](#) lists the key signals associated with the counter-compare submodule.

Table 22-22. ePWM Counter-Compare Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
HRPWM_CMPAHR	HRPWM Counter-Compare A Extension Register	10h	Yes
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

Table 22-23. ePWM Counter-Compare Submodule Key Signals

Signal	Description of Event	Register Bitfields Compared
TBCNT = CMPA	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
TBCNT = CMPB	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
TBCNT = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
TBCNT = 0	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

22.2.2.4.3 Operational Highlights for the ePWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. TBCNT = CMPA: Time-base counter equal to counter-compare A register ([EPWM_TBCNT = EPWM_CMPA](#)).
2. TBCNT = CMPB: Time-base counter equal to counter-compare B register (TBCNT = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 22.2.2.5.1](#) for more details.

The counter-compare registers [EPWM_CMPA](#) and [EPWM_CMPB](#) each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the [EPWM_CMPCTL\[4\]](#) SHDWAMODE and [EPWM_CMPCTL\[6\]](#) SHDWBMODE bits. These bits enable and disable the [EPWM_CMPA](#) shadow register and [EPWM_CMPB](#) shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Mode:** The shadow mode for the [EPWM_CMPA](#) is enabled by clearing the [EPWM_CMPCTL\[4\]](#) SHDWAMODE bit and the shadow register for CMPB is enabled by clearing the [EPWM_CMPCTL\[6\]](#) SHDWBMODE bit. Shadow mode is enabled by default for both [EPWM_CMPA](#) and [EPWM_CMPB](#).

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

- TBCNT = PRD: Time-base counter equal to the period (TBCNT = TBPRD).
- TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h)
- Both TBCNT = PRD and TBCNT = 0

Which of these three events is specified by the [EPWM_CMPCTL\[1:0\]](#) LOADAMODE and [EPWM_CMPCTL\[3:2\]](#) LOADBMODE register bits. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

- **Immediate Load Mode:** If immediate load mode is selected ([EPWM_TBCTL\[4\]](#) SHDWAMODE = 1 or [EPWM_TBCTL\[6\]](#) SHDWBMODE = 1), then a read from or a write to the register will go directly to the active register.

22.2.2.4.4 ePWM Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.

- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 22-15 to Figure 22-18 show when events are generated and how the EPWM_SYNCI signal interacts.

Figure 22-15. ePWM Counter-Compare Event Waveforms in Up-Count Mode

NOTE: An EPWM_SYNCI external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 22-16. ePWM Counter-Compare Events in Down-Count Mode

Count Up on Synchronization Event**

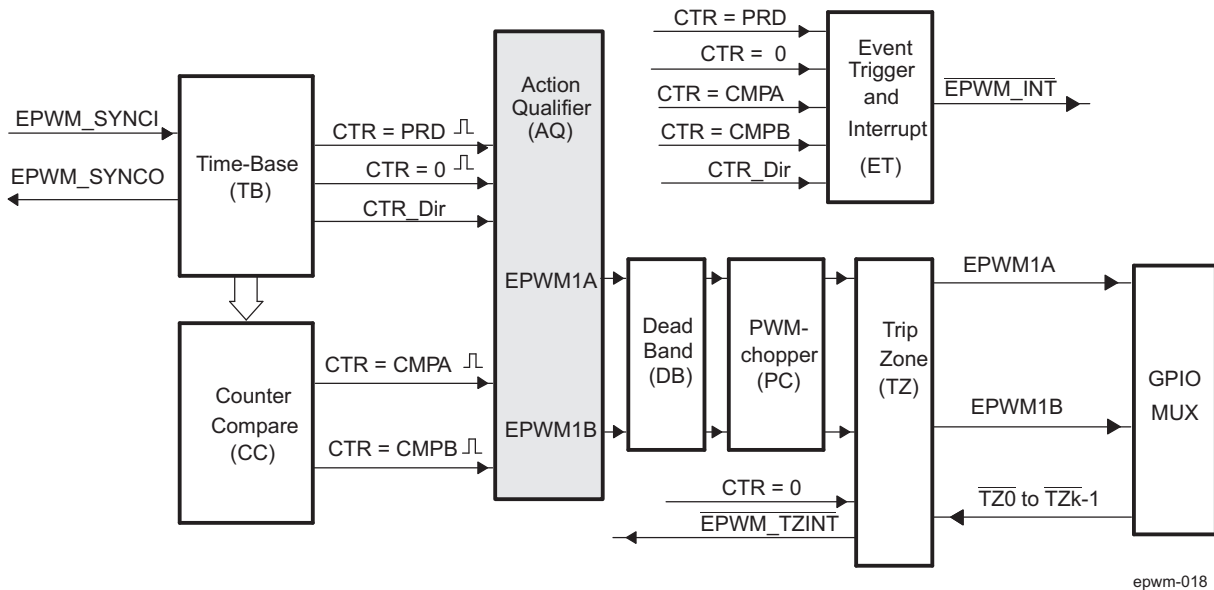

epwm-017

22.2.2.5 ePWM Action-Qualifier (AQ) Submodule

Figure 22-19 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system. The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWM1A and EPWM1B outputs.

Figure 22-19. ePWM Action-Qualifier Submodule

epwm-018

22.2.2.5.1 Purpose of the ePWM Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
 - TBCNT = PRD: Time-base counter equal to the period (TBCNT = TBPRD)
 - TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h)
 - TBCNT = CMPA: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
 - TBCNT = CMPB: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

22.2.2.5.2 Controlling and Monitoring the ePWM Action-Qualifier Submodule

Table 22-24 lists the registers used to control and monitor the action-qualifier submodule.

Table 22-24. Action-Qualifier Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWM1A)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWM1B)	18h	No
EPWM_AQSFR	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFR	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in [Figure 22-20](#). The possible input events are summarized again in [Table 22-25](#).

Figure 22-20. ePWM Action-Qualifier Submodule Inputs and Outputs

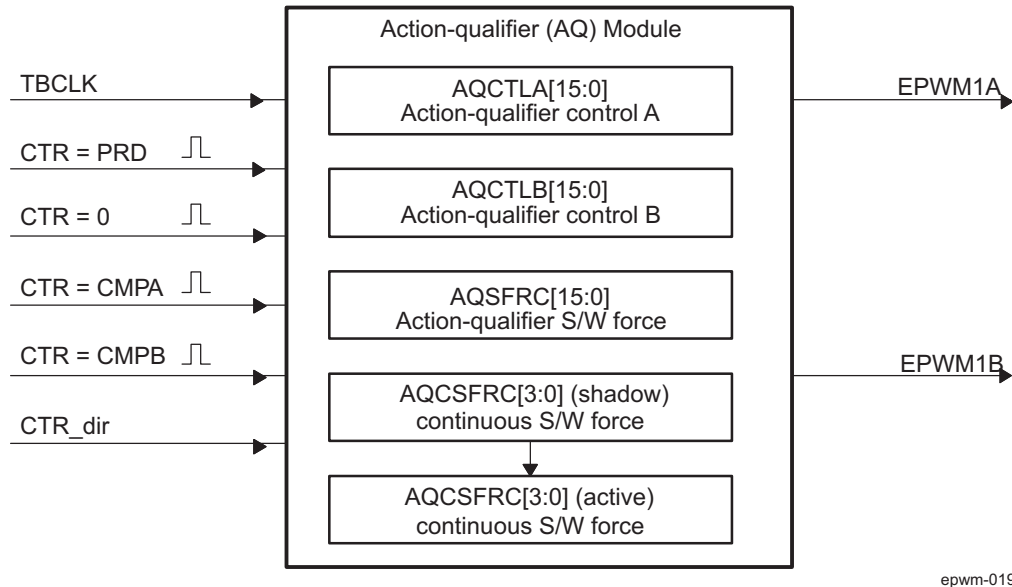

Table 22-25. ePWM Action-Qualifier Submodule Possible Input Events

Signal	Description	Register Bitfield Compared
TBCNT = PRD	Time-base counter equal to the period value	TBCNT = TBPRD
TBCNT = 0	Time-base counter equal to zero	TBCNT = 0000h
TBCNT = CMPA	Time-base counter equal to the counter-compare A	TBCNT = CMPA
TBCNT = CMPB	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers [EPWM_AQSFR](#) and [EPWM_AQCSFRC](#).

The action-qualifier submodule controls how the two outputs EPWM1A and EPWM1B behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWM1A and EPWM1B are:

- **Set High:** Set output EPWM1A or EPWM1B to a high level.
- **Clear Low:** Set output EPWM1A or EPWM1B to a low level.
- **Toggle:** If EPWM1A or EPWM1B is currently pulled high, then pull the output low. If EPWM1A or EPWM1B is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWM1A and EPWM1B at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWM1A and EPWM1B outputs, this event can still trigger interrupts. See the event-trigger submodule description in [Section 22.2.2.9](#) for details.

Actions are specified independently for either output (EPWM1A or EPWM1B). Any or all events can be configured to generate actions on a given output. For example, both TBCNT = CMPA and TBCNT = CMPB can operate on output EPWM1A. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 22-21](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

Figure 22-21. Possible Action-Qualifier Actions for EPWM1A and EPWM1B Outputs

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
					Do Nothing
					Clear Low
					Set High
					Toggle

epwm-020

22.2.2.5.3 ePWM Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 22-26](#). A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

Table 22-26. ePWM Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) ⁽¹⁾	Counter equals CMPB on up-count (CBU) ⁽¹⁾
6 (Lowest)	Counter equals CMPA on down-count (CAD) ⁽¹⁾	Counter equals CMPA on up-count (CAU) ⁽¹⁾

⁽¹⁾ To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 22-27](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 22-27. ePWM Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 22-28](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 22-28. ePWM Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 22-29](#).

Table 22-29. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match ($TBCNT = CMPA$ or $CMPB$). If $CMPA/CMPB > TBPRD$, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If $CMPA/CMPB < TBPRD$, the event will occur on a compare match ($TBCNT = CMPA$ or $CMPB$). If $CMPA/CMPB \geq TBPRD$, the event will occur on a period match ($TBCNT = TBPRD$).
Up-Down-Count Mode	If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match ($TBCNT = CMPA$ or $CMPB$). If $CMPA/CMPB \geq TBPRD$, the event will occur on a period match ($TBCNT = TBPRD$).	If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match ($TBCNT = CMPA$ or $CMPB$). If $CMPA/CMPB \geq TBPRD$, the event occurs on a period match ($TBCNT = TBPRD$).

22.2.2.5.4 Waveforms for Common ePWM Configurations

NOTE: The waveforms in this chapter show the ePWMs behavior for a static compare register value. In a running system, the active compare registers ([EPWM_CMPA](#) and [EPWM_CMPB](#)) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load [EPWM_CMPA](#) / [EPWM_CMPB](#) on zero, then use [EPWM_CMPA](#) / [EPWM_CMPB](#) values greater than or equal to 1.
- If you load [EPWM_CMPA](#) / [EPWM_CMPB](#) on period, then use [EPWM_CMPA](#) / [EPWM_CMPB](#) values less than or equal to $TBPRD - 1$.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load [EPWM_CMPA](#) / [EPWM_CMPB](#) on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to $TBPRD$ to achieve 50%-0% PWM duty.

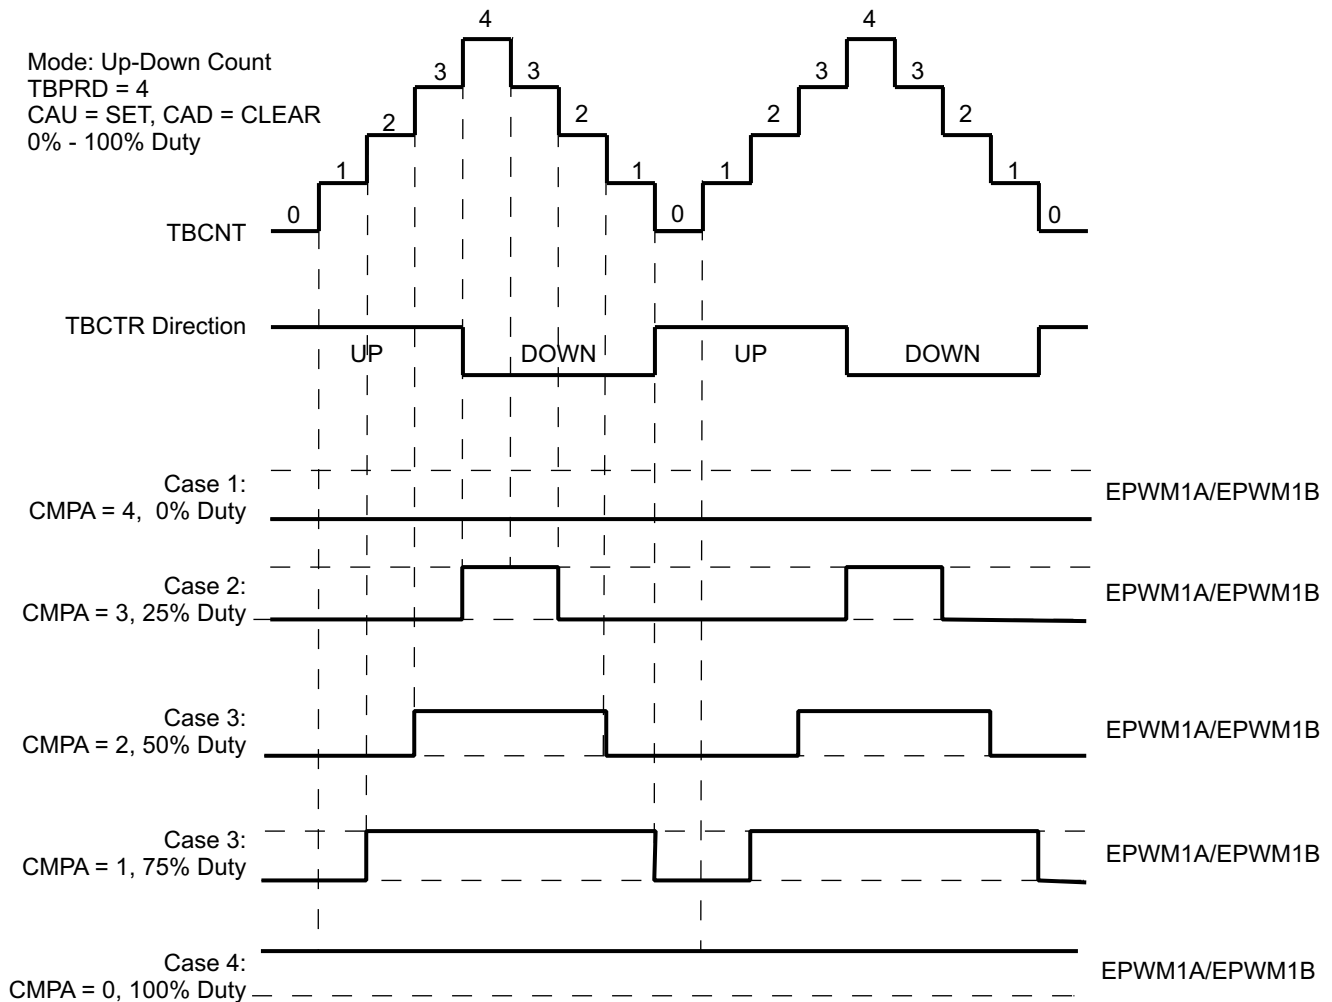

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load [EPWM_CMPA](#) / [EPWM_CMPB](#) on $TBPRD$. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to $TBPRD+1$ to achieve 0-100% PWM duty.

Figure 22-22 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When $CMPA = 0$, the PWM signal is low for the entire period giving the 0% duty waveform. When $EPWM_CMPA = EPWM_TBPRD$, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load $CMPA/CMPB$ on zero, then use $CMPA/CMPB$ values greater than or equal to 1. If you load $CMPA/CMPB$ on period, then use $CMPA/CMPB$ values less than or equal to $TBPRD-1$. This means there will always be a pulse of at least one $TBCLK$ cycle in a PWM period which, when very short, tend to be ignored by the system.

Figure 22-22. ePWM Up-Down-Count Mode Symmetrical Waveform

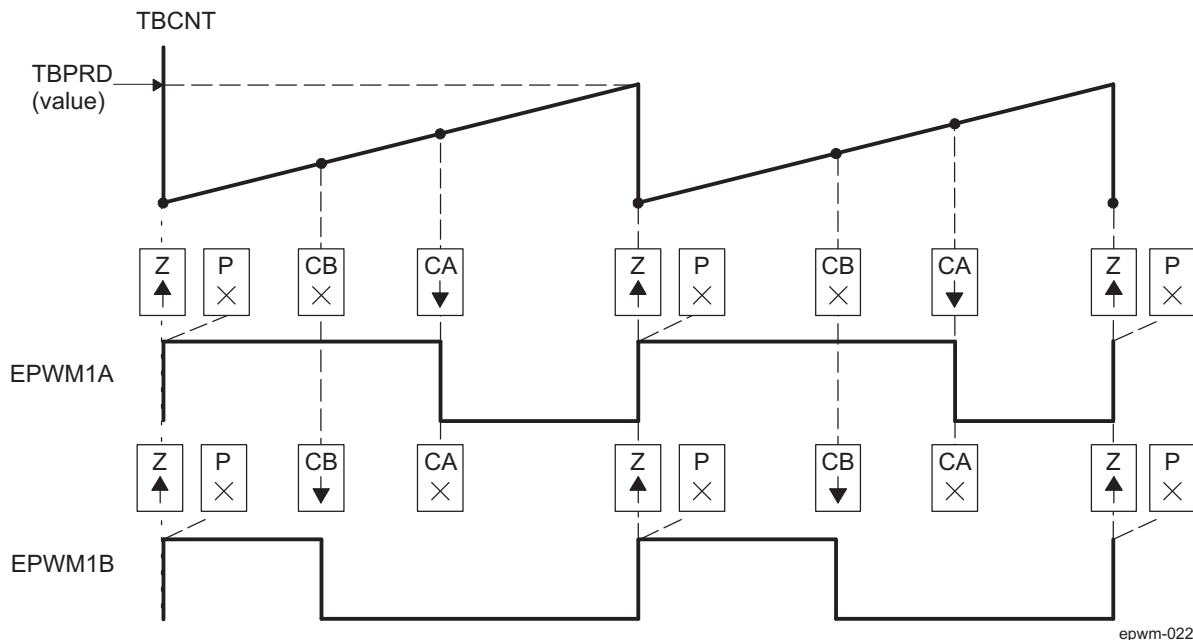

epwm-021

The PWM waveforms in [Figure 22-23](#) through [Figure 22-28](#) show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers ([EPWM_TBPRD](#), [EPWM_CMPA](#), and [EPWM_CMPB](#)). The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWM1A and EPWM1B refer to the output signals from ePWM1
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

[Table 22-30](#) and [Table 22-31](#) contains initialization and runtime register configurations for the waveforms in [Figure 22-23](#).

Figure 22-23. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWM1A and EPWM1B—Active High

- (1) $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- (2) Duty modulation for EPWM1A is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- (3) Duty modulation for EPWM1B is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- (4) The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
- (5) Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

Table 22-30. EPWM Initialization for Figure 22-23

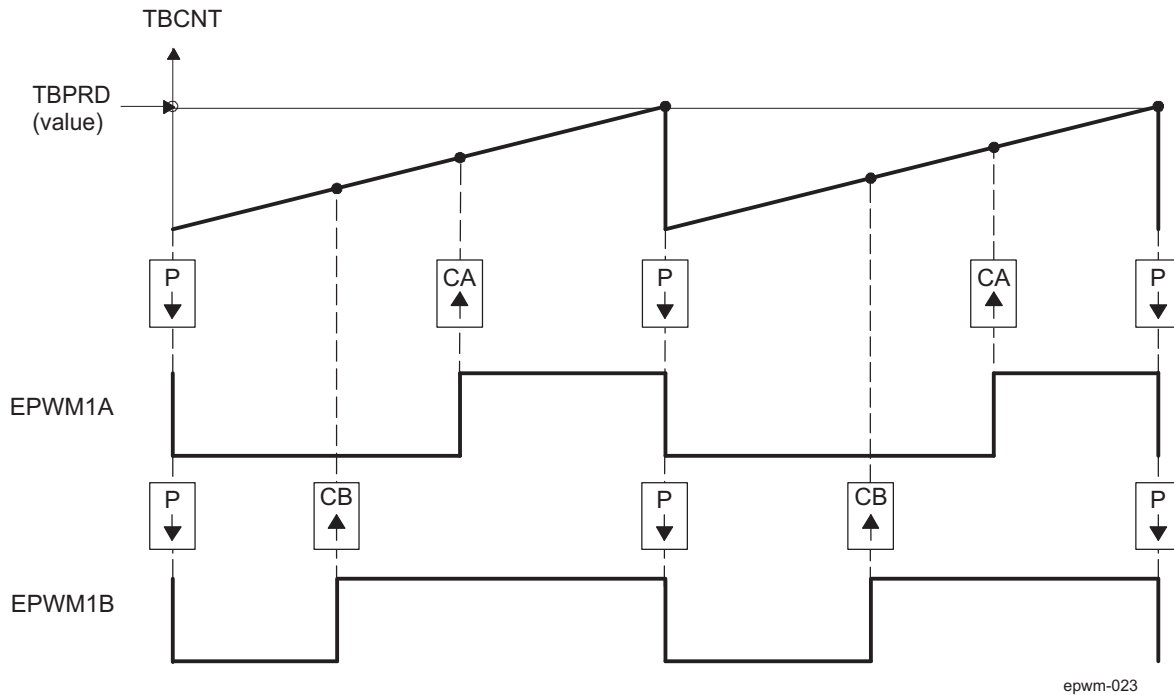

Register	Bitfield	Value	Comments
EPWM_TBPRD	TBPRD	600 (258h)	Period = 601 TBCLK counts
EPWM_TBPHS	TBPHS	0	Clear Phase Register to 0
EPWM_TBCNT	TBCNT	0	Clear TB counter
EPWM_TBCTL	CTRMODE	TB_UP	
	PHSEN	TB_DISABLE	Phase loading disabled
	PRDL	TB_SHADOW	
	SYNCOSEL	TB_SYNC_DISABLE	
	HSPCLKDIV	TB_DIV1	TBCLK = SYSCLKOUT

22.2.2.6 ePWM Dead-Band Generator (DB) Submodule

Figure 22-29 illustrates the dead-band generator submodule within the ePWM module.

Figure 22-29. Dead-Band Generator Submodule

22.2.2.6.1 Purpose of the ePWM Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWM1A and EPWM1B) with dead-band relationship from a single EPWM1A input
- Programming signal pairs for:
 - Active high (AH)
 - Active low (AL)
 - Active high complementary (AHC)
 - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

22.2.2.6.2 Controlling and Monitoring the ePWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

Table 22-42. Dead-Band Generator Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

22.2.2.6.3 Operational Highlights for the ePWM Dead-Band Generator Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in [Figure 22-30](#).

- Input Source Selection:** The input signals to the dead-band module are the EPWM1A and EPWM1B output signals from the action-qualifier. In this section they will be referred to as EPWM1A In and EPWM1B In. Using the [EPWM_DBCTL\[5:4\] IN_MODE](#) control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
 - EPWM1A In is the source for both falling-edge and rising-edge delay. This is the default mode.
 - EPWM1A In is the source for falling-edge delay, EPWM1B In is the source for rising-edge delay.
 - EPWM1A In is the source for rising edge delay, EPWM1B In is the source for falling-edge delay.
 - EPWM1B In is the source for both falling-edge and rising-edge delay.
- Output Mode Control:** The output mode is configured by way of the [EPWM_DBCTL\[1:0\] OUT_MODE](#) bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- Polarity Control:** The polarity control ([EPWM_DBCTL\[3:2\] POLSEL](#)) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 22-30. Configuration Options for the ePWM Dead-Band Generator Submodule

Although all combinations are supported, not all are typical usage modes. [Table 22-43](#) lists some classical dead-band configurations. These modes assume that the `EPWM_DBCTL[5:4] IN_MODE` is configured such that EPWM1A In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 22-43](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 22-31](#). Note that to generate equivalent waveforms to [Figure 22-31](#), configure the action-qualifier submodule to generate the signal as shown for EPWM1A.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 22-43](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 22-43. Classical Dead-Band Operating Modes

Mode	Mode Description ⁽¹⁾	EPWM_DBCTL[3:2] POLSEL		EPWM_DBCTL[1:0] OUT_MODE	
		S3	S2	S1	S0
1	EPWM1A and EPWM1B Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWM1A Out = EPWM1A In (No Delay) EPWM1B Out = EPWM1A In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWM1A Out = EPWM1A In with Rising Edge Delay EPWM1B Out = EPWM1B In with No Delay	0 or 1	0 or 1	1	0

⁽¹⁾ These are classical dead-band modes and assume that `EPWM_DBCTL[5:4] IN_MODE = 0b00`. That is, EPWM1A in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the `IN_MODE` configuration.

Figure 22-31 shows waveforms for typical cases where 0% < duty < 100%.

Figure 22-31. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the [EPWM_DBRED](#) and [EPWM_DBFED](#) registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$$\text{FED} = \text{EPWM_DBFED} \times T_{\text{TBCLK}}$$

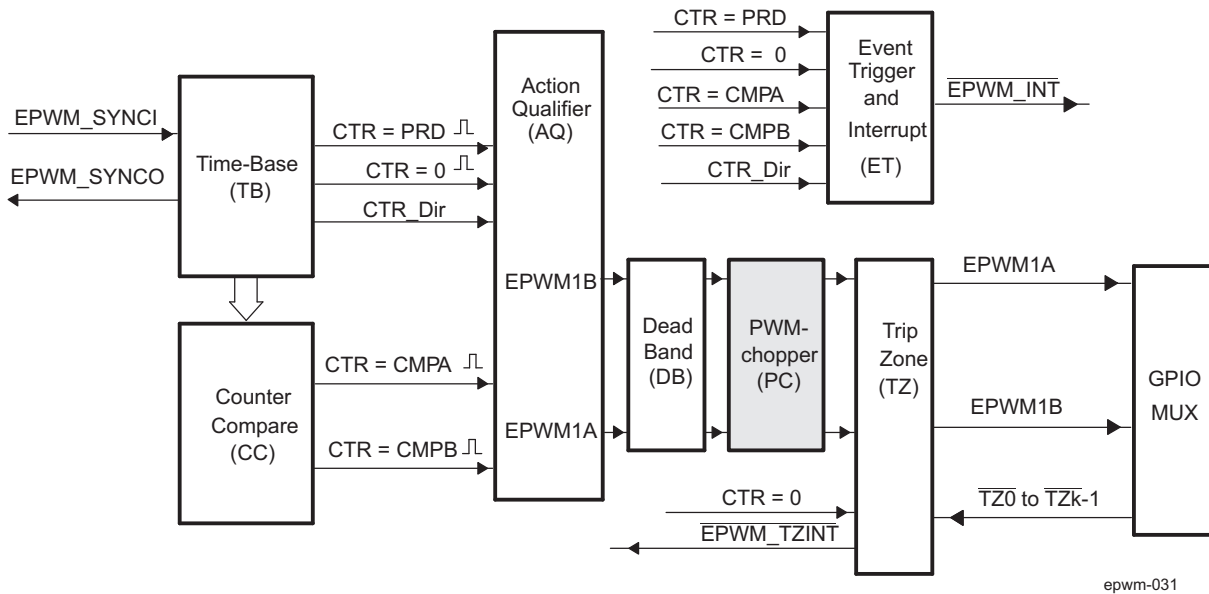

$$\text{RED} = \text{EPWM_DBRED} \times T_{\text{TBCLK}}$$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of SYSCLKOUT.

22.2.2.7 PWM-Chopper (PC) Submodule

Figure 22-32 illustrates the PWM-chopper (PC) submodule within the ePWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

Figure 22-32. PWM-Chopper Submodule

epwm-031

22.2.2.7.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

22.2.2.7.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the register in Table 22-44.

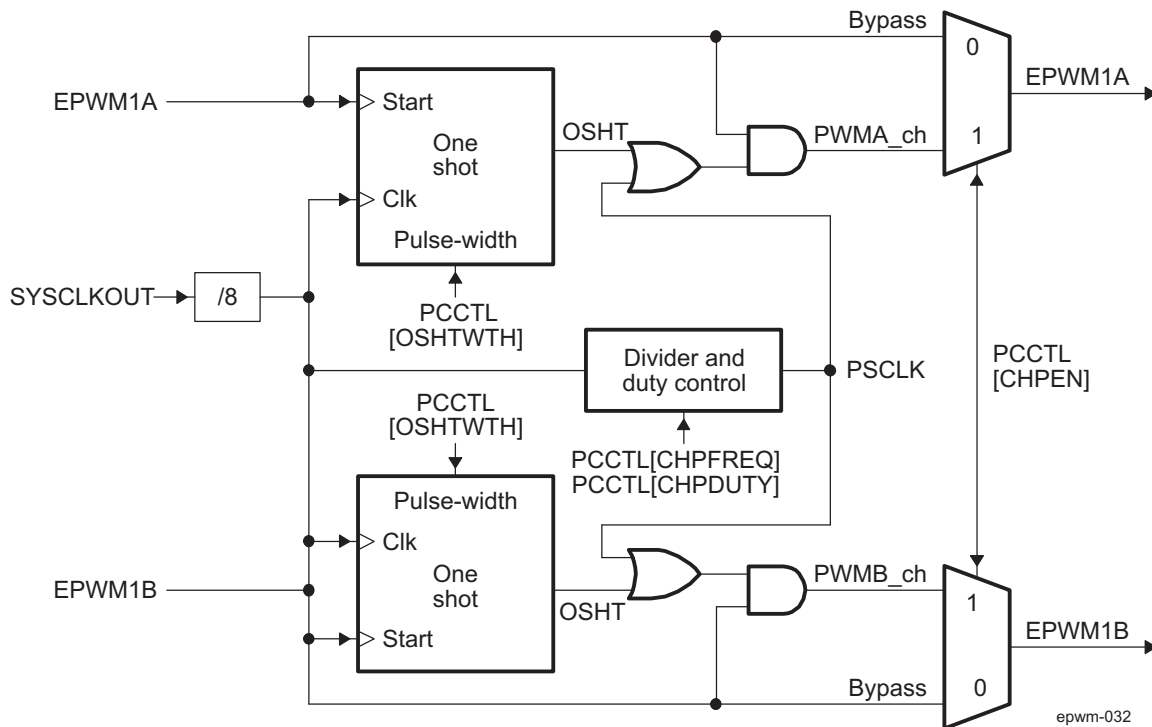

Table 22-44. PWM-Chopper Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

22.2.2.7.3 Operational Highlights for the PWM-Chopper Submodule

Figure 22-33 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from SYSCLKOUT. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 22-33. PWM-Chopper Submodule Signals and Registers

22.2.2.7.4 PWM Chopper Waveforms

Figure 22-34 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 22-34. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only

22.2.2.7.4.1 PWM-Chopper One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{SYCLKOUT} \times 8 \times OSHTWTH$$

Where $T_{SYCLKOUT}$ is the period of the system clock (SYCLKOUT) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 22-35 shows the first and subsequent sustaining pulses.

Figure 22-35. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

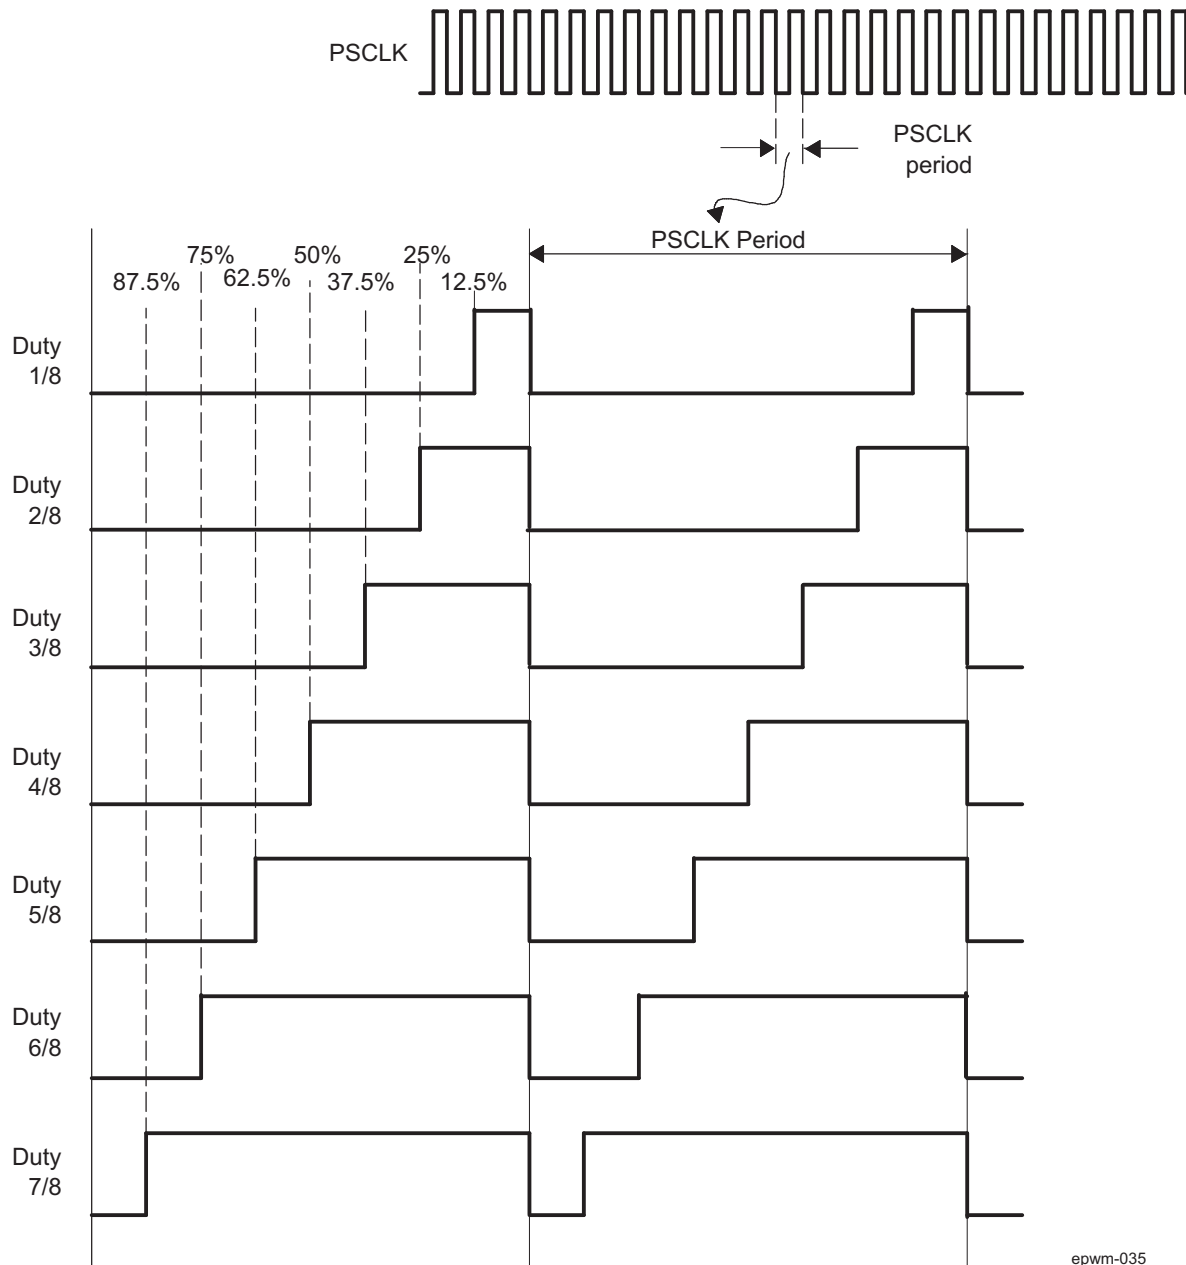

22.2.2.7.4.2 PWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 22-36 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

Figure 22-36. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

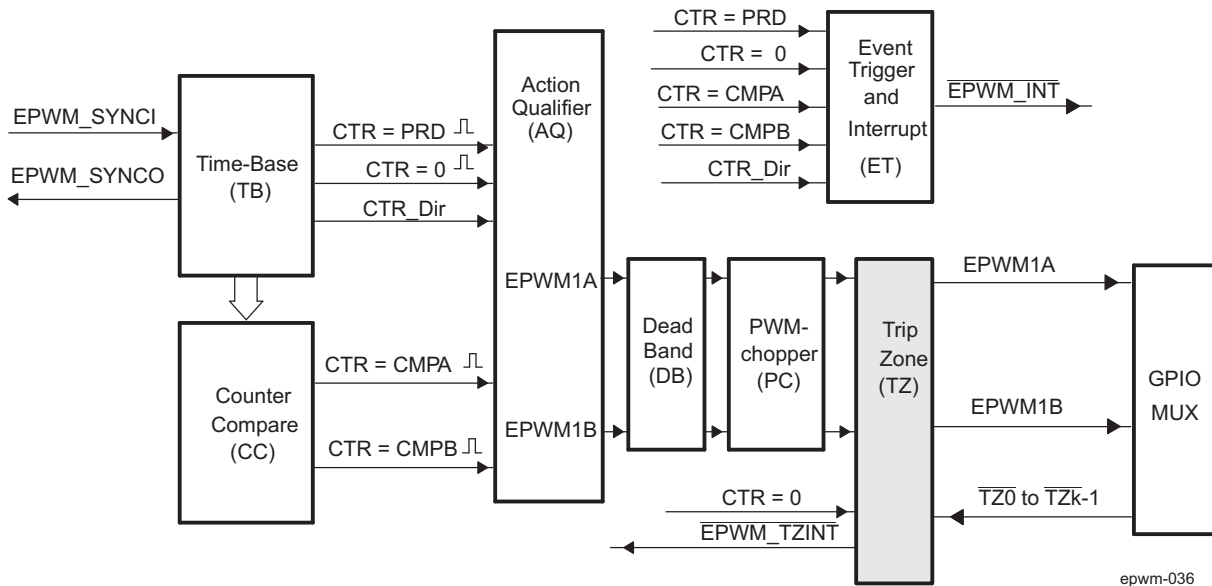

epwm-035

22.2.2.8 ePWM Trip-Zone (TZ) Submodule

Figure 22-37 shows how the trip-zone (TZ) submodule fits within the ePWM module. The ePWM module is connected to every \overline{TZ} signal that is sourced from the GPIO MUX. This signal indicates external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when a fault occurs. See Section 22.1.3 to determine the number of trip-zone pins available for the device.

Figure 22-37. ePWM Trip-Zone Submodule

epwm-036

22.2.2.8.1 Purpose of the ePWM Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs $\overline{TZ0}$ to $\overline{TZk-1}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWM1A and EPWM1B can be forced to one of the following:
 - High
 - Low
 - High-impedance
 - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

NOTE: For ePWM1, from the tripzone inputs $\overline{EPWM_TRIP_TZ}[5:0]$, ONLY the $\overline{EPWM_TRIP_TZ}[0]$ input of ePWM tripzone is chip accessible and usable, i.e. $k=1$.

22.2.2.8.2 Controlling and Monitoring the ePWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 22-45. ePWM Trip-Zone Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register	24h	No
EPWM_TZCTL	Trip-Zone Control Register	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register	30h	No

22.2.2.8.3 Operational Highlights for the ePWM Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals at pin $\overline{TZ0}$ to $\overline{TZk-1}$ is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. The ePWM module can be configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used is determined by the EPWM_TZSEL register. The trip-zone signal may or may not be synchronized to the system clock (SYSCLKOUT). A minimum of 1 SYSCLKOUT low pulse on the \overline{TZn} inputs is sufficient to trigger a fault condition in the ePWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the \overline{TZk} inputs.

NOTE: Only the TZ[0] input is accessible at chip level (i.e. k=1).

The \overline{TZk} input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a ePWM module. The configuration is determined by the EPWM_TZSEL[7:0] CBCk and EPWM_TZSEL[15:8] OSHTk bits (where k corresponds to the trip pin) respectively.

- Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWM1A and/or EPWM1B output. Table 22-46 lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM_TZFLG[1] CBC) is set and a ePWM0_TZINT interrupt is generated if it is enabled in the EPWM_TZEINT register.

The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (EPWM_TBCNT bitfield TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM_TZFLG[1] CBC bit is cleared, then it will again be immediately set.
- One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWM1A and/or EPWM1B output. Table 22-46 lists the possible actions. In addition, the one-shot trip event flag (EPWM_TZFLG[2] OST) is set and a ePWM0_TZINT interrupt is generated if it is enabled in the EPWM_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the EPWM_TZCTL[1:0] TZA and EPWM_TZCTL[3:2] TZB register bits. One of four possible actions, shown in Table 22-46, can be taken on a trip event.

Table 22-46. Possible Actions On an ePWM Trip Event

EPWM_TZCTL[1:0] TZA and/or EPWM_TZCTL[3:2] TZB	EPWM1A and/or EPWM1B	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

Example 22-2. ePWM Trip-Zone Configurations
Scenario A:

A one-shot trip event on $\overline{TZ0}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
 - EPWM_TZSEL[8] OSHT1 = 1: enables \overline{TZ} as a one-shot event source for ePWM1
 - EPWM_TZCTL[1:0] TZA = 2: EPWM1A will be forced low on a trip event.
 - EPWM_TZCTL[3:2] TZB = 2: EPWM1B will be forced low on a trip event.

22.2.2.8.4 Generating ePWM Trip Event Interrupts

Figure 22-38 and Figure 22-39 illustrate the trip-zone submodule control and interrupt logic, respectively.

Figure 22-38. ePWM Trip-Zone Submodule Mode Control Logic

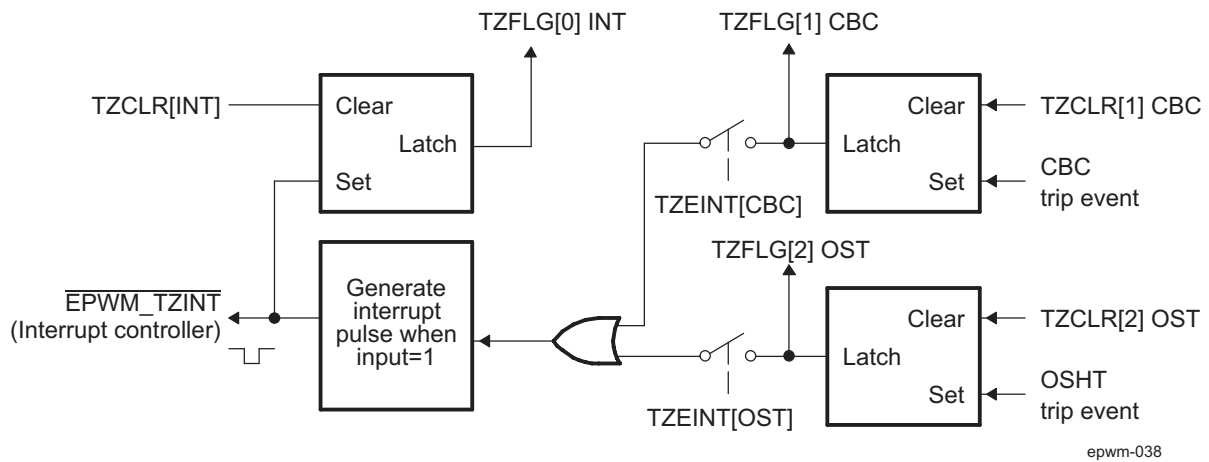

Figure 22-39. ePWM Trip-Zone Submodule Interrupt Logic

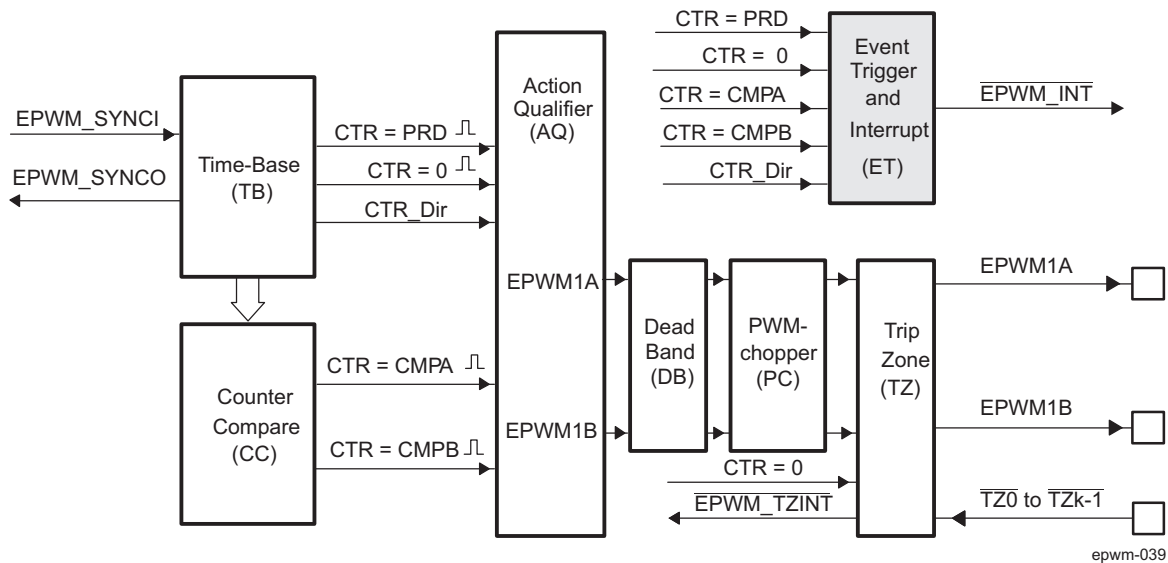

22.2.2.9 ePWM Event-Trigger (ET) Submodule

Figure 22-40 shows the event-trigger (ET) submodule in the ePWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an aggregated interrupt request.

NOTE: The ePWM1 ET interrupt request output is further routed via the device IRQ_CROSSBAR, to different device host interrupt controllers, located outside PWMSS. For more details on interrupt event routing outside the ePWM, refer to the Section 22.1.3.

Figure 22-40. ePWM Event-Trigger Submodule

22.2.2.9.1 Purpose of the ePWM Event-Trigger Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
 - Every event
 - Every second event
 - Every third event
- Provides full visibility of event generation via event counters and flags

22.2.2.9.2 Controlling and Monitoring the ePWM Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in Table 22-47:

Table 22-47. Event-Trigger Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No

Table 22-47. Event-Trigger Submodule Registers (continued)

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM_ETFRC	Event-Trigger Force Register	3Ah	No

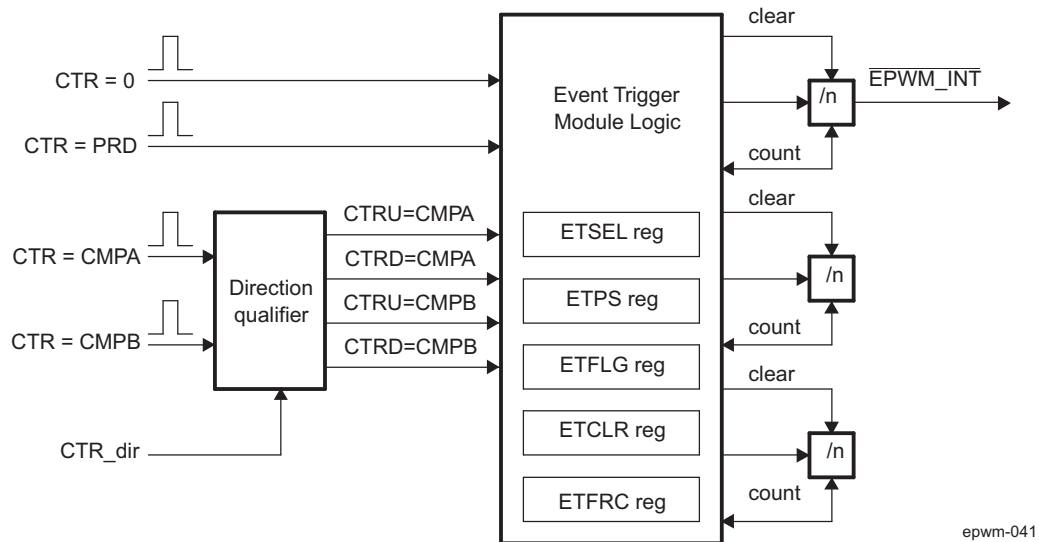

22.2.2.9.3 Operational Overview of the ePWM Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

The ePWM module has one interrupt request line.

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in [Figure 22-41](#)) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

Figure 22-41. ePWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

- **ETSEL**—This selects which of the possible events will trigger an interrupt.
- **ETPS**—This programs the event prescaling options previously mentioned.
- **ETFLG**—These are flag bits indicating status of the selected and prescaled events.
- **ETCLR**—These bits allow you to clear the flag bits in the **EPWM_ETFLG** register via software.
- **ETFRC**—These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 22-42](#).

[Figure 22-42](#) shows the event-trigger's interrupt generation logic. The interrupt-period (**EPWM_ETPS**[1:0] **INTPRD**) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (**EPWM_ETSEL**[2:0] **INTSEL**) bits. The event can be one of the following:

- Time-base counter equal to zero (**EPWM_TBCNT** bitfield **TBCNT** = 0000h).
- Time-base counter equal to period (**EPWM_TBCNT** bitfield **TBCNT** = **TBPRD** value in **EPWM_TBPRD** active register).
- Time-base counter equal to the compare A register (**EPWM_CMPA**) when the timer is incrementing.
- Time-base counter equal to the compare A register (**EPWM_CMPA**) when the timer is decrementing.
- Time-base counter equal to the compare B register (**EPWM_CMPB**) when the timer is incrementing.
- Time-base counter equal to the compare B register (**EPWM_CMPB**) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (**EPWM_ETPS**[3:2] **INTCNT**) register bits. That is, when the specified event occurs the **EPWM_ETPS**[3:2] **INTCNT** bits are incremented until they reach the value specified by **EPWM_ETPS**[1:0] **INTPRD**. When **EPWM_ETPS**[3:2] **INTCNT** = **EPWM_ETPS**[1:0] **INTPRD** the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When **EPWM_ETPS**[3:2] **INTCNT** reaches **EPWM_ETPS**[1:0] **INTPRD**, one of the following behaviors will occur:

- If interrupts are enabled, **EPWM_ETSEL**[3] **INTEN** = 1 and the interrupt flag is clear, **EPWM_ETFLG**[0] **INT** = 0, then an interrupt pulse is generated and the interrupt flag is set, **EPWM_ETFLG**[0] **INT** = 1, and the event counter is cleared **EPWM_ETPS**[3:2] **INTCNT** = 0. The counter will begin counting events again.
- If interrupts are disabled, **EPWM_ETSEL**[3] **INTEN** = 0, or the interrupt flag is set, **EPWM_ETFLG**[0] **INT** = 1, the counter stops counting events when it reaches the period value **EPWM_ETPS**[3:2] **INTCNT** = **EPWM_ETPS**[1:0] **INTPRD**.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the **ETFLG**[0] **INT** flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the **INTPRD** bits will automatically clear the counter **INTCNT** = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the **EPWM ETFRC**[0] **INT** bit will increment the event counter **INTCNT**. The counter will behave as described above when **INTCNT** = **INTPRD**. When **INTPRD** = 0, the counter is disabled and hence no events will be detected and the **EPWM ETFRC**[0] **INT** bit is also ignored.

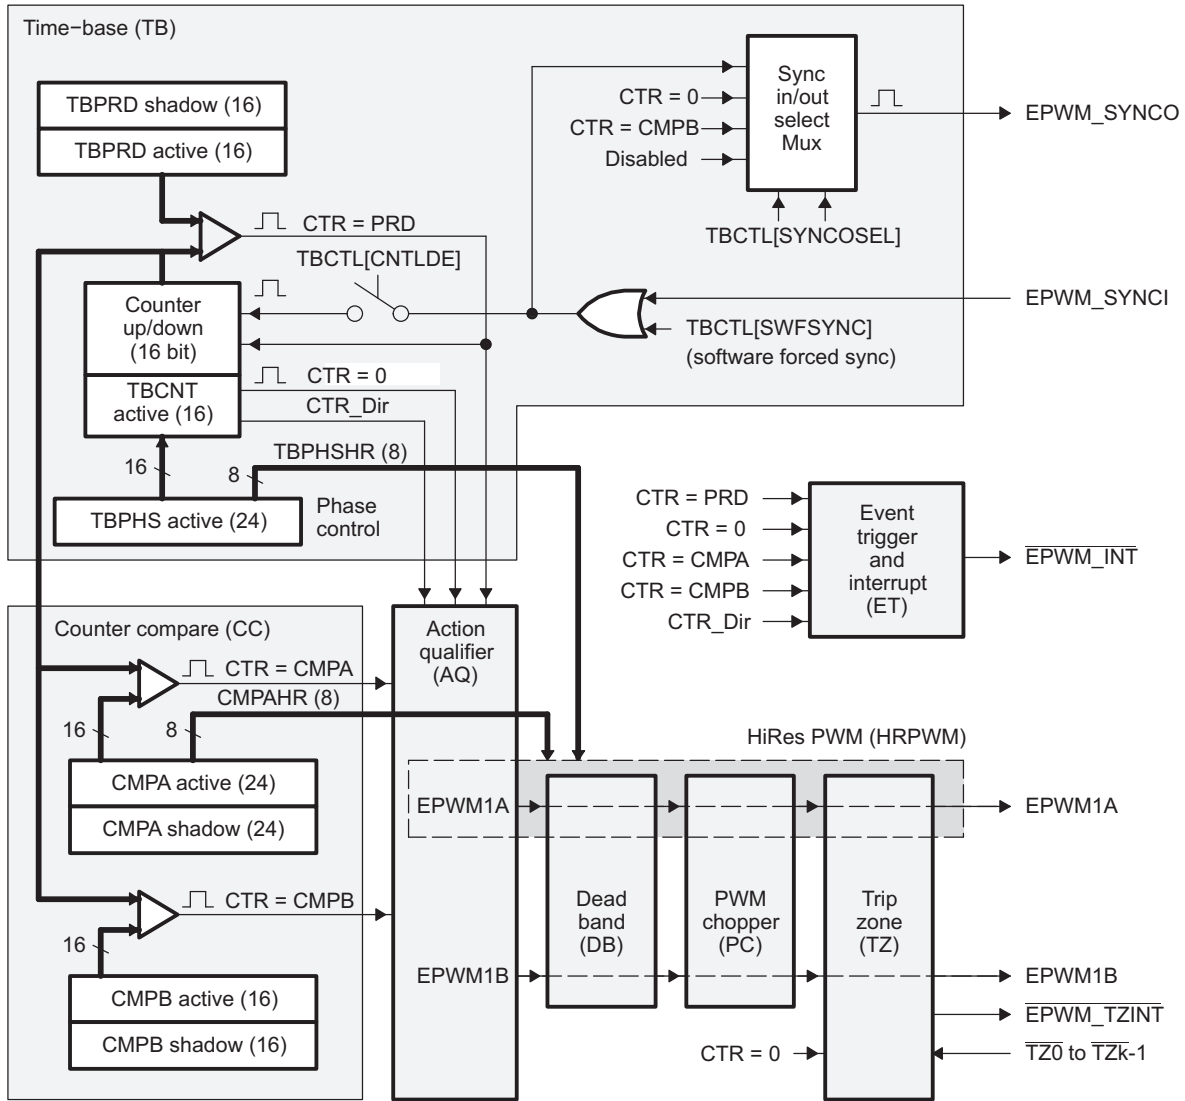

Figure 22-42. ePWM Event-Trigger Interrupt Generator

22.2.2.10 High-Resolution PWM (HRPWM) Submodule

Figure 22-43 shows the high-resolution PWM (HRPWM) submodule in the ePWM system.

Figure 22-43. HRPWM System Interface

ehrpwm-043

22.2.2.10.1 Purpose of the High-Resolution PWM Submodule

The enhanced high-resolution pulse-width modulator (eHRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWM1A output. **EPWM1B output has conventional PWM capabilities**

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 22-44, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

Figure 22-44. Resolution Calculations for Conventionally Generated PWM

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 22-48 shows resolution in bits for various PWM frequencies. Table 22-48 values assume a MEP step size of 180 ps. See your device-specific data manual for typical and maximum performance specifications for the MEP.

Table 22-48. Resolution for PWM and HRPWM

PWM Frequency (kHz)	Regular Resolution (PWM)		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

22.2.2.10.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 22-45 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (HRPWM_CMPAHR).

Figure 22-45. Operating Logic Using MEP

Number of coarse steps = integer(PWMDuty * PWMperiod)
 Number of MEP steps = fraction(PWMDuty * PWMperiod) * (MEPScaleFactor)

16-bit CMPA register value	= number of coarse steps
16-bit CMPAHR register value	= (number of MEP steps) << 8 + 0x180 (rounding) ^(A)

ehrpwm-045

A For MEP range and rounding adjustment.

To generate an HRPWM waveform, configure the TBM, CCM, and AQM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

22.2.2.10.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit EPWM_TBPHS and EPWM_CMPA registers used to control PWM operation.

- HRPWM_TBPHSHR - Time-Base Phase High-Resolution Register
- HRPWM_CMPAHR - Counter-Compare A High-Resolution Register

Table 22-49 lists the registers used to control and monitor the high-resolution PWM submodule.

Table 22-49. HRPWM Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
HRPWM_TBPHSHR	Extension Register for HRPWM Phase	4h	No
HRPWM_CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRPWM_HRCTL	HRPWM Configuration Register	1040h	No

22.2.2.10.4 Configuring the High-Resolution PWM Submodule

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the [HRPWM_HRCTL](#) register located at offset address 1040h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the [HRPWM_CMPAHR](#) register (duty cycle control) or the [HRPWM_TBPHSHR](#) register (phase control). RE or FE control mode should be used with [HRPWM_CMPAHR](#) register. BE control mode should be used with [HRPWM_TBPHSHR](#) register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the [HRPWM_CMPAHR](#) register and should be chosen to be the same as the regular load option for the CMPA register. If [HRPWM_TBPHSHR](#) is used, then this option has no effect.

22.2.2.10.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 22-50](#) shows the typical range of operating frequencies supported by the HRPWM.

Table 22-50. Relationship Between MEP Steps, PWM Frequency and Resolution

System (MHz)	MEP Steps Per SYSCLKOUT ^{(1) (2) (3)}	PWM Minimum (Hz) ⁽⁴⁾	PWM Maximum (MHz)	Resolution at Maximum (Bits) ⁽⁵⁾
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

⁽¹⁾ System frequency = SYSCLKOUT, that is, CPU clock. TBCLK = SYSCLKOUT

⁽²⁾ Table data based on a MEP time resolution of 180 ps (this is an example value)

⁽³⁾ MEP steps applied = $T_{\text{SYSCLKOUT}}/180$ ps in this example.

⁽⁴⁾ PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.

⁽⁵⁾ Resolution in bits is given for the maximum PWM frequency stated.

22.2.2.10.5.1 HRPWM Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, etc.) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. In Figure 22-46, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that you can attain. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 22-51.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 22-51 shows that in addition to the CMPA value, 22 steps of the MEP (HRPWM_CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

Figure 22-46. Required PWM Waveform for a Requested Duty = 40.5%

Table 22-51. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

CMPA (count) ⁽¹⁾ ⁽²⁾ ⁽³⁾	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

⁽¹⁾ System clock, SYSCLKOUT and TBCLK = 100 MHz, 10 ns

⁽²⁾ For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

⁽³⁾ Assumed MEP step size for the above example = 180 ps

22.2.2.10.5.2 HRPWM Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (EPWM_CMPA) and MEP (HRPWM_CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, SYSCLKOUT	= 10 ns (100 MHz)
PWM frequency	= 1.25 MHz (1/800 ns)
Required PWM duty cycle, PWMDuty	= 0.405 (40.5%)
PWM period in terms of coarse steps, PWMperiod (800 ns/10 ns)	= 80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), MEP_SF	= 55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	= 180h

Step 1: Percentage Integer Duty value conversion for EPWM_CMPA register

EPWM_CMPA register value	= int(PWMDuty × PWMperiod); int means integer part
	= int(0.405 × 80)
	= int(32.4)
EPWM_CMPA register value	= 32 (20h)

Step 2: Fractional value conversion for HRPWM_CMPAHR register

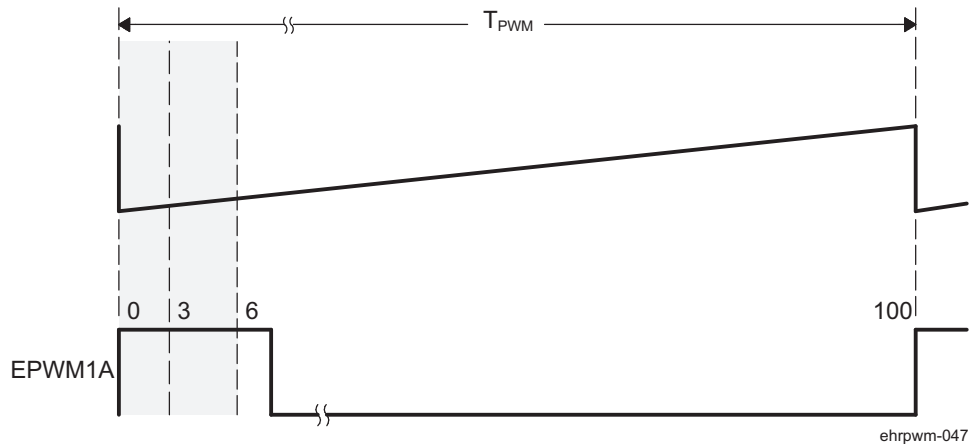

HRPWM_CMPAHR register value	= (frac(PWMDuty × PWMperiod) × MEP_SF) << 8) + 180h; frac means fractional part
	= (frac(32.4) × 55 <<8) + 180h; Shift is to move the value as CMPAHR high byte
	= ((0.4 × 55) <<8) + 180h
	= (22 <<8) + 180h
	= 22 × 256 + 180h ; Shifting left by 8 is the same multiplying by 256.
	= 5632 + 180h
	= 1600h + 180h
HRPWM_CMPAHR value	= 1780h; HRPWM_CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

22.2.2.10.5.3 HRPWM Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 SYCLKOUT cycles after the period starts.

Duty cycle range limitations are illustrated in Figure 22-47. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

Figure 22-47. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 22-48. In this case low percent duty limitation is no longer an issue.

Figure 22-48. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz

22.2.2.11 eHRPWM Functional Register Groups

The Table 22-52 lists the groups of ePWM and the high-resolution PWM module registers according to their functionalities.

Table 22-52. ePWM / HRPWM Module Control and Status Registers Grouped by Submodule

Register Name	Offset	Size (x16)	Shadow	Register Description
Time-Base Submodule Registers				

Table 22-52. ePWM / HRPWM Module Control and Status Registers Grouped by Submodule (continued)

Register Name	Offset	Size (x16)	Shadow	Register Description
EPWM_TBCTL	0h	1	No	Time-Base Control Register
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register

FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV		SWFSYNC	SYNCOSEL		PRDLD	PHSEN	CTRMODE		

Bits	Field Name	Description	Type	Reset
15:14	FREE_SOFT	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0x0 = Stop after the next time-base counter increment or decrement 0x1 = Stop when counter completes a whole cycle. (a) Up-count mode: stop when the time-base counter = period (EPWM_TBCTL bitfield TBCNT = TBPRD in EPWM_TBPRD active register). (b) Down-count mode: stop when the time-base counter = 0000 (EPWM_TBCTL bitfield TBCNT = 0000h). (c) Up-down-count mode: stop when the time-base counter = 0000 (EPWM_TBCTL bitfield TBCNT = 0000h). 0x2 = Free run 0x3 = Free run	RW	0x0
13	PHSDIR	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (EPWM_TBCTL) will count after a synchronization event occurs and a new phase value is loaded from the phase (EPWM_TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0x0 = Count down after the synchronization event. 0x1 = Count up after the synchronization event.	RW	0x0
12:10	CLKDIV	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = SYSCLKOUT / (HSPCLKDIV \times CLKDIV)$ 0x0 = /1 (default on reset) 0x1 = /2 0x2 = /4 0x3 = /8 0x4 = /16 0x5 = /32 0x6 = /64 0x7 = /128	RW	0x0

Bits	Field Name	Description	Type	Reset
9:7	HSPCLKDIV	<p>High-Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value.</p> <p>$TBCLK = SYSCLKOUT / (HSPCLKDIV \times CLKDIV)$. This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral.</p> <p>0x0 = /1 0x1 = /2 (default on reset) 0x2 = /4 0x3 = /6 0x4 = /8 0x5 = /10 0x6 = /12 0x7 = /14</p>	RW	0x0
6	SWFSYNC	<p>Software Forced Synchronization Pulse.</p> <p>0x0 = Writing a 0 has no effect and reads always return a 0. 0x1 = Writing a 1 forces a one-time synchronization pulse to be generated. This event is ORed with the EPWM_SYNCI input of the ePWM module. SWFSYNC is valid (operates) only when EPWM_SYNCI is selected by SYNCOSSEL = 00.</p>	RW	0x0
5:4	SYNCOSSEL	<p>Synchronization Output Select. These bits select the source of the EPWM_SYNCO signal.</p> <p>0x0 = EPWM_SYNC: 0x1 = TBCNT = 0: Time-base counter equal to zero (EPWM_TBCNT bitfield TBCNT= 0000h) 0x2 = TBCNT = CMPB : Time-base counter equal to counter-compare B (EPWM_TBCNT bitfield TBCNT = CMPB bitfield in EPWM_CMPB) 0x3 = Disable EPWM_SYNCO signal</p>	RW	0x0
3	PRDL	<p>Active Period Register Load From Shadow Register Select</p> <p>0x0 = The period register (EPWM_TBPRD) is loaded from its shadow register when the time-base counter, TBCNT, is equal to zero. A write or read to the EPWM_TBPRD register accesses the shadow register. 0x1 = Load the EPWM_TBPRD register immediately without using a shadow register. A write or read to the EPWM_TBPRD register directly accesses the active register.</p>	RW	0x0
2	PHSEN	<p>Counter Register Load From Phase Register Enable</p> <p>0x0 = Do not load the time-base counter (EPWM_TBCNT) from the time-base phase register (EPWM_TBPHS) 0x1 = Load the time-base counter with the phase register when an EPWM_SYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit.</p>	RW	0x0
1:0	CTRMODE	<p>Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows:</p> <p>0x0 = Up-count mode 0x1 = Down-count mode 0x2 = Up-down-count mode 0x3 = Stop-freeze counter operation (default on reset)</p>	RW	0x0

RESERVED													CTRMAX	SYNCI	CTDIR

Bits	Field Name	Description	Type	Reset
15:3	RESERVED		R	0x0000
2	CTRMAX	Time-Base Counter Max Latched Status Bit. 0x0 = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 0x1 = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.	RW1C	0x0
1	SYNCI	Input Synchronization Latched Status Bit. 0x0 = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 0x1 = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWM_SYNCI). Writing a 1 to this bit will clear the latched event.	RW1C	0x0
0	CTDIR	Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via EPWM_TBCTL[1:0] CTRMODE . 0x0 = Time-Base Counter is currently counting down. 0x1 = Time-Base Counter is currently counting up.	R	0x0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMPA															

Bits	Field Name	Description	Type	Reset
15:0	CMPA	The value in the active EPWM_CMPA register is continuously compared to the time-base counter (register EPWM_TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWM1A or the EPWM1B output depending on the configuration of the EPWM_AQCTLA and EPWM_AQCTLB registers. The actions that can be defined in the EPWM_AQCTLA and EPWM_AQCTLB registers include the following. (a) Do nothing the event is ignored. (b) Clear: Pull the EPWM1A and/or EPWM1B signal low. (c) Set: Pull the EPWM1A and/or EPWM1B signal high. (d) Toggle the EPWM1A and/or EPWM1B signal. Shadowing of this register is enabled and disabled by the EPWM_CMPCTL[4] SHDWAMODE bit. By default this register is shadowed. (a) If EPWM_CMPCTL[4] SHDWAMODE = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the EPWM_CMPCTL[1:0] LOADAMODE bit field determines which event will load the active register from the shadow register. (b) Before a write, the EPWM_CMPCTL[8] SHDWAFULL bit can be read to determine if the shadow register is currently full. (c) If EPWM_CMPCTL[4] SHDWAMODE = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. (d) In either mode, the active and shadow registers share the same memory map address.	RW	0x0

Table 22-83. EPWM_DBCTL

Address offset	0x1E							Instance	PWMSS_EPWM						
Physical Address	0x4843 E21E														
Description															
Type	RW														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED										IN_MODE	POLSEL	OUT_MODE			

Bits	Field Name	Description	Type	Reset
15:6	RESERVED		R	0x0
5:4	IN_MODE	<p>Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms, the default is EPWM1A In is the source for both falling and rising-edge delays.</p> <p>0x0 = EPWM1A In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.</p> <p>0x1 = EPWM1B In (from the action-qualifier) is the source for rising-edge delayed signal. EPWM1A In (from the action-qualifier) is the source for falling-edge delayed signal.</p> <p>0x2 = EPWM1A In (from the action-qualifier) is the source for rising-edge delayed signal. EPWM1B In (from the action-qualifier) is the source for falling-edge delayed signal.</p> <p>0x3 = EPWM1B In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.</p>	RW	0x0
3:2	POLSEL	<p>Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that EPWM_DBCTL[1:0] OUT_MODE = 0b11 and EPWM_DBCTL[5:4] IN_MODE = 0b00. Other enhanced modes are also possible, but not regarded as typical usage modes.</p> <p>0x0 = Active high (AH) mode. Neither EPWM1A nor EPWM1B is inverted (default).</p> <p>0x1 = Active low complementary (ALC) mode. EPWM1A is inverted.</p> <p>0x2 = Active high complementary (AHC). EPWM1B is inverted.</p> <p>0x3 = Active low (AL) mode. Both EPWM1A and EPWM1B are inverted.</p>	RW	0x0
1:0	OUT_MODE	<p>Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay.</p> <p>0x0 = Dead-band generation is bypassed for both output signals. In this mode, both the EPWM1A and EPWM1B output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect.</p> <p>0x1 = Disable rising-edge delay. The EPWM1A signal from the action-qualifier is passed straight through to the EPWM1A input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWM1B. The input signal for the delay is determined by EPWM_DBCTL[5:4] IN_MODE.</p> <p>0x2 = Disable falling-edge delay. The EPWM1B signal from the action-qualifier is passed straight through to the EPWM1B input of the PWM-chopper submodule. The rising-edge delayed signal is seen on output EPWM1A. The input signal for the delay is determined by EPWM_DBCTL[5:4] IN_MODE.</p> <p>0x3 = Dead-band is fully enabled for both rising-edge delay on output EPWM1A and falling-edge delay on output EPWM1B. The input signal for the delay is determined by EPWM_DBCTL[5:4] IN_MODE.</p>	RW	0x0

Physical Address	0x4843 E234								Instance				PWMSS_EPWM			
Description																
Type	RW															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RESERVED												INTCNT		INTPRD	

Bits	Field Name	Description	Type	Reset
15:4	RESERVED		R	0x0
3:2	INTCNT	<p>ePWM Interrupt Event (ePWM0INT) Counter Register. These bits indicate how many selected EPWM_ETSEL[2:0] INTSEL events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, EPWM_ETSEL[0] INT = 0 or the interrupt flag is set, EPWM_ETFLG[0] INT = 1, the counter will stop counting events when it reaches the period value EPWM_ETPS[3:2] INTCNT = EPWM_ETPS[1:0] INTPRD.</p> <p>0x0 = No events have occurred. 0x1 = 1 event has occurred. 0x2 = 2 events have occurred. 0x3 = 3 events have occurred.</p>	R	0x0
1:0	INTPRD	<p>ePWM Interrupt (ePWM0INT) Period Select. These bits determine how many selected EPWM_ETSEL[2:0] INTSEL events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (EPWM_ETSEL[0] INT = 1). If the interrupt status flag is set from a previous interrupt (EPWM_ETFLG[0] INT = 1) then no interrupt will be generated until the flag is cleared via the EPWM_ETCLR[0] INT bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the EPWM_ETPS[3:2] INTCNT bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented.</p> <p>0x0 = Disable the interrupt event counter. No interrupt will be generated and EPWM ETFRC[0] INT is ignored. 0x1 = Generate an interrupt on the first event INTCNT = 01 (first event) 0x2 = Generate interrupt on EPWM_ETPS[3:2] INTCNT = 0b10 (second event) 0x3 = Generate interrupt on EPWM_ETPS[3:2] INTCNT = 0b11 (third event)</p>	RW	0x0

22.3 Enhanced Capture (eCAP) Module

22.3.1 eCAP Overview

22.3.1.1 Purpose of the eCAP Peripheral

Uses for eCAP include:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

22.3.1.2 eCAP Features

The eCAP module includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

22.3.2 eCAP Functional Description

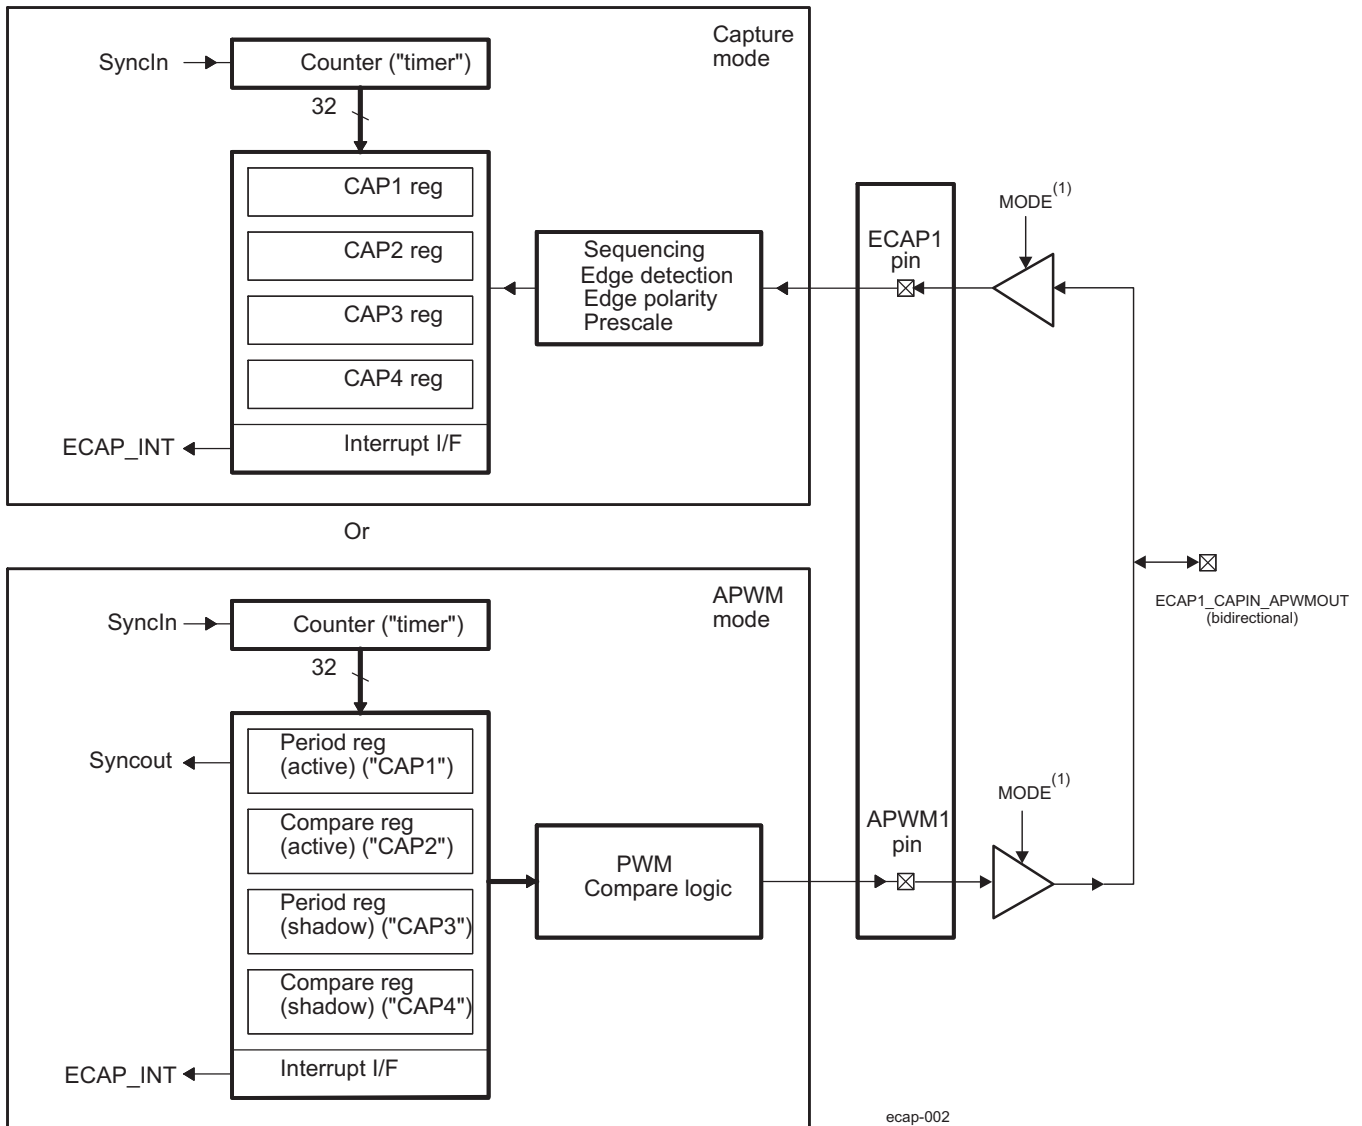

The eCAP module represents one complete capture channel that can be instantiated multiple times depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers ([PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4](#))
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer ([PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4](#)) scheme
- Interrupt capabilities on any of the 4 capture events

22.3.2.1 Capture and APWM Operating Mode

The eCAP module resources can be used to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The [PWMSS_ECAP_CAP1](#) and [PWMSS_ECAP_CAP2](#) registers become the active period and compare registers, respectively, while [PWMSS_ECAP_CAP3](#) and [PWMSS_ECAP_CAP4](#) registers become the period and capture shadow registers, respectively. [Figure 22-49](#) is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 22-49. Capture and APWM Modes of Operation

- (1) A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- (2) In APWM mode, writing any value to [PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2](#) active registers also writes the same value to the corresponding shadow registers [PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4](#). This emulates immediate mode. Writing to the shadow registers [PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4](#) invokes the shadow mode.

22.3.2.2 eCAP Capture Mode Description

Figure 22-50 shows the various components that implement the capture function.

Figure 22-50. Capture Function Diagram

22.3.2.2.1 eCAP Event Prescaler

An input capture signal (pulse train) can be prescaled by $N = 2-62$ (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 22-51 shows a functional diagram and Figure 22-52 shows the operation of the prescale function.

Figure 22-51. Event Prescale Control

- (1) When a prescale value of 1 is chosen ($PWMSS_ECAP_ECCTL1[13:9] EVTFLTPTS = 0b0000$) the input capture signal by-passes the prescale logic completely.

Figure 22-52. Prescale Function Waveforms

ecap-005

22.3.2.2.2 eCAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAP n register by the Mod4 counter. The CAP n register is loaded on the falling edge.

22.3.2.2.3 eCAP Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 22-53) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of PWMSS_ECAP_CAP1-4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of PWMSS_ECAP_CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to PWMSS_ECAP_CAP1-4 in a circular buffer sequence.

Figure 22-53. eCAP Continuous/One-shot Block Diagram

ecap-006

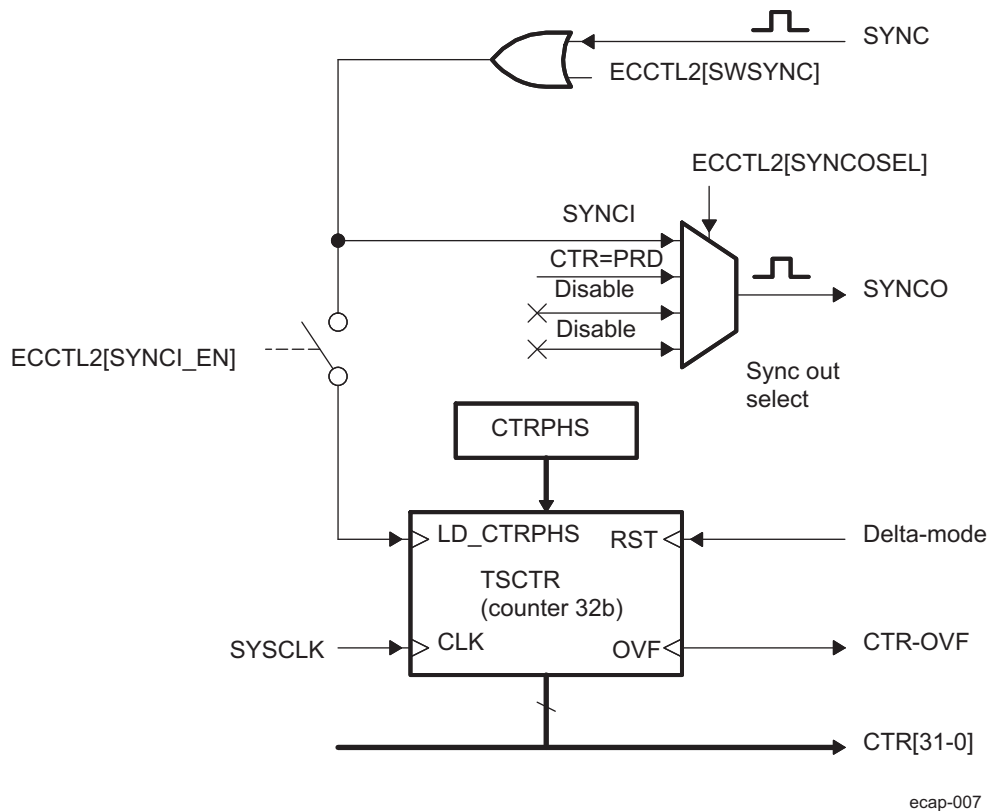

22.3.2.2.4 eCAP 32-Bit Counter and Phase Control

This counter (Figure 22-54) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

Figure 22-54. eCAP Counter and Synchronization Block Diagram

ecap-007

22.3.2.2.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

[PWMSS_ECAP_CAP1](#) and [PWMSS_ECAP_CAP2](#) registers become the active period and compare registers, respectively, in APWM mode.

[PWMSS_ECAP_CAP3](#) and [PWMSS_ECAP_CAP4](#) registers become the respective shadow registers (APRD and ACMP) for [PWMSS_ECAP_CAP1](#) and [PWMSS_ECAP_CAP2](#) during APWM operation.

22.3.2.2.6 eCAP Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CNTOVF) or APWM events (TSCNT = PRD, TSCNT = CMP). See [Figure 22-55](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAP n module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register ([PWMSS_ECAP_ECEINT](#)) is used to enable/disable individual interrupt event sources. The interrupt flag register ([PWMSS_ECAP_ECFLG](#)) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register ([PWMSS_ECAP_ECCLR](#)) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register ([PWMSS_ECAP_ECFRC](#)). This is useful for test purposes.

22.3.2.2.7 eCAP Shadow Load and Lockout Control

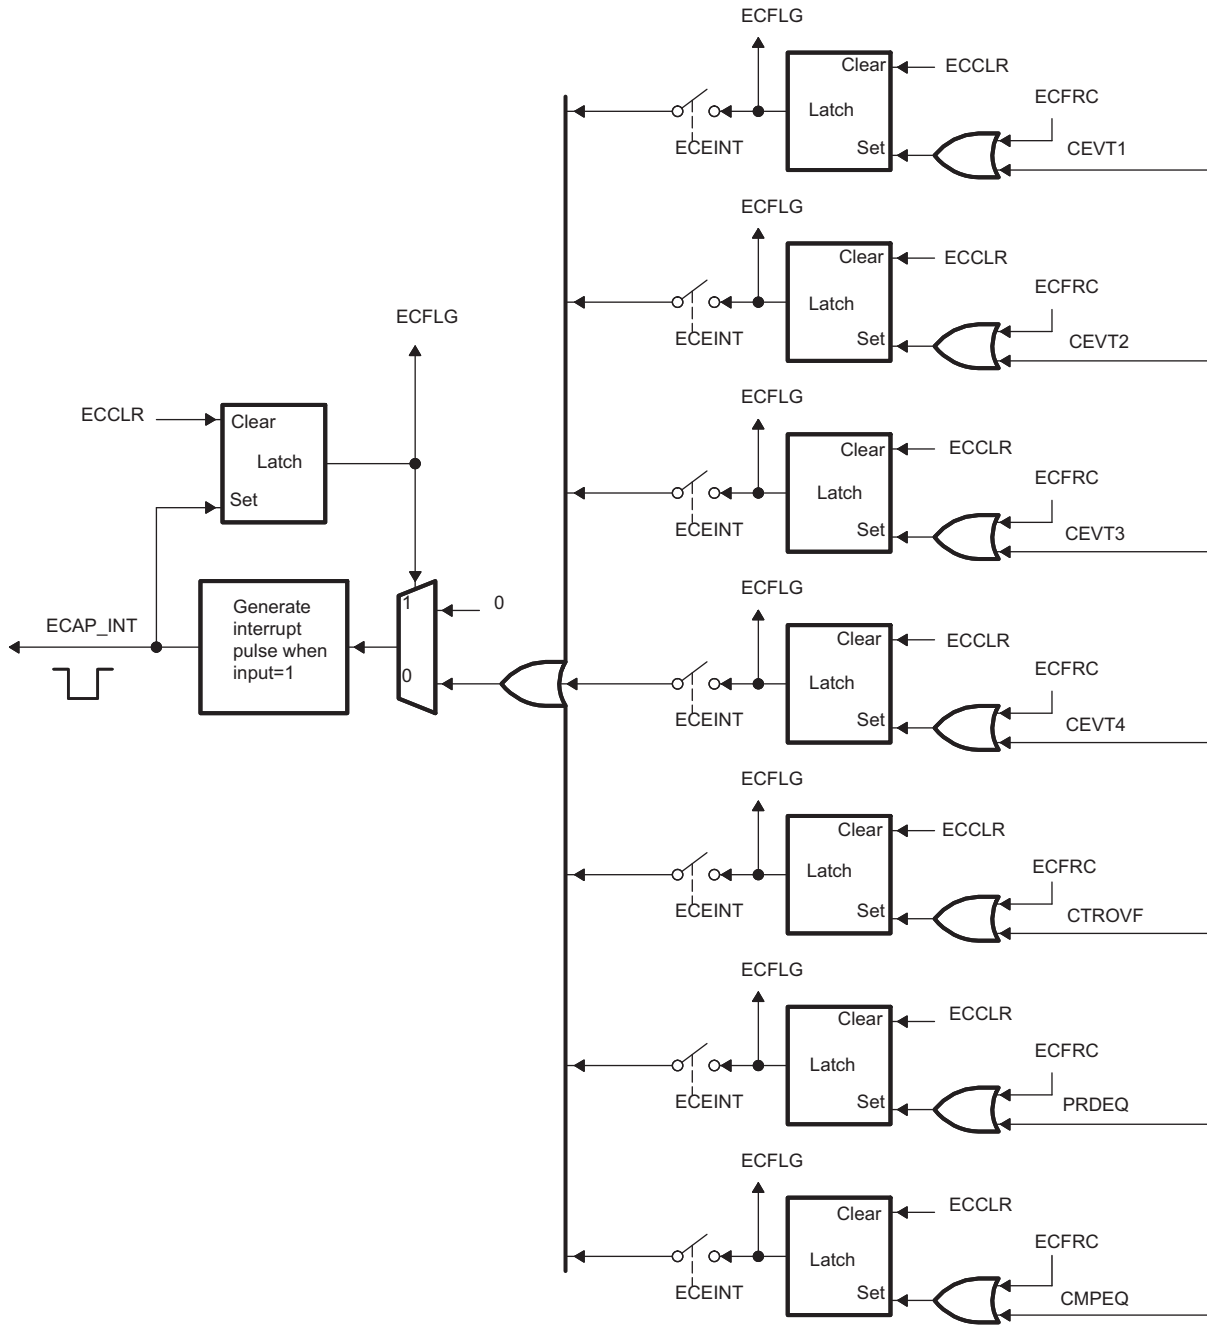

In capture mode, this logic inhibits (locks out) any shadow loading of [PWMSS_ECAP_CAP1](#) or [PWMSS_ECAP_CAP2](#) from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to [PWMSS_ECAP_CAP1](#) or [PWMSS_ECAP_CAP2](#) immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0]

NOTE: The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode ([PWMSS_ECAP_ECCTL2](#)[9] CAPAPWM == 0). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode ([PWMSS_ECAP_ECCTL2](#)[9] CAPAPWM == 1). CNTOVF flag is valid in both modes.

Figure 22-55. Interrupts in eCAP Module

ecap-008

22.3.2.2.8 eCAP Module APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When `PWMSS_ECAP_CAP1/2` registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers `APRD` and `ACMP` (`PWMSS_ECAP_CAP3/4`). The shadow register contents are transferred over to `PWMSS_ECAP_CAP1/2` registers either immediately upon a write, or on a `TSCNT = PRD` trigger.
- In APWM mode, writing to `PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2` active registers will also write the same value to the corresponding shadow registers `PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4`. This emulates immediate mode. Writing to the shadow registers `PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4` will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

Figure 22-56. PWM Waveform Details Of eCAP APWM Mode Operation

The behavior of APWM active-high mode (`APWMPOL == 0`) is:

- `CMP = 0x00000000`, output low for duration of period (0% duty)
- `CMP = 0x00000001`, output high 1 cycle
- `CMP = 0x00000002`, output high 2 cycles
- `CMP = PERIOD`, output high except for 1 cycle (<100% duty)
- `CMP = PERIOD+1`, output high for complete period (100% duty)
- `CMP > PERIOD+1`, output high for complete period

The behavior of APWM active-low mode (`APWMPOL == 1`) is:

- `CMP = 0x00000000`, output high for duration of period (0% duty)
- `CMP = 0x00000001`, output low 1 cycle
- `CMP = 0x00000002`, output low 2 cycles
- `CMP = PERIOD`, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

22.3.2.3 Summary of eCAP Functional Registers

Table 22-115 shows the eCAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode. The 16 least-significant bits of a 32-bit register are located on lowest address (even address).

NOTE: In APWM mode, writing to [PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2](#) active registers also writes the same value to the corresponding shadow registers [PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4](#). This emulates immediate mode. Writing to the shadow registers [PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4](#) invokes the shadow mode.

15:11	RESERVED		R	0x0
10	APWMPOL	APWM output polarity select. This is applicable only in APWM operating mode 0x0 = Output is active high (Compare value defines high time) 0x1 = Output is active low (Compare value defines low time)	RW	0x0

Bits	Field Name	Description	Type	Reset
9	CAPAPWM	<p>CAP/APWM operating mode select</p> <p>0x0 = ECAP module operates in capture mode. This mode forces the following configuration.</p> <p>(a) Inhibits TSCNT resets via TSCNT = PRD event.</p> <p>(b) Inhibits shadow loads on PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers.</p> <p>(c) Permits user to enable PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4 register load.</p> <p>(d) ECAP input / APWM output pin operates as a capture input.</p> <p>0x1 = ECAP module operates in APWM mode. This mode forces the following configuration.</p> <p>(a) Resets TSCNT on TSCNT = PRD event (period boundary).</p> <p>(b) Permits shadow loading on PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers.</p> <p>(c) Disables loading of time-stamps into PWMSS_ECAP_CAP1 - PWMSS_ECAP_CAP4 registers.</p> <p>(d) ECAP input / APWM output pin operates as a APWM output.</p>	RW	0x0
8	SWSYNC	<p>Software-forced Counter (TSCNT) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the TSCNT = PRD event. Note: Selection TSCNT = PRD is meaningful only in APWM mode. However, you can choose it in CAP mode if you find doing so useful.</p> <p>0x0 = Writing a zero has no effect. Reading always returns a zero</p> <p>0x1 = Writing a one forces a TSCNT shadow load of ECAP module providing the SYNCO_SEL bits are 0b00. After writing a 1, this bit returns to a zero.</p>	RW	0x0
7:6	SYNCO_SEL	<p>Sync-Out Select</p> <p>0x0 = Select sync-in event to be the sync-out signal (pass through)</p> <p>0x1 = Select TSCNT = PRD event to be the sync-out signal</p> <p>0x2 = Disable sync out signal</p> <p>0x3 = Disable sync out signal</p>	RW	0x0
5	SYNCI_EN	<p>Counter (TSCNT) Sync-In select mode</p> <p>0x0 = Disable sync-in option</p> <p>0x1 = Enable counter (TSCNT) to be loaded from PWMSS_ECAP_CNTPHS register upon either a SYNCI signal or a S/W force event.</p>	RW	0x0
4	TSCNTSTP	<p>Time Stamp (TSCNT) Counter Stop (freeze) Control</p> <p>0x0 = TSCNT stopped</p> <p>0x1 = TSCNT free-running</p>	RW	0x0
3	REARMRESET	<p>One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode.</p> <p>0x0 = Has no effect (reading always returns a 0)</p> <p>0x1 = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero. 2) Unfreezes the Mod4 counter. 3) Enables capture register loads.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
2:1	STOPVALUE	Stop value for one-shot mode. This is the number (between 1 and 4) of captures allowed to occur before the CAP (1 through 4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1 and 4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOPVALUE is compared to Mod4 counter and, when equal, the following two actions occur. (1) Mod4 counter is stopped (frozen). (2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. 0x0 = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 0x1 = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 0x2 = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 0x3 = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.	RW	0x3
0	CONTONESHT	Continuous or one-shot mode control (applicable only in capture mode) 0x0 = Operate in continuous mode 0x1 = Operate in one-shot mode	RW	0x0

22.4 Enhanced Quadrature Encoder Pulse (eQEP) Module

22.4.1 eQEP Overview

A single track of slots patterns the periphery of an incremental encoder disk, as shown in [Figure 22-57](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference.

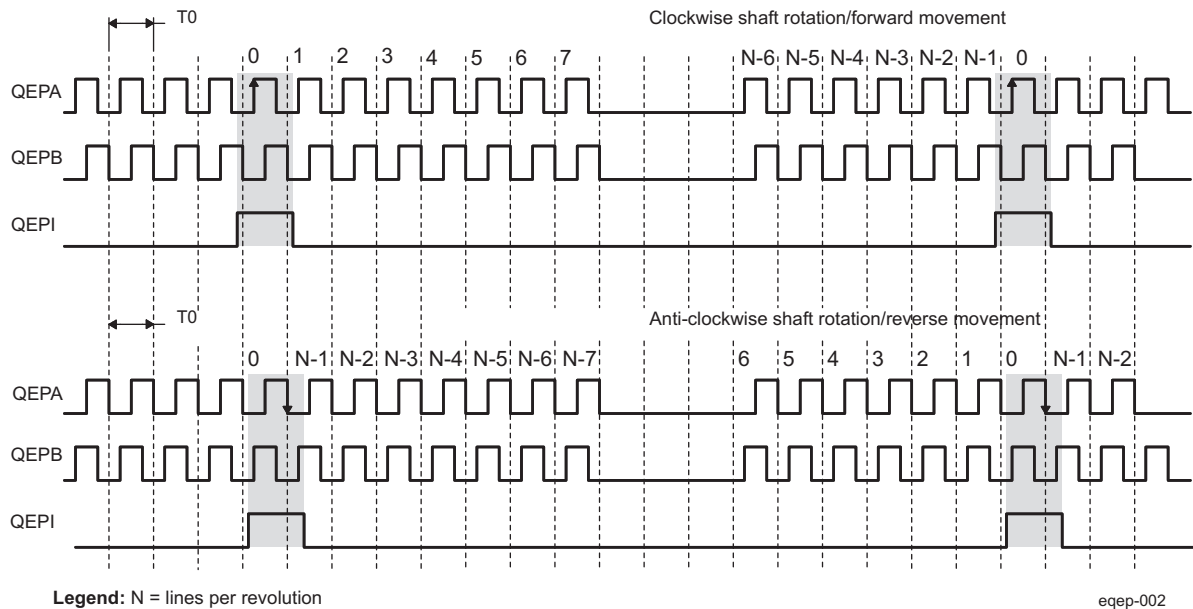

Figure 22-57. Optical Encoder Disk

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 22-58](#).

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Figure 22-58. QEP Encoder Output Signal for Forward/Reverse Movement

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 22-59. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 22-59. Index Pulse Example

Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{X(k) - X(k-1)}{T} = \frac{\Delta X}{T} \tag{16}$$

eqep-004

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \tag{17}$$

eqep-005

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement.

Equation 16 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on **Equation 16** has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, **Equation 17** provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. **Equation 17** can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does **Equation 16**. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use **Equation 17** at low speed and have the software switch over to **Equation 16** when the motor speed rises above some specified threshold.

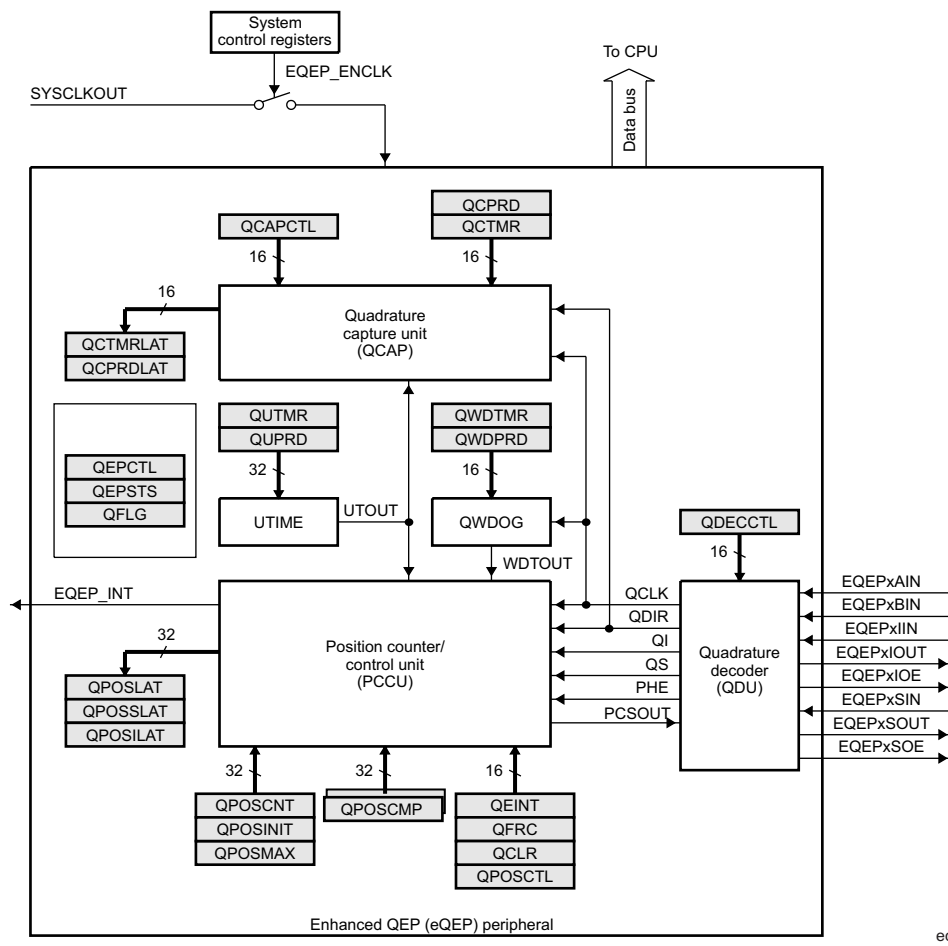

22.4.2 eQEP Module Functional Description

This section provides the eQEP functional description and corresponding functional details about EQEP inputs.

The eQEP peripheral contains the following major functional units (as shown in Figure 22-60):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

Figure 22-60. Functional Block Diagram of the eQEP Peripheral

eqep-006

22.4.2.1 eQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- QEPA/XCLK and QEPB/XDIR: These two pins can be used in quadrature-clock mode or direction-count mode.
 - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction

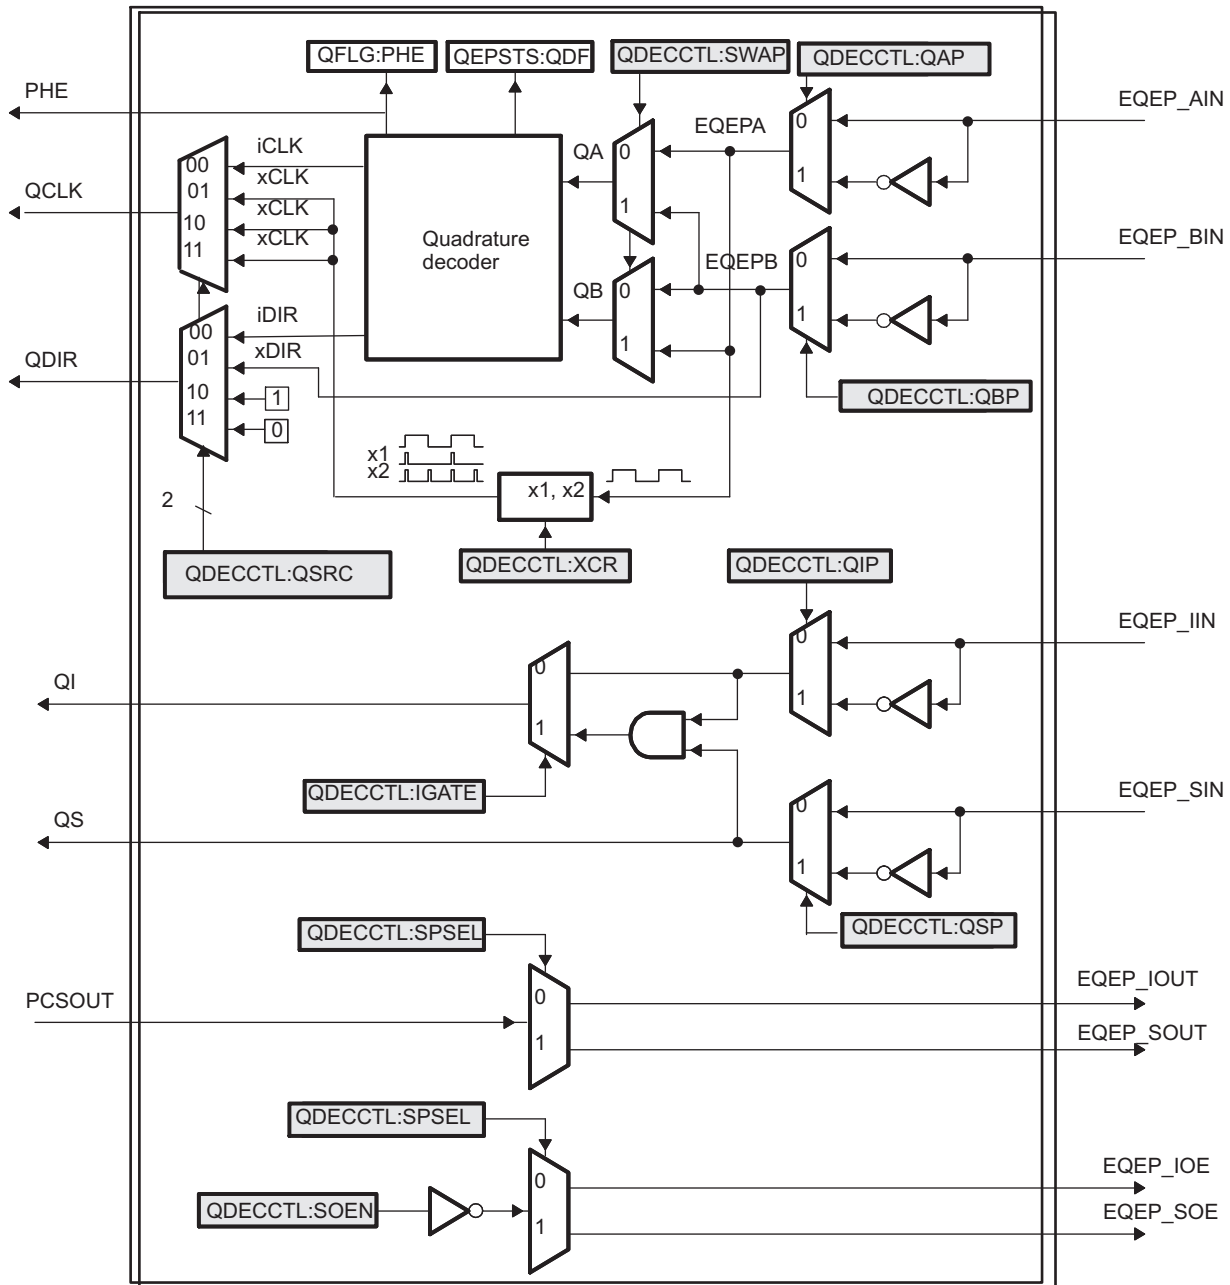

signals.

- Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- QEPI: Index or Zero Marker: The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- QEPS: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

22.4.2.2 eQEP Quadrature Decoder Unit (QDU)

[Figure 22-61](#) shows a functional block diagram of the QDU.

Figure 22-61. Functional Block Diagram of Decoder Unit

eqep-007

22.4.2.2.1 eQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the eQEP decoder control register ([EQEP_QDECCTL](#)), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

22.4.2.2.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the eQEP status register ([EQEP_QEPSTS](#)). [Table 22-144](#) and [Figure 22-62](#) show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. [Figure 22-63](#) shows the direction decoding and clock generation from the eQEP input signals.

Phase Error Flag— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the [EQEP_QFLG](#) register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 22-62](#) are invalid transitions that generate a phase error.

Count Multiplication— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 22-63](#).

Reverse Count— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the eQEP decoder control register ([EQEP_QDECCTL](#)). This will swap the input to the quadrature decoder thereby reversing the counting direction.

Table 22-144. Quadrature Decoder Truth Table

Previous Edge	Present Edge	QDIR	QPOSCNT

Figure 22-62. Quadrature Decoder State Machine

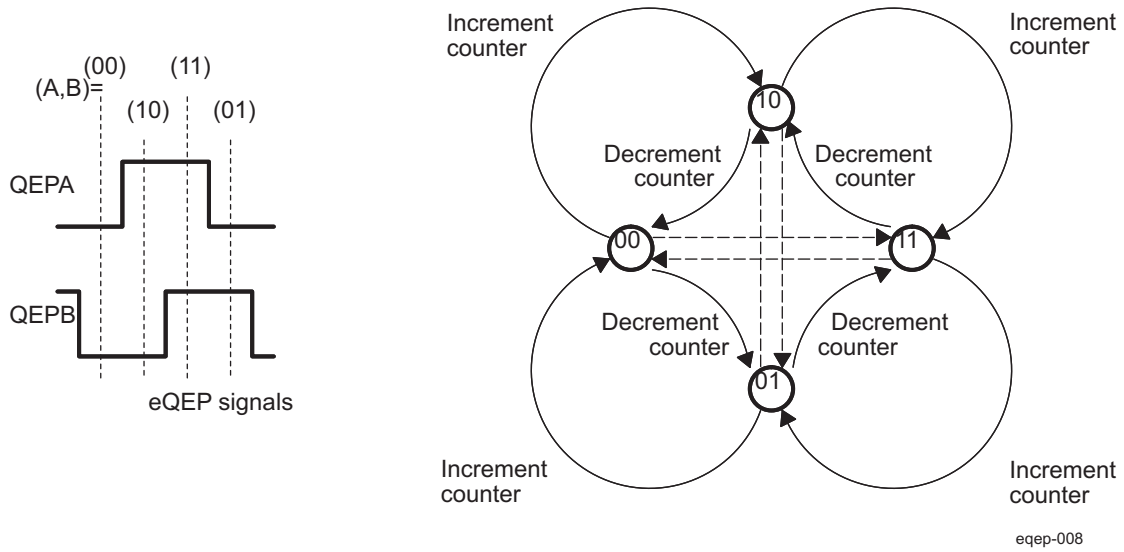

Figure 22-63. Quadrature-clock and Direction Decoding

22.4.2.2.1.2 eQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

22.4.2.2.1.3 eQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register ([EQEP_QDECCTL](#)) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2x factor.

22.4.2.2.1.4 eQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register ([EQEP_QDECCTL](#)) enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2x factor.

22.4.2.2.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using the in the eQEP decoder control register ([EQEP_QDECCTL\[8:5\]](#)) control bits. As an example, setting of the QIP bit in [EQEP_QDECCTL](#) inverts the index input.

22.4.2.2.3 eQEP Position-Compare Sync Output

The eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register ([EQEP_QPOSCNT](#)) and the position-compare register ([EQEP_QPOSCMP](#)). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the eQEP decoder control register ([EQEP_QDECCTL](#)) enables the position-compare sync output and the SPSEL bit in [EQEP_QDECCTL](#) selects either an eQEP index pin or an eQEP strobe pin.

22.4.2.3 eQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers ([EQEP_QEPCTL](#) and [EQEP_QPOSCTL](#)) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

22.4.2.3.1 eQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOS MAX bifield value in EQEP_QPOS MAX register on underflow. Overflow occurs when the position counter counts up after QPOS MAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in EQEP_QFLG register.

22.4.2.3.1.1 eQEP Position Counter Reset on Index Event (EQEP_QEPCTL[31:12] PCRM] = 0b00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOS MAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in EQEP_QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 22-64.

The position-counter value is latched to the EQEP_QPOSILAT register and direction information is recorded in the EQEP_QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (EQEP_QEPSTS[PCEF]) and error interrupt flag (EQEP_QFLG[PCE]) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (EQEP_QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (EQEP_QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration EQEP_QEPCTL[5:4] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

Figure 22-64. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or F9Fh)

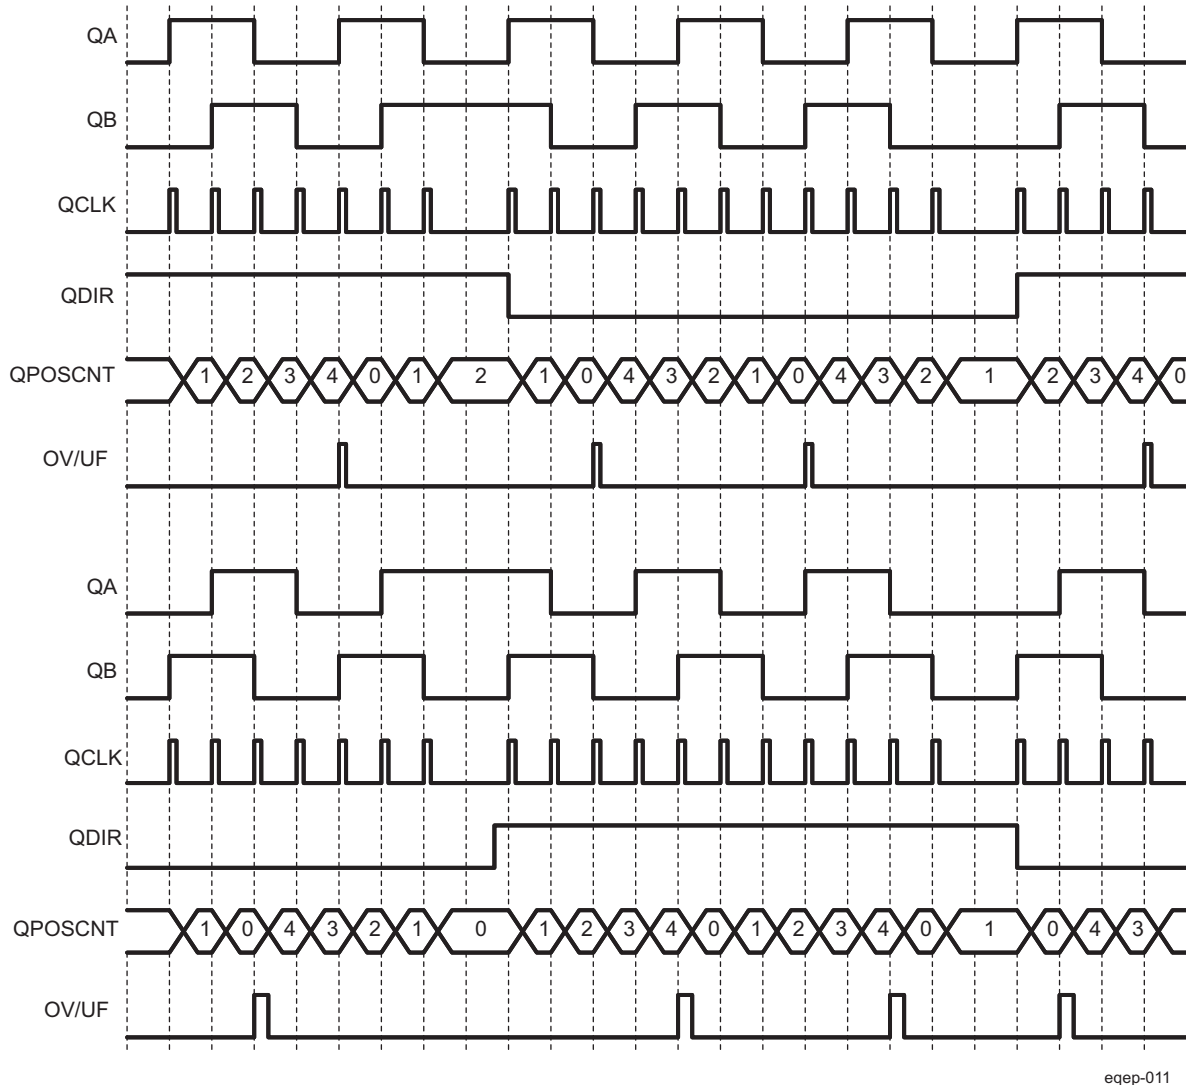

eqep-010

22.4.2.3.1.2 eQEP Position Counter Reset on Maximum Position (EQEP_QEPCTL[13:12] PCRM=0b01)

If the position counter is equal to QPOS MAX (in EQEP_QPOS MAX register), then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 22-65 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in the EQEP_QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP_QEPCTL[5:4] IEL=0b11).

Figure 22-65. Position Counter Underflow/Overflow (QPOS MAX = 4)

eqep-011

22.4.2.3.1.3 Position Counter Reset on the First Index Event (EQEP_QEPCTL[13:12] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 22.4.2.3.1.2.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in EQEP_QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP_QEPCTL[5:4] IEL= 0b11).

22.4.2.3.1.4 Position Counter Reset on Unit Time out Event (EQEP_QEPCTL[13:12] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP_QPOSILAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP_QPOSMAX register, depending on the direction mode selected by EQEP_QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

22.4.2.3.2 eQEP Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP_QPOSCNT) into QPOSILAT (EQEP_QPOSILAT register) and QPOSSLAT (EQEP_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

22.4.2.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP_QEPCTL[13:12] PCRM = 0b01 and EQEP_QEPCTL[13:12] PCRM = 0b10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP_QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (EQEP_QEPCTL[5:4] IEL = 0b01)
- Latch on Falling edge (EQEP_QEPCTL[5:4] IEL = 0b10)
- Latch on Index Event Marker (EQEP_QEPCTL[5:4] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

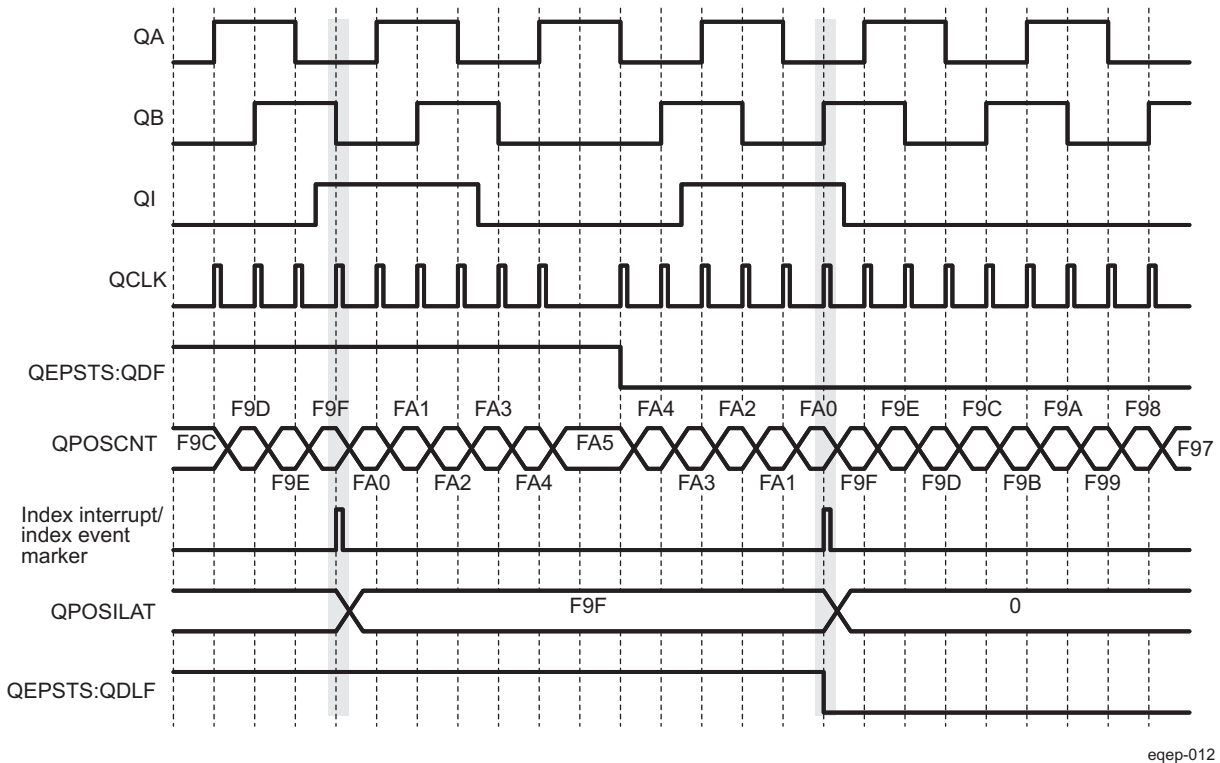

The index event latch interrupt flag (EQEP_QFLG[IEL]) is set when the position counter is latched to the EQEP_QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when EQEP_QEPCTL[13:12] PCRM = 0b00.

Latch on Rising Edge (EQEP_QEPCTL[5:4] IEL = 0b01)— The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge (EQEP_QEPCTL[5:4] IEL = 0b10)— The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (EQEP_QEPCTL[5:4] IEL = 0b11)— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in the EQEP_QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (EQEP_QEPCTL[5:4] IEL = 0b11).

Figure 22-66 shows the position counter latch using an index event marker.

Figure 22-66. Software Index Marker for 1000-line Encoder (EQEP_QEPCTL[5:4] IEL = 0b01)

22.4.2.3.2.2 eQEP Strobe Event Latch

The position-counter value is latched to the [EQEP_QPOSSLAT](#) register on the rising edge of the strobe input by clearing the [EQEP_QEPCTL\[6\]](#) SEL bit.

If the [EQEP_QEPCTL\[6\]](#) SEL bit is set, then the position counter value is latched to the [EQEP_QPOSSLAT](#) register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 22-67](#).

The strobe event latch interrupt flag ([EQEP_QFLG\[SEL\]](#)) is set when the position counter is latched to the [EQEP_QPOSSLAT](#) register.

Figure 22-67. eQEP Strobe Event Latch (EQEP_QEPCTL[6] SEL = 0b1)

22.4.2.3.3 eQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the [EQEP_QEPCTL\[9:8\]](#) IEI bits are 0b10, then the position counter ([EQEP_QPOSCNT](#)) is initialized with a value in the [EQEP_QPOSINIT](#) register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag ([EQEP_QFLG\[IEI\]](#)) is set when the position counter is initialized with a value in the [EQEP_QPOSINIT](#) register.

Strobe Event Initialization (SEI)— If the [EQEP_QEPCTL\[11:10\]](#) SEI bits are 0b10, then the position counter is initialized with a value in the [EQEP_QPOSINIT](#) register on the rising edge of strobe input.

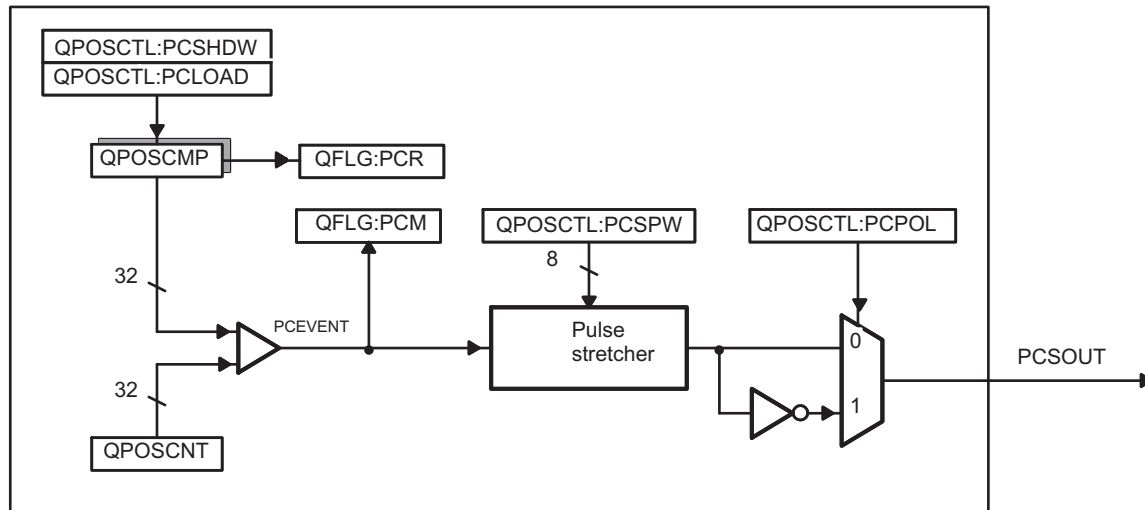

If the [EQEP_QEPCTL\[11:10\]](#) SEI bits are 0b11, then the position counter ([EQEP_QPOSCNT](#)) is initialized with a value in the [EQEP_QPOSINIT](#) register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag ([EQEP_QFLG\[SEI\]](#)) is set when the position counter is initialized with a value in the [EQEP_QPOSINIT](#) register.

Software Initialization (SWI)— The position counter can be initialized in software by writing a '1' to the [EQEP_QEPCTL\[7\]](#) SWI bit, which will automatically be cleared after initialization.

22.4.2.3.4 eQEP Position-Compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. [Figure 22-68](#) shows a diagram. The position-compare ([EQEP_QPOSCMP](#)) register is shadowed and shadow mode can be enabled or disabled using the [EQEP_QPOSCNTL\[PSSHDW\]](#) bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 22-68. eQEP Position-compare Unit

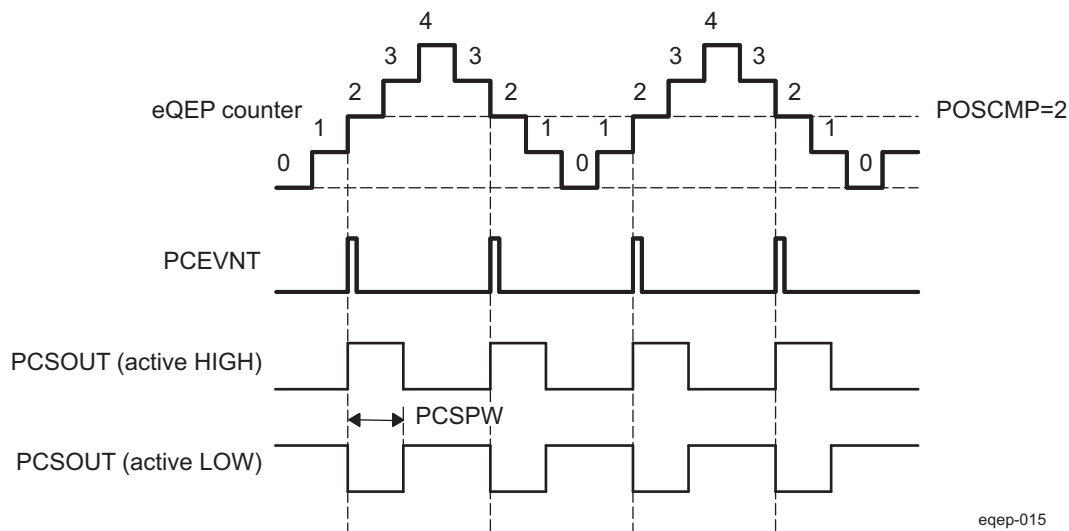

eqep-014

In shadow mode, you can configure the position-compare unit (`EQEP_QPOSCTL[PCLOAD]`) to load the shadow register value into the active register on the following events and to generate the position-compare ready (`EQEP_QFLG[PCR]`) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (`EQEP_QFLG[PCM]`) is set when the position-counter value (`QPOSCNT`) matches with the active position-compare register (`EQEP_QPOSCMP`) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if `EQEP_QPOSCMP` bitfield `QPOSCMP = 0x2`, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see [Figure 22-69](#)).

Figure 22-69. eQEP Position-compare Event Generation Points

eqep-015

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event.

22.4.2.4 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 22-70](#). This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T}$$

eqep-017

(18)

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 22-71](#))
- ΔT - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR bitfield in [EQEP_QCTMR](#) register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the [EQEP_QCAPCTL\[CCPS\]](#) bits. The capture timer QCTMR value is latched into the capture period register ([EQEP_QCPRD](#)) on every unit position event and then the capture timer is reset, a flag is set in [EQEP_QEPSTS\[UPEVNT\]](#) to indicate that new value is latched into the [EQEP_QCPRD](#) register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

NOTE: The system clock - SYSCLKOUT is the eQEP functional clock derived from the PWMSS gateable interface and functional clock PWMSS_GICLK, described in the [Section 22.1.3](#).

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag ([EQEP_QEPSTS\[COEF\]](#)) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register ([EQEP_QEPSTS\[CDEF\]](#)).

Capture Timer ([EQEP_QCTMR](#) register) and Capture period register ([EQEP_QCPRD](#)) can be configured to latch on following events.

- CPU read of [EQEP_QPOSCNT](#) register
- Unit time-out event

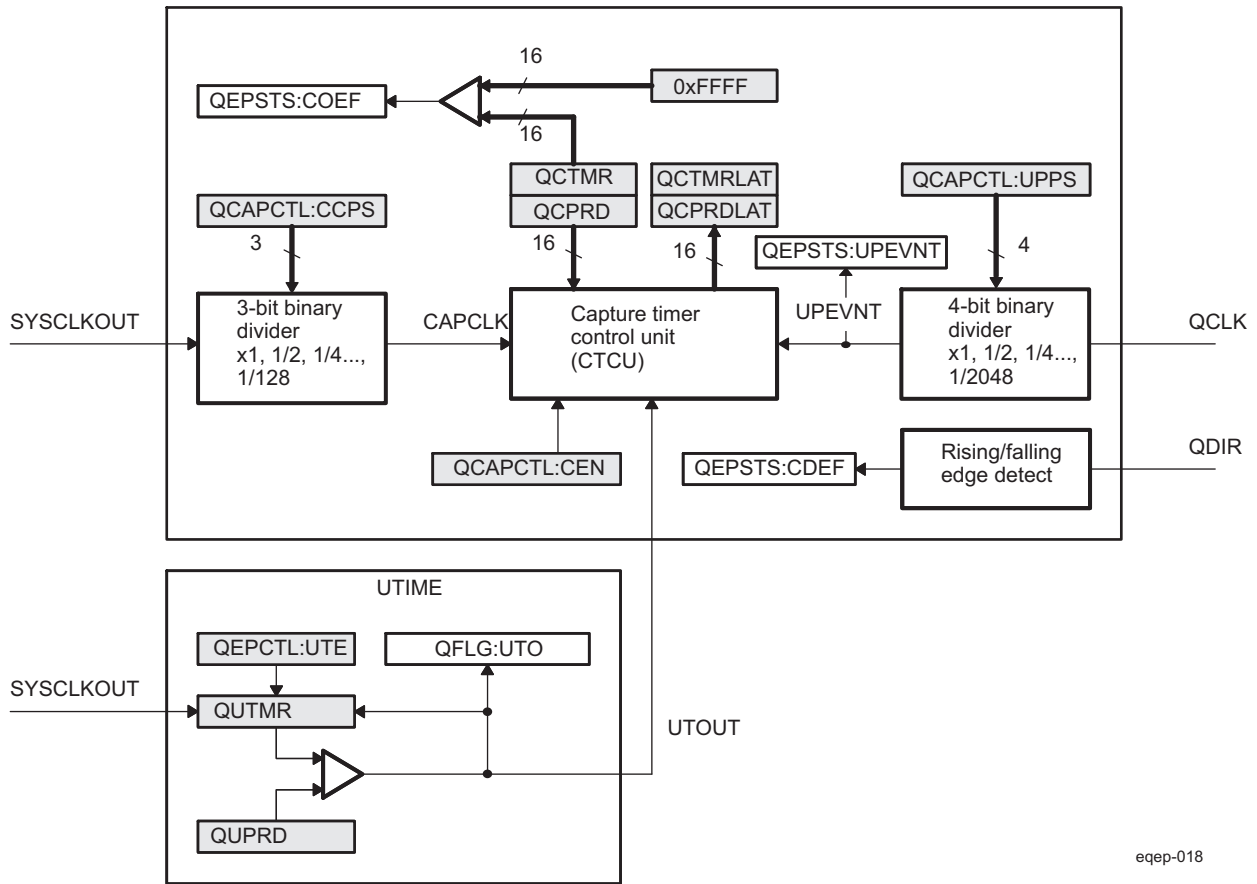

If the [EQEP_QEPCTL\[2\] QCLM](#) bit is cleared, then the capture timer and capture period values are latched into the [EQEP_QCTMRLAT](#) and [EQEP_QCPRDLAT](#) registers, respectively, when the CPU reads the position counter in [EQEP_QPOSCNT](#).

If the [EQEP_QEPCTL\[2\] QCLM](#) bit is set, then the position counter, capture timer, and capture period values are latched into the [EQEP_QPOSLAT](#), [EQEP_QCTMRLAT](#) and [EQEP_QCPRDLAT](#) registers, respectively, on unit time out.

[Figure 22-72](#) shows the capture unit operation along with the position counter.

NOTE: The [EQEP_QCAPCTL](#) register should not be modified dynamically (such as switching CAPCLK prescaling mode from QCLK/4 to QCLK/8). The capture unit must be disabled before changing the prescaler.

Figure 22-70. eQEP Edge Capture Unit

eqep-018

Figure 22-72. eQEP Edge Capture Unit - Timing Details

eqep-020

Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \circ$$

eqep_021

(19)

where

$v(k)$: Velocity at time instant k

$x(k)$: Position at time instant k

$x(k-1)$: Position at time instant $k - 1$

T : Fixed unit time or inverse of velocity calculation rate

ΔX : Incremental position movement in unit time

X : Fixed unit position

ΔT : Incremental time elapsed for unit position movement

$t(k)$: Time instant "k"

$t(k-1)$: Time instant "k - 1"

Unit time (T) and unit period (X) are configured using the [EQEP_QUPRD](#) and [EQEP_QCAPCTL\[UPPS\]](#) registers. Incremental position output and incremental time output is available in the [EQEP_QOSLAT](#) and [EQEP_QCPRDLAT](#) registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
ΔX	Incremental Position = QOSLAT(k) - QOSLAT(K - 1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

22.4.2.5 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match ($QWDPRD = QWDTMR$), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP_QFLG[WTO]). The time-out value is programmable through the watchdog period register (EQEP_QWDPRD).

Figure 22-73. eQEP Watchdog Timer

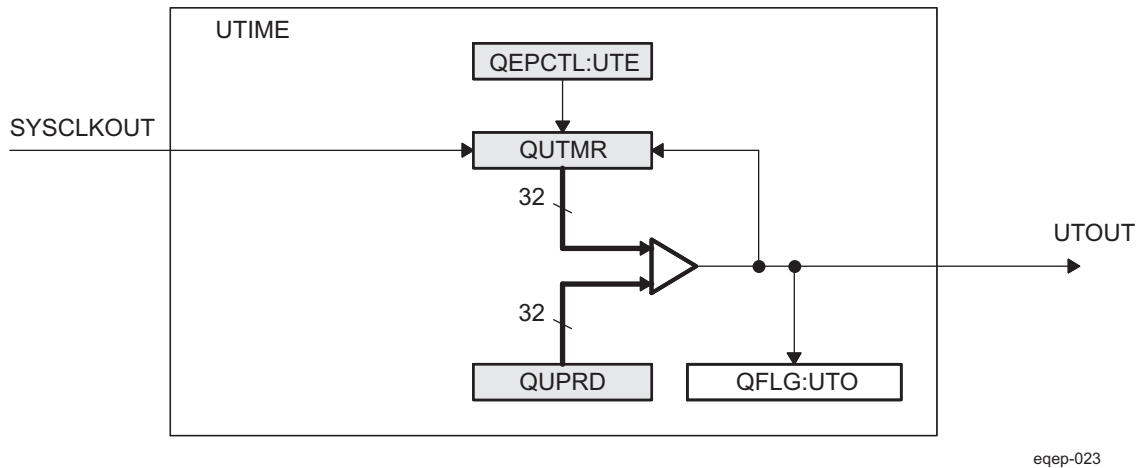

22.4.2.6 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (EQEP_QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (EQEP_QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 22.4.2.4.

Figure 22-74. eQEP Unit Time Base

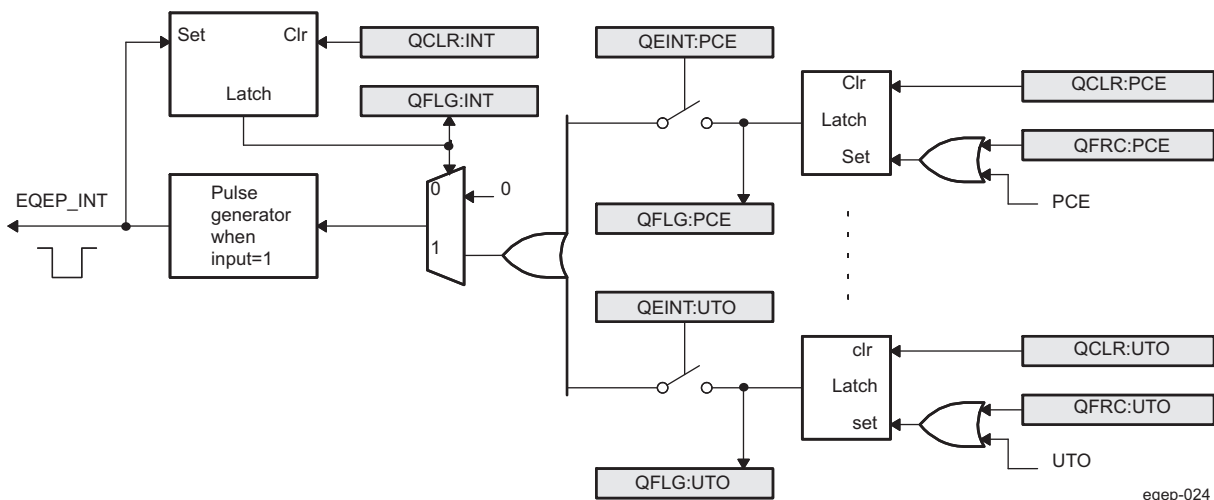

eqep-023

22.4.2.7 eQEP Interrupt Structure

Figure 22-75 shows how the interrupt mechanism works in the EQEP module.

Figure 22-75. EQEP Interrupt Generation

eqep-024

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register ([EQEP_QEINT](#)) is used to enable/disable individual interrupt event sources. The interrupt flag register ([EQEP_QFLG](#)) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register ([EQEP_QCLR](#)), before any other interrupt pulses are generated. You can force an interrupt event by way of the interrupt force register ([EQEP_QFRC](#)), which is useful for test purposes.

22.4.2.8 Summary of PWMSS eQEP Functional Registers

Table 22-145 lists the registers with their memory locations, sizes, and reset values.

22.4.3.2.2 PWMSS_EQEP Register Description
Table 22-148. EQEP_QPOSCNT

Address offset	0x0	Instance	PWMSS_EQEP
Physical Address	0x4843 E180		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSCNT																															

Bits	Field Name	Description	Type	Reset
31:0	QPOSCNT	This 32 bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point.	RW	0x0

Table 22-149. Register Call Summary for Register EQEP_QPOSCNT

Table 22-166. EQEP_QWDTMR

Address offset	0x24	Instance	PWMSS_EQEP
Physical Address	0x4843 E1A4		
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QWDTMR															

Bits	Field Name	Description	Type	Reset
15:0	QWDTMR	This register acts as time base for watch dog to detect motor stalls. When this timer value matches with watch dog period value, watch dog timeout interrupt is generated. This register is reset upon edge transition in quadrature-clock indicating the motion.	RW	0x0

Table 22-167. Register Call Summary for Register EQEP_QWDTMR

Enhanced Quadrature Encoder Pulse (eQEP) Module

- [Summary of PWMSS eQEP Functional Registers: \[0\]](#)
- [PWMSS_EQEP Registers: \[1\]](#)

Table 22-168. EQEP_QWDPRD

Address offset	0x26	Instance	PWMSS_EQEP
Physical Address	0x4843 E1A6		
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QWDPRD															

Bits	Field Name	Description	Type	Reset
15:0	QWDPRD	This register contains the time-out count for the eQEP peripheral watch dog timer. When the watchdog timer value matches the watchdog period value, a watchdog timeout interrupt is generated.	RW	0x0

Table 22-169. Register Call Summary for Register EQEP_QWDPRD

Enhanced Quadrature Encoder Pulse (eQEP) Module

Table 22-170. EQEP_QDECCTL

Address offset	0x28	Instance	PWMSS_EQEP
Physical Address	0x4843 E1A8		
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QSRC	SOEN	SPSEL	XCR	SWAP	IGATE	QAP	QBP	QIP	QSP	RESERVED					

Bits	Field Name	Description	Type	Reset
15:14	QSRC	Position-counter source selection. 0x0 = Quadrature count mode (QCLK = iCLK, QDIR = iDIR) 0x1 = Direction-count mode (QCLK = xCLK, QDIR = xDIR) 0x2 = UP count mode for frequency measurement (QCLK = xCLK, QDIR = 1) 0x3 = DOWN count mode for frequency measurement (QCLK = xCLK, QDIR = 0)	RW	0x0
13	SOEN	Sync output-enable 0x0 = Disable position-compare sync output 0x1 = Enable position-compare sync output	RW	0x0
12	SPSEL	Sync output pin selection 0x0 = Index pin is used for sync output 0x1 = Strobe pin is used for sync output	RW	0x0
11	XCR	External clock rate 0x0 = 2x resolution: Count the rising/falling edge 0x1 = 1x resolution: Count the rising edge only	RW	0x0
10	SWAP	Swap quadrature clock inputs. This swaps the input to the quadrature decoder, reversing the counting direction. 0x0 = Quadrature-clock inputs are not swapped 0x1 = Quadrature-clock inputs are swapped	RW	0x0
9	IGATE	Index pulse gating option 0x0 = Disable gating of Index pulse 0x1 = Gate the index pin with strobe	RW	0x0
8	QAP	QEPA input polarity 0x0 = No effect 0x1 = Negates QEPA input	RW	0x0
7	QBP	QEPB input polarity 0x0 = No effect 0x1 = Negates QEPB input	RW	0x0
6	QIP	QEPI input polarity 0x0 = No effect 0x1 = Negates QEPI input	RW	0x0
5	QSP	QEPS input polarity 0x0 = No effect 0x1 = Negates QEPS input	RW	0x0
4:0	RESERVED		R	0x0

- PWMSS_EQEP Registers: [10][11]

Table 22-172. EQEP_QEPCTL

Address offset	0x2A	Instance	PWMSS_EQEP
Physical Address	0x4843 E1AA		
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FREE_SOFT		PCRM		SEI		IEI		SWI	SEL		IEL	PHEN	QCLM	UTE	WDE

Bits	Field Name	Description	Type	Reset
15:14	FREE_SOFT	Emulation Control Bits. In the values 0 through 3 listed below, x is different for the four following behaviors. EQEP_QPOSCNT behavior, x refers to the Position counter. QWDTMR behavior, x refers to the Watchdog counter. QUTMR behavior, x refers to the Unit timer. QCTMR behavior, x refers to the Capture timer. 0x0 = x stops immediately. For QPOSCNT behavior, the stop is on emulation suspend. 0x1 = x continues to count until the rollover. 0x2 = x is unaffected by emulation suspend. 0x3 = x is unaffected by emulation suspend.	RW	0x0
13:12	PCRM	Position counter reset mode 0x0 = Position counter reset on an index event 0x1 = Position counter reset on the maximum position 0x2 = Position counter reset on the first index event 0x3 = Position counter reset on a unit time event	RW	0x0
11:10	SEI	Strobe event initialization of position counter 0x0 = Does nothing (action disabled) 0x1 = Does nothing (action disabled) 0x2 = Initializes the position counter on rising edge of the QEPS signal 0x3 = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe. Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe	RW	0x0
9:8	IEI	Index event initialization of position counter 0x0 = Do nothing (action disabled) 0x1 = Do nothing (action disabled) 0x2 = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 0x3 = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)	RW	0x0
7	SWI	Software initialization of position counter 0x0 = Do nothing (action disabled) 0x1 = Initialize position counter, this bit is cleared automatically	RW	0x0

Bits	Field Name	Description	Type	Reset
6	SEL	Strobe event latch of position counter 0x0 = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the EQEP_QDECCTL register. 0x1 = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe. Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe.	RW	0x0
5:4	IEL	Index event latch of position counter (software index marker) 0x0 = Reserved 0x1 = Latches position counter on rising edge of the index signal 0x2 = Latches position counter on falling edge of the index signal 0x3 = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the EQEP_QPOSILAT register and the direction flag is latched in the EQEP_QEPSTS[QDLF] bit. This mode is useful for software index marking.	RW	0x0
3	PHEN	Quadrature position counter enable/software reset 0x0 = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. 0x1 = eQEP position counter is enabled	RW	0x0
2	QCLM	eQEP capture latch mode 0x0 = Latch on position counter read by CPU. Capture timer and capture period values are latched into EQEP_QCTMRLAT and EQEP_QCPRDLAT registers when CPU reads the EQEP_QPOSCNT register. 0x1 = Latch on unit time out. Position counter, capture timer and capture period values are latched into EQEP_QPOSILAT , EQEP_QCTMRLAT and EQEP_QCPRDLAT registers on unit time out.	RW	0x0
1	UTE	eQEP unit timer enable 0x0 = Disable eQEP unit timer 0x1 = Enable unit timer	RW	0x0
0	WDE	eQEP watchdog enable 0x0 = Disable the eQEP watchdog timer 0x1 = Enable the eQEP watchdog timer	RW	0x0

ADC

This chapter describes the analog-to-digital converter in the device.

Topic	Page
23.1 ADC Overview	6475
23.2 ADC Environment	6475
23.3 ADC Integration	6476
23.4 ADC Functional Description	6478
23.5 ADC Programming Guide.....	6482
23.6 ADC Register Manual	6483

23.1 ADC Overview

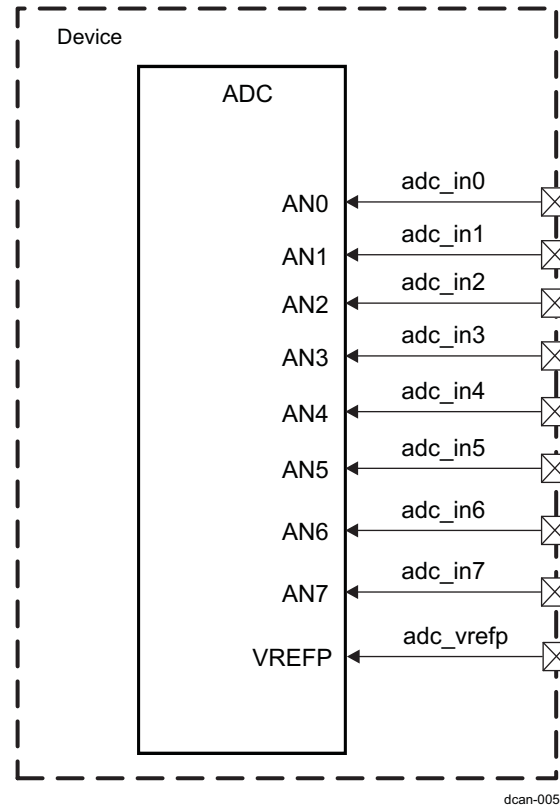

The analog-to-digital converter (ADC) module is a successive-approximation-register (SAR) general-purpose analog-to-digital converter.

The main features of the ADC include:

- 10-bit data
- 750 KSPS at 13.5-MHz ADC_CLK
- 8 channels
- Programmable FSM sequencer that supports 16 steps:
 - Software register bit for start of conversion
 - Single conversion (one-shot)
 - Continuous conversions
 - Sequence through all input channels based on a mask
 - Programmable OpenDelay before sampling each channel
 - Programmable sampling delay for each channel
 - Programmable averaging of input samples - 16/8/4/2/1
 - Store data in either of two FIFO groups – 64-deep each
 - Option to encode channel number with data
 - Support for servicing FIFOs via DMA or CPU
 - Programmable DMA Request event (for each FIFO)
 - Dynamically enable or disable channel inputs during operation
 - Stop bit to end conversion
 - Support for error offset (internal calibration or external calibration via eFuse) inside the AFE
- Support for the following interrupts and status, with masking:
 - Interrupt after a sequence of conversions (all non-masked channels)
 - Interrupt for FIFO threshold levels
 - Interrupt if sampled data is out of a programmable range
 - Interrupt for FIFO overflow and underflow conditions
 - Status bit to indicate if ADC is busy converting

23.2 ADC Environment

[Figure 23-1](#) shows the ADC IO pins.

Figure 23-1. ADC Environment

23.2.1 ADC Signals

Table 23-1 describes the module I/O signals.

Table 23-1. I/O Description

Device Signal	Signal	I/O ⁽¹⁾	Description	Reset Value ⁽²⁾
adc_in0	AN0	A/I	Analog channel input 0	Hi-Z

adc_vrefp	VREFP	A/I	Analog reference positive voltage	Hi-Z

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional; A = Analog

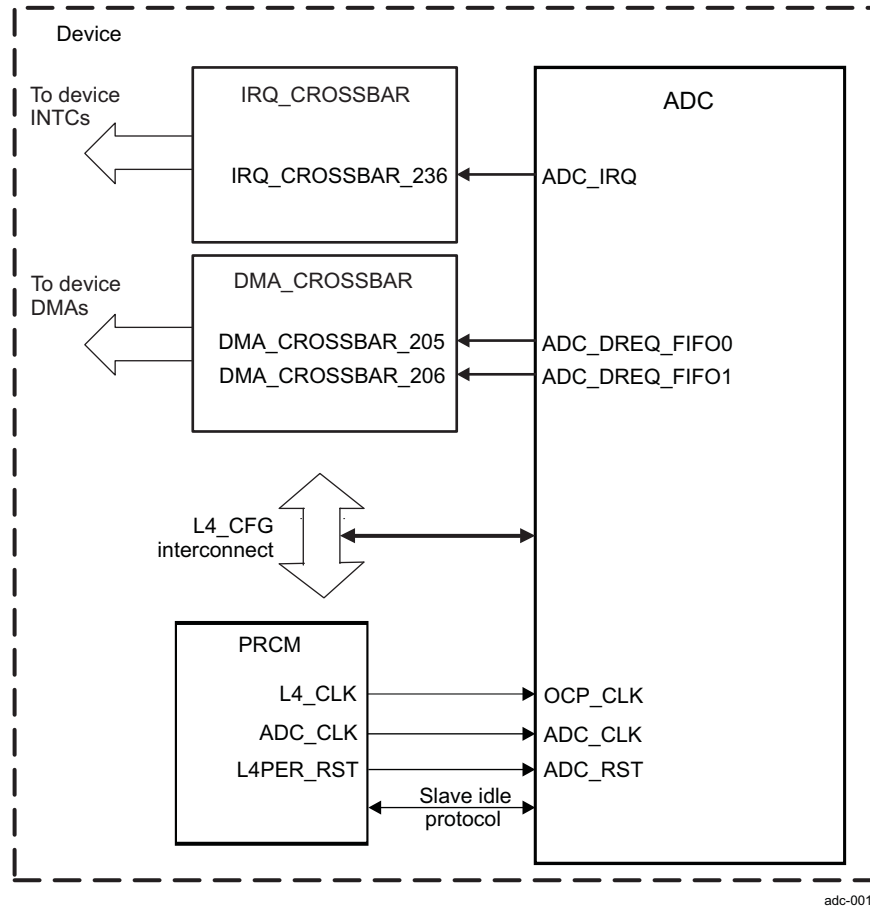

⁽²⁾ Hi-Z = High Impedance

23.3 ADC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-2 shows the module integration.

Figure 23-2. ADC Integration

adc-001

NOTE: For more information about the slave idle protocol, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 23-2 through Table 23-4 summarize the integration of the module in the device.

Table 23-2. Integration Attributes

	Power Domain	Wake-Up Capability	Interconnect
ADC	PD_COREAON	No	L4_CFG

Table 23-3. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ADC	OCP_CLK	L4_CLK	PRCM	ADC interface clock
	ADC_CLK	ADC_CLK	Control Module	ADC functional clock. 20-MHz max. Clock selection is done within Control Module. Clock division by 2 is selected via sysboot[5] pin.
Resets				
ADC	ADC_RST	L4PER_RST	PRCM	ADC reset signal

Table 23-4. GPIO Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
ADC	ADC_IRQ	IRQ_CROSSBAR_236	N/A	ADC interrupt request (level)
DMA Requests				
Module Instance	Source Signal Name	DMA_CROSSBAR Input	Default Mapping	Description
ADC	ADC_DREQ_FIFO0	DMA_CROSSBAR_205	N/A	FIFO0 reached desired data level
	ADC_DREQ_FIFO1	DMA_CROSSBAR_206	N/A	FIFO1 reached desired data level

NOTE: For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

23.4 ADC Functional Description

Before enabling the ADC module, the user must first program the [ADC_STEPCONFIGi](#) registers in order to configure a channel input to be sampled. There are 16 programmable [ADC_STEPCONFIGi](#) registers which are used by the sequencer to control which channel to sample and which mode to use (one-shot or continuous, averaging, where to save the FIFO data, and more).

23.4.1 Open Delay

The user can program the delay between driving the inputs to the AFE and the time to send the start of conversion signal. This delay is called “open delay” and can also be programmed to zero. The open delay for each step can be independently configured using the [ADC_STEPDELAYi](#) register.

23.4.2 Averaging of Samples (1, 2, 4, 8, and 16)

Each step has the capability to average the sampled data. The valid averaging options are 1 (no average), 2, 4, 8, and 16. If averaging is turned on, then the channel is immediately sampled again (up to 16 times) and final averaged sample data is stored in the FIFO. Each step can be independently configured using the [ADC_STEPCONFIGi](#) registers.

23.4.3 One-Shot (Single) or Continuous Mode

When the sequencer finishes cycling through all the enabled steps, the user can decide if the sequencer should stop (one-shot), or loop back and schedule the step again (continuous).

If one-shot mode is selected, the sequencer will take care of disabling the step enable bit after the conversion. If continuous mode is selected, it is the software’s responsibility to turn off the step enable bit.

23.4.4 Interrupts

The following interrupts are supported through enable bits and are maskable.

- Each FIFO has support for generating interrupts when the FIFO word count has reached a programmable threshold level. The user can program the desired word count at which the CPU should be interrupted. Whenever the threshold counter value is reached, it sets the [FIFOx_THRESHOLD](#) (x = 0 or 1) interrupt flag, and the CPU is interrupted if the [FIFOx_THRESHOLD](#) interrupt enable bit is set. The user can clear the interrupt flag, after emptying the FIFO, by writing a 1 to the [FIFOx_THRESHOLD](#) interrupt status bit. To determine how many samples are currently in the FIFO at a given moment, the [ADC_FIFO0COUNT/ADC_FIFO1COUNT](#) register can be read by the CPU.
- The FIFO can also generate [FIFOx_OVERRUN](#) and [FIFOx_UNDERFLOW](#) interrupts. The user can mask these events by programming the [ADC_IRQENABLE_CLR](#) register. To clear a FIFO underflow

or FIFO overrun interrupt, the user should write a 1 to the status bit in the [ADC_IRQSTATUS](#) register. The ADC does not recover from these conditions automatically. Therefore, the software will need to disable and then again enable the ADC. Before the user can turn the module back on, the user must read the [ADC_ADCSTAT](#) register to check if the status of the ADC FSM is idle and the current step is the idle step

- An END_OF_SEQUENCE interrupt is generated after the sequencer finishes servicing the last enabled step.
- An OUT_OF_RANGE interrupt is generated if sampled data is greater than programmable value, or less than a programmable value. High and low range thresholds are programmed in the [ADC_ADCRANGE](#) register.

23.4.5 DMA Requests

Each FIFO group can be serviced by either a DMA or by the CPU. To generate DMA requests, the user must set the enable bit in the [ADC_DMAENABLE_SET](#) Register. Also, the user can program the desired number of words to generate a DMA request using the [ADC_DMA0REQ/ADC_DMA1REQ](#) register. When the FIFO level reaches or exceeds that value, a DMA request is generated.

Subsequently, if the FIFO contains enough data in the FIFO, then a new DMA request is generated after the current DMA access (if this read does not cause the FIFO to be empty). The DMA request occurs on the very next cycle after the previous DMA FIFO read. The CPU can also read from the FIFO by reading from the FIFO DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers internally.

The DMA slave port allows for burst reads in order to effectively move the FIFO data. Internally, the OCP DMA address (MSB) is decoded for either FIFO 0 or FIFO 1. The lower bits of the DMA addresses are ignored since the FIFO pointers are incremented internally.

23.4.6 Power Management

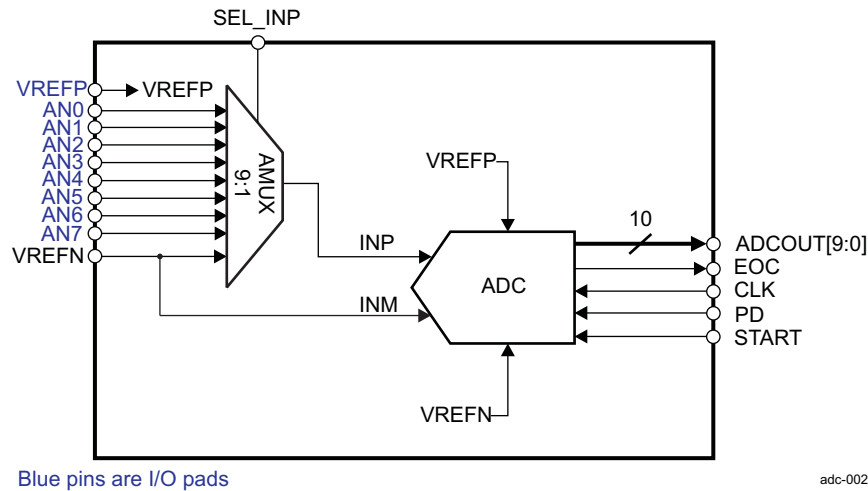

The ADC supports slave idle/request handshaking, and also supports a smart-idle mode. If the PRCM requests to power down when the [ADC_MODULE_ENABLE](#) bit is disabled, then acknowledge is returned. The ADC will also return acknowledge if sequencer is in the Idle state, and if all the [ADC_STEPENABLE](#) bits are off.

The software also has the option to turn off the AFE power by writing to the AFE [ADC_CTRL\[4\]](#) POWER_DOWN register bit. During initial power on, the AFE is powered down by default and software is responsible for turning the AFE on. software must wait minimum 4 μ s after a AFE power up and before starting a conversion (must be followed every time the AFE is powered up). It is the software's responsibility to empty the FIFO before requesting the ADC to enter sleep state.

23.4.7 Analog Front End (AFE) Functional Block Diagram

The AFE features are listed below, and some are controlled by the ADC:

- ADC sampled data is 10-bit wide
- Sampling rate can be as fast as every 17 ADC clock cycles
- Support for internal ADC clock divider logic
- Support for configuring the delay between samples also the sampling time

Figure 23-3. Functional Block Diagram

23.4.8 Operational Modes

The sequencer is completely controlled by software and behaves accordingly to how the **Step Registers** are programmed. A **step** is the general term for sampling a channel input. It is defined by the programmer who decides which input values to send to the AFE as well as how and when to sample a channel input.

The choices for each step can all be programmed using the [ADC_STEPCONFIGi](#) registers.

A step requires using these registers:

- [ADC_STEPENABLE](#): Enables or disables the step
- [ADC_STEPCONFIGi](#): Controls the input values to the ADC (which input channel to sample, averaging, and which FIFO group to save the data, range check)
- [ADC_STEPDELAYi](#): Controls the OpenDelay (the time between driving the AFE inputs until sending the start-of-conversion (SOC) signal to the AFE).

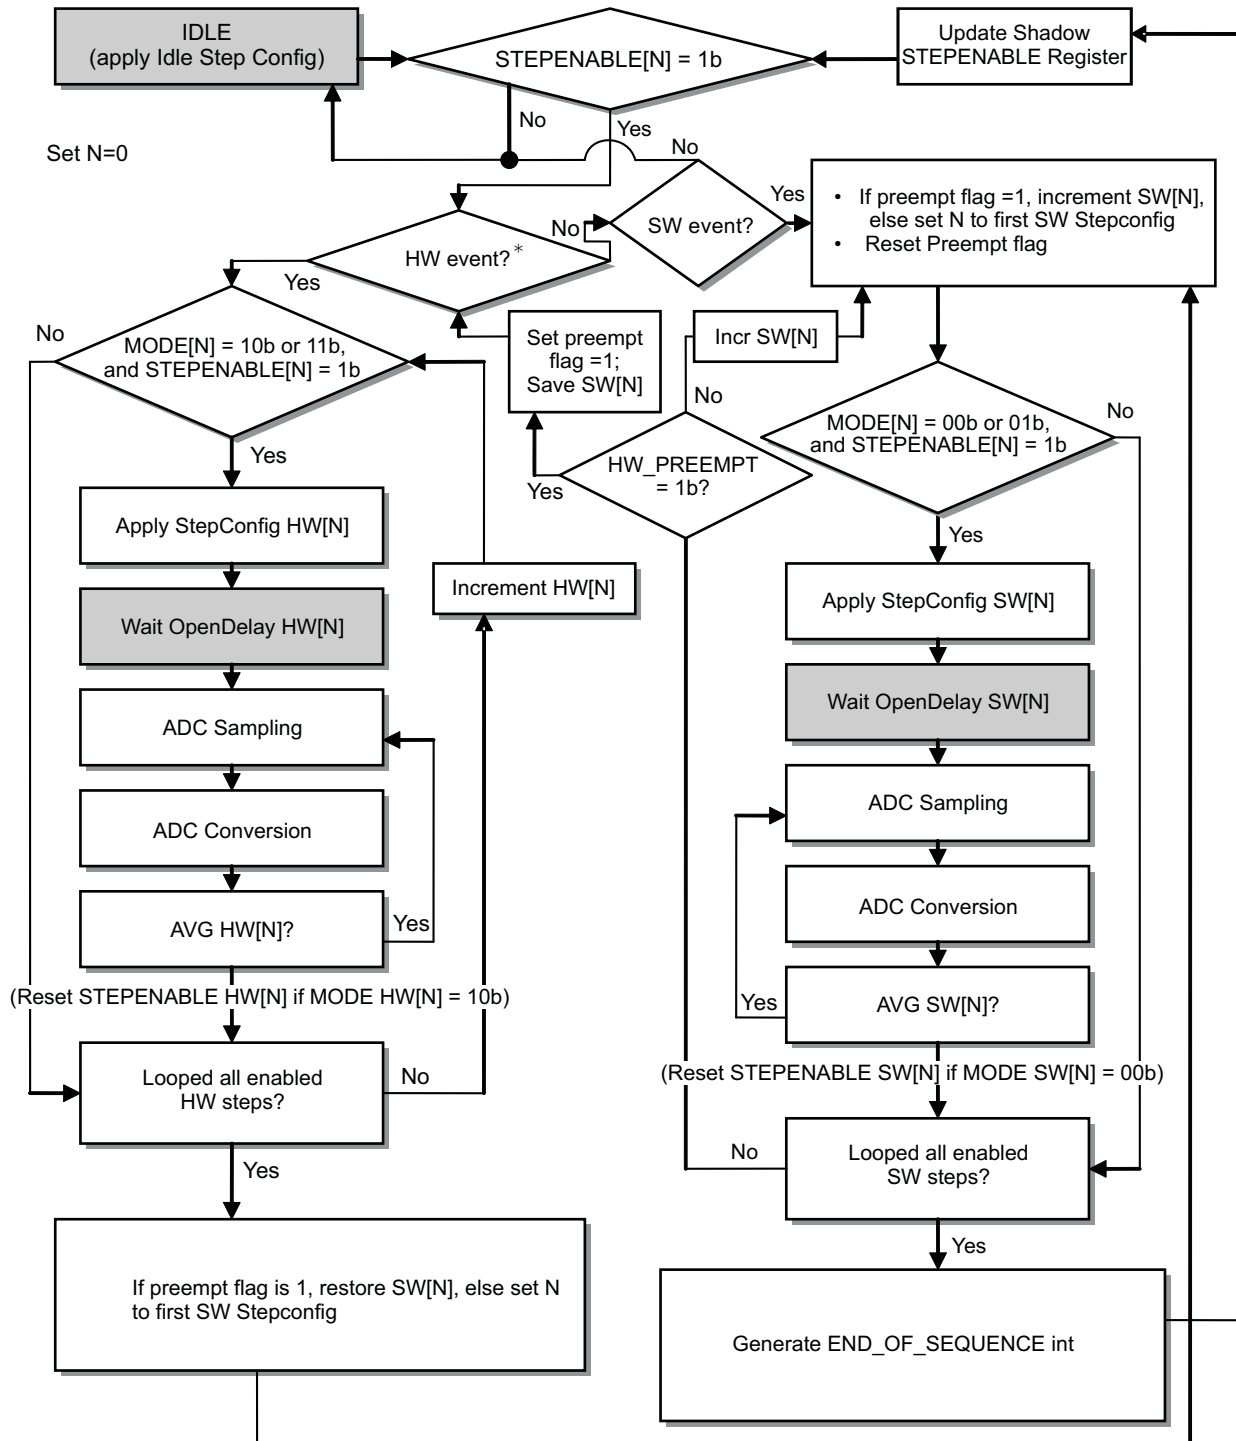

The sequencer supports a total of 16 programmable steps. Each step requires using the registers listed above.

When the ADC is first enabled, the sequencer will then wait for a [ADC_STEPENABLE](#) bit to turn on. After a step is enabled, the sequencer will start with the lowest step (1) and continue until step (16). If a step is not enabled, then sequencer will skip to the next step. If all steps are disabled, then the sequencer will remain in the IDLE state.

An END_OF_SEQUENCE interrupt is generated after the last active step is completed before going back to the IDLE state. The END_OF_SEQUENCE interrupt does not mean data is in the FIFO (should use the FIFO interrupts and [ADC_FIFO0COUNT/ADC_FIFO1COUNT](#) register).

The flowchart for the sequencer is shown in [Figure 23-4](#) and an example timing diagram in [Figure 23-5](#).

Figure 23-4. Sequencer FSM

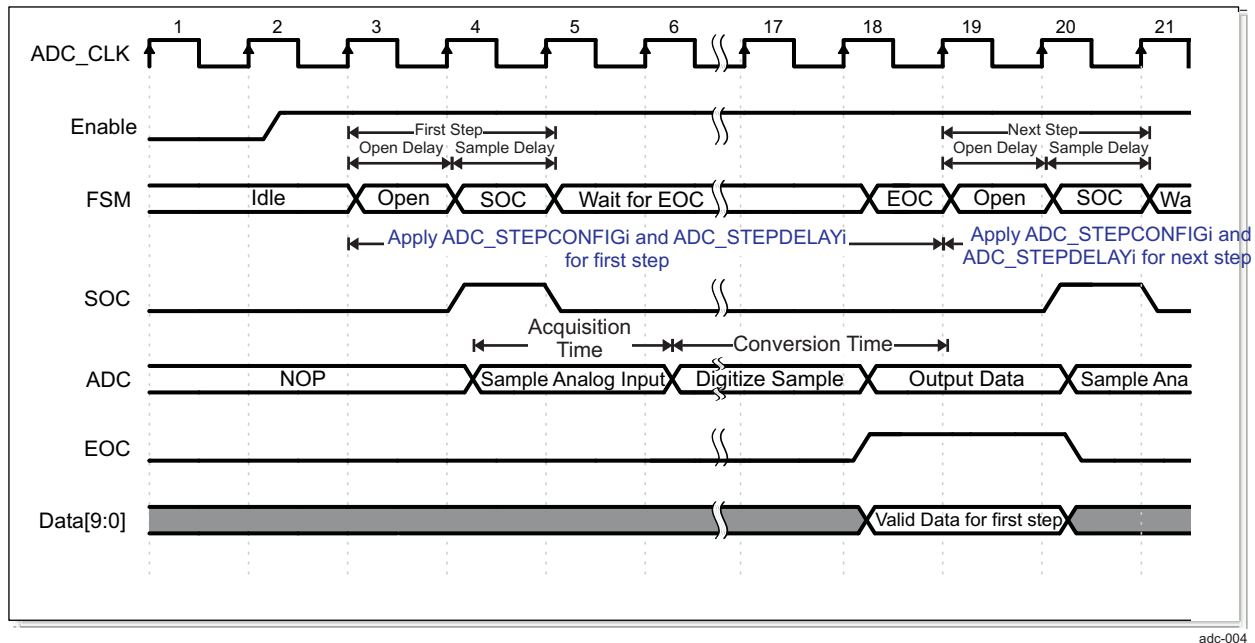

* HW event is not pinned out on this device

adc-003

Figure 23-4 does not actually represent clock cycles but instead illustrates how the scheduler will work. However, each shaded box above does represent a FSM state and will use a clock cycle. Using the minimum delay values, the ADC can sample at 17 ADC clocks per sample. Below is an example timing diagram illustrating the states of the sequencer and also the showing when the `ADC_STEPCONFIGi` and the `ADC_STEPDELAYi` registers values are applied. The below example assumes the steps are software controlled, and averaging is turned off.

Figure 23-5. Example Timing Diagram for Sequencer

Once the ADC is enabled and assuming at least one step is active, the FSM will transition from the idle state and apply the first active [ADC_STEPCONFIG_i](#) and [ADC_STEPDELAY_i](#) register settings. It is possible for the Open Delay value to be 0, and the FSM will immediately skip to the SOC state. The AFE will begin sampling of the analog voltage on high level of the SOC signal. Voltage sampling duration is 4 clock cycles long. After the AFE is finished converting the channel data (13 more cycles later), the EOC signal is sent and the FSM will then apply the next active step.

This process is repeated and continued (from step 1 to step 16) until the last active step is completed.

23.5 ADC Programming Guide

23.5.1 ADC Low-Level Programming Models

23.5.1.1 Global Initialization

23.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module is to be used for the first time after a device reset.

Table 23-5. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1, Clock Management , in Chapter 3 Power, Reset, and Clock Management .
Control module	Module specific pad muxing must be set in the control module. For more information about the module configuration, see Section 14.4.6.1, Pad Configuration Registers , in Chapter 14 Control Module . For more information about the IRQ_CROSSBAR module, see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description . For more information about the DMA_CROSSBAR module, see Section 14.4.6.5, DMA_CROSSBAR Module Functional Description .

Table 23-5. Global Initialization of Surrounding Modules (continued)

Surrounding Modules	Comments
DSP INTC	DSP INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Section 13.3.1, Interrupt Requests to DSP1_INTC , in Chapter 13, Interrupt Controllers .
IPU INTC	IPU INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Section 13.3.3, Interrupt Requests to IPU1_Cx_INTC , in Chapter 13, Interrupt Controllers .

23.5.1.1.2 General Programming Model

Table 23-6. General Programming Model

Step	Register/Bit Field/Programming Model	Value
Power up the AFE	ADC_CTRL[4] POWER_DOWN	0
Setup the input analog ADC_CLK frequency input	ADC_ADC_CLKDIV[11:0] ADC_CLKDIV	0x-
If using DMA, then enable the DMA requests lines and program DMA threshold levels; or set the CPU threshold levels to read FIFO with CPU	ADC_DMAENABLE_SET/ADC_DMA0REQ/ADC_DMA1REQ ADC_FIFO0THRESHOLD/ADC_FIFO1THRESHOLD	0x-
Setup or mask the appropriate interrupts	ADC_IRQENABLE_SET	0x-
Program the StepConfig registers for averaging, mode, etc.	ADC_STEPCONFIGi	0x-
Program the StepDelay registers for OpenDelay	ADC_STEPDELAYi	0x-
Turn on the correct StepEnable bits	ADC_STEPENABLE	0x-
Wait minimum 4 μ s before starting a conversion (reference from POWER_DOWN write to 0)		
Enable the ADC module	ADC_CTRL[0] ADC_MODULE_ENABLE	1

23.5.1.2 During Operation

Table 23-7. Turn-Off

Step	Register/Bit Field/Programming Model	Value
Turn off ADC module bit when finished. This will stop the ADC after the current step is complete.	ADC_CTRL[0] ADC_MODULE_ENABLE	0
Or, if desired to finish the complete sequence of steps, then disable all of the StepEnable bits and the ADC will stop after the last step and wait (end of sequence interrupt is generated)	ADC_STEPENABLE	0x0

Table 23-8. Turn-On After Turn-Off

Step	Register/Bit Field/Programming Model	Value
If desired to turn on the ADC again, then software must read the ADC status register to make sure the current step is idle.	ADC_ADCSTAT[4:0] STEP_ID	=0x10
Enable the ADC module enable bit	ADC_CTRL[0] ADC_MODULE_ENABLE	1

23.6 ADC Register Manual

23.6.1 ADC Instance Summary

[Table 23-9](#) summarizes the ADC instance.

Table 23-31. ADC_ADCSTAT

Address Offset	0x0000 0044	Instance	ADC
Physical Address	0x4A26 4044		
Description	ADC sequencer status. Software can read this register to find out the currently scheduled step id being converted on the ADC port. If desired to turn the controller off and then back on, then the STEP_ID bit should be checked and compared to IDLE state before enabling the ADC module again. Also, before enabling the ADC, the user should wait for the FSM_BUSY bit to read idle.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23-33. ADC_ADCRANGE

Address Offset	0x0000 0048	Instance	ADC
Physical Address	0x4A26 4048		
Description	ADC range check register. This feature requires the range check interrupt bit to be enabled first. Also, the user can decide which channel input is compared by programming the RANGE_CHECK bit of the ADC_STEPCONFIGi registers. It is up to software to sort through FIFO data to determine which channel data was out of range.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23-39. ADC_STEPENABLE

Address Offset	0x0000 0054	Instance	ADC
Physical Address	0x4A26 4054		
Description	This register contains the enable bit for each step in the sequencer. When all steps are disabled, the FSM will stay in IDLE state. These bits can be enabled or disabled dynamically during operation. When a write to this register occurs during operational mode, the HW will make sure the new settings are updated after the END_OF_SEQUENCE event (registers are shadowed and updated at that time). If a step is configured in one-shot mode, the HW will automatically reset the STEP _i bit after it is scheduled.

Safety Modules

This chapter describes the safety modules in the device.

Topic	Page
24.1 Safety Modules Overview	6504
24.2 Tester On Chip	6506
24.3 Memory Cyclic Redundancy Check Module.....	6548
24.4 Dual Clock Comparator	6592
24.5 Error Signaling Module	6610
24.6 Real Time Interrupt Module	6642

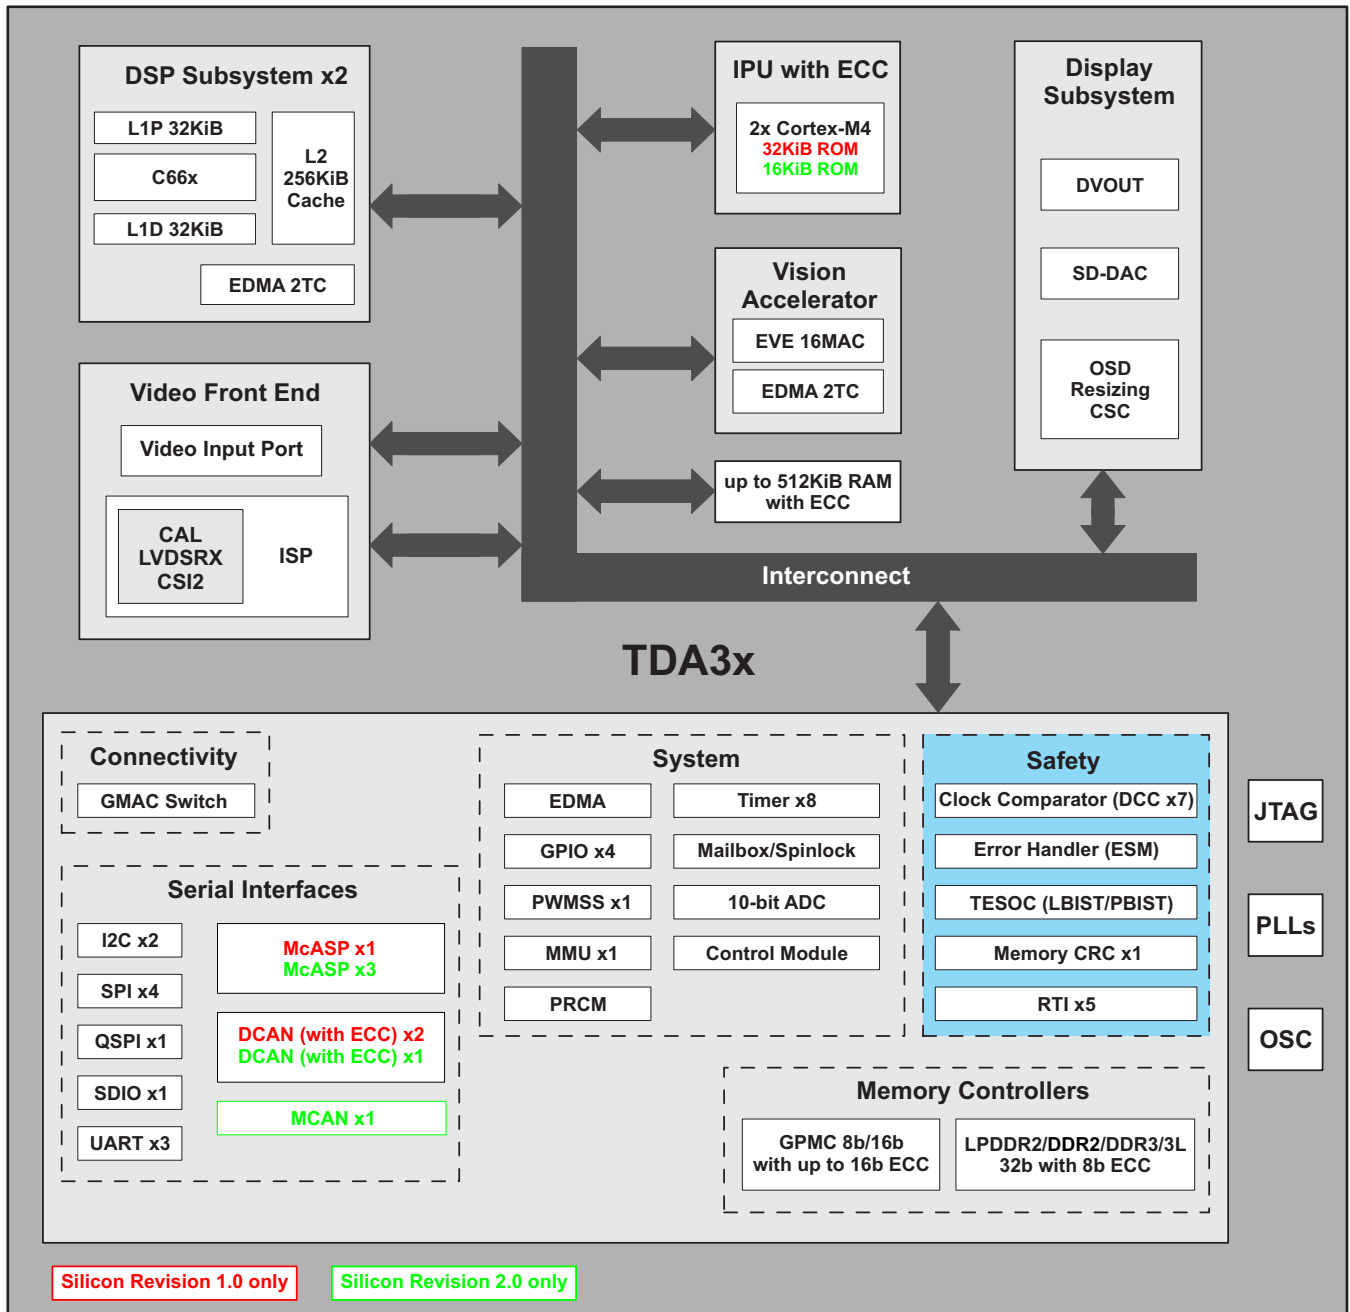

24.1 Safety Modules Overview

The device is targeted to meet functional safety standard ISO 26262. The key component to achieve the ISO 26262 compliance is the Automotive Safety Integrity Level B (ASIL-B) safety standard. As a part of ASIL-B compliance, the device integrates a field-test capability to meet Diagnostic Coverage of 90% on critical processors such as DSP, IPU, EVE. The following modules provide the field-test capabilities of the device, along with more critical testing and safety functionality. It is the end system/customer requirement to implement software to take advantage of the SoC safety features, and to ensure the full system is able to achieve the desired system ASIL requirement.

- Tester on Chip (LBIST/PBIST controller), see [Section 24.2](#).
 - Runtime Logical Built-in-self-test (LBIST) controller to test the processors DSP1/2, EVE, and IPU
 - Programmable Built-in-self-test (PBIST) controller to test all memories on-chip
 - Controllable via software
 - In-built ROM with test vectors to achieve up to 90% coverage of DSP1/2, EVE, and IPU.
- Memory Cyclic Redundancy Check (CRC) Module, see [Section 24.3](#).
 - Four channels to perform background signature verification on any memory sub-system. For each channel CRC can be performed either by MCRC or by CPU.
 - Data compression on 8, 16, 32, and 64 bit data size.
 - Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64 bit primitive polynomial.
 - Programmable 20-bit pattern counter per channel to count the number of data patterns for compression.
 - Two modes of operation are supported: Semi-CPU and Full-CPU.
- Dual Clock Comparator (DCC) (x7), see [Section 24.4](#).
 - Two independent counter blocks count clock pulses from each clock source.
 - Each counter block is programmable with seed values that respect the ratio of the two input clock.
 - Error signal generation when a clock is out of specifications.
- Error Signaling Module (ESM), see [Section 24.5](#).
 - Up to 384 interrupt/error channels divided into 3 different groups.
 - 128 channels with configurable interrupt and error signal behavior.
 - 128 error channels with predefined interrupt and error signal behavior.
 - 128 channels with predefined error signal behavior.
 - Error pad to signal severe device failure.
- Real Time Interrupt (RTI) Module (x5), see [Section 24.6](#).
 - Two independent counter blocks for generating different timebases.
 - Each block consists of one 32 bit prescale counter, one 32 bit free running counter, and two capture registers for capturing the prescale and free running counter on a special event
 - Free running counter 0 can be incremented by either the internal prescale counter or by an external event
 - Four configurable compare registers for interrupt generation, working either with counter 0 or counter 1. Compare registers 0 to 3 can also generate DMA request signals.
 - Fast enabling/disabling of interrupts.
 - Digital Watchdog with an option to enable a windowed watchdog feature.
 - All clock input from any of the available clock sources selectable from the PRCM.
 - Capability to drive a pulse-width modulated signal out on an interrupt line

[Figure 24-1](#) shows a block diagram of the Safety modules within the device.

Figure 24-1. Safety Modules Overview

safety-001

24.2 Tester On Chip

The Tester On Chip (TesOC) provides the capability of the device to software initiate structural (Logic & Memory) testing on cores and safety critical memories. The TESOC module has the following features:

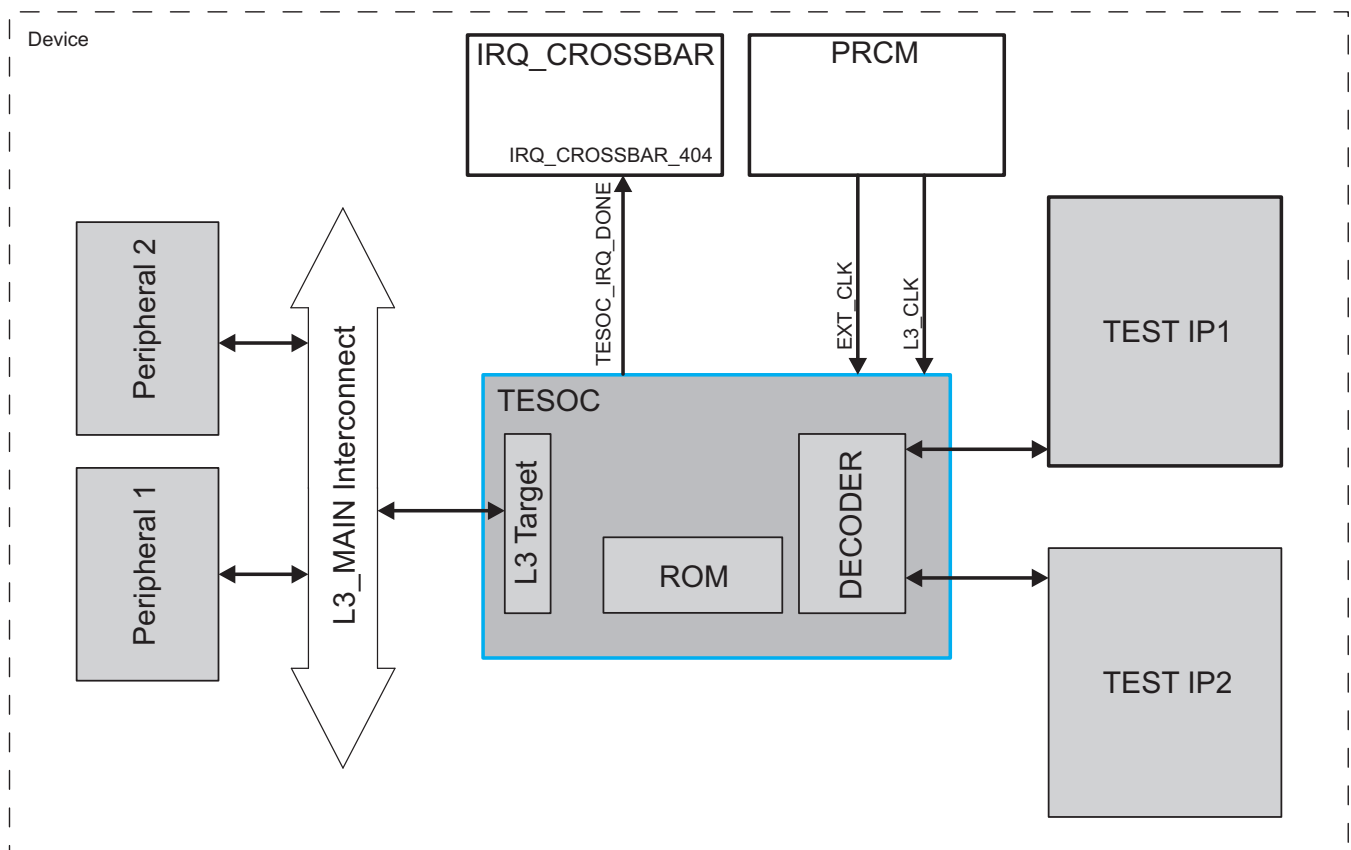

- Supports software initiated field tests during device strat up.
- Support structural Logical Build-In Self-Test (LBIST) on EVE, DSP, IPU with up to 90% stuck-at coverage
- Supports memory test of critical memories on EVE, DSP, IPU ,ISS and DSS
- In-built ROM with test vectors to achieve up to 90% coverage on EVE, DSP, and IPU.
- Interconnect interface with 128 data width Read/Write with burst write

The following lists the TesOC careabouts:

- Cannot read TesOC ROMs when field-test is running/busy
- Cannot write into configuration registers when TesOC is busy, reading of these registers is possible
- Abort register can be written/readable even when TesOC is busy
- Does not support field-test on multiple domains in a single go. Instead, it should be configured to test only one domain at a time. Software has to configure TesOC again to test next domain.

show an overview of the TESOC within the device.

Figure 24-2. TESOC Overview Diagram

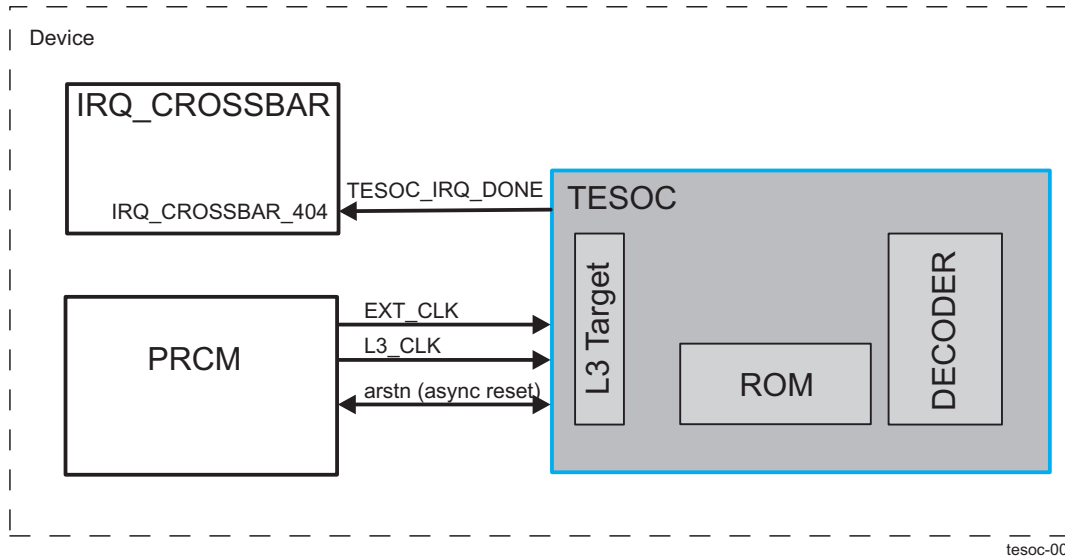

tesoc-001

24.2.1 TESOC Integration

This section describes the TESOC integration in the device as shown in .

Figure 24-3. TESOC Integration

tesoc-002

NOTE: For more information about the slave idle protocol and the wake-up request, see [Section 3.7, Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-1 through Table 24-3 summarize the integration of the module in the device.

Table 24-1. TESOC Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
TESOC	PD_COREAON	L3_MAIN

Table 24-2. TESOC Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
TESOC		L3_CLK	PRCM	Synchronous clock from L3_MAIN Interconnect. CAUTION: This clock must be running during field test execution.
		EXT_CLK	PRCM (DPLL_CORE H13 Divider)	This clock must be running during field test execution.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
TESOC	arstn		PRCM	Asynchronous reset for entire TESOC

Table 24-3. TESOC Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Destination

Table 24-3. TESOC Hardware Requests (continued)

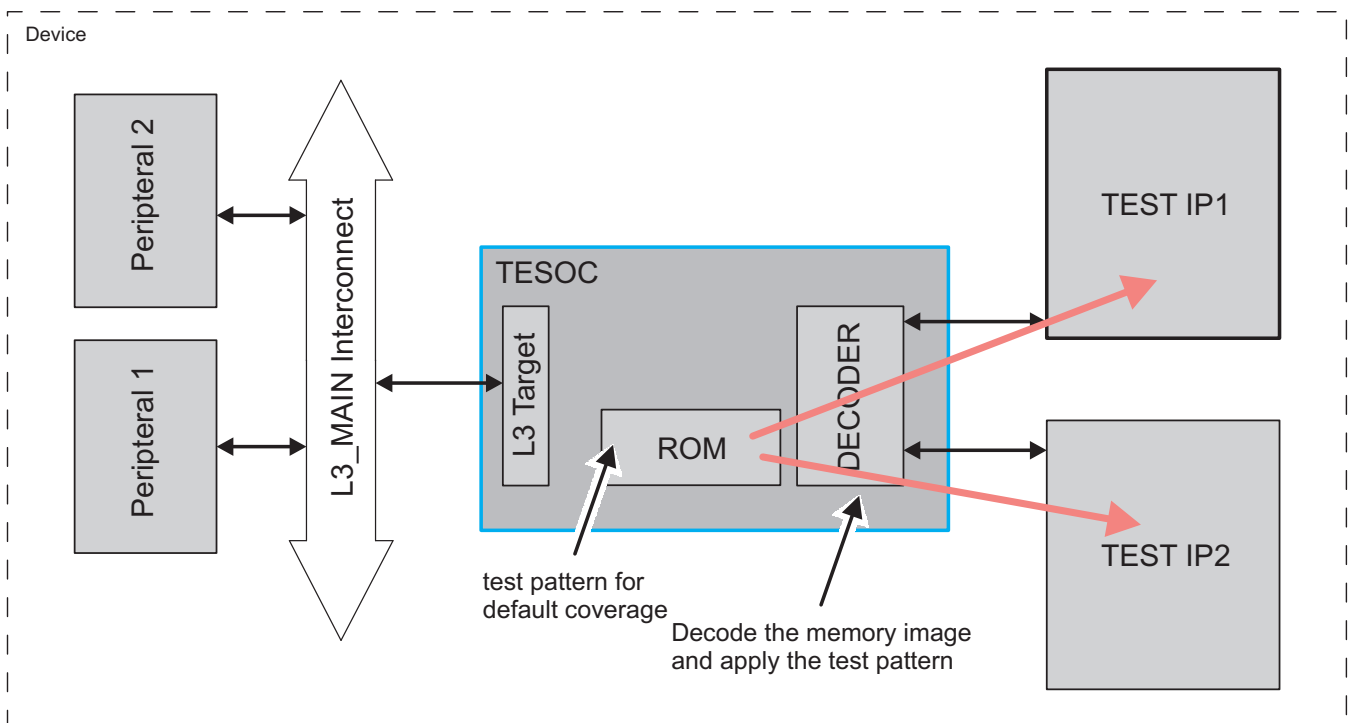

TESOC	TESOC_IRQ_DONE	IRQ_CROSSBAR_404	-	This IRQ source signal is not mapped by default to any device INTC.
-------	----------------	------------------	---	---

NOTE: The “Default Mapping” column in [Table 24-105 TESOC Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

24.2.2 TESOC Functional Description

Figure 24-4 shows the functional block diagram of the TESOC in the device

Figure 24-4. TESOC Functional Block Diagram

tesoc-003

Legend: - TESOC field test run path

The TesOC is used on this device to initiate field test at device boot-up. It is up to the software as to when to trigger field-test. General expectation in the device is that IPU boots-up first and after boot field-test is triggered. TESOC gives capability to choose to run fewer slices to reduce start-up time. During start-up the following can be performed:

- Logic and Memory test for EVE, IPU, DSP1 and DSP2
- Memory test on ISS and DSS.

24.2.2.1 TESOC Interrupt Handling

The TESOC has one interrupt line TESOC_IRQ_DONE mapped to the device IRQ Crossbar IRQ_CROSSBAR_404. Before entering into field test software must configure the IRQ from the [TESOC_INTR_ENABLE_SET](#) register. Software must also configure the device control module to route the interrupt from the crossbar to the one the device interrupt controller. For details on Control module configuration see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). Before entering another field-test procedure the IRQ must be cleared from the [TESOC_INTR_ENABLE_CLEAR](#) register.

In case the targeted test module needs to be used by software, the master who has initiated the TESOC test procedure must write into the abort register [TESOC_ABORT](#). This raises the an TESOC_IRQ_DONE interrupt indicating that TESOC has released control of the test module. Here the IRQ is automatically cleared by hardware.

24.2.2.2 TESOC Abort Field Test

The interrupts which need urgent DUT attention like NMI can be routed through the interrupt cross bar to any master that is functionally active while DUT is under field test.

Before entering into field-test of DUT, software has to configure the cross-bar interrupt controls to route the NMI or other interrupts to alternate master.

- In case NMI interrupts needs DUT attention Master who logs the NMI has to issue abort to TESOC by writing into abort bitfield [TESOC_ABORT\[3:0\] ABORT](#). As soon as abort bit is set, TESOC halts the field-test, powers-down the DUT and raises an interrupt indicating that it has released control of DUT, it can service NMI after this.
- Software has to poll [TESOC_BUSY\[3:0\] BUSY](#) to make sure TESOC is not busy. If busy, no write to configuration registers is allowed except [TESOC_ABORT](#) which can be written at any time.

24.2.2.3 TESOC Error Diagnostic

TESOC supports debug feature where user can have access to the failure data. TESOC stores 16 failures which can be accessed. Additional failures after 16 failures are not logged. Details on the fail data can be found in [TESOC_DIAG_INFO_0_i](#) to [TESOC_DIAG_INFO_15_i](#) registers. Registers will hold the cycle count on which a failure occurred. Also the address location on which failure was seen is also logged. With this information user can easily find which bit and on which cycle the failure has occurred.

From TESOC Compiler Memory image format, there are 3 sections within a slice. They are setup sequence, core sequence and exit sequence. Following are the failure categories based on where the failure happens

1. Failure in setup sequence: If failure happens in setup sequence, TESOC will start logging fail data(max 16) in the register banks, and complete execution of setup sequence followed by core section and then the exit sequence. Exit sequence is required to be run in all scenarios to make sure TESOC gracefully exits field test mode and hand-overs the controls to functional modules without any corruption. TESOC is transparent to the system and does not interfere or manipulate functional states that were prevalent where TESOC was excited.
2. Failure in core sequence: If a failure happens in core sequence, TESOC will start logging fail data(max 16) and complete execution of core sequence followed by exit sequence. Exit sequence is run to ensure graceful exit as stated above.
3. Failure in exit sequence: If a failure happens in exit sequence, TESOC will start logging fail data(max 16) and complete execution of exit sequence

TESCO stops executing once it completes the slice with failures, since there is no reason to run remaining programmed slices when previous slice has failed.

There are 16 banks of error logs. Each bank is 128bits. It is represented as an array of 32bit register [TESOC_DIAG_INFO_0_i](#) (where I = 0,1,2,3). [Table 24-4a](#) shows the mapping of the error log stored within the 128bits (4 32bit registers)

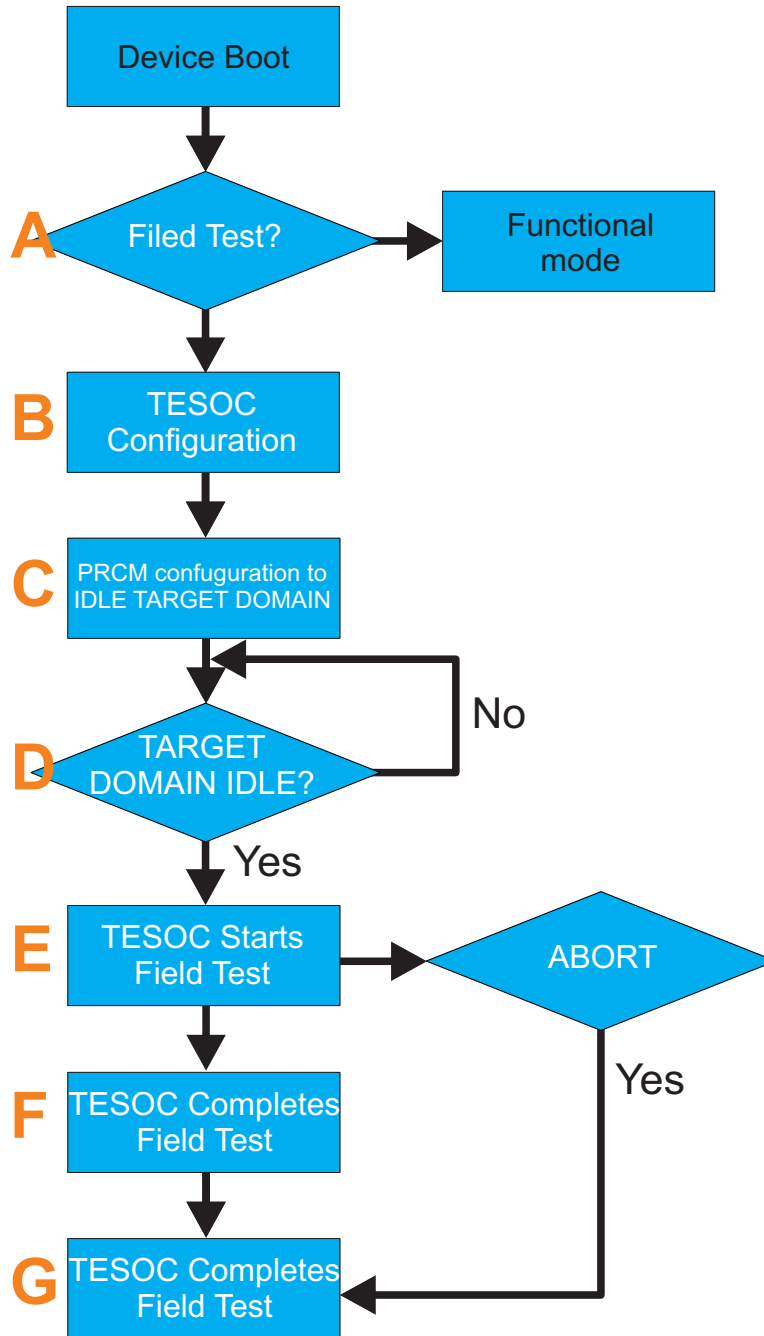

Table 24-4. TESOC Bit Error Mapping

24.2.2.4 TESOC Field Test Execution Sequence

24.2.2.4.1 TESOC Field Test Sequence Flow Chart

Figure 24-5. TESOC Flow Chart Showing Field Test Execution Sequence

tesoc-004

- A** - Filed test can be triggered at start-up.
- B** - Master configures TESOC by writing into configuration registers of TESOC – this does not trigger field test right away.
- C** - PRCM is configured by Master to put TARGET DOMAIN in idle. Disable static dependencies and all wakeup dependencies.
 - TARGET DOMAIN executes WFI or IDLE instruction and gets into "STANDBY" mode. TARGET DOMAIN gets into "IDLE" mode due to absence of dependencies.
- D** TESOC looks at idle status of TARGET DOMAIN and starts field test
- E** TESOC starts field test on configured tests on TARGET DOMAIN
- F** TESOC completes field test and sends field test completion interrupt.
- G** Software can enable TARGET DOMAIN * .

* In case of IPU field test TESOC field test completion interrupt should be enabled in WUGEN (wake up generator). Once TESOC completes field test TESOC completion interrupt wakes up IPU and IPU starts rebooting.

24.2.2.4.2 TESOC Configuration for field test

1. Before starting field test software through, PRCM should enable clocks to TESOC. See *Power, Reset, and Clock Management* chapter for details on configuring TESOC clocks.
2. Software should configure TESOC by writing into configuration registers of TESOC – this does not trigger LBIST/MBIST right away
 - a. Software has to poll [TESOC_BUSY](#) to make sure TESOC is not busy. If busy no data or configuration of the TESOC will go through.
 - b. Unlock the TESOC by writing b1010 to the Lock register [TESOC_LOCK \[3:0\] LOCK](#). Software has to clear Abort, Error Diagnostic, Status and Result Registers
 - c. Configure register [TESOC_DOMAIN_EN_DOM0](#) to [TESOC_DOMAIN_EN_DOM4](#) to enable a domain.
 - d. Software must configure the slices for field test. Slices are configured from [TESOC_SLICE_CONFIG_DOM0_n](#) to [TESOC_SLICE_CONFIG_DOM4_n](#) (n = 0 to 7) registers.
 - e. Lock the TESOC by writing b0101 to the TESOC Lock register [TESOC_LOCK \[3:0\] LOCK](#).
3. Configure PRCM to put domain in IDLE mode.
4. If the specific target domain is in powered down state and the field test enable bit is enabled for the corresponding domain, TESOC will start the LBIST/MBIST operations and generate an interrupt when completed.
5. Software has to first read [TESOC_SLICE_STATUS_DOM0_n](#) - [TESOC_SLICE_STATUS_DOM4_n](#) (n = 0 to 7) to check if slice was completely run and then read the registers ([TESOC_SLICE_RESULT_DOM0_n](#) [TESOC_SLICE_RESULT_DOM4_n](#)) to check pass/fail status.

Partial boot after IPU Field test:

1. 1As TESOC field test on IPU results in IPU reset, to differentiate between tesoc reset with other resets control module register "tesoc_last_reset_indicator" can be used. Software writes into this register before triggering field test on IPU. This register is not set by HW and software should write the correct value into this register.
2. Device ROM reads this register after coming up from reset after field-test and understands that the reset was due to TESOC. Software can choose to do partial boot using this indicator and registers

ROM_CPU0_BRANCH for CPU0 and ROM_CPU1_BRANCH for CPU1. These registers store jump addresses for respective CPUs which is used by ROM to resume execution after field test.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																LOCK															

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0
3:0	LOCK	Lock feature prevents unintentional updates to TESOC registers. Writes to TESOC registers are possible only when TESOC registers are unlocked by writing 0xA to LOCK key bits of TESOC_LOCK register. On reset, these bits are set to 0x5 and hence the TESOC registers are in the locked state. There is no built in protection based on master ID. It is the responsibility of the user to ensure that only a single valid master updates the TESOC registers. A value of 4'b0101 indicates that TESOC Configuration Registers are locked for write access. Default value is locked. To unlock, a value 4'b1010 must be written. 0x5: Locked 0xA: Unlocked	RW	0x5

Table 24-25. TESOC_ABORT

Address Offset	0x0000 00E0	Instance	TESOC
Physical Address	0x4B80 00E0		
Description	ABORT Register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ABORT															

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0
3:0	ABORT	This has to be written into by the software to abort field-test immediately and transfer control on test module to application. General usage cases are, if an interrupt is registered that needs the module being tested, software can write into this bitfield to stop field-test. A write with value of 4'b0101 creates an ABORT condition for TESOC. On seeing this, HW stops execution the slice sequence and raises the interrupt. This register is cleared by HW. 0x5: Abort	RW	0x0

CAUTION

This register must be SW cleared by writing 0 during configuration sequence as a precaution to the corner case of "Field test ended normally and Master wrote abort at the same time" now the interrupt is due to end of field test and the abort is not cleared. Hence the next field test will be aborted.

Table 24-27. TESOC_BUSY

Address Offset	0x0000 00F0	Instance	TESOC
Physical Address	0x4B80 00F0		
Description	BUSY Register.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																BUSY															

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0
3:0	BUSY	During BUSY state: <ul style="list-style-type: none"> Register write accesses will not go through by virtue of disabling the scmdaccept by HW. Only exception is the TESOC_ABORT register which can be written when BUSY. Register read accesses will go through Memory (ROM) Read and Write Accesses will not go through by virtue of disabling the scmdaccept by HW. . Software has to poll the register before sending any configuration command OR data to TESOC. It can do so only when TESOC is not busy. 0x5: Busy 0x0: Not busy Other values: Not busy	R	0x0

RESERVED																	START_DOMAIN														

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	START_DOMAIN	This bitfield indicates that a particular processor can be moved into field-test mode. This is needed more from a safety purpose and to have multiple levels of checks to avoid any false trigger of field-test on the processor. A field-test can be triggered on a processor by writing both TESOC_SLICE_CONFIG_DOM0 and TESOC_DOMAIN_EN_DOM0 registers.	RW	0x0

NOTE: TESOC will ensure that a particular module be moved into field-test mode only when there are valid bits set in both TESOC_SLICE_CONFIG_DOM0 and TESOC_DOMAIN_EN_DOM0 registers. I.e. Ensures that a soft error on any of these registers shall not be able to move an test module into field-test mode. Only a valid combination of the two register should move a module into field-test mode.

0x0: Field test for domain PD_IPU is disabled
 0x1: Field test for domain PD_IPU is enabled
 This bitfield is HW cleared once the field test is started.

24.3 Memory Cyclic Redundancy Check Module

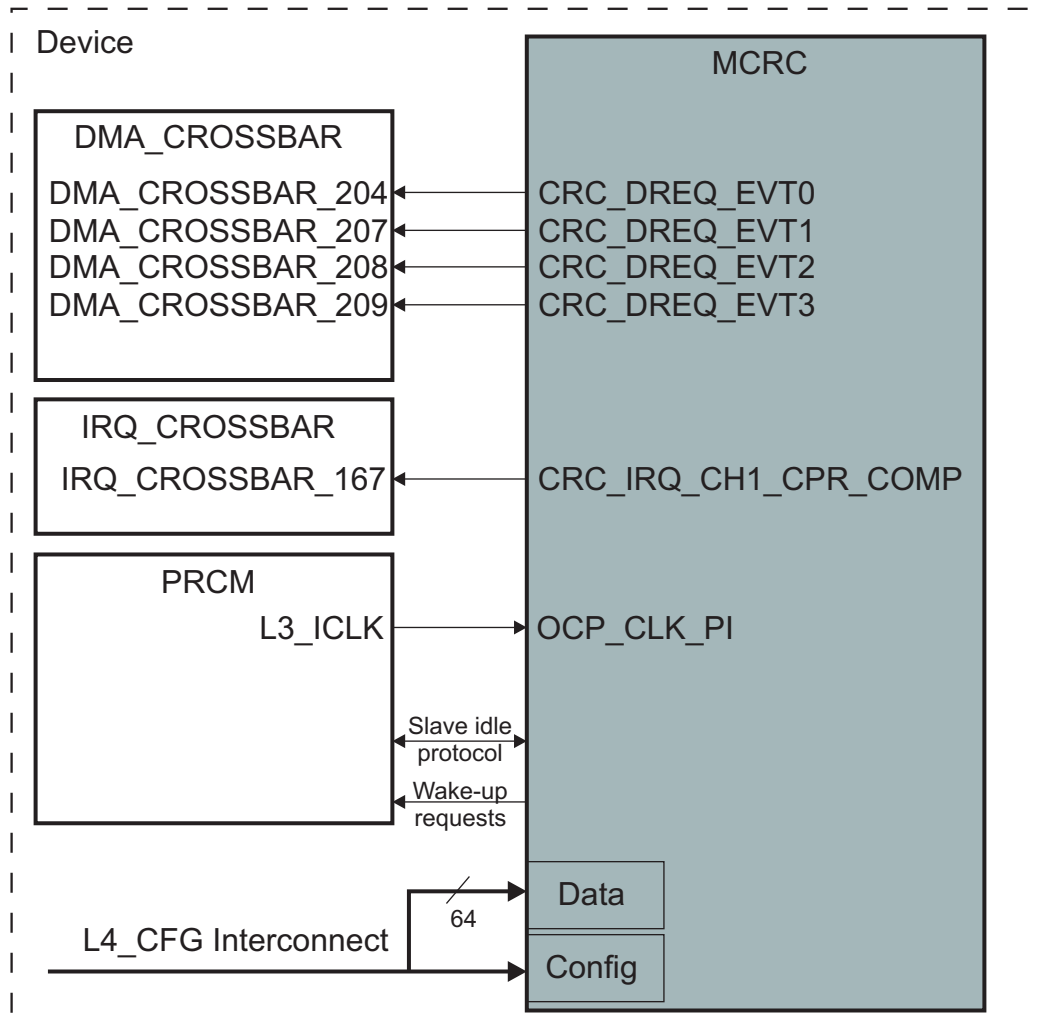

The Memory Cyclic Redundancy Check module (MCRC) within the device is designated to perform memory checks to verify the integrity of memory system. In the background, the MCRC reads memory contents and generates signature representing them. The responsibility of the MCRC is to calculate these signatures, generate interrupt to MPU for comparison against pre-determined good signature value. The module provides four channels to perform CRC calculation on multiple memories in parallel and can be used with any memory system.

Below is a list of features supported by the MCRC module:

- Four channels to perform background signature verification on any memory sub-system.
- Data compression on 8, 16, 32, and 64 bit data size with active data trace mode.
- Maximum-length of the Parallel Signature Analysis (PSA) register constructed based on 64 bit primitive polynomial.
- Each channel having its own CRC registers containing the pre-determined CRC value.
- Each channel having its own programmable 20-bit pattern counter to count the number of data patterns for compression.
- Semi-CPU and Full-CPU operation modes.
- Generate interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification
- Generate Timeout interrupt if CRC is not performed within the time limit.

[Figure 24-6](#) shows a block diagram of the MCRC module within the device

	DMA_CROSSBAR_209	CRC_DREQ_EVT3	-	This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “**Default Mapping**” column in [Table 24-105 MCRC Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

NOTE:

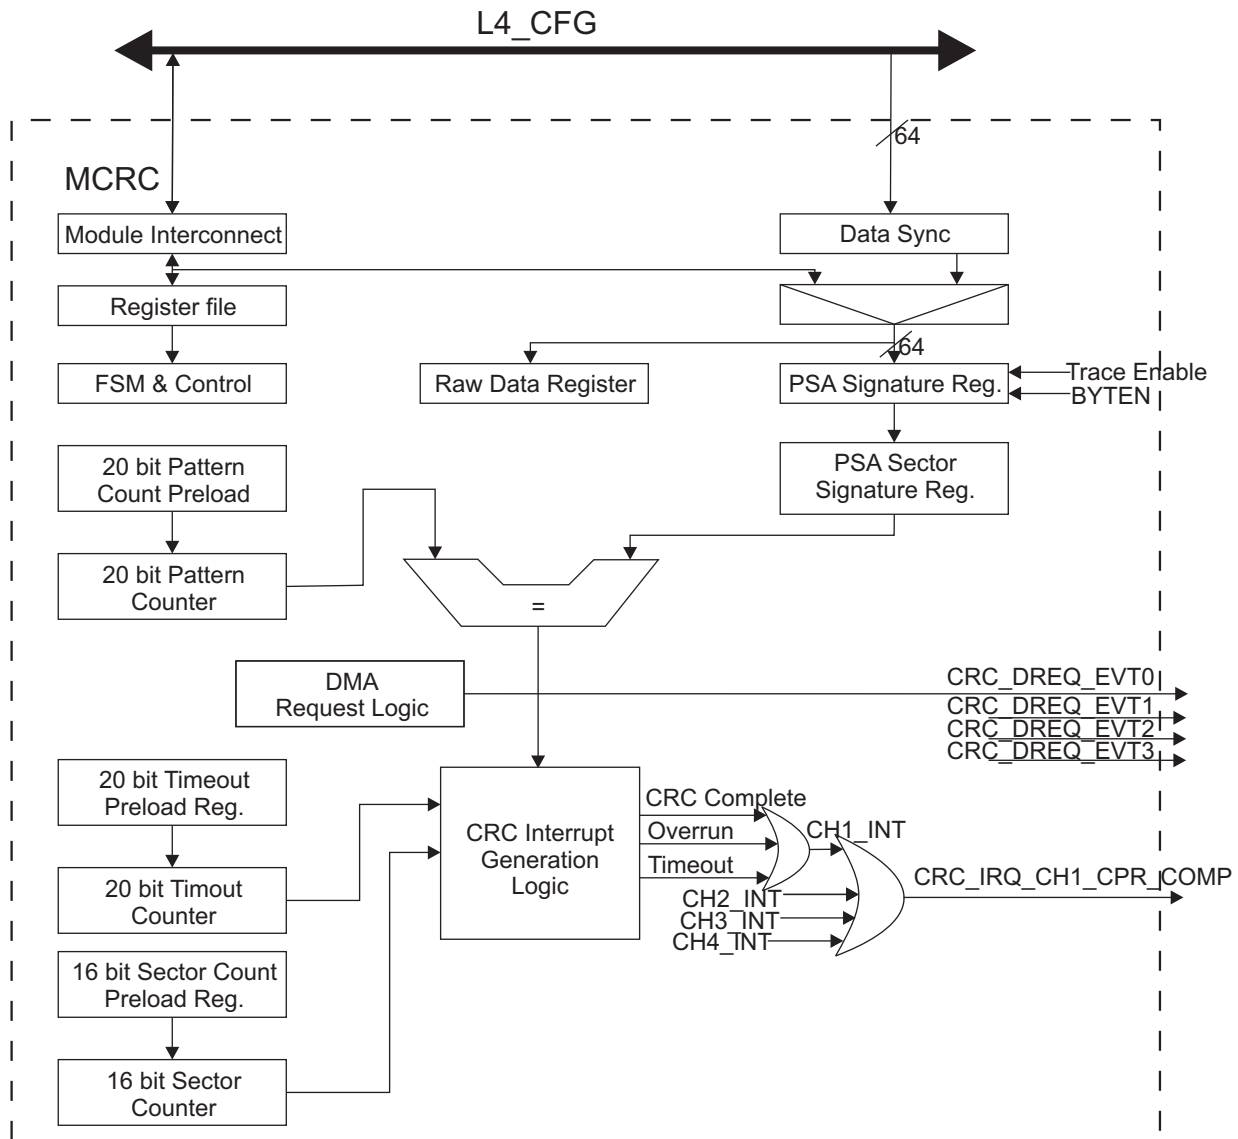

- For a description of interrupt source, see [Table 24-105](#).
 - For a description of DMA source, see [Table 24-105](#).
-

24.3.2 MCRC Functional Description

There are four channels in MCRC controller and for each channel there is a memory mapped PSA (Parallel Signature Analysis) register and a memory mapped CRC (Cyclic Redundancy Check) Value register. A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8, 16, 32, or 64 bit data. MCRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory of which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated. A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed by CPU itself in Semi-CPU or Full-CPU mode.

[Figure 24-7](#) show the MCRC module functional blocks

Figure 24-7. MCRC Architecture Overview

mcr-002

MCRC module can operate in Semi-CPU and Full-CPU modes.

Operating in Semi-CPU Mode:

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register. The CRC module generates a compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register and compare it to a pre-determined CRC value.

Operating in Full CPU Mode:

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register. After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

Table 24-106 shows DMA logic and counter logic are operating during the different modes

Table 24-106. MCRC hardware logic status during Semi-CPU and Full CPU modes

	DMA request	Pattern counter	Sector counter	Timeout counter
Semi-CPU	inactive	active	active	active
Full CPU	inactive	inactive	inactive	inactive

24.3.2.1 MCRC PSA Signature

There is one PSA Signature Register per CRC channel (PSA_SIGREGLx and PSA_SIGREGHx where x = 1 to 4). PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHx_MODE bits in the [CRC_CTRL2](#) register. If CHx_MODE=Data Capture, a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature. The 64-bit PSA Signature Register is based on the primitive polynomial found in the below equation to produce the maximum length of a Linear Feedback Shift Register.

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (20)$$

In Semi-CPU mode, each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. The OS can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

MCRC module supports doubleword, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zero's before compression.

NOTE: Comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bit because a compressed value is always expressed in 64 bit.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros. The reset can be initiated from the [CRC_CTRL0](#) register bits CH4_PSA_SWREST, CH43_PSA_SWREST, CH2_PSA_SWREST, and CH1_PSA_SWREST for the four channels. PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

24.3.2.2 MCRC PSA Sector Signature

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the PSA Sector Signature Register. PSA Signature Register is a read only register. Values can be read from the registers PSA_SECSIGREGLx and PSA_SECSIGREGHx (x = 1 to 4) During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the

compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enable to generate when overrun condition occurs from the [CRC_INTS](#) register bits CH4_OVERENS, CH3_OVERENS, CH2_OVERENS, and CH1_OVERENS for the four channels.

24.3.2.3 MCRC Pattern Counter

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register [CRC_PCOUNT_REGx](#) ($x = 1$ to 4). When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode. Then CPU must trigger signature verification of the preloaded value and the generated current signature.

NOTE: The data pattern count should be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

24.3.2.4 MCRC Sector Count - Current Sector

Each channel contains a 16 bit sector counter. The sector count register [CRC_CURSEC_REGx](#) ($x = 1$ to 4) stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register. If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure it is advisable to use the following equation during CRC and DMA setup:

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count}$$

The current sector register [CRC_CURSEC_REGx](#) ($x = 1$ to 4) is frozen from being updated until both the current sector register is read and CRC fail status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

Current sector register is reset when the PSA software reset is enabled from the [CRC_CTRL0](#) register bits CH4_PSA_SWREST, CH43_PSA_SWREST, CH2_PSA_SWREST, and CH1_PSA_SWREST for the four channels.

NOTE: Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

24.3.2.5 MCRC Raw data

Besides the compressed data stored into the PSA signature register, raw un-compressed data is stored for reference as well in the [RAW_DATAREGLx](#) and [RAW_DATAREGHx](#) ($x = 1$ to 4).

24.3.2.6 MCRC Semi-CPU sample configuration

Operation in semi-CPU mode means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. Just the M CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

For example a memory area with 2Mbyte is to be verified with the help of the CPU. CRC operation is to be performed every 1K byte. Since there are 2Mbyte(256k doublewords) of memory to be check and we want to perform a CRC every 1Kbyte(128 doublewords) and therefore there should be 2048 pre-recorded CRC values. In Semi-CPU mode, the CRC Value Register is not updated and contains indeterminate data.

DMA Setup

Setup DMA channel 1 with the source address from which the memory area to be verified are mapped. Setup the destination address to the memory mapped channel 1 PSA Signature Register. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

Timer Setup

Setup Timer to generate DMA request associated with DMA channel 1. For example, an OS can setup the timer to generate a DMA request every 10ms.

CRC Setup

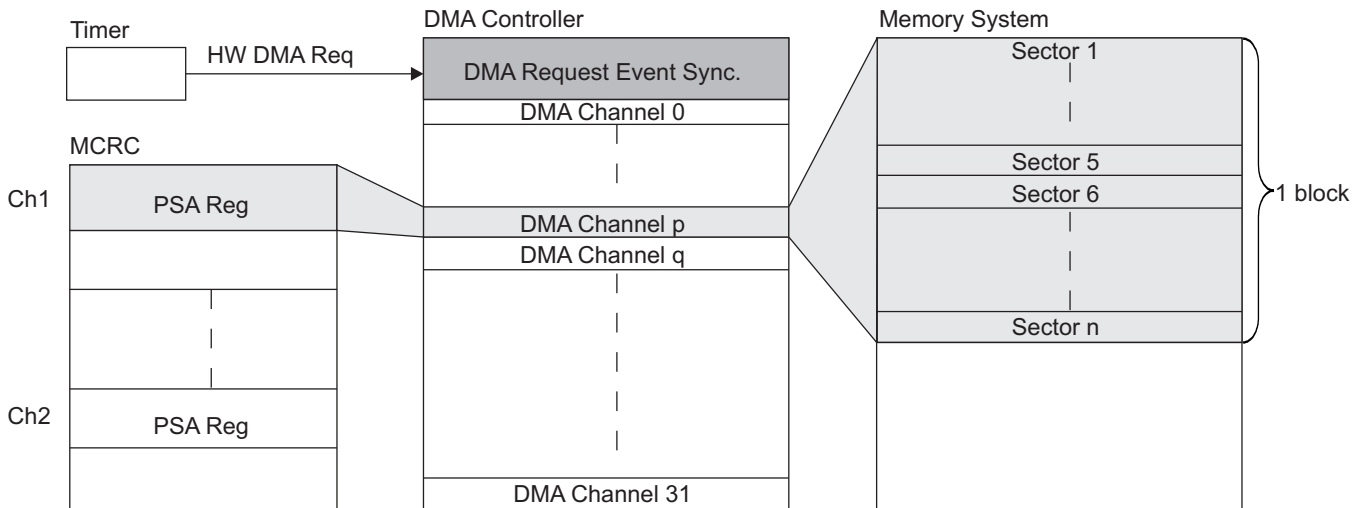

Program the pattern count to 128 from the [CRC_PCOUNT_REG1](#) register. Program the sector count to 2048 from the [CRC_SCOUNT_REG1](#).

For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load value to 15625 (5 ms / (1 CLK period x 64)) if MCRC is operating at 200Mhz.

Enable Semi-CPU mode from [CRC_CTRL1\[1:0\] CH1_MODE](#) and enable all interrupts from the [CRC_INTS](#) register channel 1.

The timer first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the PSA Signature Register, the CRC logic will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the PSA Sector Signature Register. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2Mbyte are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from PSA Sector Signature Register before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller. [Figure 24-8](#) show the DMA channel allocated for the MCRC module:

Figure 24-8. MCRC Semi-CPU Mode With Hardware Timer Trigger

mcr-003

24.3.2.7 MCRC Interrupts

The MCRC generates 3 types of interrupts in Semi-CPU mode (no interrupts are generated in Full CPU mode).

Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated.

Overrun Interrupt

During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt (see above). At the same time the signature is copied into the PSA Sector Signature Register. If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24 bit timeout counter per CRC channel. The 24 bit timeout down counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (CRC_WDTPLDx) and block complete timeout pre-load value (CRC_BCTOPLDx). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of OCP_CLK_PI clock.

Watchdog timeout pre-load register (CRC_WDTPLDx) is used to check if DMA does supply a block of data responding to a request in a given time frame. Block complete timeout pre-load register (CRC_BCTOPLDx) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with CRC_WDTPLDx after Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register, then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with CRC_BCTOPLDx the block complete timeout pre-load value.

In [Figure 24-9](#), a timer generates DMA request every 10ms to trigger one block (pattern count x sector count) transfer. Since we want to make sure that DMA does start to transfer a block every 10 ms we would set the first pre-load value to 10ms in CRC_WDTPLDx. We also want to make sure that one block of data patterns are compressed within 4ms. With such a requirement we would set the second pre-load value to 4ms in CRC_BCTOPLDx register.

Figure 24-9. MCRC Timeout Example

MCRC only generates one interrupt request to Device Interrupt Controller (CRC_IRQ_CH1_CRP_COMP). Pending interrupts can be checked from the CRC_STATUS_REG register, but also an interrupt offset register [CRC_INT_OFFSET_REG](#) is provided to indicate the source of the pending interrupt with highest priority. [Table 24-107](#) shows the offset interrupt vector address of each interrupt condition in an ascending order of priority.

Table 24-107. MCRC Interrupt priority and offset mapping

Interrupt Condition	Offset Value
Reserved	0x0-0x8
Ch1 Compression Complete	0x9
Ch2 Compression Complete	0xa
Ch3 Compression Complete	0xb
Ch4 Compression Complete	0xc
Reserved	0xd - 0x10
Ch1 Overrun	0x11
Ch2 Overrun	0x12
Ch3 Overrun	0x13
Ch4 Overrun	0x14
Reserved	0x15 - 0x20
Ch1 Timeout	0x21
Ch2 Timeout	0x22
Ch3 Timeout	0x23
Ch4 Timeout	0x24

When an interrupt is generated, host CPU should take appropriate actions to identify the source of error and restart the respective channel in DMA and MCRC module. To restart a MCRC channel user should perform the following steps:

- Write to software reset bit in CRC_CTRL register to reset the respective PSA Signature Register.
- Reset the CHx_MODE bits to "00" in CRC_CTRL register as Data capture mode.
- Set the CHx_MODE bits in CRC_CTRL register to desired new mode again.
- Release software reset from the CRC_CTRL register by writing "0" in the respective PSA Signature bitfield.

Description	Data capture mode is especially useful when it is used in conjunction when data trace (CH1_TRACEEN) for channel 1. The seed value can be planted in PSA Signature Register during data capture mode by writing a seed value into PSA Signature Register. Data trace enable bit is then set to snoop and compress any read transaction on Data buses. When trace enable bit is set, CH1_MODE is automatically reset to data capture mode. To change mode from one to another in the middle of an on-going mode user should take the following steps:		
Type	RW

RESERVED								CRC_CURSEC1																							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	CRC_CURSEC1	Channel 1 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number.	RW	0x0

RESERVED																CRC_CURSEC2															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		RW	0x0
15:0	CRC_CURSEC2	Channel 2 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	CRC_CURSEC4	In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number. In Semi-CPU mode, this register is used to indicate the sector number for which the compression complete has last happened.	RW	0x0

24.4 Dual Clock Comparator

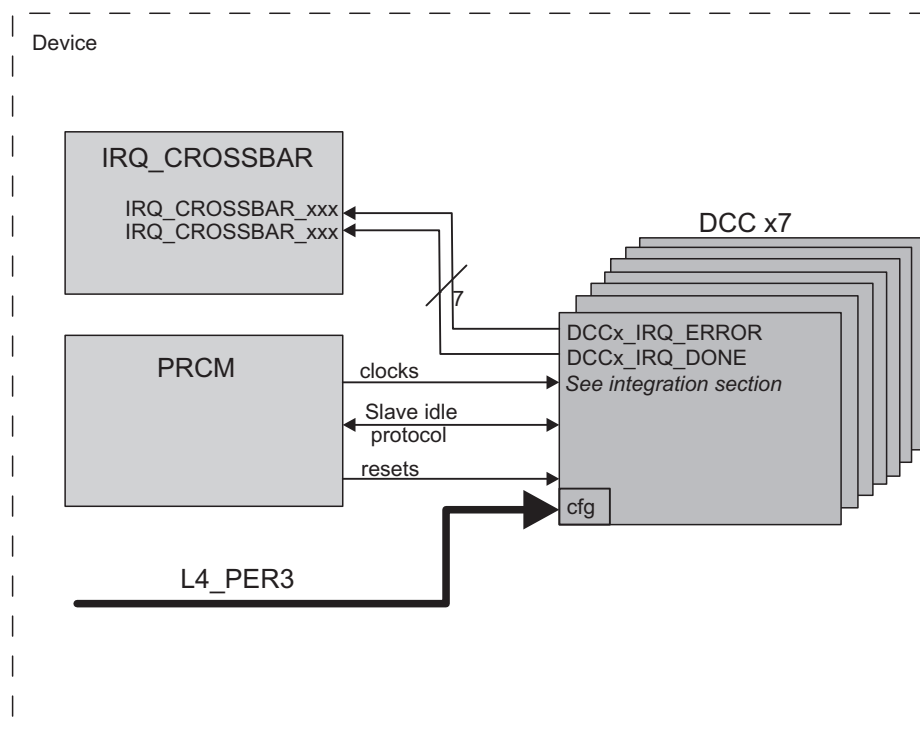

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is expected to detect 2% drift from the expected frequency within 100ms time. Moreover, the exact accuracy can also be programmed based on calculation for each application. In addition, the DCC can also measure the frequency of a selectable clock source using another input clock as a reference.

There are seven instances of the DCC within the device specifically targeted to perform verification on the DPLL_CORE, DPLL_DDR, DPLL_PER, DPLL_EVE_VID_DSP, DPLL_GMAC_DSP, XREF_CLK, SYS_CLK1, SYS_CLK2, and one of the DPLL_CORE HS-Dividers.

Main features:

- Two independent counter blocks count clock pulses from each clock source
- Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies.
- Error signal generation
- Clock frequency measurement

Figure 24-10. DCC Overview Block Diagram

DCC6	DCC6_IRQ_DONE	IRQ_CROSSBAR_422	-	This IRQ source signal is not mapped by default to any device INTC.
DCC7	DCC7_IRQ_ERROR	IRQ_CROSSBAR_423	-	This IRQ source signal is not mapped by default to any device INTC.
DCC7	DCC7_IRQ_DONE	IRQ_CROSSBAR_424	-	This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “**Default Mapping**” column in [Table 24-234 DCC](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the `IRQ_CROSSBAR` and `DMA_CROSSBAR` modules, respectively. For more information about the `IRQ_CROSSBAR` module, see [Section 14.4.6.4, *IRQ_CROSSBAR Module Functional Description*](#), in [Chapter 14, *Control Module*](#). For more information about the `DMA_CROSSBAR` module, see [Section 14.4.6.5, *DMA_CROSSBAR Module Functional Description*](#), in [Chapter 14, *Control Module*](#). For more information about the device interrupt controllers, see [Chapter 13, *Interrupt Controllers*](#). For more information about the device EDMA module, see [Chapter 12, *Enhanced DMA*](#).

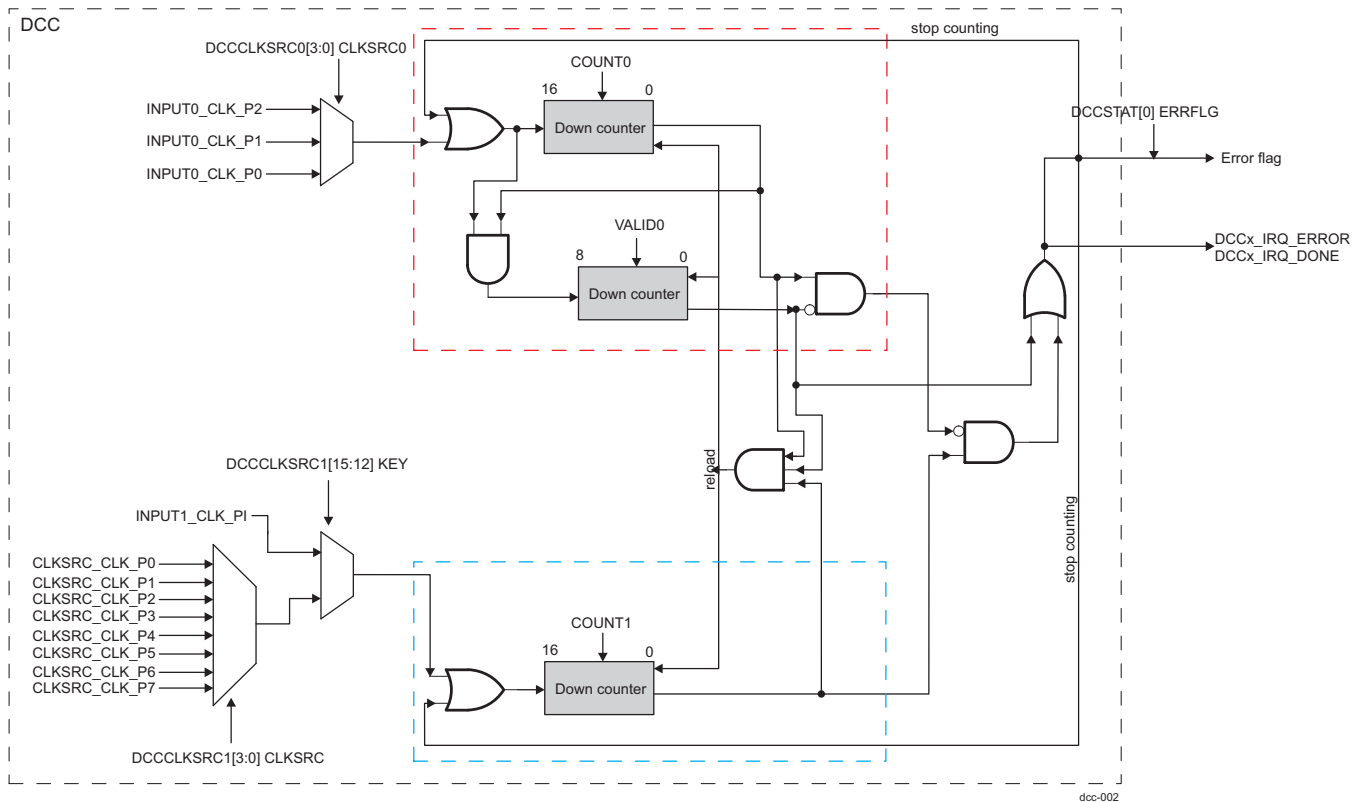

NOTE:

- For a description of interrupt source, see [Table 24-234](#).
- For a description of DMA source, see [Table 24-234](#).

24.4.2 DCC Functional Description

The DCC module supports two selectable clock sources for counter0 and counter1. Counter0 takes INPUT0_CLK_P2 at reset. Counter1 has a clock source selection INPUT1_CLK_PI which is selected at reset. Moreover, to select an alternate clock source the DCCCLKSRC1[15:12] KEY must be programmed. Figure 24-11 shows the DCC functional block diagram

Figure 24-11. DCC Functional Block Diagram

24.4.2.1 DCC Counter Operation

DCC module has two parallel counters count clock pulses for two independent clock sources:

- Counter 0 generates a fixed-width counting window (VALID0) after a preprogrammed number of pulses (COUNT0). The values for VALID0 and COUNT0 can be programmed from DCCVALIDSEED0 and DCCCNTSEED0 registers respectively.
- Counter 1 generates a fixed-width pulse (1 cycle) after a pre-programmed number of pulses (COUNT1). This pulse sets as an error signal if counter1 does not reach 0 during the time when VALID0 is running. The seed value for COUNT1 can be programmed from DCCCNTSEED1.

The error signal is generated by any one of the following conditions:

- Clock1 expires before the COUNT0 reaches 0.
- Clock1 expires after both COUNT0 and VALID0 reach 0.
- Clock1 not present.
- Clock0 not present.

Any error causes the counters to stop counting. An application may then read out the counter values to help determine what caused the error. Once, the error is detected, the counters are stopped after 3 OCP_CLK_PI and 2 source clock cycles due to the cross clock domain synchronisation.

Reloads / restarts occur under two conditions:

- The module is reset or restarted through software (e.g. software starts the module after reset, or software checks an error condition and decides to restart the module).

- COUNT0, COUNT1, and VALID0 all reach 0 without error.

CAUTION

This module does not check jitter for clock0 and clock1.

As the counter preset signal is synchronized to either of the source clock domains, the counters begin downcounting after two corresponding source clock cycles.

The error signal is captured to the OCP_CLK_PI domain. There is 1 OCP_CLK_PI period uncertainty on either side of the fixed width counting window (VALID0) in generating the error signal since the counters work in a different clock domain. This should be accounted for, when setting the count value for VALID0.

Below are examples of counters relationship and error generation

Figure 24-12. DCC Clock0 and Clock1 With no Error

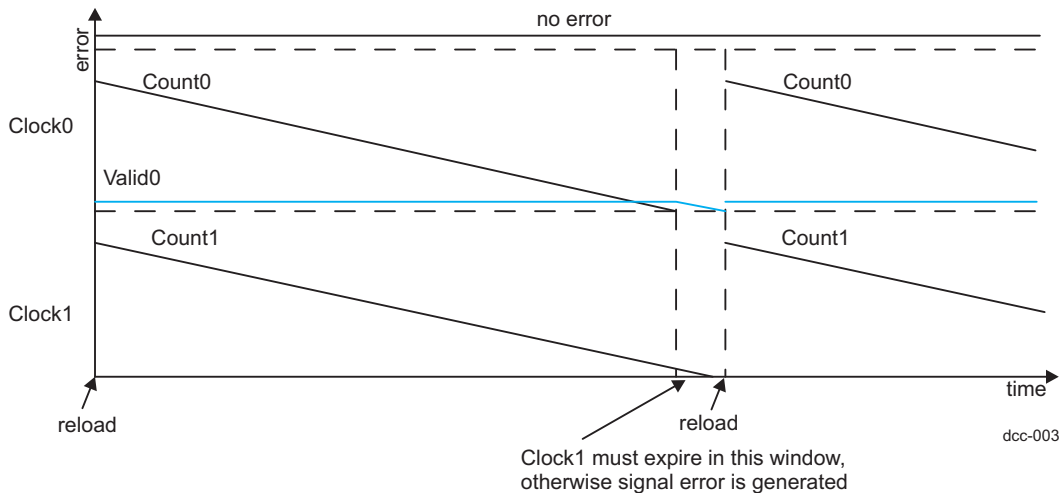

Figure 24-13. DCC Clock1 slower than Clock0 results in an error and stops counting

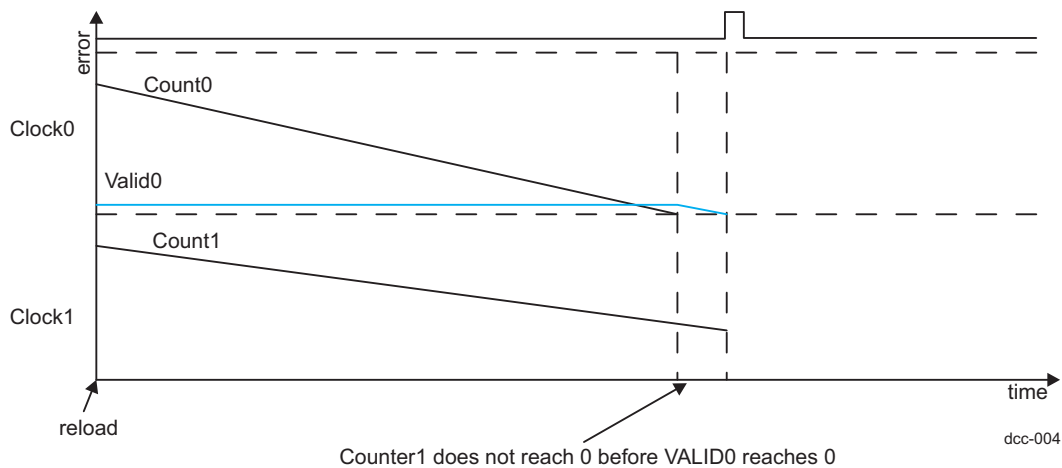

Figure 24-14. DCC Clock1 faster than Clock0 results in an error and stops counting

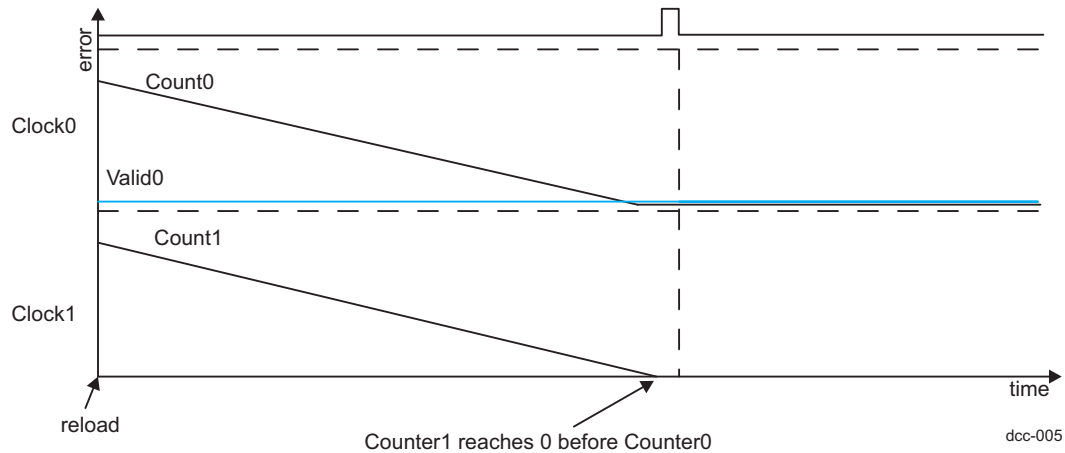

Figure 24-15. DCC Clock1 not present results in an error and stops counting

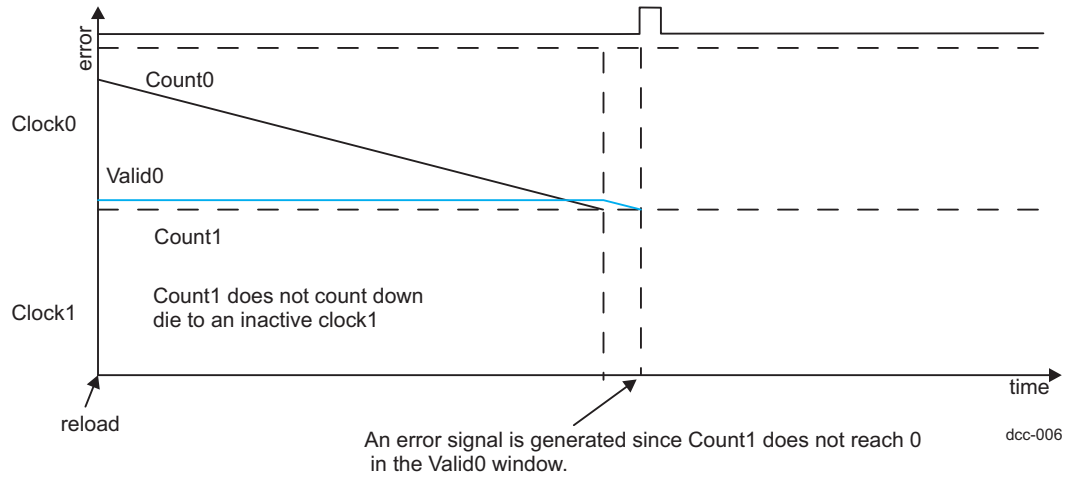

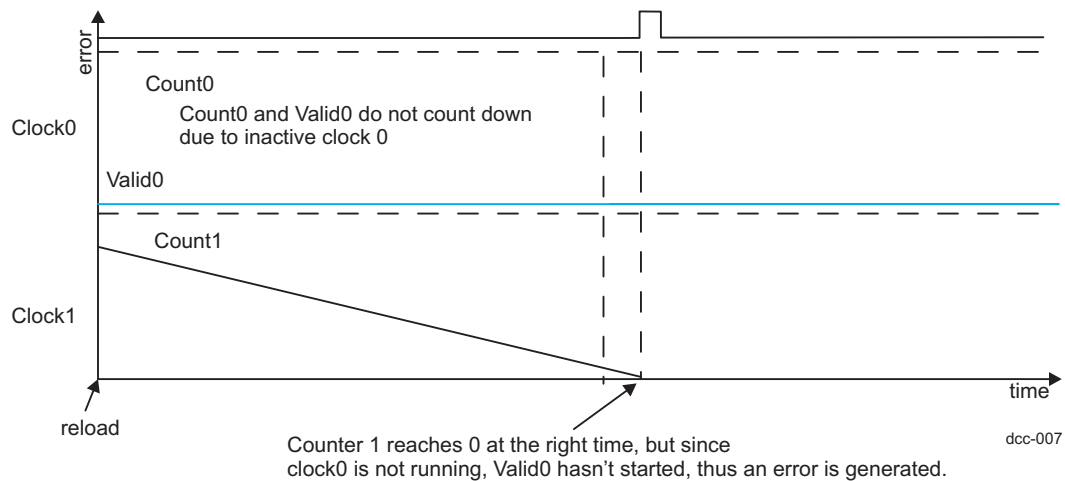

Figure 24-16. DCC Clock0 not present results in an error and stops counting

24.4.2.2 DCC Single-Shot Mode

The DCC may be programmed to count down one time using single-shot mode. In this mode, the DCC stops operation when:

- both counter 0 and valid 0 reach 0

At the end of one sequence in single-shot mode the DCC will set the enable bit field in the [DCCGCTRL\[3:0\]](#) DCCENA to disabled, which stops further counting. Single-shot mode is enabled from the [DCCGCTRL\[11:8\]](#) SINGLESHT

At the end of one sequence in single-shot mode, if there is no error which stops counting, then the done status bit is set in the [DCCSTAT\[1\]](#) DONEFLG and a done interrupt is driven. The CPU must clear the done bit before restarting counting.

24.4.3 DCC Register Manual

24.4.3.1 DCC Instance Summary

Table 24-235. DCC Instance Summary

Module Name	Base Address	Size
DCC1	0x4885 6000 (On SR1.0) 0x4882 8000 (On SR2.0)	44 Bytes
DCC2	0x4885 8000 (On SR1.0) 0x4882 A000 (On SR2.0)	44 Bytes
DCC3	0x4885 A000 (On SR1.0) 0x4882 C000 (On SR2.0)	44 Bytes

24.4.3.2.2 DCC Register Description

Table 24-242. DCCGCTRL

Address Offset	0x0000 0000		
Physical Address for SR2.0	0x4882 8000 0x4882 A000 0x4882 C000 0x4882 E000 0x4884 E000 0x4885 2000 0x4885 4000	Instance	DCC1 DCC2 DCC3 DCC4 DCC5 DCC6 DCC7
Description	DCC Global Control Register NOTE: For SR1.0 physical addresses, see Table 24-236, Table 24-238 and Table 24-240.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES																DONEENA			SINGLESHOT			ERRENA			DCCENA						

Bits	Field Name	Description	Type	Reset
31:16	RES	User, privilege, and debug mode reads return 0 and writes have no effect	R	0x0
15:12	DONEENA	The DONEENA bit enables/disables the done interrupt signal, but has no effect on the done status flag in DCCSTAT register. User, privilege, and debug mode (read): 0101 = the done signal is disabled others = the done signal is enabled Privilege and debug mode (write): 0101 = disable done signal generation others = enable done signal generation	RW	0x5
11:8	SINGLESHOT	The SINGLESHOT bit enables/disables repetitive operation of the DCC. User, privilege, and debug mode (read): 1010 = stop counting when counter0 and valid0 both reach zero 1011 = stop counting when counter1 reaches zero others = continuously repeat (until error) Privilege and debug mode (write): 1010 = stop counting when counter0 and valid0 both reach zero 1011 = stop counting when counter1 reaches zero others = continuously repeat (until error)	RW	0x5
7:4	ERRENA	The ERRENA bit enables/disables the error signal. User, privilege, and debug mode (read): 0101 = the error signal is disabled others = the error signal is enabled Privilege and debug mode (write): 0101 = disable error signal generation others = enable error signal generation	RW	0x5
3:0	DCCENA	The DCCENA bit starts and stops the operation of the dcc. User, privilege, and debug mode (read): 0101 = counters are stopped others = counters are running Privilege and debug mode (write): 0101 = stop counters and error-checking others = load the counters with their seed values and begin counting	RW	0x5

24.5 Error Signaling Module

The Error Signaling Module (ESM) is indicating a severe device failure at an external pad. The error pad is normally used as a second indication path to switch off (or reset) the device CPUs by an external device. Therefore the external controller is able to reset the device or keep the system in a fail-safe state by disabling the peripherals outside of the ECU. Below is a list of features supported by the ESM:

- Up to 384 interrupt/error channels are supported, divided into 3 different groups
 - 128 channels with configurable interrupt and error pad behavior
 - 128 error channels with predefined interrupt and error pad behavior
 - 128 channels with predefined error pad behavior
- Error pad to signal severe device failure
- Configurable timebases for error signal
- Error forcing capability

Figure 24-17 shows the ESM overview diagram.

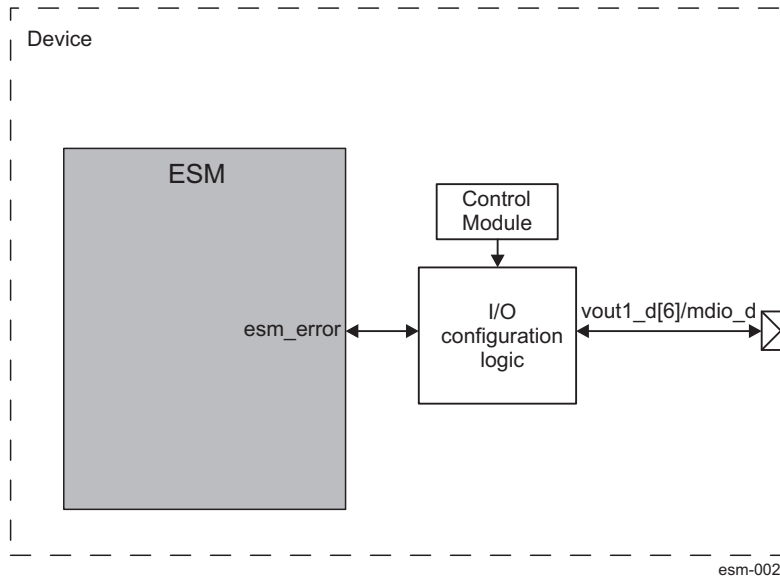

Figure 24-17. ESM Overview

24.5.1 ESM Environment

This section describes the ESM application fields from an environment point of view (external connections). It describes ESM connectivity options. Figure 24-18 shows the ESM controller pads used for typical connections with external devices.

Figure 24-18. ESM Environment

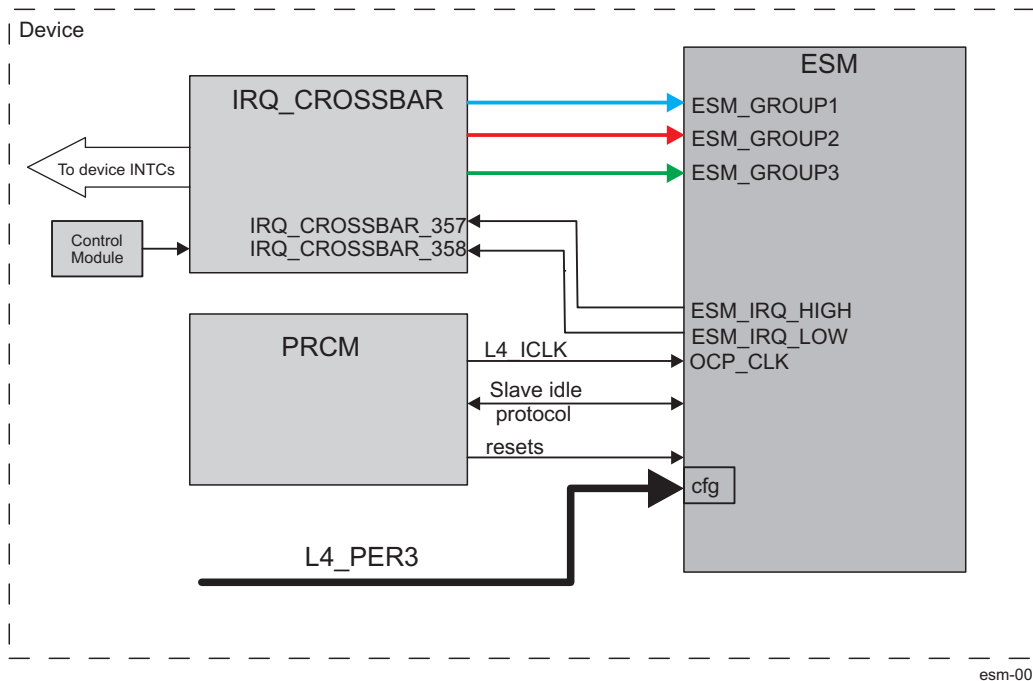

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 14.4.6.1, Pad Configuration Registers of Chapter 14, Control Module](#).

24.5.2 ESM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests. [Figure 24-19](#) shows the integration of the ESM controller in the device.

Figure 24-19. ESM Integration

NOTE: For more information about the slave idle protocol and the wake-up request, see [Section 3.7, Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 24-264](#) through [Table 24-105](#) summarize the integration of the module in the device.

Table 24-264. ESM Integration Attributes

Module Instance	Attributes

Table 24-266. ESM Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Destination
ESM	ESM_IRQ_HIGH	IRQ_CROSSBAR_357	-	This IRQ source signal is not mapped by default to any device INTC.
ESM	ESM_IRQ_LOW	IRQ_CROSSBAR_358	-	This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “**Default Mapping**” column in [Table 24-105 ESM Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

NOTE:

- For a description of interrupt source, see [Table 24-267](#).

[Table 24-267](#) list the mapping of the three interrupt group channels. Note only channel one is used. The rest are not connected.

NOTE: Above table lists all mapped interrupts to the ESM channels. The rest of the channels are not connected, therefore not shown in the table.

24.5.3 ESM Functional Description

Figure 24-20 show the ESM functional blocks and configuration bitfields. Besides the external to the device pad and error generation, the ESM generation two high and low level interrupts infernal to the device. The particular error interrupt line can is configurable and can be set from the [ESMILSR1](#), [ESMILSR4](#), [ESMILSR7\[31:0\]](#) INTLVLSET. Respectively can be read/cleared from the [ESMILCR1](#), [ESMILCR4](#), [ESMILCR7](#) registers.

Figure 24-20. ESM Functional Block Diagram

esm-006

The ESM provides diagnostic functionality to identify the source of each detected failure. The source interrupts can be enabled from [ESMIESR1](#), [ESMIESR4](#), and [ESMIESR7](#) registers. Disabling interrupt registers are [ESMIECR1](#), [ESMIECR4](#), and [ESMIECR7](#). The information about the source of the failure is kept until power-on-reset. For several failures, a more detailed information (e.g. which addresses are affected) is not supported and must be handled by the source error module.

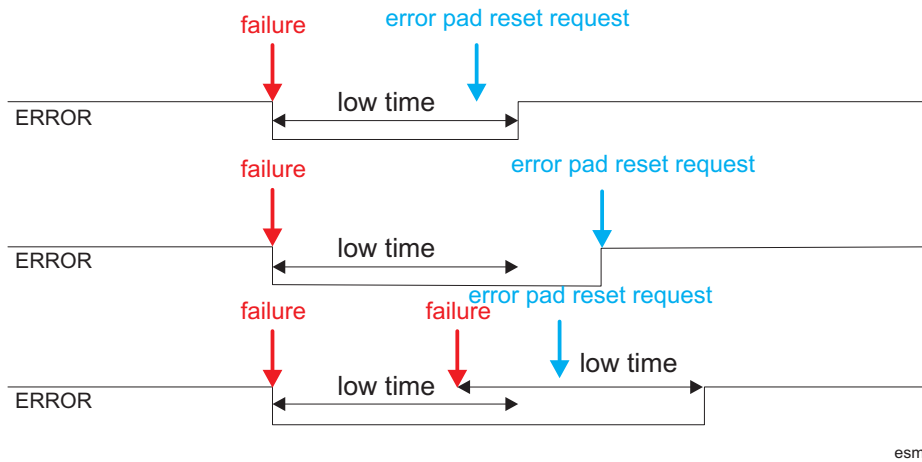

The `esm_error` pad is low active when error is generated and it is high as long as no failure is detected. The state of the pad is readable by software from [ESMEPSR\[0\]](#) EPSF and for each line status can be read from [ESMSR1](#) (line 0 - 31), [ESMSR4](#) (line 32 - 63) and [ESMSR7](#) (line 64 - 95). An internal reset does not affect the state of the pad. During power on reset, the pad have high impedance. If a failure occurs the error pin changes it's status to low in the next clock cycle. The pin remains in this state for the time specified by the Low-Time Counter Preload register [ESMLTCPR\[15:0\]](#) LTC. Based on the period of the clock, the total active time of the error pad can be calculated as

$$t_{\text{ERROR_low}} = t_{\text{OCP_CLK_PI}} * (\text{LTCP} + 1)$$

The reset of the `nERROR` is set high when the Low Time Counter ($t_{\text{ERROR_low}}$ expires) reaches its final value and software writes a valid 4-bit key to the ESM key register [ESMEKR\[3:0\]](#) EKEY. If the LTC already expired, the reset on the `nERROR` pin will take place as soon as the valid key is written into the ESM key register.

If another failure occurs within this time the pad stays low and the low time counter has to be restarted. The detection mechanisms must not be disabled as shown in [Figure 24-21](#)

Figure 24-21. ESM Error Failure Timings

If the error low time period expires, the error pin must be set to high in case the reset of the error pin was requested by the software even before the error pin low time has started as shown in [Figure 24-22](#). This case is not recommended and should be avoided by the application.

Figure 24-22. ESM Error failure reset before low time has started

The ESM support error forcing mode configured from the [ESMEKR\[3:0\]](#) EKEY. If the module is in error forcing mode, the application software should be aware of this, since it has requested the test, and therefore the module can not handle the normal error functionality during this time. When a normal failure occurs while in error forcing mode, it gets still latched and the LTC gets reset and stopped; the error output pad signal already shows the "low". When the mode is forced back to functional mode the LTC gets active. In case of pending failures, the error output pad will show "low" timed by the LTC, otherwise it will show "high" immediately.

As long as a failure is reported in functional mode (the error output pad is "low" for the LTC time) the module will not switch to the error forcing mode. The requested switching to error forcing mode is ignored. Therefore the application software should check for pending failures before it requests the error forcing mode.

If system reset occurs when nERROR pin is low, [ESMLTCR](#) register will reset to its default value to 0x3FFF. User needs to write 0x5 value to [ESMEKR](#) register so that nERROR pad will set back to high when the LTC counter decrements to zero. In this scenario, low period of the nERROR pin will vary depending on the preload of [ESMLTCPR](#) register value and user software write.

The generating of interrupts and the activation of the error pin is shown in [Table 24-268](#)

Table 24-268. ESM Interrupt and error pin behavior

Error Group	Interrupt, Level	Influence on Error Pin
1	maskable, low/high	configurable

ESM supports active high pulse interrupts/error inputs. When Error Group 1 interrupts occur, corresponding interrupt flags will be set in the status registers ([ESMSR1](#) (line 0 - 31), [ESMSR4](#) (line 32 - 63) and [ESMSR4](#) (line 64 - 95)) and offset registers ([ESMIOFFHR](#) and [ESMIOFFLR](#)). Interrupt status flag gets cleared only by a write to this register.

ESM generates active high level interrupts. The error pad gets into "output in-active" (high impedance) state with pull-down enabled during power-on-reset and into "output active" state with pull-down disabled during any other reset.

Description	ESM Interrupt Offset High Register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES																INTOFFH															

Bits	Field Name	Description	Type	Reset
31:9	RES	Reads return 0 and writes have no effect	R	0x0
8:0	INTOFFH	This vector gives the channel number of the highest pending interrupt request for the high level interrupt line. Interrupts of error group 2 have higher priority than interrupts of error group 1. Inside a group, channel 0 has highest priority and channel 63 has lowest priority. User and privilege mode (read): Returns number of pending interrupt with the highest priority for the high level interrupt line: 0000_0000 = no pending interrupt 0000_0001 = interrupt pending for channel 0, error group1 ... 0010_0000 = interrupt pending for channel 31, error group1 0010_0001 = interrupt pending for channel 0, error group2 ... 0100_0000 = interrupt pending for channel 31, error group2 0100_0001 = interrupt pending for channel 32, error group1 ... 0110_0000 = interrupt pending for channel 63, error group1 0110_0001 = interrupt pending for channel 32, error group2 ... 1000_0000 = interrupt pending for channel 63, error group2 1000_0001 = interrupt pending for channel 64, error group1 ... 1010_0000 = interrupt pending for channel 95, error group1 1010_0001 = interrupt pending for channel 64, error group2 ... 1100_0000 = interrupt pending for channel 95, error group2 1100_0001 = interrupt pending for channel 96, error group1 ... 1110_0000 = interrupt pending for channel 127, error group1 1110_0001 = interrupt pending for channel 96, error group2 ... 1_0000_0000 = interrupt pending for channel 127, error group2 Reading the interrupt vector will clear the corresponding flag in the ESMSR2 , ESMSR5 , ESMSR8 and ESMSR11 registers and the offset register gets updated. User and privilege mode (write): Writes have no effect.	R	0x0

24.6 Real Time Interrupt Module

The device is targeted to offer the processing solutions for automotive vision customer end applications. These applications include but are not limited to the following broad categories:

- Front camera analytics
- Rear view camera analytics
- Surround view camera analytics
- RADAR based analytics
- Fusion systems where steering and braking decisions are made based on feedback from multiple systems such as Radar based sensing and auto-vision

Many of these systems will require compliance to strict automotive functional safety requirements. These requirements mandate different ASIL requirements for an end-system depending upon the failure scenarios of the system, their probability of occurrence and the risk they pose to human life.

Below is a list of system scenarios which require use of the features provided by Real Time Interrupt (RTI) module:

- A scenario where tasks in an automotive system do follow a strict time schedule. This scheduling is mandatory in terms of the starting of the task and how much minimum and maximum time is it supposed to take for completion. If this scheduling constraint is violated, then an interrupt is generated by the RTI.
- A scenario where there is a need for a time-stamp such as a SW or HW event can be used to capture a timestamp for its occurrence. These timestamps may be necessary for drivers to schedule events as well as assess whether they finished within a certain required time interval. If the constraint is violated, then an interrupt is generated by the RTI.
- The debug scenarios where the occurrence of 2 events needs to be timed precisely.
- Software performance benchmarking, that is assessing how much time elapsed before completion of a given function or other code.
- Scheduling ticks required by OS or "controlling software loop" for different time bases, that is, a "RTOS scheduler" that requires 2 ticks such that one of these arrives every 12 ms while the other arrives every 13 ms.
- Scheduling ticks and interrupts that are synchronized either to a clock sent out of the device or to an external clock received by the device.
- Safety diagnostics requirement where two counters are needed with second counter as a diagnostic element

To fulfill the above scenarios, the RTI provides timer functionality for operating systems and for benchmarking code by incorporates several counters, which define the timebases needed for scheduling. This module is specifically designed to fulfill the requirements for OSEK (translated: "Open Systems and the Corresponding Interfaces for Automotive Electronics") as well as OSEK/Time compliant operating systems. The timers also give the ability to benchmark certain areas of code by reading the counter contents at the beginning and the end of the desired code range and calculating the difference between the values.

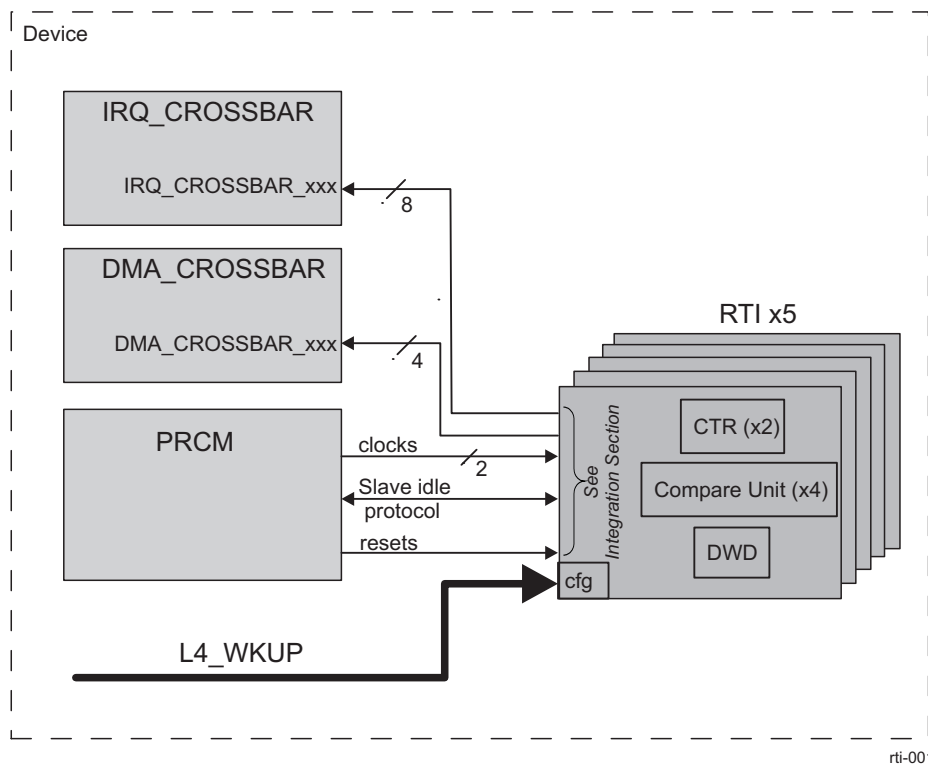

Apart from the timers, the module also explicitly integrates an instance of Digital Watchdog Timer (DWT) . The DWT must be enabled by software. The DWD starts counting down from the reset value of the register [RTIDWDCNTR](#) (DWD Counter Register). Once DWD is enabled by software, the digital watchdog is disabled only after system reset. In other words, application can not disable it again.

The Real Time Interrupt (RTI) module provides the following main features:

- Two independent 64 bit counter blocks (counter block 0 or counter block 1).
- Four configurable compares for generating operating system ticks or DMA requests. Each event can be driven by either counter block 0 or counter block 1.
- Fast enabling/disabling of events.
- Capture events to capture timestamps through recording of timer status.
- Two time-stamp (capture) functions for system or peripheral interrupts, one for each counter block.
- Digital Watchdog with an option to enable a windowed watchdog feature.

RTI4	RTI4_DREQ_EVT1	DMA_CROSSBAR_223	-	This DMA source signal is not mapped by default to any device DMA.
RTI4	RTI4_DREQ_EVT2	DMA_CROSSBAR_224	-	This DMA source signal is not mapped by default to any device DMA.
RTI4	RTI4_DREQ_EVT3	DMA_CROSSBAR_225	-	This DMA source signal is not mapped by default to any device DMA.
RTI5	RTI5_DREQ_EVT0	DMA_CROSSBAR_226	-	This DMA source signal is not mapped by default to any device DMA.
RTI5	RTI5_DREQ_EVT1	DMA_CROSSBAR_227	-	This DMA source signal is not mapped by default to any device DMA.
RTI5	RTI5_DREQ_EVT2	DMA_CROSSBAR_228	-	This DMA source signal is not mapped by default to any device DMA.
RTI5	RTI5_DREQ_EVT3	DMA_CROSSBAR_229	-	This DMA source signal is not mapped by default to any device DMA.

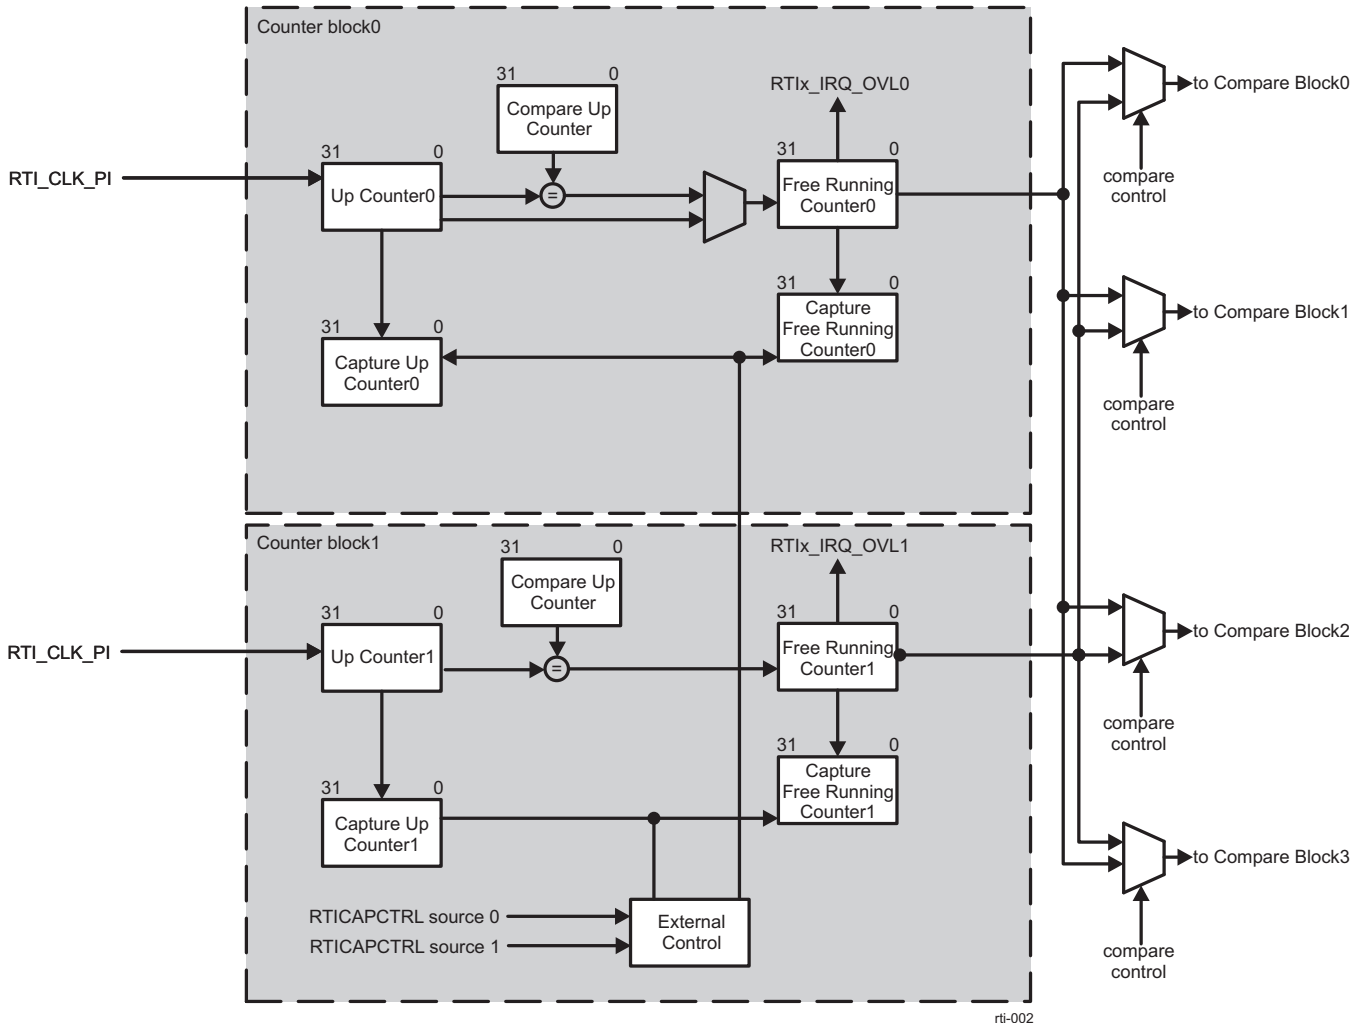

NOTE: The “**Default Mapping**” column in [Table 24-234 RTI](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

24.6.2 RTI Functional Description

24.6.2.1 RTI Counter Operation

[Figure 24-24](#) shows the RTI module counter blocks. The RTI module supports two counter blocks.

Figure 24-24. RTI Counters Block diagram

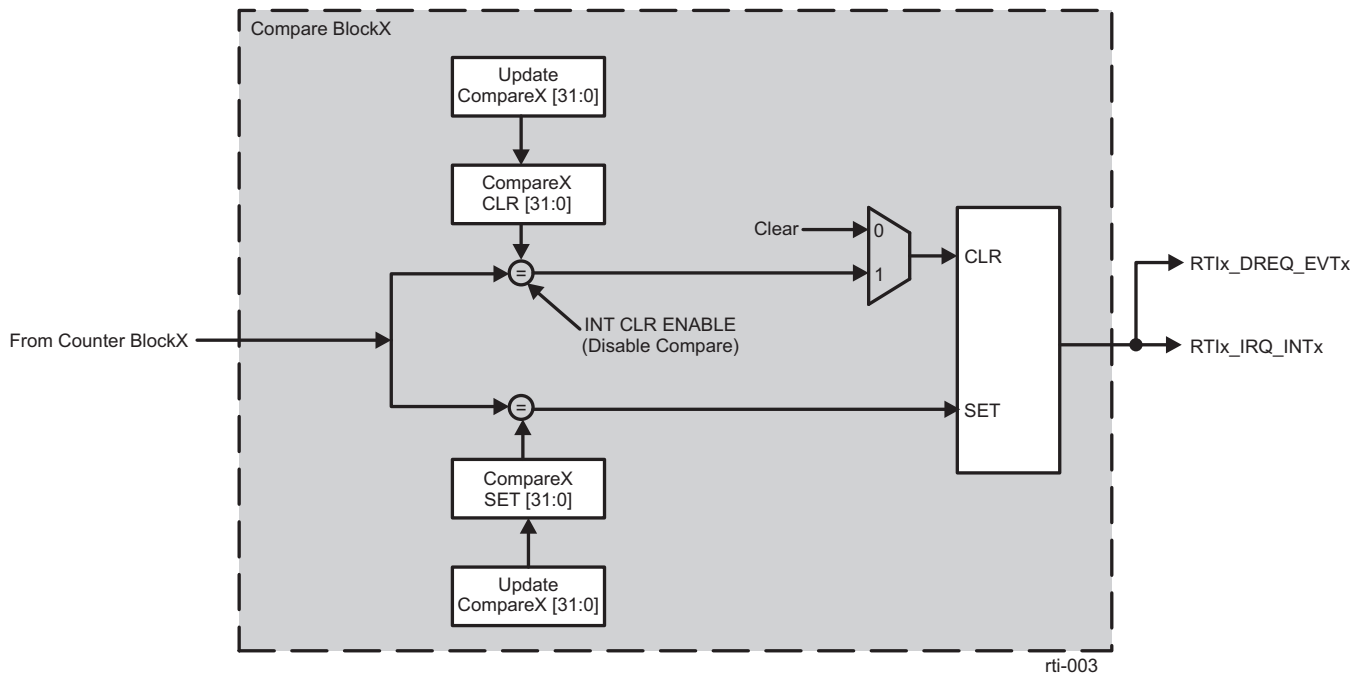

Each block consists of two 32 bit up counters - Up Counter and Free Running Counter (FRC). The Up Counter (**RTIUC0** or **RTIUC1** register) is driven by the RTI_CLK_PI and counts up until the compare value in the Compare Up Counter register (**RTICPUC0** or **RTICPUC1**) is reached. When the compare matches, the second counter (**RTIFRC0** or **RTIFRC1** register), which is a free running counter is incremented. At the same time UCx is reset to zero. If FRCx overflows a interrupt is generated.

To ensure the consistency of the counters, when both counter value have to be determined, the Free Running Counter has to be read first. This will ensure that at the CPU read cycle, the Up Counter value is stored in the counter register. The second read is done on the Up Counter register, which holds then the value of the counter cycle of the previous read on the Free Running Counter register.

Both blocks provide also a capture feature on external events. Two capture sources can trigger the capture event. Which event triggers block 0 or block 1 is configurable from the **RTICAPCTRL** register . The sources are coming from the interrupt manager, in order to be able to generate a capture event when one of the peripheral modules has generated an interrupt. The peripheral, which can generate an event is configured in the interrupt manager. When the event is detected, UCx and FRCx are stored in Capture Up Counter (**RTICAUC0** or **RTICAUC1**) and Capture Free Running Counter (**RTICAFRC0** or **RTICAFRC1**) registers. The read order of the captured values has to be like the order of the actual counters. So the CAFRCx has to be read first and the CAUCx registers has to be read after the CAFRCx value was determined. While the CAFRCx is read the CAUCx value is loaded into a shadow register to ensure data consistency, when during the two reads of the captured data another capture event happens. If the application fails to read the two registers before a second capture event happens, the previous data will be overwritten.

Figure 24-25 shows the block diagram for one compare block. The RTI module supports four compare blocks.

Figure 24-25. RTI Compare Block Diagram

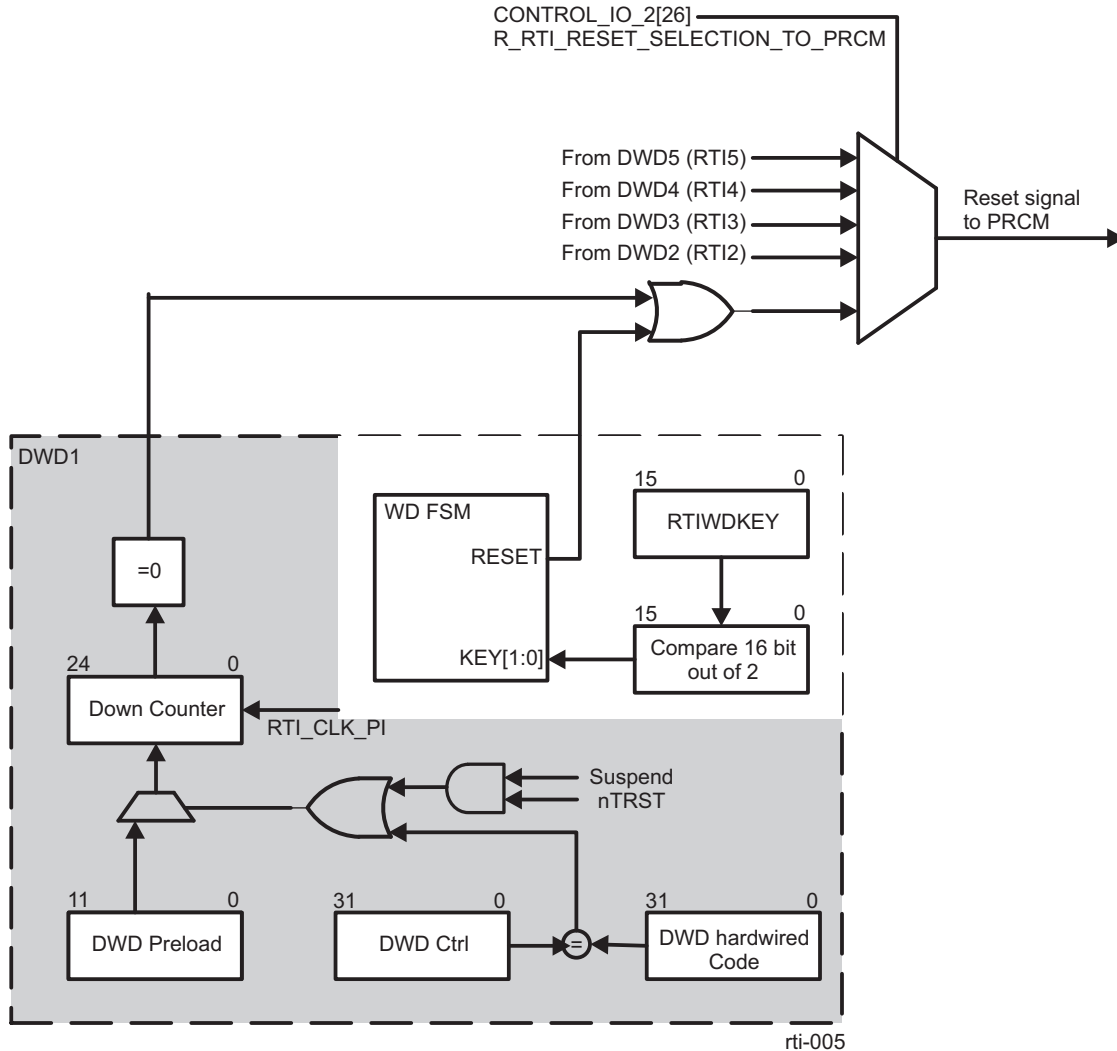

In order to generate interrupt requests to the interrupt manager, there are four compare registers ([RTICOMP0](#), [RTICOMP1](#), [RTICOMP2](#), and [RTICOMP3](#)). Each of the compare registers can be configured to work either on FRC0(Counter block0) or FRC1(Counter block1). When the counter value matches the compare value, an interrupt is generated. This sets an interrupt request line to the interrupt manager. The compare value gets updated automatically with the value stored in Update Compare ([RTIUDCP0](#), [RTIUDCP1](#), [RTIUDCP2](#), and [RTIUDCP3](#)) registers when the compare matches. This gives the ability to generate periodic interrupts/DMA requests without having to update the compare value by software.

An optional feature allows an application to program another compare value which is then used to clear the interrupt request line. This feature is supported by four compare clear registers ([RTICOMP0CLR](#), [RTICOMP1CLR](#), [RTICOMP2CLR](#), and [RTICOMP3CLR](#)). When the counter value matches the compare clear value, the interrupt line is cleared. This clears the interrupt request line to the interrupt manager. The compare clear value gets updated automatically with the value stored in Update Compare (RTIUDCPx) registers when the compare matches.

24.6.2.2 RTI Digital Watchdog

Some applications might use a digital watchdog (DWD) integrated in the RTI module. The digital watchdog generates resets after a programmable period, if no correct key sequence is written to the [RTIWDKEY](#) register. Figure 24-26 show the Digital Watchdog functional block.

Figure 24-26. RTI Digital Watchdog Functional Block Diagram

The digital watchdog functionality is implemented such that it can be enabled by software.

The DWD starts counting down from the reset value of the [RTIDWDCNTR](#) (DWD Counter Register). The DWD preload register can be configured at any time by the application according to the desired time-out period.

When enabled by software, the digital watchdog is disabled after system reset. If it should be used, it has to be enabled by writing 0xA98559DA to the [RTIDWDCTRL](#) register. The DWD timeout period must be configured using the DWD preload register before the DWD is enabled. The DWD cannot be disabled by the application once it is enabled.

NOTE: When the DWD is enabled by software, any system reset will disable the DWD. This reset could have been generated by the watchdog itself.

If the correct key sequence is written to the [RTIWDKEY](#) register (0xE51A followed by 0xA35C), the 25-bit DWD Down Counter is reloaded with the 12-bit preload value stored in [RTIDWDPRLD](#) register. If any incorrect value is written to the [RTIWDKEY](#) register, a watchdog reset will occur immediately. A reset will also be generated, when the DWD Down Counter is decremented to 0.

The user has to take into account that the write to the DWDKEY register takes 3 OCP_CLK_PI cycles. This needs to be considered for the DWD expiration calculation.

The DWD Down Counter will be decremented with RTI_CLK_PI frequency. If the RTI_CLK_PI is switched off via the PRCM clock domain disable registers, the DWD counter stops decrementing. The DWD module cannot generate a reset under this condition.

Figure 24-27. RTI DWD Operation

The expiration time of the DWD Down Counter can be determined with following equation:

$$t_{exp} = (RTIDWDPRLD + 1) \times 2^{13} / RTI_CLK_PI \tag{21}$$

where **RTIDWDPRLD** = 0...4095

24.6.2.3 RTI Digital Windowed Watchdog

In addition to the time-out boundary configurable via the DWD discussed in previous section, some applications may also want to configure the start-time boundary of the watchdog. This is enabled by the digital windowed watchdog (DWWD) feature.

Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a non-maskable interrupt to the CPU. This is controlled by configuring the **RTIWWDRXNCTRL** register. As stated earlier, when the watchdog needs to be enabled by software, the watchdog counter is disabled on a system reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The RTIx_IRQ_WWD interrupt handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key **RTIWDKEY** register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the RTIx_IRQ_WWD handler does not service the watchdog in time, it could count down all the way to zero and wrap around. No second exception for a time out is generated in this case.

Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD.

Figure 24-28. RTI Digital Windowed Watchdog Timing Example

rti-007

Figure 24-29. RTI Digital Windowed Watchdog Operation Block Diagram

rti-008

24.6.2.4 RTI Low Power Mode Operation

The operation of the RTI Module is guaranteed in Run, Doze and Snooze mode. In Sleep or Hibernate mode all clocks will be switched off and the RTI Module will not work.

In Doze and Snooze modes all parts of the RTI are active, since it has to be able to wake up the device with Compare and Timebases interrupts. Capturing events generated by the Interrupt Module is also possible since in both modes the peripheral modules are able to generate interrupts, which can trigger capture events. The RTI Module will generate Compare, Timebases and Overflow interrupts. The Compare interrupts will periodically wake up the device. The Overflow interrupt will notify the operating system that a counter overflow occurred.

NOTE: In the special case of Doze Mode with DPLL off, RTI_CLK_PI might have a different period than with DPLL enabled, since RTI_CLK_PI will be derived from the oscillator output. It has to be ensured that the OCP_CLK_PI to RTI_CLK_PI ratio is at least 3:1.

The DWD/DWWD remains active when the device enters low power mode as long as the RTI_CLK_PI is kept active.

24.6.2.5 RTI Debug Mode Behavior

Once the system enters debug mode, the behavior of the RTI depends on the [RTIGCTRL\[15\]](#) COS bit. If the bit is cleared and debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode. The DWD counter will not decrement in debug mode and will hold its current value.

NOTE: The user must not service the watchdog while in debug mode.

Table 24-417. RTIDWDCTRL

Address Offset	0x0000 0090		
Physical Address	0x4AE3 1090 0x4AE3 3090 0x4AE3 3090 0x4AE3 5090 0x4AE3 5090 0x4AE3 7090 0x4AE3 7090 0x4AE3 9090 0x4AE3 9090	Instance	RTI1 RTI1 RTI2 RTI1 RTI3 RTI2 RTI4 RTI2 RTI5
Description	This register s functionality is dependent on whether the DWD is implemented to be always enabled or not. If the DWD is always enabled, then the DWD is automatically enabled after system reset is released and cannot be disabled by software. In that case, this register is redundant and any writes to this register have no effect on the DWD functionality. If, however, the DWD is not enabled upon release of system reset, then the software has to write to the DWDCTRL field in order to enable the DWD, as described below. Once enabled, the watchdog can only be disabled by a system reset. The application cannot disable the watchdog. The DWDCTRL register also implements a one-time-write constraint. That is, once the application writes to this register to enable the watchdog, all further writes are ignored.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DWDCTRL_31_16																DWDCTRL_15_0															

Bits	Field Name	Description	Type	Reset
31:16	DWDCTRL_31_16	Digital Watchdog Control. User and privilege mode (read): 5312ACEDh = DWD counter is disabled. This is the default value. A98559DAh = DWD counter is enabled Any other value = DWD counter state is unchanged (enabled or disabled) Privilege mode (write): A98559DAh = DWD counter is enabled Any other value = State of DWD counter is unchanged (stays enabled or disabled) One-Write Functionality of DWDCTRL Register: The RTIDWDCTRL register implements a one-write functionality, such that the application cannot write to this register more than once. Writing the default value will not enable the watchdog as described above. Writing the enable value will start the watchdog counters. A write to RTIDWDCTRL will only be enabled after a system reset again.	RW	0x14c0
15:0	DWDCTRL_15_0	Digital Watchdog Control. User and privilege mode (read): 5312ACEDh = DWD counter is disabled. This is the default value. A98559DAh = DWD counter is enabled Any other value = DWD counter state is unchanged (enabled or disabled) Privilege mode (write): A98559DAh = DWD counter is enabled Any other value = State of DWD counter is unchanged (stays enabled or disabled) One-Write Functionality of DWDCTRL Register: The RTIDWDCTRL register implements a one-write functionality, such that the application cannot write to this register more than once. Writing the default value will not enable the watchdog as described above. Writing the enable value will start the watchdog counters. A write to RTIDWDCTRL will only be enabled after a system reset again.	RW	0x0

RESERVED																DWDPRLD															

Bits	Field Name	Description	Type	Reset
31:12	RESERVED		R	0x0
11:0	DWDPRLD	Digital Watchdog Preload Value. User and privilege mode (read): A read from this register in any CPU mode returns the current preload value. Privilege mode (write): If the DWD is always enabled after reset is released: The DWD starts counting down from the reset value of the counter, that is, 0x002DFFFF. The application can configure the DWD preload register any time before this down counter expires. When the application services the DWD, the preload register contents are copied left-justified into the DWD down counter and it starts counting down from that value. If the DWD is implemented such that the down counter is enabled by software: The DWD preload register can be configured only when the DWD is disabled. Therefore, the application can only configure the DWD preload register before it enables the DWD down counter. The expiration time of the DWD Down Counter can be determined with following equation: ARRAY(0x1f75d70) where: RTIDWDPRLD = 0...4095	RW	0x0

Description	The values of the following status bits will not be affected by a system reset. These bits are cleared by a power up reset, or by the application.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED																												DWWD_ST	END_TIME_VIOL	START_TIME_VIOL	KEYST	_DWDST	AWDST

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0
5	DWWD_ST	Windowed Watchdog Status. This bit denotes whether the time-window defined by the windowed watchdog configuration has been violated, or if a wrong key or key sequence was written to service the watchdog. User and privilege mode (read): 0 = no time-window violation has occurred. 1 = a time-window violation has occurred. The watchdog will generate either a system reset or a non-maskable interrupt to the CPU in this case. Privilege mode (write): 0 = leaves the current value unchanged. 1 = clears the bit to 0. This will also clear all other status flags in the RTIWDSTATUS register except for the AWDST flag. Clearing of the status flags will deassert the non-maskable interrupt generated due to violation of the DWWD.	R	0x0
4	END_TIME_VIOL	Windowed Watchdog End Time Violation Status. This bit denotes whether the end-time defined by the windowed watchdog configuration has been violated. This bit is effectively a copy of the DWD ST status flag. User and privilege mode (read): 0 = no end-time window violation has occurred. 1 = the end-time defined by the windowed watchdog configuration has been violated. Privilege mode (write): 0 = leaves the current value unchanged. 1 = clears the bit to 0.	R	0x0
3	START_TIME_VIOL	Windowed Watchdog End Time Violation Status. This bit denotes whether the start-time defined by the windowed watchdog configuration has been violated. This indicates that the WWD was serviced before the service window was opened. User and privilege mode (read): 0 = no start-time window violation has occurred. 1 = the start-time defined by the windowed watchdog configuration has been violated. Privilege mode (write): 0 = leaves the current value unchanged. 1 = clears the bit to 0.	R	0x0
2	KEYST	Watchdog KeyStatus.	R	0x0
1	_DWDST	Digital Watchdog Status.	R	0x0
0	AWDST	Analog Watchdog Status.	R	0x0

RESERVED																WDKEY															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	WDKEY	Watchdog Key. User and privilege mode reads are indeterminate. Privilege mode (write): A write of 0xE51A followed by 0xA35C in two separate write operations defines the Key Sequence and discharges the watchdog capacitor. This also causes the upper 12 bits of the DWD down counter to be reloaded with the contents of the DWD preload register and the lower 13 bits to become all 1 s. Writing any other value causes a digital watchdog reset. Register write access time precaution: The user has to take into account that the write to the register takes 3 OCP_CLK_PI cycle. This needs to be considered for the AWD/DWD expiration calculation.	RW	0xa35c

Initialization

This chapter introduces the steps in the general-purpose (GP) device initialization.

Topic	Page
25.1 Initialization Overview	6684
25.2 Preinitialization	6686
25.3 Booting Overview	6696
25.4 Memory Maps	6698
25.5 Overall Booting Sequence	6701
25.6 Startup and Configuration	6703
25.7 Peripheral Booting	6707
25.8 Memory Booting	6710
25.9 Image Format	6715
25.10 Tracing	6722

25.1 Initialization Overview

This chapter provides an overview of the requirements to initialize the device from power on to operating system (OS) and application execution, the overall initialization process (including hardware- and software-related steps), the general ROM code operational requirements, and behavior expectations.

25.1.1 Terminology

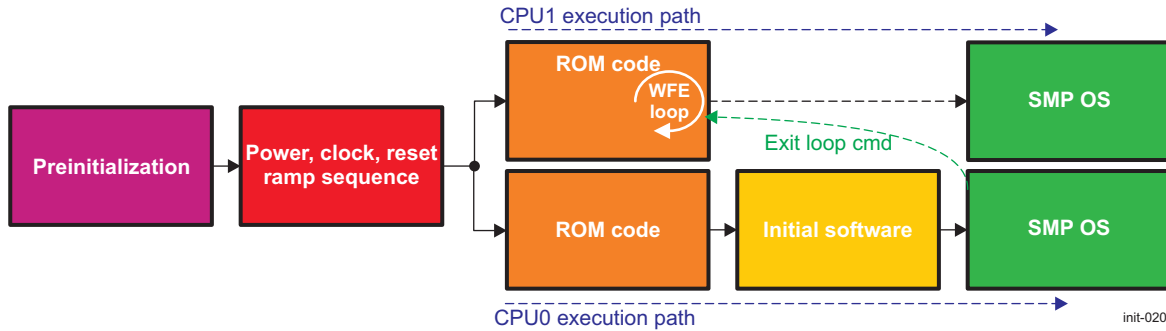

- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The Arm® Cortex®-M4 CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after a warm reset.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in device ROM that implements booting
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **Slave CPU:** The Arm Cortex-M4 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.

25.1.2 Initialization Process

Figure 25-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

Figure 25-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins and the associated configuration registers that are vital to the correct initialization of the device.

25.2 Preinitialization

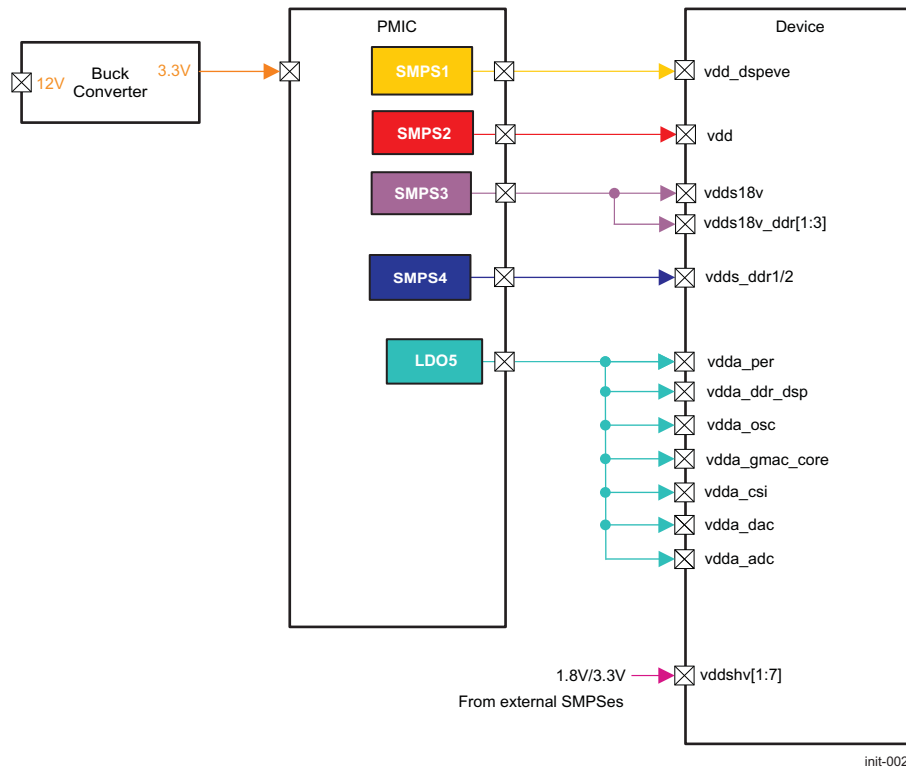

To accomplish a successful boot-up operation, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly to successfully initialize the device. The following sections describe the specific requirements for the preinitialization stage.

25.2.1 Power Requirements

The device can be supplied by an external power-management integrated circuit (PMIC). TI provides a global solution with the device connected to the power-management IC companion chips. Refer to Data Manual for information about the TI's power-management IC companion chips supported for this device.

Figure 25-2 shows typical power connections between the device and a PMIC companion chip.

Figure 25-2. Power Supply Connections Example

NOTE: Figure 25-2 is an example of power connections between the device and the PMIC, representing only one of the multiple PMIC/OTP options. These connections depend on the actual application, PMIC, and OTP used. Refer to the Device Data Manual, respective PMIC Data Sheet, and all related application notes before starting a new design.

Table 25-1 describes the device power balls.

Table 25-1. Device Power Balls

dds1_ext_vref0	EMIF channel 1 vref
dds1_ext_vref1	EMIF channel 2 vref
vdda_dds_dsp	Analog power supply for DPLL_DDR and DDR HSDIVIDER , DPLL_EVE_VID_DSP
vdda_per	Analog power supply for DPLL_PER, PER HSDIVIDER
vdda_gmac_core	Analog power supply for DPLL_GMAC_DSP and HSDIVIDER, DPLL_CORE and HSDIVIDER
vdda_spi	I/O Supply for NAND Flash on PoP memory (QSPI)
vddshv1	Dual-voltage GENERAL group I/Os
vddshv2	Dual-voltage GPMC group I/Os
vddshv3	Dual-voltage MMC4 group I/Os
vddshv4	Dual-voltage RGMII group I/Os
vddshv5	Dual-voltage VIN1 group I/Os
vddshv6	Dual-voltage VOUT group I/Os
vddshv7	Dual-voltage WIFI group I/Os
vdda_csi	CSI analog power supply
vdda_dac	DAC analog power supply
vdda_adc	ADC analog power supply
vdda_osc	I/O supply for oscillator section

NOTE: For a complete description of the power balls on the device package, see the *Device Data Manual*.

For more information about power management, see [Section 3.6 Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

25.2.2 Interaction With the PMIC Companion

The ROM code does not perform any I²C/SPI transactions with the PMIC. This makes ROM code PMIC-independent. The following system conditions must be met to perform device initialization:

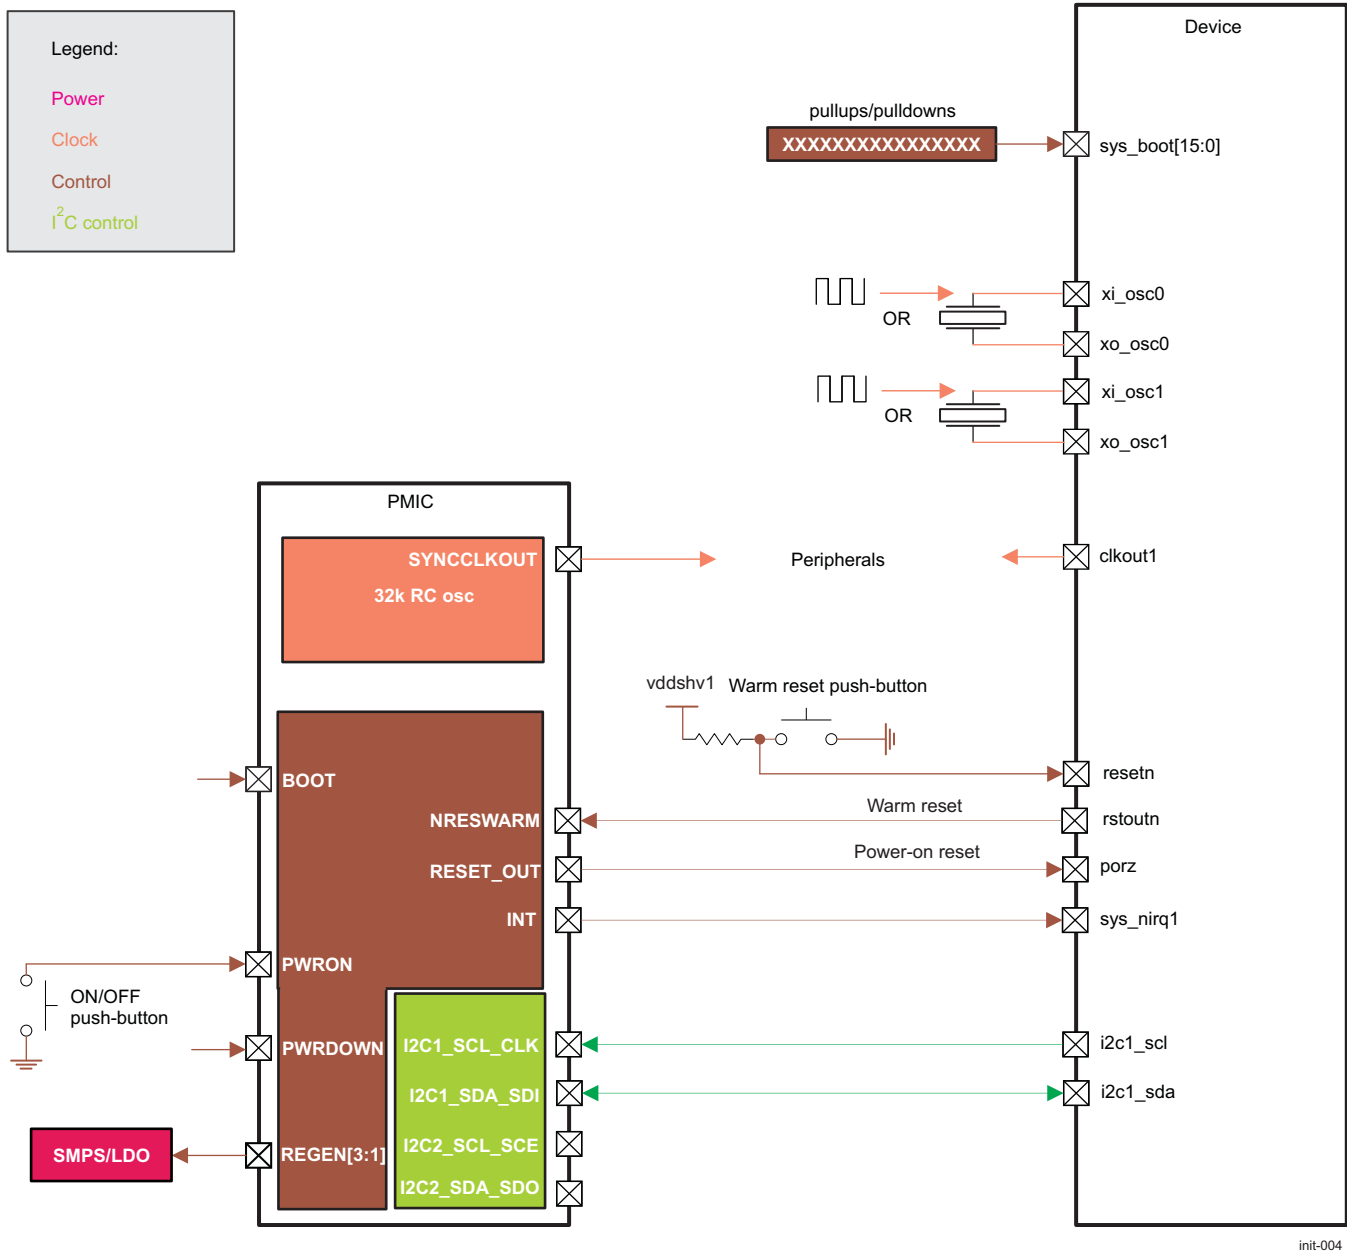

- Devices must be appropriately powered and be up and ready at platform startup:
 - QSPI
 - GPMC

25.2.3 Clock, Reset, and Control

25.2.3.1 Overview

[Figure 25-3](#) shows the clock and reset environment where clocks and reset-related signals are gathered at the system level, the system-expansion signals, and the crystal oscillator connection.

Figure 25-3. Clock, Reset, and Control Environment Overview

NOTE: Figure 25-3 is a typical example of clock, reset and control connections between the device and a PMIC. Refer to the Device Data Manual for the supported PMIC(s) for your device and for more information on these balls. For PMIC ball description, see the respective PMIC Data Sheet.

The main features of the system interface are:

- Accepts crystals connected between device xi_osc0 and xo_osc0 pads, and xi_osc1 and xo_osc1 pads to generate SYS_CLK1 and SYS_CLK2, respectively
- Accepts external LVCMOS clock sources connected to xi_osc0, and xi_osc1 pads for SYS_CLK1 and SYS_CLK2, respectively
- Two reference clock inputs
- Three configurable clock outputs

- sysboot[15:0] input signals to define the boot mode, system clock speed, and GPMC in XIP mode
- Two reset sources
 - Power-on reset (porz)
 - Warm reset (resetrn)
- Three external interrupt lines (sys_nirq1, sys_nirq2, and nmin)
- Four external DMA requests

25.2.3.2 Clocking Scheme

The device operation requires external input clocks, as follows:

- System clocks: The device supports two system clocks with two clock sources each:
 - SYS_CLK1 (main system clock):
 - Crystal on OSC0 pins. An internal oscillator (OSC0) embedded in the device is used.
 - External LVCMOS clock on xi_osc0
 - SYS_CLK2 (optional system clock):
 - Crystal on OSC1 pins. An internal oscillator (OSC1) embedded in the device is used.
 - External LVCMOS clock on xi_osc1
- The device can deliver digital clocks to peripherals ICs.

The device provides wide choice of clocks that can be delivered on clkout[1:3] pads to companion devices. For more information, see [Section 3.3, PRCM Subsystem Environment](#), in [Chapter 3, Power, Reset, and Clock Management](#). For more information on pad multiplexing, see [Chapter 14, Control Module](#).

[Table 25-2](#) lists the mapping for the device clock input sources. lists the PMIC clock requirements.

Table 25-2. Mapping for Input Sources

Clock	Clock Source	Ball Mapping	Frequency Range/List	Type
SYS_CLK1	Internal oscillator 0 (OSC0)	xi_osc0 and xo_osc0	19.2, 20, and 27 MHz	Crystal connection pins
	External	xi_osc0	19.2, 20, and 27 MHz	External LVCMOS
SYS_CLK2	Internal oscillator 1 (OSC1)	xi_osc1 and xo_osc1	19.2 ÷ 32 MHz	Crystal connection pins
	External	xi_osc1	12 ÷ 38.4 MHz	External LVCMOS

25.2.3.3 Reset Configuration

25.2.3.3.1 ON/OFF Interconnect and Power-On-Reset

The entire system is typically awakened by an ON/OFF push button connected to the PMIC chip. This signal belongs to the VSYS - system power domain and is active low (the PMIC internal pullup ties it to VSYS). The PMIC power-up event is propagated through its NRESPWRON output pin to the device porz pad (that is, the PRM SYS_PWRON_RST signal) when the PMIC power-up sequence is achieved. The device porz input pin is held low all the time during VDD core and I/O power-up.

25.2.3.3.2 Warm Reset

A warm reset can be asserted by the device, by an external button (typically for development platform), or by any other chip connected to it (normally tied to PMIC companion NRESWARM output pin).

The device warm reset pad (resetrn - device signal SYS_WARM_IN_RST) is used to trigger a warm reset on the device, which resets part of the device when it has already booted (for example, to recover from a software crash). When an internal device reset occurs, SYS_NRES_WARM_OUT output and device pad rstoutn go low and reset all the peripherals.

The device releases the SYS_NRES_WARM_OUT output signal after SYS_PWRON_RST is deasserted.

25.2.3.3.3 Peripheral Reset by GPIO

Most peripherals can be reset and powered on or off by GPIO. By default, under POR, most device signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of the device control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the device registers to validate GPIO use and the default configuration of the control module.

25.2.3.3.4 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event occurs, the output buffer is disabled. Consequently, two different behaviors can be defined with regard to what is expected by the platform:

- GPIO sensitive to warm reset:

To prevent a floating pad, user software is designed to have the internal pad PU and PD resistors enabled immediately, before the software warm reset action, because the warm reset-sensitive GPIO controllers will change I/O direction to input after an device warm reset. This is necessary if the warm reset-sensitive GPIO controller pin has been configured for output before the warm reset occurrence. The pulls-enabled-before-warm-reset condition should be set by default in case the user has configured a GPIO as an input, because in this case the user is expected to have enabled the internal PU and PD pads during GPIO configuration (unless external pull resistors were used).

NOTE: If the PU and PD resistors are enabled immediately by software after a POR (cold reset) for a GPIO that is planned to be used only as an output, then unnecessary consumption can occur.

While the dynamically-enable-the-pull-just-before-warm-reset condition is possible during a software warm reset (because the user software is aware of the exact moment a warm reset event occurs), it is not possible when the warm reset is triggered by hardware (for example, a watchdog reset, SYS_NRESWARM signal assertion, and so forth), because the software is not aware of the exact moment of these warm reset assertions.

- GPIO not sensitive to warm reset:

To avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time a dedicated GPIO register is accessed.

NOTE: To avoid unnecessary consumption, the user software must ensure that internal pull resistor is disabled when the GPIO buffer is driving.

For the description of the reset sequences and information about the device reset management, see [Section 3.5, Reset Management Functional Description](#), in [Chapter 3, Power, Reset and Clock Management](#). For more information about the device reset sequences, see the device *Data Manual*.

25.2.3.4 Power-Management IC Companion Control

The device and PMIC companion implement the basic power-management interface, as follows:

- Two system resets: power-on (cold) reset and warm reset
- I²C control
- One interrupt

- I²C:
The device interfaces: system interface I/Os, and I2C1 are involved in system interactions between the device and external power, reset and clock management IC companions.
- INT:
PMICs can activate their output interrupt request signal (INT) at any time when requires the device (host) device to monitor their activity. When receiving such an interruption, the device checks, through the I²C, to determine the source of the interrupt. These INT pins are active low.

25.2.3.5 PMIC Request Signals

The PMIC drives three external enable-output signals, which allows switching on some external resources at different stages of the power-up sequence:

- REGEN[1:3] belong to the VSYS power domain. REGEN[1:3] can typically be used for buck boost control and power switches.

The PMIC companion chip can receive three power resource requests: ENABLE[1:2] and NSLEEP. These pins allow an external device to request PMIC internal resources. The PMIC companion power behavior when pins are activated must be programmed after the first boot (resources and ENABLE pins allocated by group, resource behavior upon group activation, and so forth).

The use of NSLEEP is especially required when PMIC chip is in sleep mode, because it cannot handle an I²C command. Any device that requires the PMIC companion resource to wake up must first activate its associated ENABLE signal. All power-management chip power regulators are off or in sleep mode when it is in sleep mode.

25.2.4 Sysboot Configuration

The device implements 16 sampled-on-reset sysboot pads.

Table 25-3. Sysboot Pads Description⁽¹⁾

Pad	Description
sysboot[15]	Must be pulled high to 1 for proper device operation.
sysboot[14]	[Functional in SR2.0] Selects between SYS_CLK1 and SYS_CLK2 as reference clock to DPLL_CORE. Must be pulled down to 0 for proper SR1.0 device operation.
sysboot[13:10]	Used to configure the GPMC interface when booting from XIP memory connected to GPMC. See Section 25.2.4.1, GPMC Configuration for XIP .
sysboot[9:8]	Selects the SYS_CLK1 clock speed. sysboot[9:8] must be set correctly on the PCB according to the speed of the connected crystal. See Section 25.2.4.2, System Clock Speed Selection .
sysboot[7]	Device package selection. See Section 25.2.4.3, Miscellaneous Sysboot Settings .
sysboot[6]	Reserved. Pull down to 0.
sysboot[5]	ADC clock divider. See Section 25.2.4.3, Miscellaneous Sysboot Settings .
sysboot[4:0]	Select interfaces or devices for the booting list. See Section 25.2.4.4, Booting Device Order Selection .

⁽¹⁾ Boards should be implemented with a mechanism to easily modify the pull-up/down state to enable any future modifications.

All sysboot pads are sampled and latched onto the CTRL_CORE_BOOTSTRAP register (in control module) after POR. After booting, these pads can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. For more information about pad multiplexing configuration, see [Section 14.4.6.1, Pad Configuration Registers](#), in [Chapter 14, Control Module](#).

NOTE: If used as GPIOs, the sysboot[15:0] pads must be used only in output mode to ensure that the input values always match a certain hardware predefined boot pattern, interpreted after each POR.

25.2.4.1 GPMC Configuration for XIP

Table 25-4 describes the GPMC interface configuration used in XIP and fast-XIP modes controlled by sysboot[13:10]. These pin values are routed to the GPMC controller by hardware.

Table 25-4. GPMC for XIP Configuration

sysboot[13]	Bus Width
0	8-bit
1	16-bit
sysboot[12:11]	A/D-muxed/non-muxed Device on CS0
0b00	Non-muxed device
0b01	A/D-muxed device
sysboot[10]	Wait-pin Monitoring for Read Accesses
0	Disabled
1	Enabled

25.2.4.2 System Clock Speed Selection

There are three crystal speeds available to be selected by means of sysboot[9:8], as described in Table 25-5. User is responsible to set the correct value depending on the actual clock supplied to the device.

Table 25-5. System Clock (SYS_CLK1) Speed Selection

sysboot[9:8]	SYS_CLK1 Speed
0b00	Reserved
0b01	20 MHz
0b10	27 MHz
0b11	19.2 MHz

25.2.4.3 Miscellaneous Sysboot Settings

Additional sysboot settings are described in Table 25-6.

Table 25-6. Miscellaneous Sysboot Settings

sysboot[14]	DPLL_CORE Reference Clock ⁽¹⁾
0	SYS_CLK1
1	SYS_CLK2 ⁽²⁾
sysboot[7]	Device Package
0	15x15
1	12x12
sysboot[6]	Reserved
sysboot[5]	ADC Clock Divider
0	Divide by 2 (assuming SYS_CLK1 = 27 MHz)
1	No division (assuming SYS_CLK1 up to 20 MHz)

⁽¹⁾ There is also a software control provided. The device can boot with DPLL_CORE REF_CLK = SYS_CLK1 and later switch to SYS_CLK2. For more information, refer to Section 3.6.3.3.1, *Programming Guide For Control Module*.

⁽²⁾ If SYS_CLK2 is selected, set sysboot[9:8] to 0b10 (27 MHz) to avoid DPLL_CORE generating clocks faster than allowed during ROM boot time.

25.2.4.4 Booting Device Order Selection

The ROM code creates the device list (order) based on information from the sysboot[4:0] external configuration pins. They are sensed in the device CTRL_CORE_BOOTSTRAP register during POR. The sysboot[4:0] configuration pads have two main purposes: configure ROM code software in terms of interfaces and devices used for booting and configuring hardware after a POR or cold reset.

The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the third devices.

The following names are used in the tables:

- Memory types:
 - Execute-in-place (XIP): NOR (CFI) flash memory or other XIP device. See [Section 25.8.3, XIP Memory](#)
 - QSPI_1: 1-bit SPI flash memories. See [Section 25.8.4, SPI/QSPI Flash Devices](#)
 - QSPI_4: 4-bit (Quad) SPI flash memories. See [Section 25.8.4, SPI/QSPI Flash Devices](#)
- Peripheral interfaces:
 - UART: UART interface. See [Section 25.7, Peripheral Booting](#)
- [Table 25-7](#) lists the permanent booting devices in bold typeface.

NOTE: After a warm reset, the ROM code builds a device list featuring only the permanent booting devices (in **bold**)

[Table 25-7](#) lists the booting device order selected by ROM code depending on sysboot[4:0] pins.

Table 25-7. Booting Devices Order

sysboot[4]	sysboot[3:0]	First Device	Second Device	Third Device
Peripheral Preferred Booting				
0b0	0b0000	UART	QSPI_1	
0b0	0b0001	UART	QSPI_4	
0b0	0b0010	UART	XIP	
0b0	0b0011	UART	QSPI_4(XIP)	
Automotive Recovery/Upgrade or Development Booting ⁽¹⁾				
0b0	0b1000	UART		
0b0	0b1001	UART		
0b0	0b1010	UART		
0b0	0b1011	UART		
Memory Preferred Booting				
0b1	0b0000	QSPI_1	UART	
0b1	0b0001	QSPI_4	UART	
0b1	0b0010	XIP	UART	
0b1	0b0011	QSPI_4(XIP)	UART	
Automotive Production Booting ⁽¹⁾				
0b1	0b1000	QSPI_1		
0b1	0b1001	QSPI_4		
0b1	0b1010	XIP		
0b1	0b1011	QSPI_4(XIP)		

⁽¹⁾ After 10 failed loops through the device list, ROM code initiates immediate global warm reset.

25.2.4.5 Sysboot Pin Mapping

[Table 25-8](#) lists the sysboot pin multiplexing for 15×15 and 12×12 packages. There is no dedicated sysboot balls in either of the packages.

Table 25-8. Sysboot Pin Mapping

Sysboot Pin	15x15 Package		12x12 Package	
	Device Ball	Note	Device Ball	Note
sysboot[15]	gpmc_ad[15]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b1	
sysboot[14]	gpmc_ad[14]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	DPLL_CORE REF clock is SYS_CLK1
sysboot[13]	gpmc_ad[13]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	GPMC not supported
sysboot[12]	gpmc_ad[12]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	GPMC not supported
sysboot[11]	gpmc_ad[11]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	GPMC not supported
sysboot[10]	gpmc_ad[10]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	GPMC not supported
sysboot[9]	gpmc_ad[9]	In MuxMode=0xF ⁽¹⁾	spi1_d[0]	In MuxMode=0xF ⁽¹⁾
sysboot[8]	gpmc_ad[8]	In MuxMode=0xF ⁽¹⁾	spi1_d[1]	In MuxMode=0xF ⁽¹⁾
sysboot[7]	spi2_d[0]	In MuxMode=0xF ⁽¹⁾	spi2_d[0]	In MuxMode=0xF ⁽¹⁾
sysboot[6]	gpmc_ad[6]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	
sysboot[5]	gpmc_ad[5]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b1	No ADC clock division. ADC supports up to 20-MHz SYS_CLK1
sysboot[4]	gpmc_ad[4]	In MuxMode=0xF ⁽¹⁾	spi2_d[1]	In MuxMode=0xF ⁽¹⁾
sysboot[3]	gpmc_ad[3]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b1	Using only UART, QSPI_1 and QSPI_4
sysboot[2]	gpmc_ad[2]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	Using only UART, QSPI_1 and QSPI_4
sysboot[1]	gpmc_ad[1]	In MuxMode=0xF ⁽¹⁾	N/A, Tied-off to 0b0	Using only UART, QSPI_1 and QSPI_4
sysboot[0]	gpmc_ad[0]	In MuxMode=0xF ⁽¹⁾	uart2_ctsn	In MuxMode=0xF ⁽¹⁾

⁽¹⁾ Reset-default mux mode.

25.2.4.6 Boot Interface Pin Multiplexing

Table 25-9 lists the pin multiplexing configuration supported by ROM code according to boot interface. These settings are not restored to default values at ROM Code exit.

NOTE: The ROM code examines the interfaces that are selected to be searched until a valid bootable interface or device is found. The activities on the pads of the searched interfaces must be considered if they are connected to any other peripherals for any other purposes (for example, a LED connected to a GPMC pad muxed internally to a GPIO).

Table 25-9. Pin Multiplexing According to Boot Interface

Boot Device	Boot Interface	Pads	In MuxMode	Interface Signals
XIP	GPMC	gpmc_cs[0]	0x0	gpmc_cs[0]
		gpmc_advn_ale	0x0	gpmc_advn_ale
		gpmc_oen_ren	0x0	gpmc_oen_ren
		gpmc_wen	0x0	gpmc_wen
		gpmc_wait0	0x0	gpmc_wait0
		gpmc_ad[0:7]	0x0	gpmc_ad[0:7]
		gpmc_ad[8:15]	0x0	gpmc_ad[8:15]
		vout1_d[16:23]	0x3	gpmc_a[0:7]
		vin1a_d[8:15]	0x3	gpmc_a[8:15]
		uart1_ctsn	0x3	gpmc_a16
		uart1_rtsn	0x3	gpmc_a17
		uart2_ctsn	0x3	gpmc_a18
		uart2_rtsn	0x3	gpmc_a19

Table 25-9. Pin Multiplexing According to Boot Interface (continued)

Boot Device	Boot Interface	Pads	In MuxMode	Interface Signals
QSPI_1	QSPI1	gpmc_cs[1]	0x1	qspi1_cs[0]
		gpmc_cs[6]	0x1	qspi1_sclk
		uart1_rtsn	0x8	qspi1_rtclk ⁽¹⁾
		gpmc_cs[5:2]	0x1	qspi1_d[0:3]
QSPI_4	QSPI1	gpmc_cs[1]	0x1	qspi1_cs[0]
		gpmc_cs[6]	0x1	qspi1_sclk
		uart1_rtsn	0x8	qspi1_rtclk ⁽¹⁾
		gpmc_cs[5:2]	0x1	qspi1_d[0:3]
UART	UART3	spi1_sclk	0x1	uart3_rxd
		spi1_cs[0]	0x1	uart3_txd

⁽¹⁾ When the QSPI interface operates in Mode 3, this signal is not required to be connected to QSPI chip.

25.3 Booting Overview

25.3.1 Booting Types

Booting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. A software (warm) reset can be performed after the image is burned.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory devices and executes it. This process is normally performed after a cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface by using the sysboot pad configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

25.3.2 ROM Code Architecture

Figure 25-4 shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the ROM code: multicore startup, RTI and clock configurations, interrupt management, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure modules. End booting devices (typically external flash components) are attached to the device I/O pads.

Figure 25-4 shows the three layers with their modules.

Figure 25-4. ROM Code Architecture

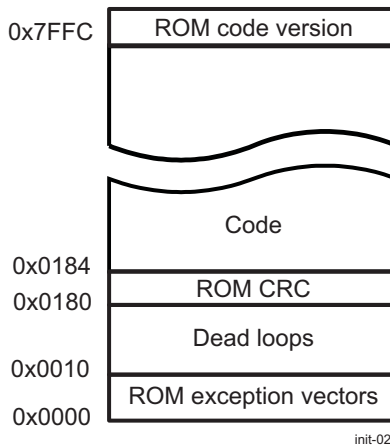

init-006

25.4 Memory Maps

25.4.1 ROM Memory Map

Figure 25-5 shows the ROM memory map in SR1.0.

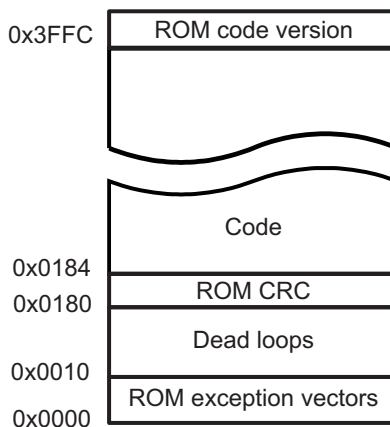

Figure 25-5. ROM Memory Map (SR1.0)

init-022

Figure 25-6 shows the ROM memory map in SR2.0.

Figure 25-6. ROM Memory Map (SR2.0)

init-022_sr2

- ROM exception vectors
Exceptions are redirected to ROM exception vectors (see [Table 25-10](#)). The reset exception is redirected to the ROM code startup. Once the ROM Code has started its execution, exception vector base address can be remapped in Internal RAM

Table 25-10. ROM Exception Vectors

Address	Exception	Content
0x0000	Stack Pointer	Address for r13 (stack pointer)
0x0004	Reset	Entry of the ROM Code
0x0008	NMI ISR Location	Address of the DEADLOOP_NMI
0x000C	Hard Fault ISR Location	Address of the DEADLOOP_HardFault

By default the NVIC vector table starts at address 0x0 at boot process, and these four exception vectors are mandatory. They are required because the NMI and Hard Fault can potentially occur during the boot process. Other exceptions cannot take place until they are enabled.

- ROM code cyclic redundancy check (CRC)

The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x0000–0x7FFF (SR1.0) and 0x0000–0x3FFC (SR2.0). The 4-byte CRC code is stored at location 0x180.

- Dead loops

Dead loops are branch instructions coded in Arm mode. They have multiple purposes (see [Table 25-11](#)). The fixed location of these dead loops facilitates debugging and testing

Table 25-11. Dead Loops

Address	Purpose
0x0010	NMI Interrupt
0x0012	Hard Fault
0x0014	Memory Management
0x0016	Bus Fault
0x0018	Usage Fault
0x001A	SVC Call
0x001C	Debug Monitor
0x001E	Pendable request
0x0020	System Tick timer
0x0022	Test Pass
0x0024	Test Fail
0x0026	Bad Cortex
0x0028	BadFlash
0x002A	BootMemError
0x002C	Reserved
0x002E	Reserved

- Code

This space is used to hold code and constant data.

- ROM code version

The ROM code version consists of two BCD numbers: major and minor. It can be used to identify the ROM code release version burned in a given IC. The ROM code version is a 32-bit hexadecimal value at address 0x7FFC (SR1.0) and 0x3FFC (SR2.0).

ROM Code version number is:

- 0x4001 for SR1.0
- 0x4002 for SR2.0

25.4.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in [Figure 25-7](#) is used during the booting process.

Figure 25-7. RAM Memory Map

- **Downloaded image**
This space is used by the ROM code to store a downloaded booting image. It can be up to 504 KiB.
- **Tracing data**
This area contains trace vectors reflecting the execution path of the ROM code. [Table 25-12](#) describes the ROM code tracing data. For more information about ROM code tracing, see [Section 25.10, Tracing](#).

Table 25-12. Tracing Data

Address	Size	Description
0x4037 F040	32 bits	Current tracing vector, word 1
0x4037 F044	32 bits	Current tracing vector, word 2
0x4037 F048	32 bits	Current tracing vector, word 3
0x4037 F04C	32 bits	Current tracing vector, word 4
0x4037 F050	32 bits	Cold reset run tracing vector, word 1
0x4037 F054	32 bits	Cold reset run tracing vector, word 2
0x4037 F058	32 bits	Cold reset run tracing vector, word 3
0x4037 F05C	32 bits	Cold reset run tracing vector, word 4
0x4037 F060	32 bits	Current copy of the PRM_RSTST register (reset reasons)

25.4.3 AMMU Mapping

The ROM Code configures AMMU to map certain address space to allow eXecute-In-Place (XIP) for IPU. [Table 25-13](#) indicates the physical/virtual mapping correspondence.

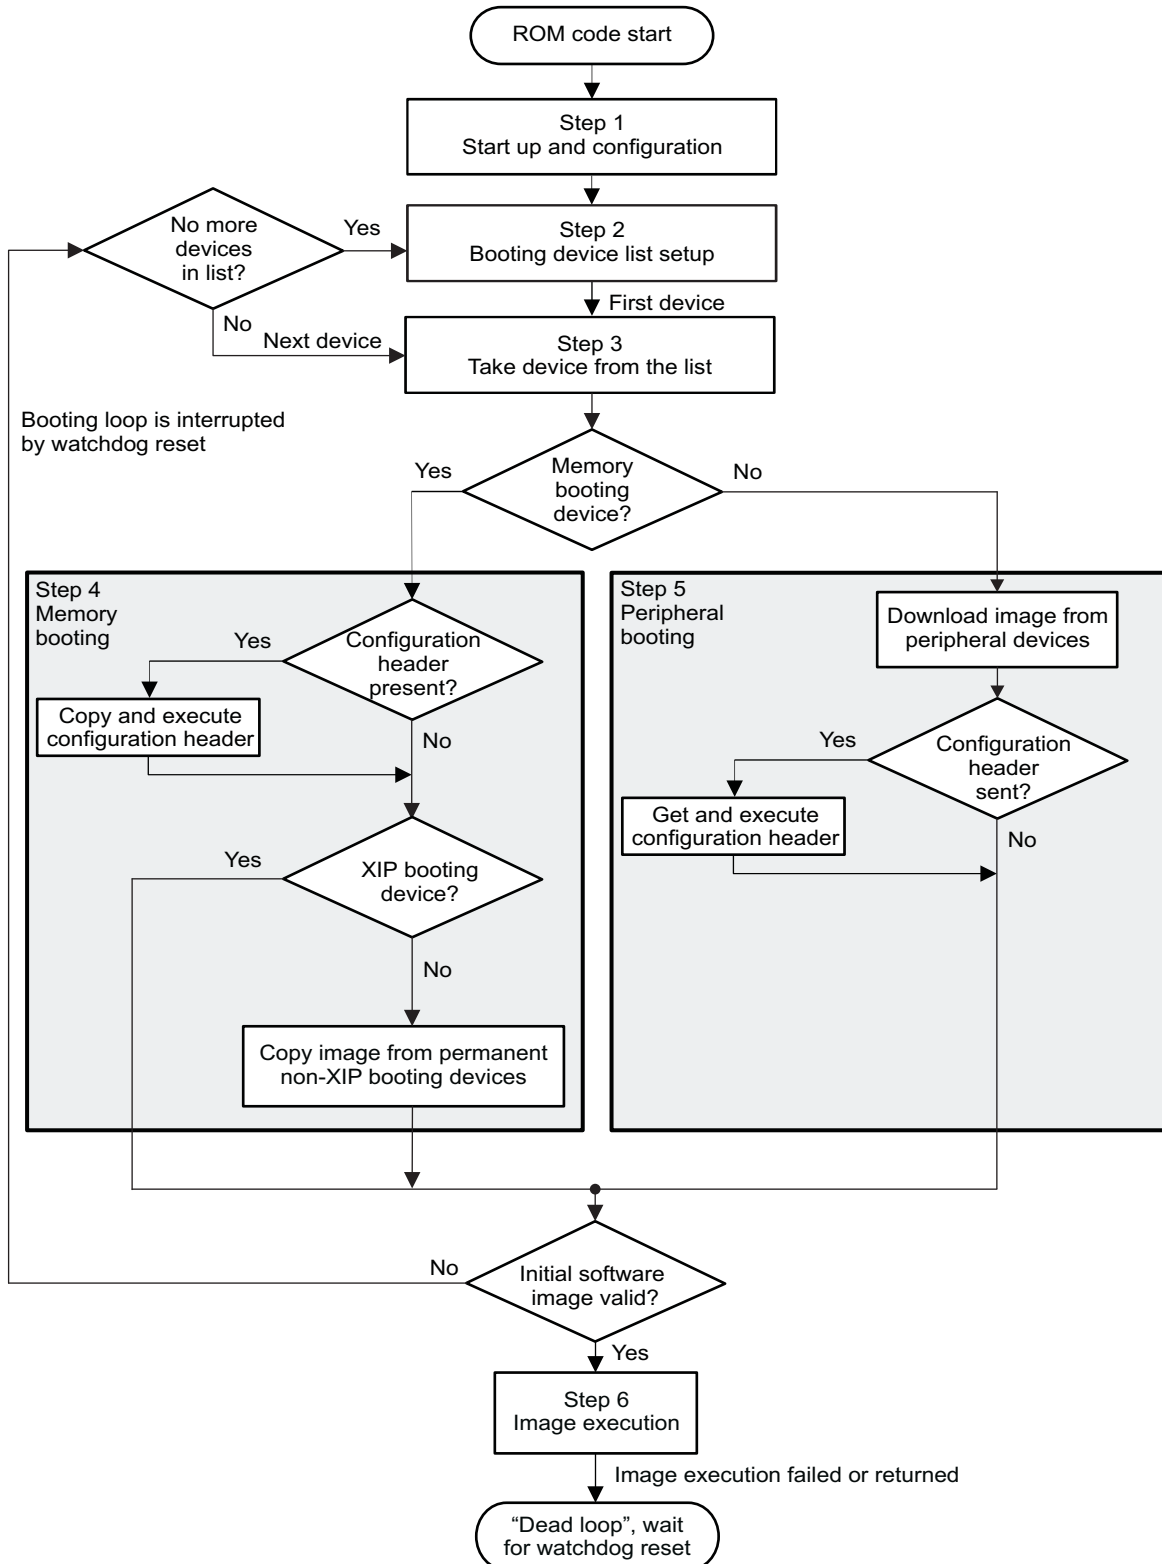

Table 25-13. AMMU Mapping

Module	Physical Address	Virtual Address	Mapped Size	Note
IPU ROM	0x5500 0000	0x0000 0000	32 KiB	
IPU RAM	0x5502 0000	0x0002 0000	64 KiB	
OCMC RAM(L3)	0x4030 0000	0x0030 0000	512 KiB	For XIP
GPMC - Memory	0x0800 0000	0x0800 0000	32 MiB	For XIP
QSPI- Memory	0x5C00 0000	0x0400 0000	32 MiB	For XIP

25.5 Overall Booting Sequence

Figure 25-8 shows the ROM code flow chart.

Figure 25-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

- Step 1. Basic configuration and initialization. Reading of SYSBOOT pins.
- Step 2. A booting device list is created (see [Section 25.6.5, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the SYSBOOT pins.
- Step 3. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or when the watchdog expires. If an image is found, ROM code executes memory booting or peripheral booting, depending on the type of the current booting device:
 - Memory booting is executed when the booting device is XIP memory, QSPI, or SPI.
 - Peripheral booting is executed when the booting device is UART.
- Step 4. Memory booting reads data from memory-type devices. Memory booting is described in detail in [Section 25.8, Memory Booting](#).
- Step 5. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in [Section 25.7, Peripheral Booting](#).
- Step 6. For a GP device, boot image automatically starts.

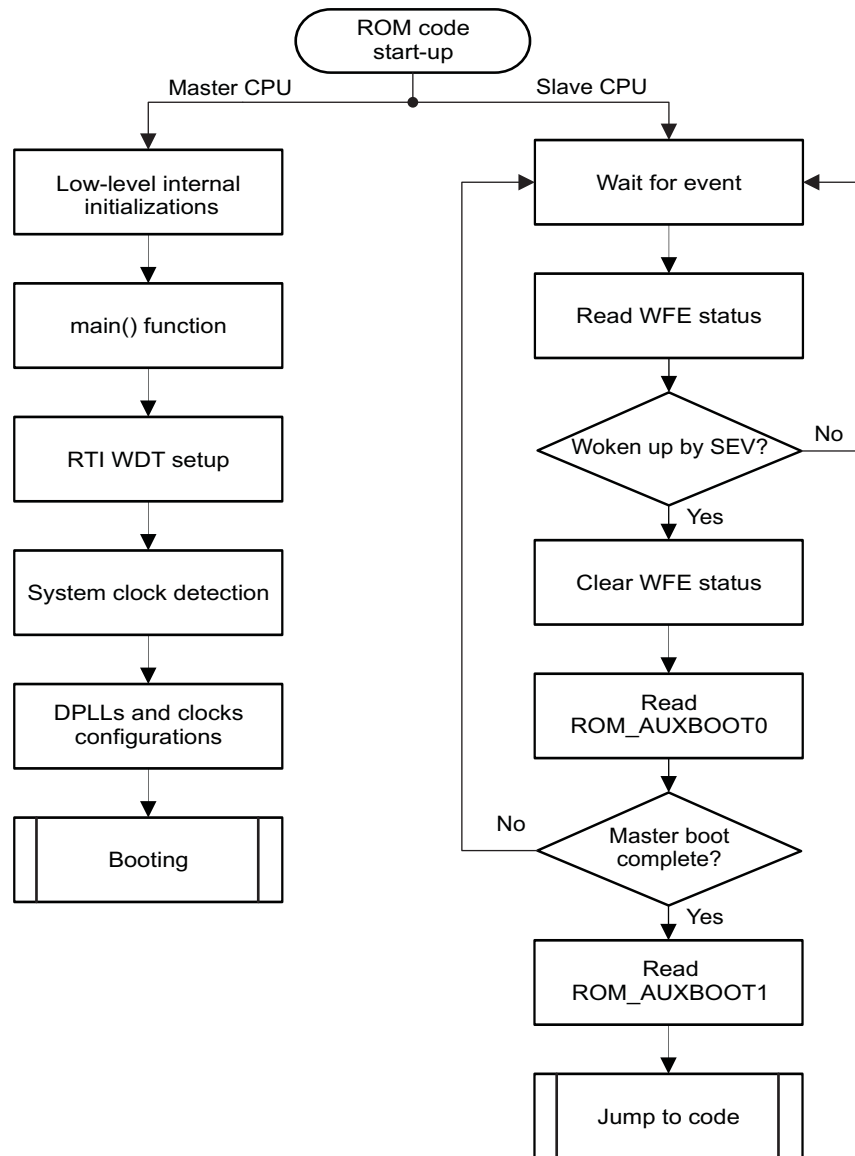

An additional feature of the booting module is the execution of the Configuration Header (CH). The CH configures the system for faster and more flexible booting from the selected permanent or peripheral booting device. The CH, which is optional, is described in [Section 25.9.2, Configuration Header](#).

25.6 Startup and Configuration

25.6.1 Startup

Figure 25-9 shows the ROM code start-up sequence.

Figure 25-9. ROM Code Multiprocessor Start-Up Sequence

init-042

The base address of the public vector is configured to the reset vector of ROM code (0x0000). The master CPU performs the basic initialization. Next, CPU configures RTI WDT (set to 3 minutes), detects system clock, and configures the system clock tree. Finally, the CPU jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset. The slave CPU is rapidly held in wait-for-event (WFE) state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The ROM_AUXBOOT0 and ROM_AUXBOOT1 registers are in the Control Module.

- ROM_AUXBOOT0 is used as a status register to signal the slave CPU that it must wake up after the

send event operation initiated by the master CPU.

- ROM_AUXBOOT1 contains the physical address location to which the slave CPU must jump after wakeup.

25.6.2 Control Module Configuration

Table 25-14 lists the Control Module registers modified at each ROM code startup. It is a Control Module requirement to be met prior to modify any of the pad control registers. These registers are not reverted back to default values (that is, to LOCK state) when ROM code completes.

Table 25-14. Control Module Registers Modified by ROM Code at Each Startup

Register	Value	Meaning
CTRL_CORE_MMR_LOCK_1	0x2FF1AC2B	Unlock Control Module registers starting at address offset 0x0000 0100 and ending at 0x0000 079F
CTRL_CORE_MMR_LOCK_2	0xF757FDC0	Unlock Control Module registers starting at address offset 0x0000 07A0 and ending at 0x0000 0D9F
CTRL_CORE_MMR_LOCK_3	0xE2BC3A6D	Unlock Control Module registers starting at address offset 0x0000 0DA0 and ending at 0x0000 0FFF
CTRL_CORE_MMR_LOCK_4	0x1EBF131D	Unlock Control Module registers starting at address offset 0x0000 1000 and ending at 0x0000 13FF
CTRL_CORE_MMR_LOCK_5	0x6F361E05	Unlock Control Module registers starting at address offset 0x0000 1400 and ending at 0x0000 1FFF

Once the booting device list is completed, the ROM code applies the pin multiplexing settings as described in Section 25.2.4.6, *Pin Multiplexing According to Boot Peripheral*.

25.6.3 PRCM Module Mode Configuration

Table 25-15 lists the PRCM module mode, clock control, and power control registers modified at each ROM code startup. These registers are not reverted back to default values when ROM code completes.

Table 25-15. PRCM Module Mode Registers Modified by ROM Code

Register	Field	Value
CM_L3INSTR_L3_INSTR_CLKCTRL	MODULEMODE	DISABLED
CM_L3INSTR_OCP_WP_NOC_CLKCTRL	MODULEMODE	DISABLED
CM_CM_CORE_PROFILING_CLKCTRL	MODULEMODE	DISABLED
CM_PRM_PROFILING_CLKCTRL	MODULEMODE	DISABLED
CM_CM_CORE_AON_PROFILING_CLKCTRL	MODULEMODE	DISABLED
CM_EMU_CLKSTCTRL	CLKTRCTRL	HW_AUTO
CM_DSP1_CLKSTCTRL	CLKTRCTRL	HW_AUTO
CM_DSP1_DSP1_CLKCTRL	MODULEMODE	DISABLED
PM_DSP1_PWRSTCTRL	POWERSTATE	OFF
CM_DSP2_CLKSTCTRL	CLKTRCTRL	HW_AUTO
CM_DSP2_DSP2_CLKCTRL	MODULEMODE	DISABLED
PM_DSP2_PWRSTCTRL	POWERSTATE	OFF

25.6.4 Clocking Configuration

The ROM code detects the system clock frequency (SYS_CLK1) from the sysboot[9:8] pin value. These pins should be set accordingly on the PCB. The supported system clock frequencies in the device are:

- 19.2 MHz
- 20 MHz

- 27 MHz

See [Section 25.2.3.2, Clocking scheme](#), and [Section 25.2.4.2, System clock speed configuration](#).

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- DPLL_PER: locked to provide clocks to peripheral blocks
- DPLL_CORE: locked to provide L3_MAIN interconnect and L4 interconnect

The DPLLs and PRCM clock dividers are configured with the default values of the ROM code (depending on the detected system input clock) after cold or warm reset in order to give the same working conditions to the ROM code sequence.

[Table 25-16](#) summarizes the default ROM code clock settings.

Table 25-16. ROM Code Default Clock Settings

Clock	Frequency (MHz)	Source
DPLL_CORE clock with F _{DPLL} locked frequency	2128	Gated SYS_CLK1
EMIF_PHY_GCLK ⁽¹⁾	44.33	DPLL_DDR (M2)
EMIF_DLL_GCLK	266	DPLL_DDR.HSDIVIDER (H11)
CORE_X2_CLK	266	DPLL_CORE.HSDIVIDER (H12)
CORE_CLK	266	CORE_X2_CLK
DSP2_CLK	212.8	DPLL_CORE.HSDIVIDER (H14)
CORE_IPU_ISS_BOOST_CLK	212.8	DPLL_CORE.HSDIVIDER (H22)
CORE_ISS_MAIN_CLK	152	DPLL_CORE.HSDIVIDER (H23)
L3_ICLK	133	CORE_CLK
L4_ICLK	66.5	L3_ICLK
DSP_DPLL_HS_CLK	266	CORE_X2_CLK
DPLL_PER – clock with F _{dpll} locked frequency	768	Gated SYS_CLK1
FUNC_192M_CLK	192	DPLL_PER (M2)
FUNC_256M_CLK	256	DPLL_PER.HSDIVIDER (H11)
DSS_GFCLK	192	DPLL_PER.HSDIVIDER (H12)
PER_QSPI_CLK	192	DPLL_PER.HSDIVIDER (H13)

⁽¹⁾ This clock is intentionally set up at low frequency to ensure correct initialization of external DRAM components.

However it is possible to override the default clock settings. There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in [Table 25-16](#). They are always applied at any reset.
- The CH, described in [Section 25.9.2, Configuration Header](#). The CH lets users have a known configuration (about GPMC and clock registers) after memory or peripheral booting.

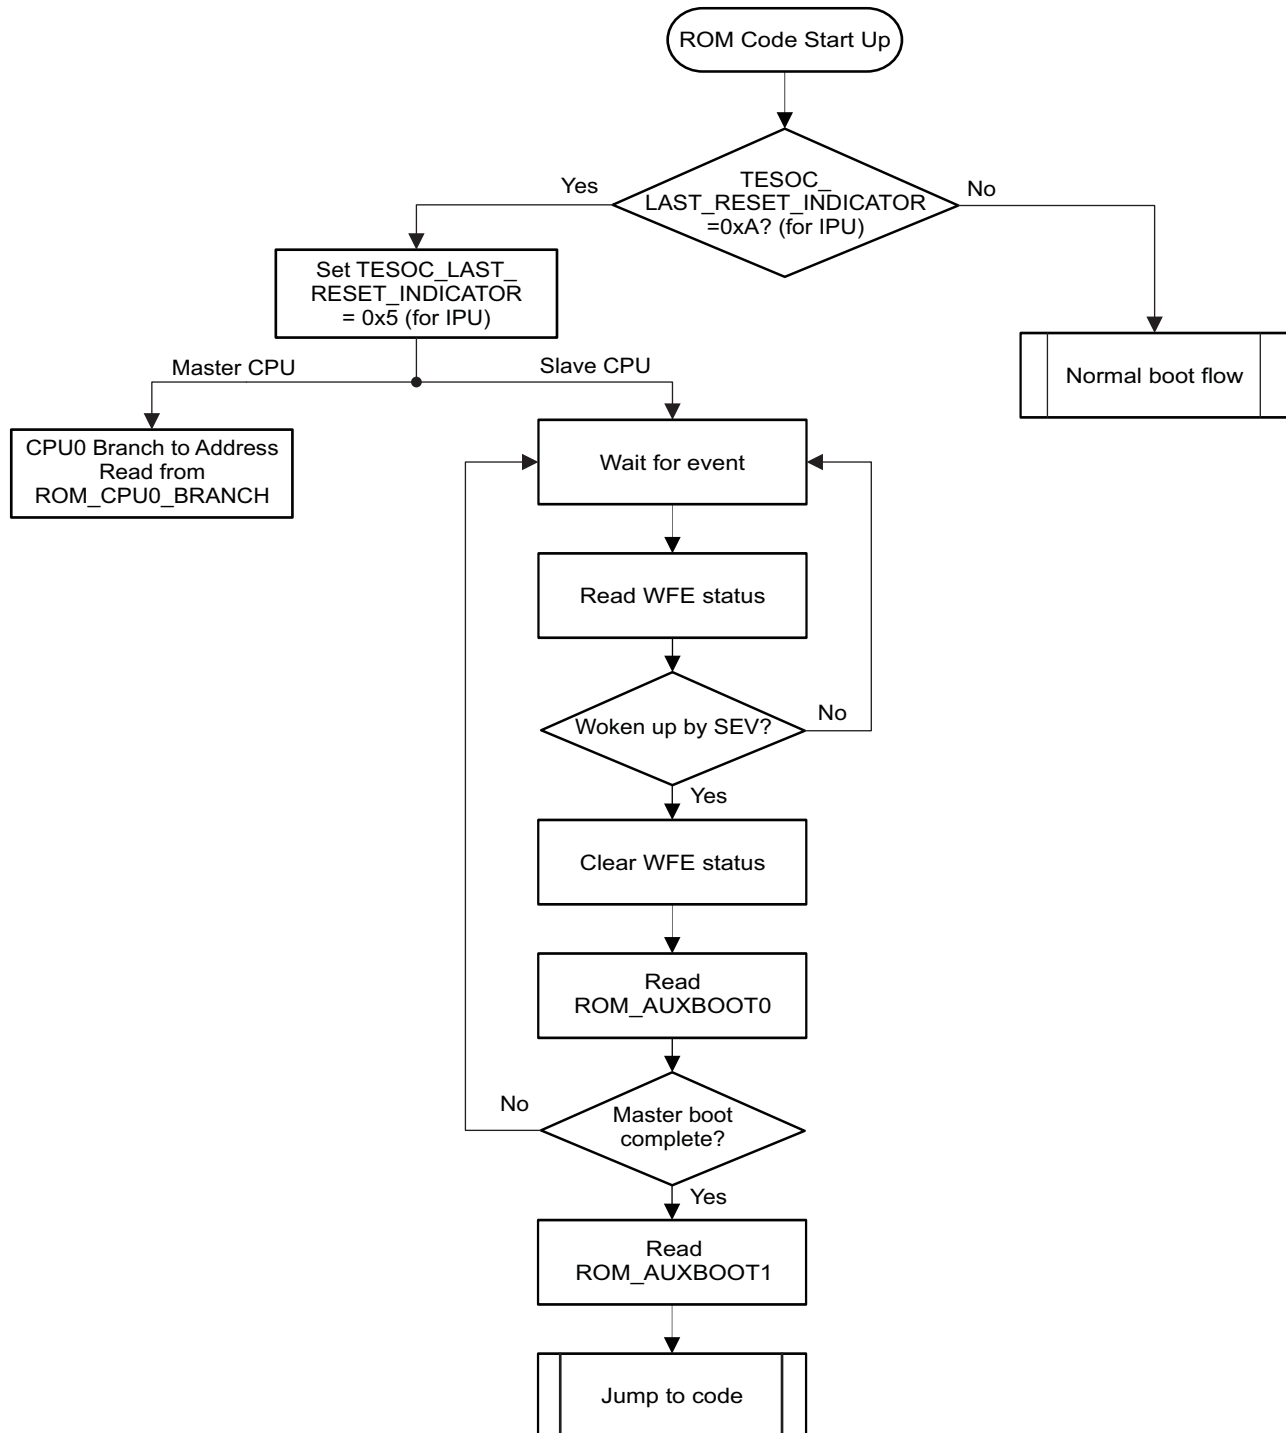

25.6.5 Booting Device List Setup

The ROM code creates a device list based on sysboot pins. The sysboot[4:0] signals latched in the control module are used to index the device table from which the list of devices is extracted. Only permanent booting devices are put to the list when the reset is not power-on and the devices are taken from the sysboot pins.

25.6.6 Warm Reset Device Selection

After a warm reset the ROM Code wakes up IPU to software wakeup registers available in Control Module (if present and valid) as shown in Figure 25-10. When the reset is a Tester-On-Chip (TESOC) reset, only partial boot is performed. Master CPU jumps to address written in the ROM_CPU0_BRANCH register. When TESOC is not the reset reason, the SYSBOOT configuration takes place and normal boot is performed.

Figure 25-10. Warm Reset Wakeup Flow

init-050

25.7 Peripheral Booting

25.7.1 Description

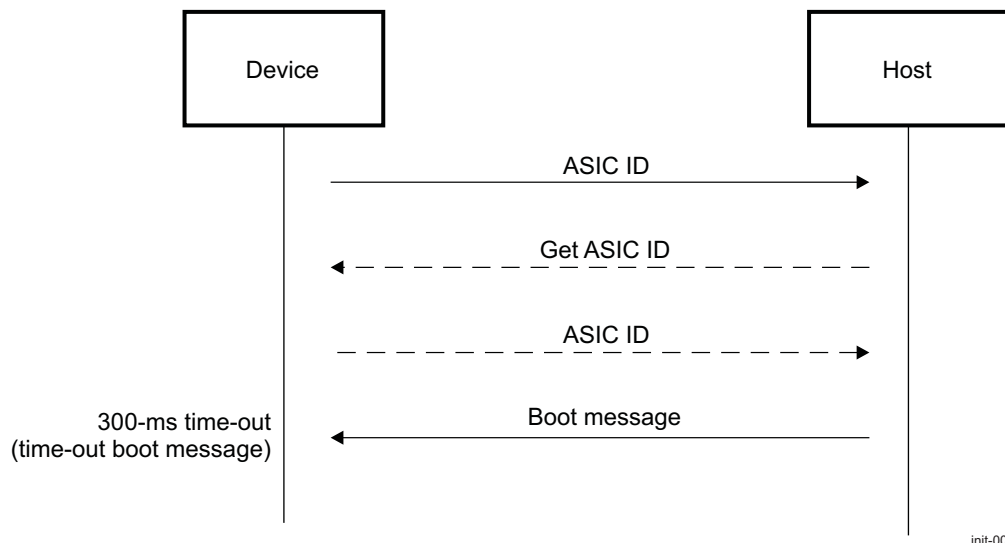

The ROM code can boot from these peripherals:

- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit, no flow control

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the device (for example, in the case of initial flashing, firmware update or servicing). Figure 25-12 shows the overall peripheral booting procedure. It consists of a synchronization phase (handshake between the host and the device) and a transfer phase.

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. Figure 25-11 shows this procedure.

Figure 25-11. Synchronization Phase for UART

During the synchronization phase (see Figure 25-11), the device can provide a small packet of data called the ASIC ID (described in Table 25-17). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The host can decide the desired operation by providing a booting message (see Table 25-20). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting procedure aborts. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, then the image can be executed.

The flash loader image is downloaded directly into internal RAM from address 0x4030 0000 and the maximum size of the downloaded image is 504 KiB.

NOTE: Sending an image size of zero skips the peripheral booting procedure.

The UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can reuse the currently established connection.

Table 25-17. ASIC ID Structure

ASIC ID Item	Size (Bytes)	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved subblock	4	This subblock is transmitted, but does not contain useful information in case of GP device
Reserved subblock	23	This subblock is transmitted, but does not contain useful information in case of GP device
Reserved subblock	35	This subblock is transmitted, but does not contain useful information in case of GP device

Table 25-18. Items

Offset	Size (Bytes)	Description
0x00	1	0x04: Number of subblocks (UART boot)

Table 25-19. ID Subblock

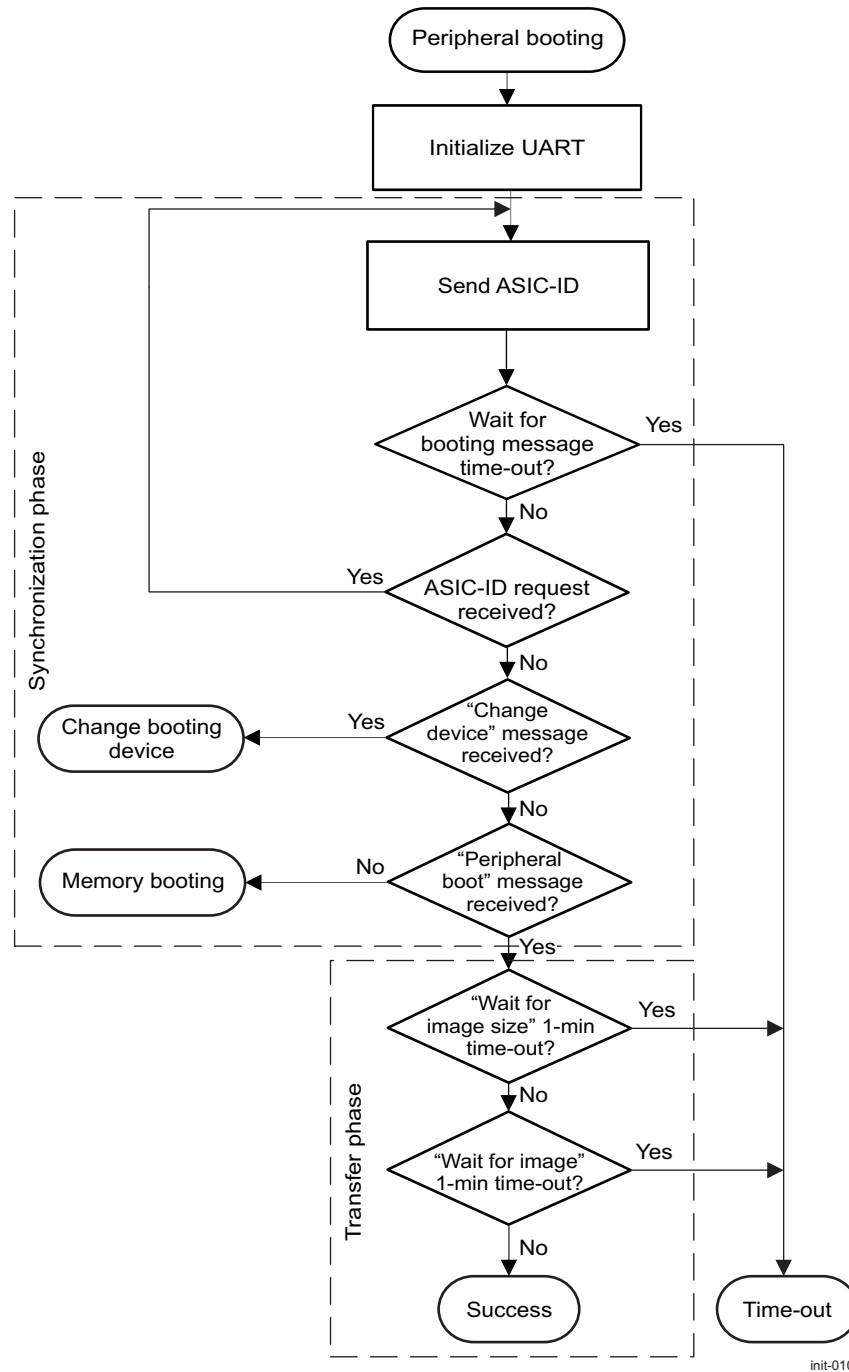

Offset	Size (Bytes)	Description
0x01	1	0x01: Subblock ID
0x02	1	0x05: Subblock size
0x03	1	0x01: Fixed value
0x04	2	Device ID number
0x06	1	0x07: CH enabled 0x17: CH disabled
0x07	1	ROM code revision 0x01: SR1.0 0x02: SR2.0

Table 25-20. Booting Messages

Message Name	Value	Description
Peripheral boot	0xF003 0002	Continue peripheral booting.
Get ASIC ID	0xF003 0003	ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. Table 25-17 describes the structure of the ASIC ID.
Change device	0xF003 xx06	Skip current peripheral booting and continue booting from device type indicated by xx: 0x01: XIP 0x02: XIP (with wait monitoring) 0x0A: QSPI_1 0x0B: QSPI_4 0x0C: QSPI_4(XIP) 0x43: UART Others: Reserved
Next device	0xFFFF FFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

Figure 25-12 shows the peripheral booting procedure.

Figure 25-12. Peripheral Booting Procedure

25.7.2 Initialization Phase for UART Boot

The ROM code supports booting from a UART interface with the following characteristics:

- UART3 interface
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit, no flow control
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

25.8 Memory Booting

25.8.1 Overview

The memory booting process starts an external code in memory devices. ROM code can use only the memory type of booting devices as permanent booting devices (that is, devices examined after both cold [POR] and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices (or other XIP devices) on GPMC
- SPI/QSPI flash memories

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

[Figure 25-13](#) shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the device can temporarily lose a connection with XIP memory during CH execution (for example, while updating interface timings). The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

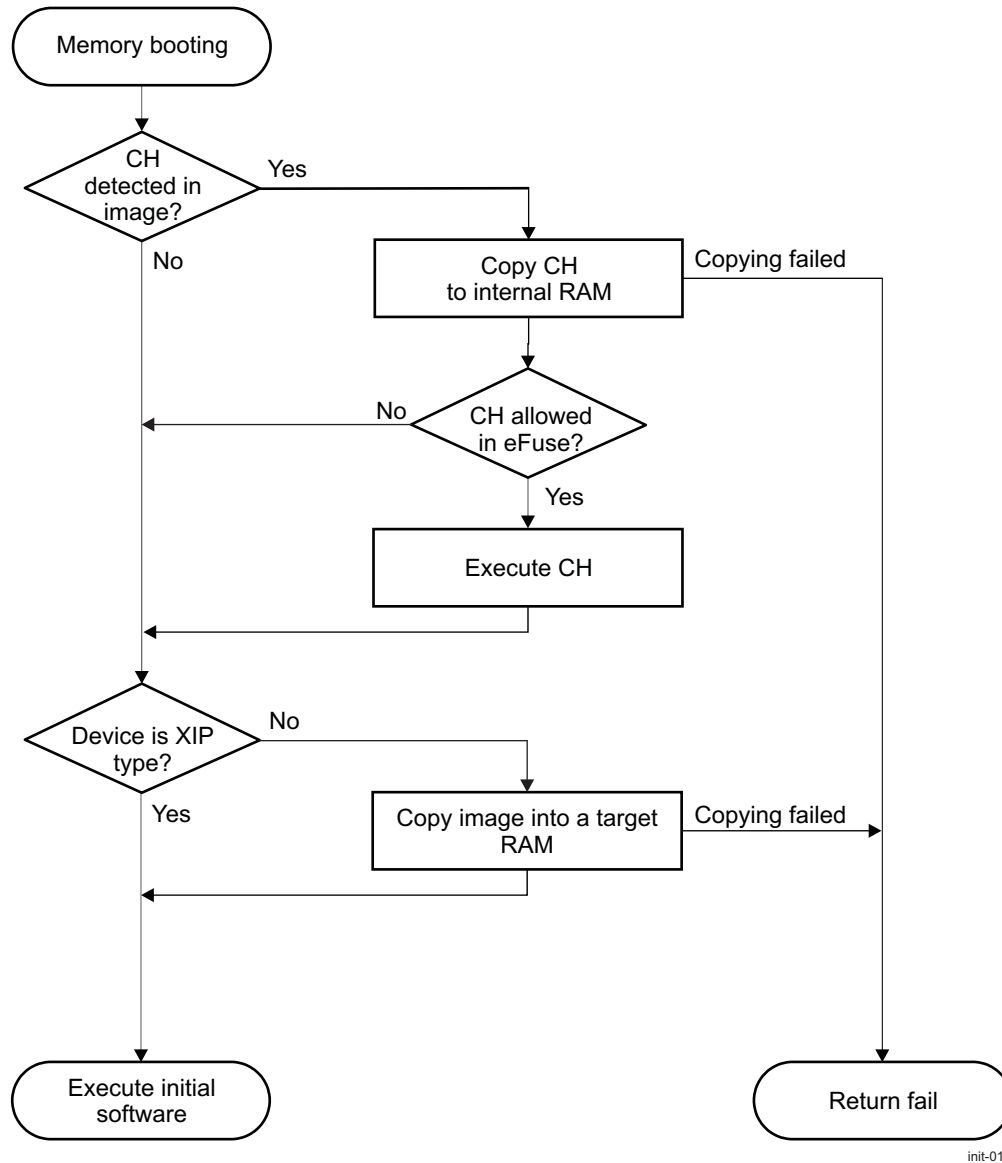

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

NOTE: A booting image is considered to be present on a GP device, when the first 4-byte word of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector (512 bytes) call, sectors are copied to a temporary device on-chip SRAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target device on-chip SRAM location so it is required to reread the first image sector. For a GP device, the GP header is not copied into target buffer location; therefore, only executable code is in device on-chip RAM, with the first executable instruction at the destination address.

SPI/QSPI devices can hold up to two copies of the booting image. Therefore, the ROM code searches for one valid image, if present, by walking over the first blocks of mass storage space.

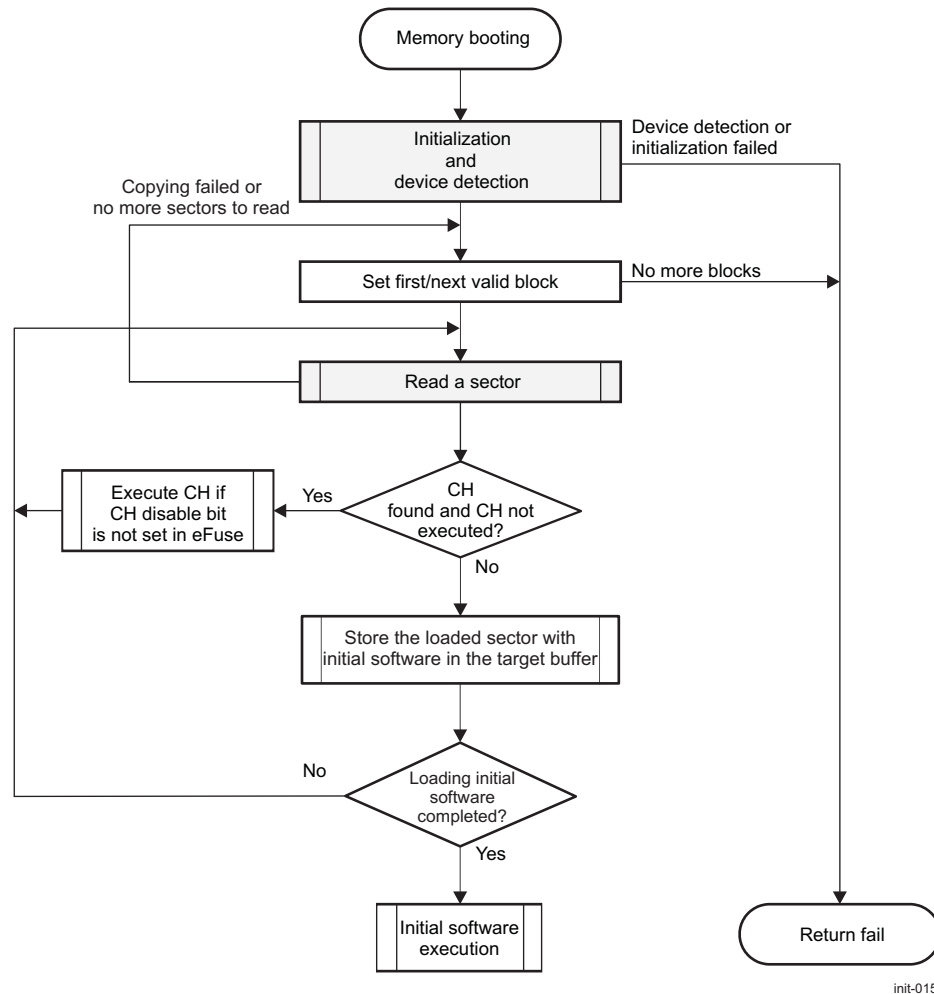

Figure 25-13. Memory Booting Procedure

25.8.2 Non-XIP Memory

Figure 25-14 shows the procedure used when memory booting runs with non-XIP memories. The shaded procedures are specific to each memory. The ROM code searches for the image in the first two physical blocks of the memories. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 25-14. Image Shadowing on GP Device

init-015

For more information about the GPMC module, see [Section 11.3, General-Purpose Memory Controller](#). The following sections describe the supported device types.

25.8.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1Gibit (128MiB) can be connected.
- 8-bit or 16-bit data bus width, configured through sysboot[13] (=1 for 16-bit)
- Non-muxed or address/data multiplexed mode, configured through sysboot[12:11] (=0x1 for A/D mux)
- The GPMC clock is 133 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin gpmc_wait0 signal is monitored according to the sysboot[10] configuration pin (=1 is enabled)
- For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

Bootting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If the CH is present, copy the entire sector (512 bytes) to internal RAM and execute the CH.
3. Set the image location:
 - 0x0800 0000 if the CH is not found
 - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. If the image is found, execute it.
6. If the image is not found, return from XIP booting to the main booting loop.

25.8.3.1 GPMC Initialization

Table 25-21 lists the timing settings of the GPMC when set for XIP and other address-data accessible devices. Table 25-21 is included for debug information.

Table 25-21. XIP Timing Parameters

Parameter	Value (Clock Cycles) ⁽¹⁾	Register Initialized (where i = 0)
Write cycle period	17	GPMC_CONFIG5_i[12:8] WRCYCLETIME
Read cycle period	17	GPMC_CONFIG5_i[4:0] RDCYCLETIME
CS low time	1	GPMC_CONFIG2_i[3:0] CSONTIME
CS high time	16	GPMC_CONFIG2_i[12:8] CSRDOFFTIME
ADV low time	1	GPMC_CONFIG3_i[3:0] ADVONTIME
ADV high time	2	GPMC_CONFIG3_i[12:8] ADVRDOFFTIME
OE low time	3	GPMC_CONFIG4_i[3:0] OEONTIME
OE high time	16	GPMC_CONFIG4_i[12:8] OEOFFTIME
WE low time	3	GPMC_CONFIG4_i[19:16] WEONTIME
WE high time	15	GPMC_CONFIG4_i[28:24] WEOFFTIME
Data latch time	15	GPMC_CONFIG5_i[20:16] RDACCESSTIME

⁽¹⁾ The one clock cycle is approximately 7.5 ns, which corresponds to a 133-MHz frequency.

There is no specific identification routine executed before booting from an XIP device.

25.8.4 SPI/QSPI Flash Devices

SPI/QSPI Flash memories provide a storage solution for systems with limited space, pins and power.

The ROM code support for SPI/QSPI devices has the following characteristics:

- 24-bit addressing, up to 128 Mbit (16 MiB), no banking
- QSPI1 on CS0 is the communication interface
- Uses Mode 3:
 - Clock inactive state = high
 - Data input captured on rising edge of clock
 - Data output generated on falling edge of clock
- QSPI 4-bit data read mode at 48 MHz in configuration port mode
 - Read command is 0x6B (Fast Quad Read), 3 address bytes, 1 dummy bytes and read type is quad read
 - ROM will not perform any quad-enable sequence nor bank register update
- SPI 1-bit data read mode at 12 MHz in configuration port mode
 - Read command is 0x03 (Single Read), 3 address bytes, 0 dummy bytes and read type is normal read.

- Up to two redundant images can be stored in SPI/QSPI. The offset between them must be 256 KiB.

A booting image is considered to be present on a GP device, when the first 4-bytes word is not equal to 0000 0000h or FFFF FFFFh.

NOTE: ROM code does not perform any specific action to detect, reset or power up the QSPI device. QSPI is assumed to be properly powered and reset to be completed before every attempt to boot by ROM code.

25.9 Image Format

25.9.1 Overview

An image has two major parts:

- An optional Configuration Header (CH)
- Software to execute

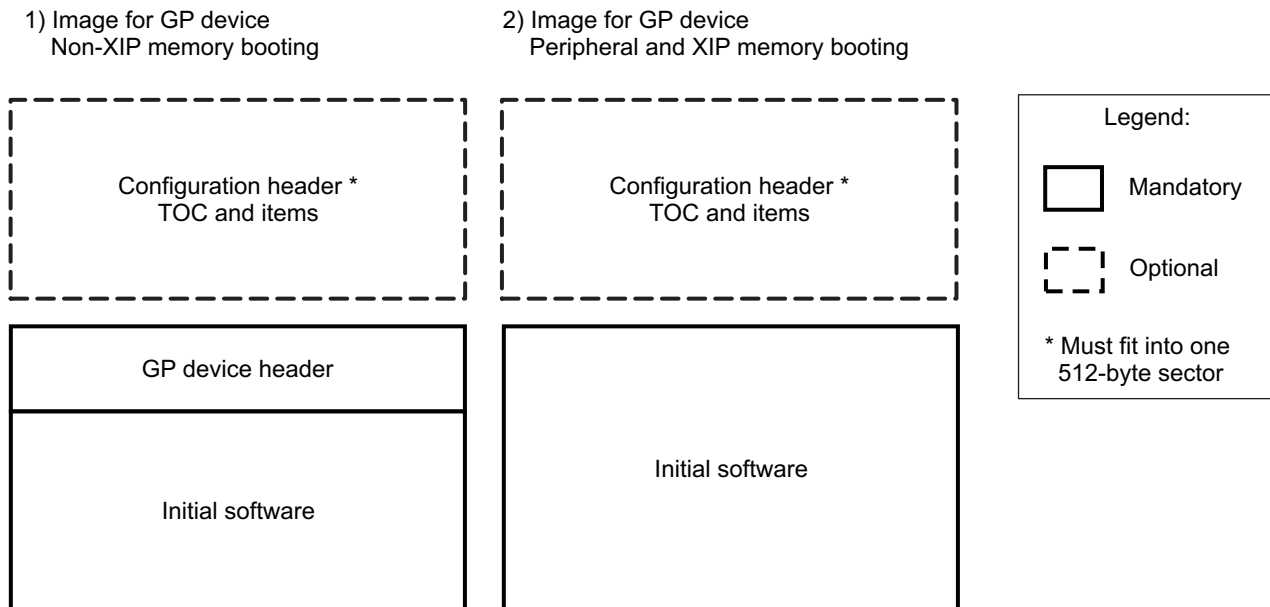

The CH can contain several parameters set by users to speed up booting. It is further described in [Section 25.9.2, Configuration Header](#).

The second part contains the software that is loaded into the memory and executed.

[Figure 25-15](#) is an overview of the boot image formats. There are two image types:

1. GP non-XIP memory booting: This image type is used for memories that require shadowing (for example, SPI). A GP image for non-XIP memory may not contain a CH and start straight from the GP header. Next, there must be a small header (referred to as a GP header) that contains information about the size and the destination address.
2. When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

Figure 25-15. Image Formats

init-018

25.9.2 Configuration Header

The ROM code default settings (such as clock frequencies, GPMC, or QSPI interfaces) can be tuned by the user by using the CH.

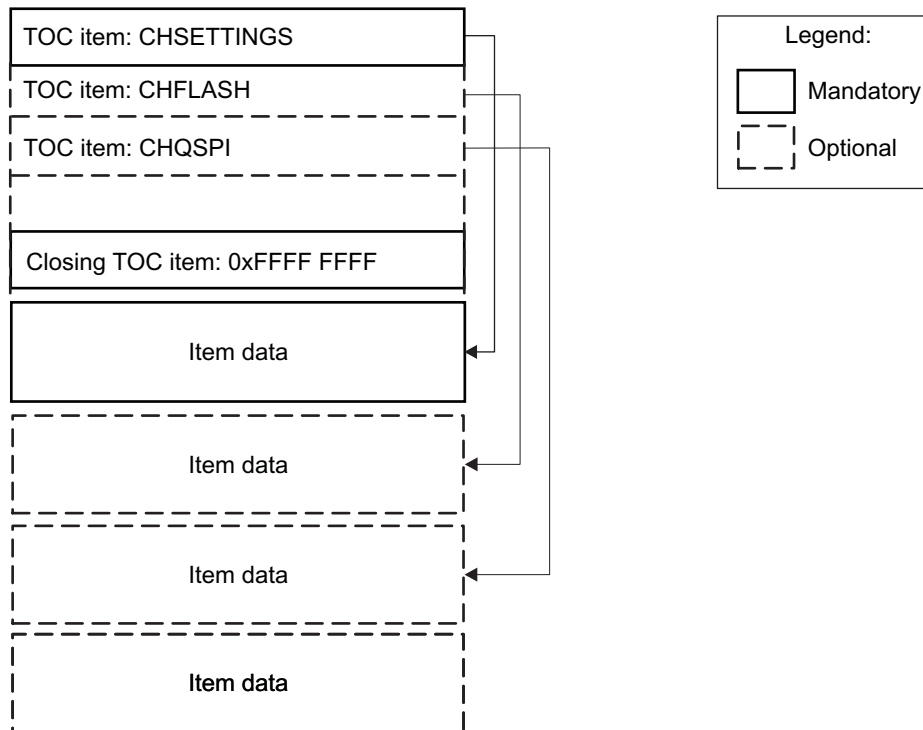

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- FLASH: Flash interface (GPMC) settings
- QSPI: QSPI interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in [Figure 25-16](#). Each TOC item is a simple structure described in [Table 25-22](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHFLASH, etc.). Next, the TOC is identified and searched until a 0xFFFF FFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

Figure 25-16. CH Format

init-019

Table 25-22. CH TOC Item

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of the TOC to the actual address of item contents
0x0004	Size	4	Size of item
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	TOC Filename	12	12-character name of a TOC item, including the NULL termination character. That is, this is an array where first byte accomodates the first character.

The ROM Code recognizes sections pointed to by the TOC based on the filename as described in [Table 25-23](#)

- The X-LOADER, 2ND, or ULO section contains the Initial Software
- Optionally, TOC may contain CH sections. The CHSETTINGS is a mandatory section of CH and is used to recognize CH presence.

Table 25-23. TOC Filenames

Filename	Item Type	Usage	Description
ULO	Initial Software	UART Peripheral Booting	"UART LOader"
2ND	Initial Software	UART Peripheral Booting	"Secondary Loader"
X-LOADER	Initial Software	Other devices	"eXternal LOADER"
CHSETTINGS	Configuration Header	Memory and Peripheral Booting	Configuration Header General Setting Item
CHFLASH	Configuration Header	Memory and Peripheral Booting	Configuration Header GPMC Item
CHQSPI	Configuration Header	Memory and Peripheral Booting	Configuration Header QSPI Item

25.9.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the device clocking to some default settings as described in [Section 25.6.4, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

[Table 25-24](#) describes the fields. The clocking setting structure are described in [Table 25-25, Clocking Settings](#).

Table 25-24. CHSETTINGS Item

Offset	Field	Description
0000h	Section key	Key used for item verification: C0C0C0C1h

25.9.2.3 CHQSPI Item

The CHQSPI configuration header contains settings specific to the QSPI interface controller. For more information, see [Section 19.4, Quad Serial Peripheral Interface](#). [Table 25-27](#) describes the fields.

Table 25-27. CHQSPI Item

Offset	Register Field Modified	Description
0000h	Section key	Key used for section verification C0C0C0C6h
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	SPI Clock	SPI clock rate: 0x01: 64 MHz 0x03: 32 MHz 0x07: 16 MHz 0x13: 48 MHz 0x17: 24 MHz 0x1F: 12 MHz All others: reserved
0009h	RCMD	Read command
000Ah	READ_TYPE	Determines if the read command is a single, dual or quad read mode command
000Bh	NUM_A_BYTES	Number of address bytes to be sent
000Ch	NUM_D_BYTES	Number of dummy bytes to be used for fast read

25.9.3 GP Header

When the booting memory device is non-XIP (for example, SPI) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. [Table 25-28](#) describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 25-28. GP Header Image Format

Field	Non-XIP Device Offset	XIP Device Offset	Size (Bytes)	Description
Size	0x0000	–	4	Size of the image (including GP header)
Destination	0x0004	–	4	Address where to store the code or code entry point
Image Code	0x0008	0x0000	x	Executable code

NOTE: The Destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

25.9.4 Image Execution

The image is executed when the ROM code performs the branch to the first executable instruction in the initial software. For a GP device in non-XIP, the execution address is the first word after the GP header. The branch is performed in public Arm supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. [Table 25-29](#) shows the booting parameter structure.

Table 25-29. Booting Parameter Structure

Offset	Field	Size (Bytes)	Description
0x00	Booting message	4	Last received booting message
0x04	Memory booting device descriptor	4	Pointer to the memory device descriptor that has been used during the memory booting process
0x08	Current booting device	1	Code of device used for booting: 0x01: XIP 0x02: XIP (with wait monitoring) 0x0A: QSPI_1 0x0B: QSPI_4 0x0C: QSPI_4(XIP) 0x43: UART Others: Reserved
0x09	Reset reason	1	Current reset reason bit mask (bit = 1, event present): direct copy from lower byte of PRM_RSTST (more bits exist in PRM_RSTST): [0]: Power-on (cold) reset [1]: Global software warm reset [2]: Reserved [3]: MPU watchdog reset [RESERVED] [4]: Reserved [5]: External warm reset

Table 25-29. Booting Parameter Structure (continued)

Offset	Field	Size (Bytes)	Description
			[6]: Reserved [7]: Reserved
0x0A	CH flags	1	Configuration header items flag. Each item is described by 1 bit. A set bit indicates that the item was executed: [0]: CHSETTINGS [2]: CHFLASH [4]: CHQSPI Other bits: Reserved

25.10 Tracing

Tracing in the public ROM code consists in 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. [Table 25-30](#) through [Table 25-32](#) list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors ([Table 25-12](#), *Tracing Data*). The first set is the current trace information (after a cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after a cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during a cold reset.

[Table 25-30](#) lists the organization of tracing vector 1.

Table 25-30. Tracing Vector 1

Bit	Group	Meaning
0	Boot	Passed the reset vector
1	Boot	Entered main function
2	Boot	Running after the cold reset
3	Boot	Main booting routine entered
4	Memory boot	Memory booting started
5	Peripheral boot	Peripheral booting started

26.1 Introduction

Debugging a system that contains an embedded processor involves an environment that connects high-level debugging software running on a host computer to a low-level debug interface supported by the target device. Between these levels, a debug and trace controller (DTC) facilitates communication between the host debugger and the debug support logic on the target chip.

The DTC is a combination of hardware and software that connects the host debugger to the target system. The DTC uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG® commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

For easy integration into applications, a set of application-programming interfaces (APIs) for debug-IP programming and a software message library are provided. CToolsLib is a library of embedded target APIs to enable easy programmatic access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

<http://processors.wiki.ti.com/index.php/CToolsLib>

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

NOTE: TI also provides a Register Descriptor Tool (RDT). The RDT is a Java™- based stand-alone application. It is an interactive device register database configuration software. It allows the user to:

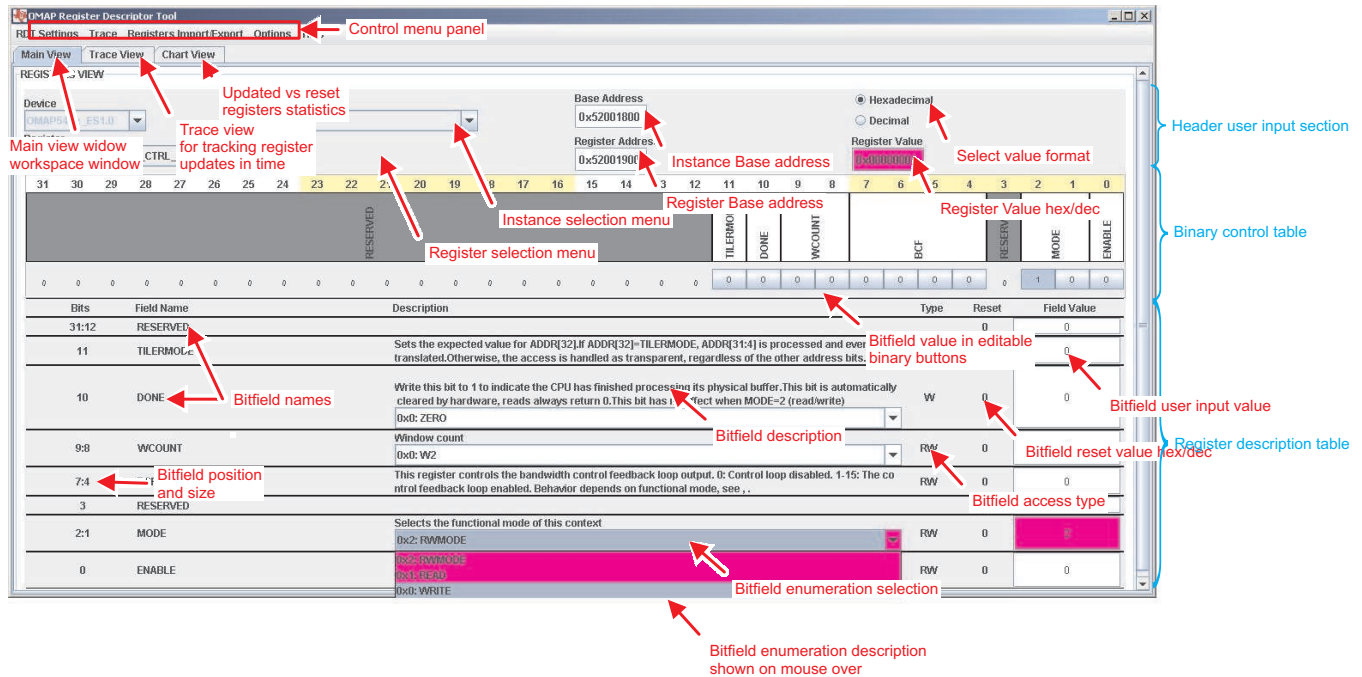

- Visualize device register settings
- Manipulate device registers easily
- Read in complete device configurations from various file formats into registers easily
- Dump out complete device configurations to various file formats
- Trace the register changes in time and during debugging
- See, understand, and work with device IPs, Instances, Registers, Bitfields, descriptions, and so on
- Extract and read in registers and register dumps for Code Composer Studio, and Lauterbach

The advantage of the tool is that the user can visualize the register state on power-on reset and then customize the configuration of the device for the specific use-case and identify the device register settings associated to that configuration.

Being an interactive visual tool, the RDT gives the user a global view of the device setting architecture and allows determining the exact register settings to obtain the specific configuration.

[Figure 26-1](#) is a screenshot diagram of the RDT.

Figure 26-1. Register Descriptor Tool (RDT)

26.1.1 Key Features

The device deploys Texas Instrument's CTools debug technology for on-chip debug and trace support. It provides the following features:

- External debug interfaces:
 - Primary debug interface - IEEE1149.1 (JTAG)
 - Used for debugger connection
 - Controls ICEPick™ (generic test access port [TAP] for dynamic TAP insertion) to allow the debugger to access several debug resources through its secondary (output) JTAG ports (for more information, see [Section 26.3.3.1, ICEPick Secondary TAPs](#)).
 - For more information about IEEE1149.1, see [Section 26.2.1, IEEE1149.1](#).
 - Debug (trace) port
 - Can be used to export processor or system trace off-chip (to an external trace receiver)
 - Can be used for cross-triggering with an external device
 - Configured through debug resources manager (DRM) module instantiated in the debug subsystem
 - For more information about debug (trace) port, see [Section 26.2.2, Debug \(Trace\) Port](#), and [Section 26.10, Concurrent Debug Modes](#).
- JTAG based processor debug on:
 - C66x in DSP1, DSP2
 - Cortex-M4 (x2) in IPU
 - ARP32 in EVE
- Dynamic TAP insertion
 - Controlled by ICEPick
 - For more information, see [Section 26.3.3, Dynamic TAP Insertion](#).
- Power and clock management
 - Debugger can get the status of the power domain associated to each TAP.

- Debugger may prevent the application software switching off the power domain.
- Application power management behavior can be preserved during debug across power transitions.
- For more information, see [Section 26.6.1](#), *Power and Clock Management*.
- Reset management
 - Debugger can configure ICEPick to assert, block, or extend the reset of a given subsystem.
 - For more information, see [Section 26.6.2](#), *Reset Management*.
- Cross-triggering
 - Provides a way to propagate debug (trigger) events from one processor, subsystem, or module to another:
 - Subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device.
 - Subsystem B can be programmed to be sensitive to the trigger line input and to generate an action on trigger detection.
 - Two global trigger lines are implemented
 - Device-level cross-triggering is handled by the XTRIG (TI cross-trigger) module implemented in the debug subsystem
 - For more information about cross-triggering, see [Section 26.4.2](#), *Cross-Triggering*.
- Suspend
 - Provides a way to stop a closely coupled hardware process running on a peripheral module when the host processor enters debug state
 - For more information about suspend, see [Section 26.4.3](#), *Suspend*.
- Processor trace
 - C66x (DSP) processor trace is supported
 - Two exclusive trace sinks:
 - CoreSight Trace Port Interface Unit (CS_TPIU) – trace export to an external trace receiver
 - CTools Trace Buffer Router (CT_TBR) in buffer mode – trace history store into on-chip trace buffer
 - For more information, see [Section 26.8](#), *Processor Trace*.
- System instrumentation (trace)
 - Supported by a CTools System Trace Module (CT_STM), implementing MIPI System Trace Protocol (STP) (rev 2.0)
 - Real-time software trace
 - System-on-chip (SoC) software instrumentation through CT_STM (STP2.0)
 - OCP watchpoint (OCP_WP_NOC)
 - OCP target traffic monitoring: OCP_WP_NOC can be configured to generate a trigger upon watchpoint match (that is, when target transaction attributes match the user-defined attributes).
 - SoC events trace
 - DMA transfer profiling
 - Statistics collector (performance probes)
 - Computes traffic statistics within a user-defined window and periodically reports to the user through the CT_STM interface
 - Embedded in the L3_MAIN interconnect
 - 10 instances:
 - 1 instance dedicated to target (SDRAM) load monitoring
 - 9 instances dedicated to master latency monitoring
 - EVE instrumentation
 - Supported through a software message and system trace event (SMSET) module embedded in the EVE subsystem

- ISS instrumentation
 - Supported through system trace event (CTSET) module embedded in the ISS subsystem
- Power-management events profiling (PM instrumentation [PMI])
 - Monitoring major power-management events. The PM state changes are handled as generic events and encapsulated in STP messages.
- Clock-management events profiling (CM instrumentation [CMI]) for CM_CORE_AON clocks
 - Monitoring major clock management events. The CM state changes are handled as generic events and encapsulated in STP messages.
 - One instance:
 - CM1 Instrumentation (CMI1) module mapped in the PD_CORE_AON power domain
- For more information, see [Section 26.9](#), *System Instrumentation*.
- Performance monitoring
 - Supported by subsystem counter timer module (SCTM) for IPU
 - For more information, see [Section 26.7](#), *Performance Monitoring*.

26.2 Debug Interfaces

26.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- Two EMU [1:0] TI extensions

[Table 26-1](#) describes the IEEE1149.1 signals.

Table 26-1. IEEE1149.1 Signals

Device Pad Name	Internal Signal Name	Type ⁽¹⁾	Function	Description
trstn	nTRST	I	Test reset	When asserted (active low), resets all test and debug logic in the device along with the IEEE1149.1 interface.
tclk	TCK	I	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is either a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring.
rtck	RTCK	O	Returned (synchronized) test clock	Depending on the DTC attached to the device, the JTAG signals are either clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK.
tms	TMS	I/O	Test mode select input	Directs the next state of the IEEE1149.1 TAP state-machine.
tdi	TDI	I	Test data input	Scans data input to the device.
tdo	TDO	O	Test data output	Scans data output by the device.
emu0	EMU0	I/O	Emulation 0	Channel 0 trigger or boot mode or trace port.
emu1	EMU1	I/O	Emulation 1	Channel 1 trigger or boot mode or trace port.

(1) I = Input; O = Output; I/O = bidirectional

NOTE: For more information about device pads pull type resistors, see the device Data Manual, Section Signal Descriptions in Chapter Terminal Configuration and Functions.

NOTE: The device JTAG ID code can be accessed through ICEPick. For information about the JTAG ID code value, see [Chapter 1, Introduction](#).

26.2.2 Debug (Trace) Port

On-chip debug and trace events can be exported to external equipment through the debug (trace) port of the device. The following exportable debug events and trace sources are supported:

- Debug events
 - Triggers. For more information about triggers, see [Section 26.4.2, Cross-Triggering](#).
- Trace sources
 - Processor trace: C66x DSP trace is supported. For more information about the processor trace, see [Section 26.8, Processor Trace](#).
 - System trace: Trace coming from various system instrumentation modules, and supported by the CT_STM module. For more information about the system trace, see [Section 26.9, System Instrumentation](#).

Note that not all debug and trace features can be supported concurrently because of the limited number of pins allocated to debug. Thus, multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection occur through the DRM module embedded in the debug subsystem.

[Table 26-2](#) describes the trace port signals.

Table 26-2. Trace Port Signals

Pin Name	Internal Signal Name	I/O ⁽¹⁾	Pull Type ⁽²⁾	Description
emu19	EMU19	O	PD	Emulator pin 19
emu18	EMU18	O	PD	Emulator pin 18
emu17	EMU17	O	PD	Emulator pin 17
emu16	EMU16	O	PD	Emulator pin 16
emu15	EMU15	O	PD	Emulator pin 15
emu14	EMU14	O	PD	Emulator pin 14
emu13	EMU13	O	PD	Emulator pin 13
emu12	EMU12	O	PD	Emulator pin 12
emu11	EMU11	O	PD	Emulator pin 11
emu10	EMU10	O	PD	Emulator pin 10
emu9	EMU9	O	PD	Emulator pin 9
emu8	EMU8	O	PD	Emulator pin 8
emu7	EMU7	O	PD	Emulator pin 7
emu6	EMU6	O	PD	Emulator pin 6
emu5	EMU5	O	PD	Emulator pin 5
emu4	EMU4	O	PD	Emulator pin 4
emu3	EMU3	O	PD	Emulator pin 3
emu2	EMU2	O	PD	Emulator pin 2
emu1	EMU1	I/O	PU	Emulator pin 1
emu0	EMU0	I/O	PU	Emulator pin 0

⁽¹⁾ I = Input; O = Output; I/O = bidirectional

⁽²⁾ PU = internal pullup; PD = internal pulldown

NOTE: The emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the emu[19:0] pins, the user must program the device application pin manager (Control Module) appropriately. For more information, see [Chapter 14, Control Module](#).

For more information about DRM multiplexing and concurrent debug modes, see [Section 26.10, Concurrent Debug Modes](#).

26.2.3 Trace Connector and Board Layout Considerations

Texas Instruments supports a variety of eXtended Development System (XDS) JTAG controllers with various debug capabilities beyond only JTAG support. Because this device supports the export of processor trace and system trace over the EMU pins, if you want your target to be compatible with XDS products capable of acquiring either trace types, see the following document for guidelines: *Emulation and Trace Headers* (literature number SPRU655). You can also find more information at the “XDS Target Connection Guide” TI wiki page:

http://processors.wiki.ti.com/index.php/XDS_Target_Connection_Guide

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

26.3 Debugger Connection

26.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the ICEPick module embedded in the debug subsystem.

NOTE: ICEPick version D (ICEPick-D) is used in the device.

SoC designs typically have multiple processors, each having a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
 - Serially linking up to 32 TAP controllers
 - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management (PRCM)
 - Provides the power and clock states of each domain
 - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
 - Applies system reset
 - Provides wait-in-reset (WIR) boot mode
 - Provides global and local WIR release
 - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key is properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see [Section 26.3.3, Dynamic TAP Insertion](#).

For more information about ICEPick PRCM features, see [Section 26.6, Power, Reset, and Clock Management Debug Support](#).

26.3.2 ICEPick Boot Modes

The initial configuration of ICEPick is determined by the level of the EMU0 and EMU1 pins at POR release. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins are free when POR is released.

[Table 26-3](#) summarizes the ICEPick boot modes.

Table 26-3. ICEPick Boot Modes at POR

EMU1	EMU0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + WIR mode
1	1	ICEPick	TAP only (default mode)

26.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This mode is the recommended boot mode.

26.3.2.2 Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP or non-JTAG debug cores through ICEPick are held in reset until released. Individual processors can be released from reset (local), or all processors held in the reset state can be released at the same time (global).

26.3.3 Dynamic TAP Insertion

26.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From the external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

[Table 26-4](#) lists the secondary debug TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP number shows the position of the TAP in the scan chain.

Table 26-4. ICEPick Secondary Debug TAPs Mapping

10 – 15	Reserved

26.4 Primary Debug Support

26.4.1 Processor Native Debug Support

26.4.1.1 Cortex-M4 Processor

The Cortex-M4 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watchpoint on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M4 native debug support features, see the *Cortex-M4 Technical Reference Manual*.

26.4.1.2 DSP C66x

The main components of the DSP subsystem are:

- TMS320C66x DSP core with an execution control and analysis module that uses TI's ICEMaker™ technology. The core includes the following debug capabilities:
 - Up to four hardware breakpoints and a breakpoint counter
 - Software breakpoints
 - Internally and externally generated triggers
 - Reset control
 - Emulation interrupt support
 - Modes for debugging without halting time-critical blocks of code
 - Options to protect user-selected blocks of code against debug activity
- Emulation memory access hardware. This hardware enables several methods for reading and writing memory and registers in the DSP subsystem during debugging.
- Advanced Event Triggering (AET) unit is used to generate debug actions for managing breakpoints, watchpoint, trace, timers/counters, event outputs to external logic of DSP, based on events detected by instruction and data bus comparators or by auxiliary event detectors. DSP's AET can also handle complex events with event state machine and event counters.

26.4.1.3 ARP32

The APR32 processor in the EVE subsystem offers the following debug capabilities:

- Manual halt
- Single-step execution
- Breakpoint
- Cross-triggering
- Global run

26.4.2 Cross-Triggering

The device supports a cross-triggering feature that provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, a given subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another subsystem B can be programmed to be sensitive to the trigger line input and to generate an action on trigger detection.

Examples of debug events are: Processor entering debug state, watchpoint match, and so forth.

Examples of debug actions are: Debug request generation, restart, interrupt request generation, start/stop trace, and so forth.

The device implements two global cross-triggering lines: Trigger0 and Trigger1, also referred to as EMU0 and EMU1, respectively.

Subsystem cross-triggering is consolidated at the device level by the XTRIG module, which is embedded in the debug subsystem.

NOTE: XTRIG is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

The Trigger0 and Trigger1 lines can also be configured as external triggers and contribute to cross-triggering.

26.4.2.1 SoC-Level Cross-Triggering

Device-level cross-triggering is handled by the XTRIG module. XTRIG manages two emulation triggers: Trigger0 and Trigger1. These trigger lines are shared by all the device subsystems implementing cross-triggering and are used to facilitate co-emulation.

Table 26-6 summarizes the device cross-triggering capabilities.

Table 26-6. Device Cross-Triggering

Subsystem	Module		Cortex-M4	Cortex-M4	DSP-C66x	DSP-C66x	EVE ARP32	EVE SMSET	ISS CMSET	PMI	CMI	NOC_SC	OCP_WP_NOC	EMU0/EMU1

26.4.2.2 Cross-Triggering With External Device

Based on DRM settings, the Trigger0 and Trigger1 lines may also be used as external triggers. Trigger0 is connected to the EMU0 device pin, and Trigger1 is connected to the EMU1 device pin. The user must make sure to program the DRM module in accordance with [Table 26-27](#).

26.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a closely coupled hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (IPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1 bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

26.4.3.1 Debug Aware Peripherals and Host Processors

[Table 26-7](#) lists the mapping of the device processors to the suspend control input lines.

Table 26-7. Debug Subsystem Suspend Input Lines

Suspend Input Line	Host Processor
0	DSP1
1	Reserved

26.5 Real-Time Debug

26.5.1 Real-Time Debug Events

26.5.1.1 Emulation Interrupts

A few device interrupt channels are dedicated to debug support. [Table 26-9](#) summarizes the emulation interrupt events.

Table 26-9. Emulation Interrupts

Interrupt Request	Subsystem	Source	Description
RTOS_INT	DSP	DSP ICEMaker	RTOS interrupt from analysis event
DLOG_INT			Data logging transfer complete
EMUINT2			Monitor mode debug
ICNEMUINTR	IPU	Cortex-M4 ICECrusher-CS	Debug Control & Status register; Emulation trigger
ICNCOMMRX			Debug Communication Channel
ICNCOMMTX			
ICNEMUINTR		Cortex-M4 ICECrusher-CS	Debug Control & Status register; Emulation trigger
ICNCOMMRX			Debug Communication Channel
ICNCOMMTX			
SC_ALERT	L3_MAIN	Statistics collectors	Performance monitoring alert (metric out of range)
DCC_UART_TX	DEBUGSS	CT_UART (BDX client)	Transmit empty
DCC_UART_RX			Receiver data available

26.6 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
 - Current power setting indicating whether the power domain is on or off
 - Loss of power detected since the software last checked the status
 - Current clock setting indicating whether the clock domain is on or off
 - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
 - Subsystem reset state
 - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

26.6.1 Power and Clock Management

26.6.1.1 Power and Clock Control Override From Debugger

The debugger can override the application software power and clock management settings through the ICEPick module. It can configure ICEPick to force a domain active or prevent it from going to sleep once it is active. This can be achieved through the following debugger directives:

- FORCEACTIVE
- INHIBITSLEEP

26.6.1.1.1 Debugger Directives

26.6.1.1.1.1 FORCEACTIVE Debugger Directive

To ensure that the subsystem debug registers can always be accessed, regardless of the application power-management scenarios, a FORCEACTIVE directive can be issued through the debugger along the entire debug session. From an application standpoint, the system state, status, and timing are preserved, but the subsystem power domain is never shut down. Therefore, the emulation setup is preserved across power transitions, regardless of where the debug hardware is implemented.

If the debugger connects and the subsystem were previously powered down, a FORCEACTIVE directive wakes up the system and allows the debugger to take control of the system.

26.6.1.1.1.2 INHIBITSLEEP Debugger Directive

The debugger can use the INHIBITSLEEP directive to keep a subsystem powered and clocked, even if the applicative settings request that this subsystem go to sleep. Contrary to the FORCEACTIVE directive, the INHIBITSLEEP command does not wake up a subsystem that is already powered down by the application.

The typical use of the INHIBITSLEEP directive is to prevent power and clock transitions on the subsystem during a debug session. In this situation, when the applicative scenario initiates a transition, the transition does not take place, but from an applicative point of view the subsystem is not accessible.

26.6.1.1.2 Intrusive Debug Model

The use of debugger directives is intrusive from the standpoint of the power and clock controls, because they affect the power-management behavior of the application.

26.6.1.2 Debug Across Power Transition

26.6.1.2.1 Nonintrusive Debug Model

To preserve the power-management behavior of the device and allow the subsystem power and clock to be switched off by application software, the subsystem TAP must be disconnected from the ICEPick scan chain. The subsystem is then completely ignored by the debugger and the host-to-target communication is no longer affected by the state of the subsystem power and clocks. The debugger can still be informed that the disconnected subsystem entered the debug state by polling the Debug Attention status bit from ICEPick. The debugger can then insert the TAP, take control of the subsystem power and clock, and examine the system state.

This debug model is nonintrusive, because it allows the power-management behavior of the application to be preserved.

26.6.1.2.2 Debug Context Save and Restore

26.6.1.2.2.1 Debug Context Save

The device partitioning is such that not all the debug components are mapped to an always-on domain. Typically, the programmer wants the debug setup to be preserved along a debug session, including subsystem power cycling. When debug registers are memory mapped and not implemented within the emulation power domain, the application software must save the state of the debug registers before going to sleep and restore them upon wakeup.

26.6.1.2.2.2 Debug Context Restore

When the application software performs a context restore, it must be able to write to all the debug registers to restore their contents, regardless of the previous ownership. After subsystem power domain ramp up, the debug resources are in the available state, and ownership is restored. The debug context save and restore sequences are protected. All debug functionality is disabled and debugger accesses are blocked.

26.6.2 Reset Management

The debugger can take control of the system reset for each subsystem through ICEPick. The debugger can configure ICEPick to assert, block, or extend the subsystem reset.

26.6.2.1 Debugger Directives

26.6.2.1.1 Assert Reset

The debugger can program ICEPick to generate a subsystem reset request to the device reset management module. The debugger reset event is then merged with system reset events.

26.6.2.1.2 Block Reset

The debugger can program ICEPick to request the device reset management module to block an unsafe application system or subsystem reset event.

A reset originated by some safe reset sources cannot be blocked by the debugger.

26.6.2.1.3 Wait-In-Reset

WIR mode is latched from boot mode (see [Section 26.3.2, Boot Modes](#)) and allows the user to hold a secondary TAP module in reset state when a reset is applied (and thus, extend the reset). This mode lets the user control the following system level activities:

- Gain emulation control of any processor in a power domain at POR
- Capture and extend system-generated functional resets while running (under emulation control or not)
- Hold an entire power domain in reset until emulation control of the subsystem can be established

- Stall the entire system while reset is extended to a power domain
- Reset extension is visible external to the power domain.
- Debug execution of code from the first cycle of execution
- Prevent processor execution of random instructions in uninitialized program memory at power up
- Download code before any code execution takes place
- Coordinate debug initialization across multiple cores before code execution begins

WIR mode extends only the processor reset. During reset extension, the debugger can still access modules such as L2 memory and MMU, even if they are embedded in the device subsystem affected by WIR.

When the debugger task is complete, the DTC releases the subsystem reset by programming the corresponding ICEPick TAP control register.

26.7 Performance Monitoring

26.7.1 IPU Subsystem Performance Monitoring

26.7.1.1 Subsystem Counter Timer Module

The IPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- Forty-four shared cache events
- Four sleep/deep-sleep events from Cortex-M4 cores (one sleep and one deep sleep event per core)

[Table 26-10](#) describes the repartition of the IPU SCTM counters.

Table 26-10. IPU SCTM Counters Repartition

Counters	Features
0–1	Timer and event
2–3	64-bit chained + shadowing
4–5	64-bit chained + shadowing
6–7	Event

26.7.1.2 Cache Events

[Table 26-11](#) summarizes the SCTM events for the IPU subsystem.

Table 26-11. SCTM Events for IPU Subsystem

Input Index	Event Description

48	IPU_C0 sleep

NOTE: Input index [0] is reserved for free-running subsystem clock (used for total cycle profiling).

26.7.2 DSP Subsystem Performance Monitoring

26.7.2.1 Advanced Event Triggering

The Advanced Event Trigger (AET) unit has the capability to generate the debug actions based on events detected by instruction and data bus comparators or by auxiliary event detectors to manage:

- **Hardware Program Breakpoints:** specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- **Data Watchpoints:** specify data variable address, address ranges, or data values that can generate events such as halting the processor or triggering the trace captures.
- **Counters:** count the occurrence of an event of cycles for performance monitoring.
- **State Sequencing:** allows combinations of hardware program breakpoint and data Watchpoints to precisely generate events for complex sequences.

For more information on AET, see the following documents:

- *Using Advanced Event triggering to Find and Fix Intermittent Real-Time Bugs* application report (SPRA753).
- *Using Advanced Event Triggering to Debug Real-Time Problems in High Speed Embedded Microprocessor System* application report (SPRA387)

26.7.3 EVE Subsystem Performance Monitoring

26.7.3.1 EVE Subsystem Counter Timer Module

The EVE subsystem includes an SCTM, which is embedded in the EVE subsystem and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- ARP32 program cache events
- EDMA events
- Interrupt events
- VCOP processor events

[Table 26-12](#) describes the configuration of the EVE SCTM counters.

Table 26-12. EVE SCTM Counters Configuration

Counters	Features
0–1	Timer and event
2–3	64-bit chained + shadowing
4–5	64-bit chained + shadowing
6–7	Event

26.7.3.2 EVE Subsystem SCTM Events

[Table 26-13](#) summarizes the SCTM events for EVE subsystem.

Table 26-13. SCTM Events for EVE Subsystem

Input Index	Event Description
0	Cache miss
1	Cache hit
2	Cache miss stall

26	VCOP wr_ibufh
27	VCOP wr_wbuf
28	VCOP loop_start
29	VCOP done

26.8 Processor Trace

The device supports DSP (C66x) processor trace for each DSP subsystem.

26.8.1 DSP Processor Trace

Trace targets the debug of unstable code, performance analysis, and quality assurance. This infrastructure component use bus snoopers to collect and export trace data using hardware dedicated to the trace function. The use of dedicated hardware to both collect, buffer, transfer trace data to the host makes trace non-intrusive. DSP processor trace characteristics are:

- Program trace
- Data trace (address and value)
- Time stamp
- Two exclusive trace sinks:
 - CS_TPIU – trace exported to an external trace receiver
 - CT_TBR – trace history stored into on-chip buffer

The trace function can collect and export a record of the program flow and timing at the same rate generated by the CPU. Tracing data references must be restricted however as the export mechanism is generally limited to size of on-chip CT_TBR to sustain tracing of all memory references. In the case of data trace, the Advanced Event Triggering facilities provide a means to restrict the trace data exported to data of interest to maintain the non-intrusive aspect of trace. This reduces the export bandwidth needs and facilitates the successful collection of the data of interest. Error indications are embedded in the debug stream in the event the export logic is unable to keep up with the data rate generated by the collection logic. This notification allows the user to scale back the amount of requested data collection.

The user can optionally select the export of all specified trace data. In this case the CPU is stalled to avoid the loss of trace data, with trace becoming intrusive to the application if trace related stalls are generated. The user is notified that trace stalls.

26.8.2 Trace Export

The debug subsystem implements two exclusive trace sinks:

- CS_TPIU
- CT_TBR

26.8.2.1 Trace Exported to External Trace Receiver

Processor trace can be exported to an external trace receiver through the CS_TPIU module. To achieve this, the debugger or application software must ensure to program the DRM module properly (that is, according to [Table 26-27](#)).

The CS_TPIU has a configurable export width of maximum 16 data pins (TRACEDATA) plus a dedicated export clock (TRACECLK) and a control signal (TRACECTL).

26.8.2.2 Trace Captured Into On-Chip Trace Buffer

Processor trace flow can be redirected to the on-chip trace buffer (CT_TBR working in buffer mode). The CT_TBR provides on-chip storage of trace data using a 32-KiB RAM memory.

The CT_TBR receives trace flow data through its ATB port. The debugger can then access trace data through CS_DAP (APB port).

The CT_TBR supports two modes when in buffer mode configuration:

- Circular buffer mode for continuous capture. In this mode, the CT_TBR functions as a circular buffer where the oldest data is overwritten with the most recent entries.
- Stop-on-full mode for no-loss (single shot) capture. In this mode, the buffer fills linearly and then halts when the last entry is written.

26.9 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace
 - SoC software instrumentation via CT_STM (STP2.0) (see [Section 26.9.3.1, SoC Software Instrumentation](#))
- OCP watchpoint
 - OCP target traffic monitoring (see [Section 26.9.4.1, OCP Target Traffic Monitoring](#))
 - SoC events trace (see [Section 26.9.4.2, Messages Triggered from System Events](#))
 - DMA transfer profiling (see [Section 26.9.4.3, DMA Transfer Profiling](#))
- Statistics collector
 - L3 Master Latency Monitoring (see [Section 26.9.7.1, L3 Master Latency Monitoring](#))
- PM events trace (see [Section 26.9.8, PM Instrumentation \[PMI\]](#))
- CM events trace (see [Section 26.9.9, CM Instrumentation \[CMI\]](#))

26.9.1 MIPI STM (CT_STM)

CT_STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 2.0) with the following characteristics:
 - Highly optimized for software-generated traces
 - Automatic timestamping of messages
 - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
 - Software messages
 - Hardware instrumentation trace from hardware agents:
 - OCP_WP_NOC
 - PMI
 - CMI
 - EVE SMSET
 - ISS CTSET
 - L3 NoC statistics collectors
- Supports the following trace export paths:
 - ATB export – to CS_TPIU or CT_TBR
- Timestamps:
 - Can use local relative timestamp if exported to the CS_TPIU/CT_TBR (through ATB)
- Dedicated 128 × 32-bit FIFO buffer
- Mechanism to generate repeat MASTER and C8 messages periodically even if not needed

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

26.9.2 System Trace Export

26.9.2.1 CT_STM ATB Export

If a trace receiver cannot be attached to the device, or relevant CT_STM trace port pins are unavailable for a particular reason, the user can configure the CT_STM module to redirect the STP trace stream as an ATB stream to the CS_TPIU or CT_TBR and enable local timestamp. This is accomplished by outputting a local timestamp granularity (LTSG) message, which is a TI addition to the MIPI standard messages.

NOTE: For CT_STM timestamps when output to the ATB interface, the timestamp (TS) field is no longer the CT_STM FIFO depth, but is the time from the previous message.

Granularity is a function of the instrumentation port clock frequency.

26.9.2.2 Trace Streams Interleaving

Two levels of interleaving system instrumentation flows and arbitrating between instrumentation masters are implemented:

- CORE L3 instrumentation interconnect interleaves data coming from the following bus masters:
 - OCP_WP_NOC
 - L3 NoC statistics collectors, or software instrumentation (interleaving at the L3 level)
 - EVE SMSET and ARP32 (software instrumentation)
- EMU L3 instrumentation interconnect interleaves data coming from the following bus masters:
 - CORE L3 instrumentation interconnect
 - CMI
 - PMI

26.9.3 Software Instrumentation

26.9.3.1 SoC Software Instrumentation

The CT_STM module embedded in the debug subsystem provides a flexible interface for trace instrumentation.

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the ongoing debugging task. The message structures in STP-2.0 are optimized to provide an efficient transport for software data through the CT_STM module.

The software masters are:

- DAP (for testing purpose)
- DSP subsystem
- IPU subsystem
- EVE subsystem
- EDMA TPTC WR1 and WR2 channels

Each software master has a master-ID assigned to it (see [Section 26.9.10, Master-ID Encoding](#), for more information).

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

26.9.4 OCP Watchpoint

26.9.4.1 OCP Target Traffic Monitoring

The L3_MAIN interconnect provides several functional probes embedded and attached to the following L3_MAIN targets:

- GPMC
- L4_PER1, L4_PER2, L4_PER3

- L4_CFG
- L4_WKUP
- OCMC_RAM
- EMIF

The probes output are muxed together and then sent to the L3_MAIN interconnect debug port. A component called OCP_WP_NOC is used to collect data from functional probes and then transmit captured data to the CT_STM module. The OCP_WP_NOC drives a probe-ID signal to the L3_MAIN interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP_WP_NOC provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
 - Address range
 - Initiator-ID (see [Table 26-15](#))
 - Transaction type
 - Transaction qualifier
- Generating a trigger upon watchpoint match
- Starting and stopping OCP traffic monitoring upon:
 - WP address match
 - External trigger
- Profiling DMA transfers
- Generating hardware message upon system event
- OCP_WP_NOC messages can be interleaved with software messages
- Programming from:
 - Debugger
 - Application

NOTE: The OCP_WP_NOC is restricted to monitor request flow only.

[Table 26-14](#) summarizes the OCP targets that can be monitored by the OCP_WP_NOC and their respective probe-ID.

Table 26-14. L3_MAIN Interconnect Functional Probe Mapping

Probe-ID	L3 OCP Target
0000	Reserved
0001	GPMC

26.9.4.2 Messages Triggered from System Events

The OCP_WP_NOC can be programmed to export a message through the CT_STM upon detection of a system event (interrupt, DMA request, etc.). A bus of 16 system events pre-selected at SoC level from a large number of observable events is routed to the OCP_WP_NOC. This can be useful to determine interrupts latencies:

- Interrupt request traced through OCP_WP_NOC system event detection
- ISR boundary tracked either through CT_STM software trace or OCP_WP_NOC address range detection

26.9.4.3 DMA Transfer Profiling

The OCP_WP_NOC can be configured to profile DMA transfers. This feature provides to the user visibility on:

- DMA logical channel interleaving
- DMA channel ID
- DMA transfer duration (time stamp)
- DMA burst size
- DMA reads
- DMA writes

When operating in this mode, the OCP_WP_NOC exports to CT_STM:

- DMA channel ID
- Burst size
- R/W

The CT_STM module encapsulates the information above in a compact STP message.

The address range filtering remains active but OCP address data are not encapsulated into the trace message to maximize CT_STM throughput.

26.9.5 EVE SMSET

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding EVE VCOP micro-task sequencing. This is supported through a SMSET module instantiated in the EVE subsystem. The VCOP start and done events are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the CT_STM module.

The EVE instrumentation scheme allows the user to understand micro-task dependencies, and potential bottlenecks. DMA transfer boundaries are reported as EVE events. Software messages from ARP32 execution can be interleaved with EVE VCOP events.

26.9.6 ISS Hardware Instrumentation

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding ISS key system events. The events are encapsulated in STP messages with an Event-ID and Global Time Stamp and are exported through the CTSET module.

The ISS instrumentation setup allows programming a sampling window. All the events detected within the user-defined sampling window will be reported with a common time-stamp.

The ISS instrumentation can be exported to a trace receiver or stored into an on-chip buffer.

26.9.7 L3 NOC Statistics Collector

The L3_MAIN interconnect supports a built-in performance monitoring feature by implementing a statistics collector (NOC_SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the CT_STM interface. The following NOC_SC instances are instantiated in the device:

- Four statistics collectors dedicated to L3 Master Latency Monitoring – STAT_COLL1 through STAT_COLL4 (see [Section 26.9.7.1, L3 Master Latency Monitoring](#), for more information)

Statistics collectors can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- Percent link occupancy on the request link (for store transactions) during a sampling window
- Percent link occupancy on the response link (for load transactions) during a sampling window
- Percent arbitration conflict cycles on the request link
- Percent initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16, 16–32, 32–128) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3_MAIN interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the NTPP and OCP link events summarized in [Table 26-16](#).

Table 26-16. Performance Monitoring Events Detection

Link Event	Definition
NONE	No event selected
ANY	Any clock cycles

Table 26-16. Performance Monitoring Events Detection (continued)

Link Event	Definition
TRANSFER	Word has been accepted by the receiver.
WAIT	Transfer has been initiated but the transmitter currently has no data to send.
BUSY	Receiver applies flow control
PKT	Transfer of a new packet header
DATA	Transfer of a payload word
IDLES	No communication over the link
LATENCY	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in [Table 26-17](#).

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

NOTE: Statistics collectors counter values are accessible by application software.

Table 26-20 summarizes the performance probe aggregation modes.

Table 26-20. Aggregation Modes

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when the filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the selected event information is within range.

Table 26-20. Aggregation Modes (continued)

Aggregation Mode	Description
	<ul style="list-style-type: none"> – Payload length (bytes) – Pressure value – Request/response latency (clock cycles)
EVT_INFO	The selected event information is added to the counter value when the filter hits. Payload length (bytes) Pressure value Request/response latency (clock cycles)
AND_FILTER	The counter increments by 1 when all unit filters hit.
OR_FILTER	The counter increments by 1 when at least one unit filter hits.
SUM_REQ_EVT	The counter sums the events from any request port.
SUM_RSP_EVT	The counter sums the events from any response port.
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

26.9.7.1 L3 Master Latency Monitoring

The L3 interconnect implements performance monitoring probes on initiator (master) interfaces. The master latency statistics are computed within a user-defined window and periodically reported to the user through the CT_STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with ongoing execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

26.9.7.1.1 STAT_COLL1 Configuration

STAT_COLL1 supports the following main features:

- Six probe inputs:
 - Probe 0: EMIF_SYS
 - Probe 1: IPU
 - Probe 2: DSP1_MDMA
 - Probe 3: DSP2_MDMA
 - Probe 4: GMAC_SW
 - Probe 5: ISS_NRT1
- Four 32-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter

- Identifier is 0x0 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 26-21 shows the STAT_COLL1 port mapping.

Table 26-21. STAT_COLL1 Port Mapping

Probe	Description	Link	Port
0	EMIF_SYS	NTTP REQ	0
		NTTP RSP	1
1	IPU	NTTP REQ	2
		NTTP RSP	3
2	DSP1_MDMA	NTTP REQ	4
		NTTP RSP	5
3	DSP2_MDMA	NTTP REQ	6
		NTTP RSP	7
4	GMAC_SW	NTTP REQ	8
		NTTP RSP	9
5	ISS_NRT1	NTTP REQ	10
		NTTP RSP	11

26.9.7.1.2 STAT_COLL2 Configuration

STAT_COLL2 supports the following main features:

- Eight probe inputs:
 - Probe 0: DSS
 - Probe 1: MMU
 - Probe 2: EDMA_TC0_RD
 - Probe 3: EDMA_TC0_WR
 - Probe 4: DSP2_CFG
 - Probe 5: DSP2_EDMA
 - Probe 6: Reserved
 - Probe 7: Reserved
- Four 32-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 26-22 shows the STAT_COLL2 port mapping.

Table 26-22. STAT_COLL2 Port Mapping

Probe	Description	Link	Port
0	DSS	NTTP REQ	0
		NTTP RSP	1
1	MMU	NTTP REQ	2
		NTTP RSP	3
2	EDMA_TC0_RD	NTTP REQ	4
		NTTP RSP	5
3	EDMA_TC0_WR	NTTP REQ	6
		NTTP RSP	7
4	DSP2_CFG	NTTP REQ	8
		NTTP RSP	9
5	DSP2_EDMA	NTTP REQ	10
		NTTP RSP	11
6	Reserved	NTTP REQ	12
		NTTP RSP	13
7	Reserved	NTTP REQ	14
		NTTP RSP	15

26.9.7.1.3 STAT_COLL3 Configuration

STAT_COLL3 supports the following main features:

- Seven probe inputs:
 - Probe 0: VIP1_P1
 - Probe 1: VIP1_P2
 - Probe 2: ISS_RT
 - Probe 3: ISS_NRT2
 - Probe 4: OCMC_RAM
 - Probe 5: DSP1_CFG
 - Probe 6: DSP1_EDMA
- Four 32-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

[Table 26-22](#) shows the STAT_COLL3 port mapping.

Table 26-23. STAT_COLL3 Port Mapping

Probe	Description	Link	Port
0	VIP1_P1	NTTP REQ	0
		NTTP RSP	1
1	VIP1_P2	NTTP REQ	2
		NTTP RSP	3
2	ISS_RT	NTTP REQ	4
		NTTP RSP	5
3	ISS_NRT2	NTTP REQ	6
		NTTP RSP	7
4	OCMC_RAM	NTTP REQ	8
		NTTP RSP	9
5	DSP1_CFG	NTTP REQ	10
		NTTP RSP	11
6	DSP1_EDMA	NTTP REQ	12
		NTTP RSP	13

26.9.7.1.4 STAT_COLL4 Configuration

STAT_COLL4 supports the following main features:

- Eight probe inputs:
 - Probe 0: EVE_P1
 - Probe 1: EVE_P2
 - Probe 2: Reserved
 - Probe 3: GPMC
 - Probe 4: McASP (SR1.0) / McASP1 (SR2.0)
 - Probe 5: EDMA_TC1_RD
 - Probe 6: EDMA_TC1_WR
 - Probe 7: Reserved
- Four 32-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x4 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

[Table 26-22](#) shows the STAT_COLL4 port mapping.

Table 26-24. STAT_COLL4 Port Mapping

Probe	Description	Link	Port
0	EVE_P1	NTTP REQ	0
		NTTP RSP	1

5	EDMA_TC1_RD	NTTP REQ	10
		NTTP RSP	11
6	EDMA_TC1_WR	NTTP REQ	12
		NTTP RSP	13
7	Reserved	NTTP REQ	14
		NTTP RSP	15

26.9.7.1.5 Statistics Collector Alarm Mode

Statistic collectors can be used to provide the application software with information about the NoC or SDRAM reaching corner cases (for example, too much traffic for a given OPP) while in application mode where for an end product use case the debug subsystem (which is normally exporting the statistic frames) is off. An interrupt-based scheme using a dedicated signal (L3_MAIN_IRQ_STAT_ALARM) is implemented to avoid CPU polling periodically statistic registers. This interrupt alert is fired when a given metric is out of specified range (below the programmed MIN threshold or above the programmed MAX threshold). The L3_MAIN_IRQ_STAT_ALARM interrupt is connected to the IRQ_CROSSBAR_16 input and the user can map it to any device INTC via Control Module.

NOTE: NTTP statistic collectors (SC_LAT) support latency measurement. However, comparison cannot be done on the latency counter. In case of latency measurement the comparison has to be done on number of latencies in user defined range, not on the latency value itself.

26.9.7.1.6 Statistics Collector Suspend Mode

The statistics collector module implements a suspend input that is used to avoid statistics collector counters to be updated while the processor has entered the debug state. This avoids triggering false alerts upon execution resume. When the statistics collector is asserted to 1, it freezes the monitoring process. When it goes back to 0, the monitoring resumes. If a frame is being dumped, it will not be stopped by suspend.

NOTE: Each statistic collector has an 'ignore suspend' register, which can be used to disable the suspend feature.

26.9.8 PM Instrumentation

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power-management events. This is supported through a PMI module (PM profiler) instantiated in the PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the CT_STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at CT_STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change
- Memory power domain state change

The PMI has a unique hardware master-ID assigned to it (see [Section 26.9.10, Master-ID Encoding](#)).

The PMI supports the possibility to report on activity in different event classes in the same sampling window. The user can size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

The PM module implements an instrumentation port that directly interfaces with the debug subsystem (used to export PM events to CT_STM).

26.9.9 CM Instrumentation

The device instantiates a CMI module (CM profiler). It has a unique hardware master-ID assigned to it (for more information, see [Section 26.9.10, Master-ID Encoding](#)).

NOTE: Only CM_CORE_AON instrumentation is supported in this device. CM_CORE instrumentation is not supported.

The CM events profiling is similar to the PMI. Two exclusive instrumentation modes are supported:

- Clock activity:
 - Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
 - Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
 - Exposes to the user periodically the active cycles count of the target modules
 - Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
 - Clock domain state
 - DPLL settings update
 - Clock frequency divider ratio
 - Clock source selection update
- Module activity collection mode – two classes:
 - Target module activity
 - Initiator module activity

When in events capture mode, the CMI supports the possibility of reporting on activity in different event classes in the same sampling window. The user can size the capture sampling window.

26.9.10 Master-ID Encoding

A master-ID (MReqMstID[7:0]) field is used by the CT_STM to encode a MASTER type of message:

- MReqMstID[7] – Differentiates software versus hardware masters (0 for software masters; 1 for hardware masters)

- MReqMstID[6:2] – Master address exported by the L3_MAIN interconnect debug subsystem target
- MReqMstID[1:0] – Additional qualifier for multicore masters (IPU)

26.9.10.1 Software Masters

The CT_STM module allows:

- Enabling a maximum of four SoC software masters
- Masking MReqMstID[1:0]
- Differentiating multicore software masters through MReqMstID[1:0]

Table 26-25 summarizes the software initiators that can export trace messages through the CT_STM.

Table 26-25. STM Message Software Masters

Initiator	MReqMstID				Restriction/Comment
	ConnID	[7]	[6:2]	[1:0]	
CS_DAP	0x4	0	00100	–	STP link testing
DSP1 MDMA	0x8	0	01000	–	
DSP1 CFG	0x9	0	01001	–	
DSP1 DMA	0xA	0	01010	–	Data logging
DSP2 DMA	0xB	0	01011	–	Data logging
DSP2 CFG	0xC	0	01100	–	
DSP2 MDMA	0xD	0	01101	–	
EVE	0x10	0	10000	–	Software messages routed through the EVE instrumentation port
IPU	0x18	0	11000	00	IPU_C0
				01	IPU_C1
EDMA_TC1 WR	0x1C	0	11100	–	Data logging
EDMA_TC2 WR	0x1D	0	11101	–	Data logging

26.9.10.2 Hardware Masters

The CT_STM module allows enabling a subset of SoC hardware masters (maximum = 4).

Table 26-26 summarizes the hardware initiators that can export trace messages through the STM.

Table 26-26. STM Message Hardware Masters

Initiator	MReqMstID			
	ConnID	[7]	[6:2]	[1:0]
EVE instrumentation (SMSET)	0x34	1	10100	00

CMI events profiling	0x3E	1	11110	00

⁽¹⁾ Master-ID assigned by the L3_MAIN interconnect

26.10 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

[Table 26-27](#) summarizes the trace port configuration.

Table 26-27. Trace Port Configuration

Pin Name	Internal Signal Name	I/O	Trigger	CS_TPIU (DSP, CS_STM, CT_STM)
emu19	EMU19	O		TRACEDATA[15]
emu18	EMU18	O		TRACEDATA[14]
emu17	EMU17	O		TRACEDATA[13]
emu16	EMU16	O		TRACEDATA[12]
emu15	EMU15	O		TRACEDATA[11]
emu14	EMU14	O		TRACEDATA[10]

26.11.2.2 DRM Register Description

Table 26-31. DRM_SUSPEND_CTRL0

Address Offset	0x0000 0200	Instance	DRM
Physical Address	0x5416 0200		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SUSPEND_SEL		SUSPEND_DEFAULT_OVERRIDE	RESERVED	SENSCTRL											

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x0
8:4	SUSPEND_SEL	Suspend signal selection. Selects which suspend signal affects the peripheral. Only valid when SUSPEND_DEFAULT_OVERRIDE=0 and SENSCTRL=1. When read, these bits reflect the default suspend signal. 0000b: CPU suspend signal. All other values are reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
3	SUSPEND_DEFAULT_OVERRIDE	Enable or disable the override value in SUSPEND_SEL. 0: SUSPEND_SEL field will select which suspend signal reaches the peripheral. 1: SUSPEND_SEL field ignored. Default suspend signal will reach the peripheral.	R	0x0
2:1	RESERVED	Reserved	R	0x0
0	SENSCTRL	Sensitivity Control for suspend signals. When SUSPEND_DEFAULT_OVERRIDE=1, this bit is ignored and read as a 1. When SUSPEND_DEFAULT_OVERRIDE=0, 0: Suspend signal will not reach the peripheral. Peripheral will act as normal even during a debug halt. 1: Suspend signal will reach the peripheral. Peripheral will be suspended during debug halt.	RW	0x0

Table 26-89. DRM_SUSPEND_CTRL29

Address Offset	0x0000 0274	Instance	DRM
Physical Address	0x5416 0274		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SUSPEND_SEL		SUSPEND_DEFAULT_OVERRIDE	RESERVED	SENSCTRL											

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x0
8:4	SUSPEND_SEL	Suspend signal selection. Selects which suspend signal affects the peripheral. Only valid when SUSPEND_DEFAULT_OVERRIDE=0 and SENSCTRL=1. When read, these bits reflect the default suspend signal. 0000b: CPU suspend signal. All other values are reserved.	RW	0x0
3	SUSPEND_DEFAULT_OVERRIDE	Enable or disable the override value in SUSPEND_SEL. 0: SUSPEND_SEL field will select which suspend signal reaches the peripheral. 1: SUSPEND_SEL field ignored. Default suspend signal will reach the peripheral.	R	0x0
2:1	RESERVED	Reserved	R	0x0

Bits	Field Name	Description	Type	Reset
0	SENSCTRL	Sensitivity Control for suspend signals. When SUSPEND_DEFAULT_OVERRIDE=1, this bit is ignored and read as a 1. When SUSPEND_DEFAULT_OVERRIDE=0, 0: Suspend signal will not reach the peripheral. Peripheral will act as normal even during a debug halt. 1: Suspend signal will reach the peripheral. Peripheral will be suspended during debug halt.	RW	0x0

Glossary

2

2D— Two Dimensional

3

3A— AF + AE + AWB

3D— Three Dimensional

3G— 3rd Generation of mobile communication systems

A

A/D— Analog to Digital Converter

ABB— Adaptive Body Bias

ABE— Audio Back End

ABS— Absolute Value

ACE— ASIC Compiler Environment.

ACK— Acknowledge

ADC— Analog-to-Digital Converter/Conversion.

ADMA— Advanced DMA

AET— Advanced Event Triggering - this capability can be used to debug complex problems as well as understand performance characteristics of user applications

AFE— Analog Front End

AFSX— Audio transmit frame synchronization

AHB— Advanced High-performance Bus

AHB-AP— Advanced High-performance Bus - Access Port

ALE— Address Latch Enable

AMBA— Advanced Micro-Controller Bus Architecture

AMMU— Attribute Memory Management Unit

AP— Address Protection

APB— Advanced Peripheral Bus

APB-AP— Advanced Peripheral Bus - Access Port

APWM— Asymmetrical Pulse Width Modulation (eCAP)

AR— Automatic Reload

ARGB— Alpha Red Green Blue

ARM— Advanced RISC Machine
ASCII— American Standard Code for Information Interchange
ASIC— Application–Specific Integrated Circuit
ASIL— Automotive Safety Integrity Level
ATB— AMBA Advanced Trace Bus
AVB— Audio Video Bridging
AVS— Adaptive Voltage Scaling
AWD— Analog Watchdog

B

B— Byte, 8 bits
BB— Bus Busy
BCD— Binary–Coded Decimal.
BCH— Bose-Chaudhuri-Hocquenghem (CRC Code)
BE— Big Endian.
BGA— Ball Grid Array
BGT— Block Guard Time
BIOS— Basic Input/Output System.
BOF— Beginning of Frame
BOL— Beginning of Line
BSP— Buffered Serial Port.
BTA— Bus Turn Around
BW— Band Width
BWM— Band Width Manager (functional entity in the TMS320C66x DSP CorePac)

C

CAN— Controller Area Network
CAS— Column Address Strobe
CBC— Cipher Block Chaining
CBUF— Circular Buffer (Associated with OCMC)
CC— Channel Controller
CCCR— Card Common Control Registers (SDIO)
CE— Chip Enable
CFI— Common Flash Interface device
CH— Configuration Header. To use different settings than ROM Code defaults, i.e. clock frequencies, SDRAM settings, GPMC settings if the customer wants.
CIF— Common Intermediate Format.

- CIR**— Consumer Infra Red
- CL**— Command List (SATA)
- CLE**— Command Latch Enable
- CLK**— Clock
- CLUT**— Color Look-Up Table
- CM**— Clock Management
- CME**— Credit Management Engine
- CMOS**— Complimentary Metal Oxide Semiconductor
- COS**— Class of Service
- CPI**— Camera Parallel Interface
- CPPI**— Communications Port Programming Interface
- CPR**— Color Phase Rotation
- CPU**— Central Processing Unit
- CRC**— Cyclic Redundancy Check
- CS**— Chip-Select
- CSI**— Camera Serial Interface
- CSWR**— Closed switch retention
- CTM**— Counter-Timer Module
- CTRL**— Control
- CTS**— Clear to Send
- CTT**— Clock Tree Tool. Interactive PC tool from TI to assist PRCM software user.
- CVBS**— Composite Video Broadcast Signal
- ConnID**— Connection Identifier. An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is used for security and error logging mechanism.

D

- DAC**— Digital to Analog Converter
- DAP**— Debug Access Port
- DC**— Direct Current
- DCAN**— CAN Controller Module
- DCC**— Duty Cycle Correction Circuit
- DCD**— Data Carrier Detect
- DCO**— Digitally Controlled Oscillator
- DDR**— Double Data Rate
- DE**— Data Enable
- DED**— Double Error Detection

DFF— Data Flip-Flop
DFT— Design For Test
DIR— Digital audio Interface Receiver
DISPC— Display Controller
DLB— Data Loopback.
DLL— Delay-Locked Loop
DMA— Direct Memory Access.
DMC— Digital Motor Control
DMEM— Data Memory
DMT— Display Monitor Timing
DPC— Defect Pixel Correction
DPI— Display Parallel Interface
DPLL— Digital Phase-Locked Loop. Digital implementation of PLL.
DPS— Digital Power Switching
DRDY— Data Ready
DRM— Digital Rights Management
DSI— Display Serial Interface
DSP— Digital Signal Processor.
DSR— Data Set Ready
DSS— Display Sub-System
DTC— Debug and Trace Controller
DTCM— Data Tightly Coupled Memory
DTR— Data Transmit Ready
DVFS— Dynamic Voltage and Frequency Scaling
DWD— Digital Watchdog

E

EAV— End of Active Video
ECC— Error Checking and Correction. Also Error Correction Code.
ED— Endpoint Descriptor
EDC— Error Detection Code
EDI— Edge Directed Interpolation
EDMA— Enhanced DMA
EDMA_TPCC— Enhanced DMA Third Party Channel Controller
EDMA_TPTC— Enhanced DMA Third Party Transfer Controller
EEE— Energy Efficient Ethernet

EMC— External Memory Controller
EMIF— External Memory Interface
EOB— End of Block
EOF— End of Frame
EOL— End of Line
EOP— End of Packet
EOT— End of Transfer
EPM— Emulation Pin Manager
ESM— Error Signaling Module
ESR— Event Set Register
ETB— Embedded Trace Bus
ETM— Embedded Trace Macrocell
EVE— Embedded Vision Engine

F

FC— Frame Counter
FCLK— Functional Clock
FE— Framing Error
FF— Flip-Flop
FIFO— First In First Out
FIQ— Fast Interrupt Request. See ISR.
FIR— Fast Infrared
FM— Frequency Modulation
FRC— Free Running Counter
FROM— eFuse ROM
FS— Frame Synchronisation
FSC— Frame Start Code. Also Frame Start Count.
FSM— Finite State Machine.
FW— Firewall

G

GFX— Graphics
GMII— Gigabit Media Independent Interface
GP— General-purpose
GPIO— General Purpose Input/Output
GPMC— General Purpose Memory Controller

H

H/W— Hardware

HAL— Hardware Abstraction Layer

HBP— Horizontal Back Porch

HC— Host Controller

HD— High Definition

HDMI— High-Definition Multimedia Interface

HDTV— High-Definition Television

HFP— Horizontal Front Porch

HLOS— High-Level Operating System

HPF— High-Pass Filter

HRPWM— High Resolution Pulse Width Modulator (eHRPWM only)

HS— High-Speed

HSSCLL— High-Speed Serial Control Channel

HSW— Horizontal Synchronization Pulse Width

HSYNC— Horizontal Synchronization.

HW— Hardware

HWOBS— Hardware Observability

I

I/F— Interface

I/O— Input/Output

I2C— Inter-Integrated Circuit

I2S— Inter-IC Sound

IA— Identifier Address

ICE— In-Circuit Emulation

ICEPICK— Generic TAP for emulation control

ICLK— Interface Clock

ID— Identification

IDE— Integrated Development Environment. A programming environment integrated into an application.

INT— Interrupt .

INTC— Interrupt Controller

IP— Intellectual Property

IPC— Interprocessor Communication. (also referred to as “mailbox” on occasion)

IPU— Image-processing unit

IR— Infrared

IRQ— Interrupt Request.
ISA— Instruction Set Architecture
ISO— Isochronous.
ISP— Image Signal Processor
ISR— Interrupt Service Routine.
ISS— Imaging SubSystem
IST— Interrupt Service Thread.
ITCCHEN— Intermediate transfer completion chaining enable.
ITCINTEN— Intermediate transfer completion interrupt enable.
ITCM— Instruction Tightly Coupled Memory
IVA— Image and Video Accelerator

J

JEDEC— Joint Electronic Devices Engineering Council
JTAG— Joint Test Action Group.

K

KB— Kilobyte, 1024 B
Kbps— Kilobits per second

L

L1— Level 1 cache/memory
L2— Level 2 cache/memory
L3— First level of interconnect
L4— Second level of interconnect
LA— Logical Address
LAN— Local Area Network
LBIST— Logical Built-In Self-Test
LCD— Liquid Crystal Display.
LD— Lens Distortion
LDO— Low Dropout
LE— Little Endian.
LED— Light Emitting Diode.
LF— Loop Filter
LH— Local Host
LINK— Link Layer Device
LLP— Low-Level Protocol

LPP— Lines Per Panel
LRU— Least Recently Used
LSB— Least Significant Bit
LSR— Linear Shift Register
LTC— Low Time Counter
LVC MOS— Low Voltage Complementary Metal Oxide Semiconductor

M

MAC— Multiply Accumulate. Also Medium Access Control
MBIST— Memory Built-In Self-Test
MCAN— Modular CAN Controller Module
McSPI— Multichannel Serial Peripheral Interface
MCU— Microcontroller Unit
MDIO— Management Data Input/Output
MDMA— Modem DMA. Second meaning is : Master DMA port of the DSPSS TMS320C66x CorePac.
MIF— Memory InterFace
MII— Media Independent Interface
MIPI— Mobile Industry Processor Interface
MIR— Medium Infrared
MMC— Multimedia Card
MMR— Memory Mapped Register
MMU— Memory Management Unit.
MPU— Microprocessor Unit.
MSB— Most Significant Bit
MUX— Multiplex/Multiplexer
Mbps— Mega bits per second
Modem— Modulator Demodulator
MuxMode— Refers to top-level pin multiplexing

N

N/A— Not Applicable
NAND— NAND Flash memory.
NIU— Network Interface Unit
NMI— Non-Maskable Interrupt
NOP— No OPeration (DSP/CPU instruction)
NOR— A type of flash memory
NRT— Nonreal-Time

NRZ— Non-Return-to-Zero

NTSC— National Television System Committee. Television broadcast system.

NVIC— Nested Vectored Interrupt Controller

O

OCM— On-chip Memory

OCMC— On-chip Memory Controller

OCP— Open-Core Protocol

OE— Output Enable

OMAP— Open Multimedia Application Platform

OPP— Operating Performance Point

OS— Operating System

P

PC— Program Counter

PCB— Printed Circuit Board

PCLK— Pixel Clock

PCM— Pulse Code Modulation.

PDC— Power-down Controller

PE— Parity Error

PFPW— Prefetch and Prewrite posting engine

PHY— Physical Layer Device

PID— Proportional-Integral-Derivative

PLL— Phase-Locked Loop

PM— Programming Model

PMEM— Program Memory

PMFW— Power Management FrameWork

PMIC— Power management Integrated Circuit

POR— Power-On Reset

PPL— Pixels per Line

PPM— Pulse-Position Modulation

PRCM— Power, Reset, Clock Management module

PRM— Power and Reset manager

PSA— Parallel Signature Analyzer

PSC— Prescaler Counter

PTI— Parallel Trace Interface

PWM— Pulse Width Modulation

PaRAM— Programmable RAM that stores 32-byte channel transfer definition that EDMA channels, QDMA channels, and linking uses.

Q

QDMA— Quick DMA

QOS— Quality of Service

QSPI— Quad Serial Peripheral Interface

R

R/W— Read/Write. Also RW.

RAM— Random Access Memory

RE— Read Enable

REQ— Request

RFBI— Remote Frame Buffer Interface

RFF— Retention Flip-Flop

RFU— Receive Format Unit

RGB— Red Green Blue

RGBA— Red Green Blue Alpha

RGMII— Reduced Gigabit Media Independent Interface

RI— Ring Indicator

RISC— Reduced Instruction Set Computing. A CPU whose instruction set and related decode mechanism are much simpler than those of microprogrammed complex instruction set computers. The result is a higher instruction throughput and a faster real-time interrupt service response from a smaller, cost-effective chip.

RMII— Reduced Media Independent Interface

RO— Read Only

ROM— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

RST— Reset

RT— Real-Time

RTA— Retention Till Access

RTC— Real-Time Clock. A clock that keeps track of the time even when the device is turned off.

RTI— Real Time Interrupt

RTOS— Real-Time Operating System

RTS— Request to Send

RX— Receive/Receiver

RXD— Receive Data

S

S/PDIF— Sony/Philips Digital Interface

- S/W**— Software
- SAF**— Standby Associated Function
- SAR**— Save and Restore. Hardware context saving for power saving.
- SAV**— Start of Active Video
- SCL**— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.
- SCR**— SDIO Configuration Registers
- SCTM**— System Counter Timer Module
- SD**— Sigma-Delta. Also Secure Digital card (a non-volatile memory card).
- SDA**— Serial Data. Serial data bus in the I2C interface.
- SDIO**— Secure Digital Input/Output
- SDMA**— System Direct Memory Access module, Second meaning is: The Slave DMA port of the DSPSS TMS320C66x CorePac
- SDP**— Software Development Platform
- SDR**— Single Data Rate
- SDRAM**— Synchronous Dynamic Random Access Memory
- SDRC**— SDRAM Controller.
- SDTV**— Standard Digital Television
- SEC**— Single Error Correction
- SECEDED**— Single-Error Correction Dual-Error Detection
- SFI**— Serial Flash Interface
- SIF**— Source Input Format
- SIMCOP**— Still image coprocessor
- SIMD**— Single Instruction-Stream, Multiple Data-Stream
- SIR**— Slow Infrared
- SL2**— Shared Level 2 (memory/interface)
- SLM**— Static Leakage Management
- SMPS**— Switch Mode Power Supply
- SMSET**— Software Message and System Event Trace module
- SOC**— System-On-a-Chip
- SOF**— Start Of Frame
- SP**— Serial Port or Small Page or Stack Pointer
- SPI**— Serial Peripheral Interface
- SRAM**— Static Random Access Memory
- SRC**— Sample Rate Conversion
- SS**— Subsystem

- SSC**— Spread Spectrum Clocking
- STC**— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG2 encoder or decoder system.
- STM**— Synchronous Transfer Mode or Store Multiple.
- STN**— Super-Twist Nematic. A technique for improving LCD display screens by twisting light rays.
- SVC**— Supervisor Call
- SW**— Software
- SWI**— Software Interrupt
- SWJ-DP**— CoreSight™ Serial Wire JTAG Debug Port
- SYNCDIM**— Transfer synchronization dimension.
- SmartReflex**— Dynamic voltage sensing module that generates the voltage error signal proportional to the difference in desired voltage and the current voltage

T

- TA**— Target Agent
- TAP**— Test Access Port
- TBCLK**— Time Base Clock (PWMSS ePWM / eHRPWM related)
- TBCNT**— Time Base Clock - driven Counter (PWMSS ePWM / eHRPWM related)
- TBPRD**— Period Value of the Time Base Counter (PWMSS ePWM / eHRPWM related)
- TC**— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP. Also, in PCI Express context - this means Traffic Class, mapped to a virtual channel
- TCCHEN**— Transfer complete chaining enable.
- TCINTEN**— Transfer complete interrupt enable.
- TCK**— Test Clock
- TCM**— Tightly Coupled Memory
- TDI**— Test Data Input
- TDM**— Time Division Multiplex/Multiplexing
- TDO**— Test Data Output
- TESOC**— Tester On-chip
- TFT**— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.
- TI**— Texas Instruments
- TILER**— Tiling Isometric Lightweight Engine for Rotation
- TLB**— Translation Lookaside Buffer. A cache that contains entries for virtual-to-physical address translation and access permission checking.
- TM**— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).
- TMS**— Test Mode Select

TOC— Table of Contents
TPIU— Trace Port Interface Unit
TR— Transfer Request
TRM— Technical Reference Manual
TRST— Test Reset
TS— Transmission Start or Time-Stamp
TSHUT— Temperature Shutdown.
TTL— Transistor Transistor Logic or Time To Live (networking)
TWL— Table Walking Logic
TX— Transmit/Transmitter
TXC— Bidirectional Serial Transmit Clock
TXD— Transmit Data

U

UART— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.
UHS— Definition of SD cards with higher frequency

V

VA— Virtual Address
VBP— Vertical Back Porch
VBUF— Virtual Frame Buffer
VC-1— Video Codec Standard
VCOP— Vector Coprocessor
VENC— Video Encoder
VESA— Video Electronics Standards Association
VFP— Vertical Front Porch
VID— VLAN Identifier
VIP— Video Input Port
VLAN— Virtual Local Area Network
VLD— Variable Length Coder
VLIW— Very Long Instruction Word
VP— Video Port
VS— Vertical Synchronization
VSW— Vertical Synchronization Pulse Width
VSYNC— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode). Also VS.

W

- WB**— Write Buffer
- WC**— Word Count
- WD**— Watchdog
- WDT**— Watchdog Timer. See WD.
- WE**— Write Enable
- WFI**— Wait For Interrupt
- WIR**— Wait In Reset
- WNP**— Write Non-Posted
- WP**— Write Protect
- WSS**— Wide-Screen Signaling
- WT**— Write Through
- WUGEN**— Wake-Up Generator
- WWD**— Windowed Watchdog
- Word16**— 16 bits word

X

- X-LOADER**— A user-defined pre-operating system bootstrap code that resides at the beginning of the external flash.
- XIP**— eXecution In Place
- XMC**— Extended Memory Controller (a functional entity in the TMS320C66X DSP CorePac)

Y

- YUV**— Luminance-Bandwidth-Chrominance

e

- eCAP**— Enhanced Capture Module
- eHRPWM**— Enhanced PWM module with an integrated High Resolution PWM feature
- ePWM**— Enhanced Pulse Width Modulation Logic (excluding high resolution PWM feature)
- eQEP**— Enhanced Quadrature Encoder Pulse Module

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.
