Revision History	326
Preface	327
1 Introduction	334
1.1 TDA3x Overview	335
1.2 TDA3x Environment	337
1.3 TDA3x Description	338
1.3.1 Block Diagram	338
1.3.2 MCU Subsystem	339
1.3.3 DSP Subsystem	339
1.3.4 EVE Subsystem	339
1.3.5 Imaging Subsystem	340
1.3.6 Video Input Capture	341
1.3.7 Display Subsystem	341
1.3.8 On-Chip Debug Support	342
1.3.9 On-Chip Memory	342
1.3.10 Memory Management	342
1.3.11 External Memory Interfaces	342
1.3.12 Power, Reset, and Clock Management	343
1.3.13 System and Connectivity Peripherals	343
1.3.13.1 System Peripherals	343
1.3.13.2 Connectivity Peripherals	344
1.3.13.3 Serial Control Peripherals	344
1.4 TDA3x Family	345
1.5 TDA3x Device Identification	345
1.6 TDA3x Package Characteristics Overview	347
2 Memory Mapping	348
2.1 Introduction	349
2.2 L3_MAIN Memory Map	351
2.2.1 L3_INSTR Memory Map	353
2.3 L4 Memory Map	355
2.3.1 L4_CFG Memory Map	355
2.3.2 L4_WKUP Memory Map	357
2.4 L4_PER Memory Map	358
2.4.1 L4_PER1 Memory Space Mapping	358
2.4.2 L4_PER2 Memory Map	360
2.4.3 L4_PER3 Memory Map	361
2.5 IPU Memory Map	363
2.6 DSP Memory Map	365
2.7 EVE Memory Map	366
3 Power, Reset, and Clock Management	367
3.1 Device Power Management Introduction	368
3.1.1 Device Power-Management Architecture Building Blocks	369
3.1.1.1 Clock Management	369
3.1.1.1.1 Module Interface and Functional Clocks	369

3.1.1.1.2	Module-Level Clock Management	370
3.1.1.1.3	Clock Domain	375
3.1.1.1.4	Clock Domain-Level Clock Management	376
3.1.1.1.5	Clock Domain HW_AUTO Mode Sequences	377
3.1.1.1.6	Clock Domain Sleep/Wake-up	380
3.1.1.1.7	Clock Domain Dependency	381
3.1.1.2	Power Management	387
3.1.1.2.1	Power Domain	387
3.1.1.2.2	Module Logic and Memory Context	389
3.1.1.2.3	Power Domain Management	389
3.1.1.3	Voltage Management	391
3.1.1.3.1	Voltage Domain	391
3.1.1.3.2	Voltage Domain Management	392
3.1.1.3.3	AVS Overview	393
3.1.2	Power-Management Techniques	395
3.1.2.1	Standby Leakage Management	395
3.1.2.2	Dynamic Voltage and Frequency Scaling	395
3.1.2.3	Dynamic Power Switching	396
3.1.2.4	Adaptive Voltage Scaling	397
3.1.2.5	Combining Power-Management Techniques	397
3.1.2.5.1	DPS Versus SLM	398
3.2	PRCM Subsystem Overview	399
3.2.1	Introduction	399
3.2.2	Power-Management Framework Features	400
3.3	PRCM Subsystem Environment	402
3.3.1	External Clock Signals	402
3.3.2	External Boot Signals	402
3.3.3	External Reset Signals	402
3.3.4	External Voltage Inputs	403
3.4	PRCM Subsystem Integration	404
3.4.1	Device Power-Management Layout	404
3.4.2	Power-Management Scheme, Reset, and Interrupt Requests	406
3.4.2.1	Power Domain	406
3.4.2.2	Resets	406
3.4.2.3	PRCM Interrupt Requests	407
3.5	Reset Management Functional Description	408
3.5.1	Overview	408
3.5.1.1	Reset Management Functional Description	408
3.5.1.1.1	Power-On Reset	408
3.5.1.1.2	Warm Reset	408
3.5.1.2	PRM Reset Management Functional Description	408
3.5.2	General Characteristics of Reset Signals	408
3.5.2.1	Scope	409
3.5.2.2	Occurrence	409
3.5.2.3	Source Type	409
3.5.2.4	Retention Type	409
3.5.3	Reset Sources	410
3.5.3.1	Global Reset Sources	410
3.5.3.2	Local Reset Sources	410
3.5.4	Reset Logging	411
3.5.5	Reset Domains	411
3.5.6	Reset Sequences	422
3.5.6.1	IPU1 Subsystem Power-On Reset Sequence	422

3.5.6.2	DSP1 Subsystem Power-On Reset Sequence	423
3.5.6.3	DSP1 Subsystem Software Warm Reset Sequence.....	424
3.5.6.4	DSP2 Subsystem Power-On Reset Sequence	425
3.5.6.5	DSP2 Subsystem Software Warm Reset Sequence.....	425
3.5.6.6	EVE Subsystem Power-On Reset Sequence.....	426
3.5.6.7	EVE Subsystem Software Warm Reset Sequence	427
3.5.6.8	Global Warm Reset Sequence	427
3.6	Clock Management Functional Description	430
3.6.1	Overview	430
3.6.2	External Clock Inputs.....	430
3.6.2.1	High-Frequency System Clock Input.....	430
3.6.2.2	External Reference Clock Input	431
3.6.3	Internal Clock Sources/Generators	431
3.6.3.1	PRM Clock Source	431
3.6.3.2	CM Clock Source	433
3.6.3.2.1	CM_CORE_AON Clock Generator	433
3.6.3.2.2	CM_CORE_AON_CLKOUTMUX Overview	439
3.6.3.2.3	CM_CORE_AON_TIMER Overview	443
3.6.3.2.4	CM_CORE_AON_MCASP1 Overview	444
3.6.3.3	Clock Control in Control Module.....	447
3.6.3.3.1	Programming Guide For Control Module	449
3.6.3.4	Generic DPLL Overview	450
3.6.3.4.1	DPLLs Output Clocks Parameters	450
3.6.3.4.2	Enable Control, Status, and Low-Power Operation Mode	452
3.6.3.4.3	DPLL Power Modes	452
3.6.3.4.4	DPLL Recalibration	453
3.6.3.4.5	DPLL Output Power Down.....	454
3.6.3.5	DPLL_PER Description	455
3.6.3.5.1	DPLL_PER Overview.....	455
3.6.3.5.2	DPLL_PER Synthesized Clock Parameters	455
3.6.3.5.3	DPLL_PER Power Modes	456
3.6.3.5.4	DPLL_PER Recalibration	456
3.6.3.6	DPLL_CORE Description.....	457
3.6.3.6.1	DPLL_CORE Overview	457
3.6.3.6.2	DPLL_CORE Synthesized Clock Parameters.....	457
3.6.3.6.3	DPLL_CORE Power Modes	458
3.6.3.6.4	DPLL_CORE Recalibration	459
3.6.3.6.5	Fractional M-factor (SR2.0).....	459
3.6.3.7	DPLL_EVE_VID_DSP Description	459
3.6.3.7.1	DPLL_EVE_VID_DSP Overview	459
3.6.3.7.2	DPLL_EVE_VID_DSP Synthesized Clock Parameters	459
3.6.3.7.3	DPLL_EVE_VID_DSP Power Modes	460
3.6.3.7.4	DPLL_EVE_VID_DSP Recalibration	460
3.6.3.8	DPLL_GMAC_DSP Description	461
3.6.3.8.1	DPLL_GMAC_DSP Overview	461
3.6.3.8.2	DPLL_GMAC_DSP Synthesized Clock Parameters	461
3.6.3.8.3	DPLL_GMAC_DSP Power Modes.....	462
3.6.3.8.4	DPLL_GMAC_DSP Recalibration.....	462
3.6.3.9	DPLL_DDR Description.....	463
3.6.3.9.1	DPLL_DDR Overview	463
3.6.3.9.2	DPLL_DDR Synthesized Clock Parameters.....	463
3.6.3.9.3	DPLL_DDR Power Modes	463
3.6.3.9.4	DPLL_DDR Recalibration	464

3.6.4	Clock Domains	464
3.6.4.1	CD_WKUPAON Clock Domain	464
3.6.4.1.1	Overview	464
3.6.4.1.2	Clock Domain Modes	465
3.6.4.1.3	Clock Domain Dependency	466
3.6.4.1.4	Clock Domain Module Attributes	466
3.6.4.2	CD_DSP1 Clock Domain	468
3.6.4.2.1	Overview	468
3.6.4.2.2	Clock Domain Modes	469
3.6.4.2.3	Clock Domain Dependency	469
3.6.4.2.4	Clock Domain Module Attributes	470
3.6.4.3	CD_DSP2 Clock Domain	470
3.6.4.3.1	Overview	470
3.6.4.3.2	Clock Domain Modes	471
3.6.4.3.3	Clock Domain Dependency	471
3.6.4.3.4	Clock Domain Module Attributes	472
3.6.4.4	CD_CUSTEFUSE Clock Domain	473
3.6.4.4.1	Overview	473
3.6.4.4.2	Clock Domain Modes	473
3.6.4.4.3	Clock Domain Dependency	474
3.6.4.4.4	Clock Domain Module Attributes	474
3.6.4.5	CD_L4PER1 Clock Domain	474
3.6.4.5.1	Overview	474
3.6.4.5.2	Clock Domain Modes	475
3.6.4.5.3	Clock Domain Dependency	476
3.6.4.5.4	Clock Domain Module Attributes	483
3.6.4.6	CD_L4PER2 Clock Domain	486
3.6.4.6.1	Overview	486
3.6.4.6.2	Clock Domain Modes	486
3.6.4.6.3	Clock Domain Dependency	487
3.6.4.6.4	Clock Domain Module Attributes	489
3.6.4.7	CD_L4PER3 Clock Domain	491
3.6.4.7.1	Overview	491
3.6.4.7.2	Clock Domain Modes	492
3.6.4.7.3	Clock Domain Dependency	492
3.6.4.7.4	Clock Domain Module Attributes	492
3.6.4.8	CD_L3INIT Clock Domain	493
3.6.4.8.1	Overview	493
3.6.4.8.2	Clock Domain Modes	494
3.6.4.8.3	Clock Domain Dependency	494
3.6.4.8.4	Clock Domain Module Attributes	495
3.6.4.9	CD_EMU Clock Domain	496
3.6.4.9.1	Overview	496
3.6.4.9.2	Clock Domain Modes	496
3.6.4.9.3	Clock Domain Dependency	496
3.6.4.9.4	Clock Domain Module Attributes	497
3.6.4.10	CD_DSS Clock Domain	497
3.6.4.10.1	Overview	497
3.6.4.10.2	Clock Domain Modes	497
3.6.4.10.3	Clock Domain Dependency	498
3.6.4.10.4	Clock Domain Module Attributes	499
3.6.4.11	CD_L4_CFG Clock Domain	499
3.6.4.11.1	Overview	499

3.6.4.11.2	Clock Domain Modes.....	500
3.6.4.11.3	Clock Domain Dependency	500
3.6.4.11.4	Clock Domain Module Attributes.....	501
3.6.4.12	CD_L3_INSTR Clock Domain	502
3.6.4.12.1	Overview	502
3.6.4.12.2	Clock Domain Modes.....	502
3.6.4.12.3	Clock Domain Dependency	502
3.6.4.12.4	Clock Domain Module Attributes.....	503
3.6.4.13	CD_L3_MAIN1 Clock Domain	504
3.6.4.13.1	Overview	504
3.6.4.13.2	Clock Domain Modes.....	504
3.6.4.13.3	Clock Domain Dependency	505
3.6.4.13.4	Clock Domain Module Attributes.....	505
3.6.4.14	CD_EMIF Clock Domain	507
3.6.4.14.1	Overview	507
3.6.4.14.2	Clock Domain Modes.....	507
3.6.4.14.3	Clock Domain Dependency	508
3.6.4.14.4	Clock Domain Module Attributes.....	508
3.6.4.15	CD_IPU Clock Domain	509
3.6.4.15.1	Overview	509
3.6.4.15.2	Clock Domain Modes.....	509
3.6.4.15.3	Clock Domain Dependency	510
3.6.4.15.4	Clock Domain Module Attributes.....	510
3.6.4.16	CD_IPU1 Clock Domain	512
3.6.4.16.1	Overview	512
3.6.4.16.2	Clock Domain Modes.....	512
3.6.4.16.3	Clock Domain Dependency	513
3.6.4.16.4	Clock Domain Module Attributes.....	513
3.6.4.17	CD_CRC Clock Domain	514
3.6.4.17.1	Overview	514
3.6.4.17.2	Clock Domain Modes.....	514
3.6.4.17.3	Clock Domain Module Attributes.....	515
3.6.4.18	CD_CAM Clock Domain	515
3.6.4.18.1	Overview	515
3.6.4.18.2	Clock Domain Modes.....	516
3.6.4.18.3	Clock Domain Dependency	516
3.6.4.18.4	Clock Domain Module Attributes.....	517
3.6.4.19	CD_COREAON_L4 Clock Domain.....	517
3.6.4.19.1	CD_COREAON_L4 Overview.....	517
3.6.4.19.2	Clock Domain Modes.....	518
3.6.4.19.3	Clock Domain Dependency	518
3.6.4.20	CD_GMAC Clock Domain	519
3.6.4.20.1	Overview	519
3.6.4.20.2	Clock Domain Modes.....	519
3.6.4.20.3	Clock Domain Dependency	520
3.6.4.20.4	Clock Domain Module Attributes.....	520
3.6.4.21	CD_ISS Clock Domain.....	521
3.6.4.21.1	CD_ISS Overview.....	521
3.6.4.21.2	Clock Domain Modes.....	521
3.6.4.21.3	Clock Domain Dependency	522
3.6.4.21.4	Clock Domain Module Attributes.....	522
3.6.4.22	CD_EVE1 Clock Domain	523
3.6.4.22.1	CD_EVE1 Overview	523

3.6.4.22.2	Clock Domain Modes.....	523
3.6.4.22.3	Clock Domain Dependency	524
3.6.4.22.4	Clock Domain Module Attributes.....	524
3.7	Power Management Functional Description.....	526
3.7.1	PD_WKUPAON Description	526
3.7.1.1	Power Domain Modes	526
3.7.1.1.1	Logic and Memory Area Power Modes	526
3.7.2	PD_DSP1 Description.....	527
3.7.2.1	Power Domain Modes	527
3.7.2.1.1	Logic and Memory Area Power Modes	527
3.7.2.1.2	Logic and Memory Area Power Modes Control and Status	528
3.7.3	PD_DSP2 Description.....	528
3.7.3.1	Power Domain Modes	529
3.7.3.1.1	Logic and Memory Area Power Modes	529
3.7.3.1.2	Logic and Memory Area Power Modes Control and Status	529
3.7.4	PD_CUSTEFUSE Description	530
3.7.4.1	Power Domain Modes	530
3.7.4.1.1	Logic and Memory Area Power Modes	530
3.7.4.1.2	Logic and Memory Area Power Modes Control and Status	530
3.7.5	PD_IPU Description	531
3.7.5.1	Power Domain Modes	531
3.7.5.1.1	Logic and Memory Area Power Modes	531
3.7.5.1.2	Logic and Memory Area Power Modes Control and Status	532
3.7.6	PD_DSS Description	532
3.7.6.1	Power Domain Modes	533
3.7.6.1.1	Logic and Memory Area Power Modes	533
3.7.6.1.2	Logic and Memory Area Power Mode Control and Status	533
3.7.7	PD_CAM Description.....	534
3.7.7.1	Power Domain Modes	534
3.7.7.1.1	Logic and Memory Area Power Modes	534
3.7.7.1.2	Logic and Memory Area Power Mode Control and Status	534
3.7.8	PD_MMAON Description	535
3.7.8.1	Power Domain Modes	535
3.7.9	PD_COREAON Description	535
3.7.9.1	Power Domain Modes	537
3.7.10	PD_ISS Description	538
3.7.10.1	Power Domain Modes	538
3.7.10.1.1	Logic and Memory Area Power Modes	538
3.7.10.1.2	Logic and Memory Area Power Modes Control and Status	538
3.7.11	PD_EVE1 Description.....	539
3.7.11.1	Power Domain Modes	539
3.7.11.1.1	Logic and Memory Area Power Modes	539
3.7.11.1.2	Logic and Memory Area Power Modes Control and Status	540
3.8	Voltage-Management Functional Description	541
3.8.1	Overview	541
3.8.2	Voltage-Control Architecture	541
3.8.3	Internal LDOs Control	542
3.8.3.1	VDD_CORE_L and VDD_DSPEVE_L Control	542
3.8.3.1.1	Adaptive Voltage Scaling	542
3.8.3.2	Memory LDOs.....	542
3.8.3.3	BANDGAP Control	542
3.8.3.4	Memory LDO Transitions.....	542
3.8.3.5	VDD_WKUP_L Transitions.....	543

3.9	Device Low-Power States	544
3.9.1	Device Wake-Up Source Summary	544
3.9.2	Wakeup Upon Global Warm Reset.....	545
3.9.3	Global Warm Reset During a Device Wake-Up Sequence	545
3.9.4	I/O Management	546
3.9.4.1	Isolation / Wakeup Sequence.....	546
3.9.4.1.1	Software-Controlled I/O Isolation	547

About This Manual

Information About Cautions and Warnings

This book may contain cautions and warnings.

CAUTION

This is an example of a caution statement.

A caution statement describes a situation that could potentially damage your software or equipment.

WARNING

This is an example of a warning statement.

A warning statement describes a situation that could potentially cause harm to you.

The information in a caution or a warning is provided for your protection. Please read each caution and warning carefully.

Register, Field, and Bit Calls

The naming convention applied for a call consists of:

- For a register call: *<Module name>.<Register name>*; for example: UART.UASR
- For a bit field call:
 - *<Module name>.<Register name>[End:Start] <Field name> field*; for example, UART.UASR[4:0] SPEED bit field
 - *<Field name> field <Module name>.<Register name>[End:Start]*; for example, SPEED bit field UART.UASR[4:0]
- For a bit call:
 - *<Module name>.<Register name>[pos] <Bit name> bit*, for example, UART.UASR[5] BIT_BY_CHAR bit
 - *<Bit name> bit <Module name>.<Register name>[pos]*; for example, BIT_BY_CHAR bit UART.UASR[5]

To help the reader navigate the document, each register call is hyperlinked to its register description in the register manual section. After each register description, a table summarizes all hyperlinked register calls.

Coding Rules

The programming models or code listings follow the rules:

Type	Definition	Example
File	Starts with the module name	PRCM_test1.c MCBSP1_init.h
Variable	Global variables are prefixed by "g_" Pointers are prefixed by "p" Global pointers are prefixed by "g_p"	g_SDMA_LogicalChan pAddrCounter g_pSDMA_LogicalChan
Function	Starts with the module name	PRCM_SetupClocks() ArmIntC_MaskInterrupts()
Typedef	Ends with "_t"	PRCM_Struct_t
Definition	Starts with the module name and is followed by the register name	#define SMS_ERR_TYPE *((volatile Uint32*)0x680080F4) #define MCBSP2_RCR1_REG *((volatile Uint32*)0x4807401C)
Enumeration	Starts with the module name	Typedef enum DMA_Mode_Label { INPUT_MODE OUTPUT_MODE } DMA_Mode_t;

Flow Chart Rules

Flow charts follow the following rules:

Shape	Name	Definition
	Process	Any computational steps or processing function of a program; defined operation(s) causing change in value, form, or location of information
	Decision	A decision or switching-type operation that determines which of a number of alternate paths is followed
	Predefined process or sub-process	One or more named operations or program steps specified in a subroutine or another set of flow charts
	Data or I/O	General I/O function; information available for processing (input) or recording of processed information (output)
	Terminator	Terminal point in a flow chart: start, stop, halt, delay, or interrupt; may show exit from a closed subroutine
	Annotation	Additional descriptive clarification, comment
	On page connector (reference)	Exit to, or entry from, another part of chart in the same page
	Off page connector (reference)	The flow continues on a different page.
	Summing Junction	Logical AND
	Or	Logical OR
	Parallel mode (ISO)	Beginning or end of two or more simultaneous operations
	Flow Line	Lines indicate the sequence of steps and the direction of flow.

1.1 TDA3x Overview

TDA3x is an ADAS applications device based on enhanced OMAP™ architecture integrated on a 28-nm technology. TDA3x complements the TDA2x ADAS device family by using a common architecture, enabling scalability from entry to high performance for a broad range of applications.

- The device family is targeted at ADAS applications including Front Camera, Intelligent Rear Camera, Radar and Mirror Replacement.

NOTE: The supported set of features and peripherals is device part number dependent. Refer to device Data Manual, for more information.

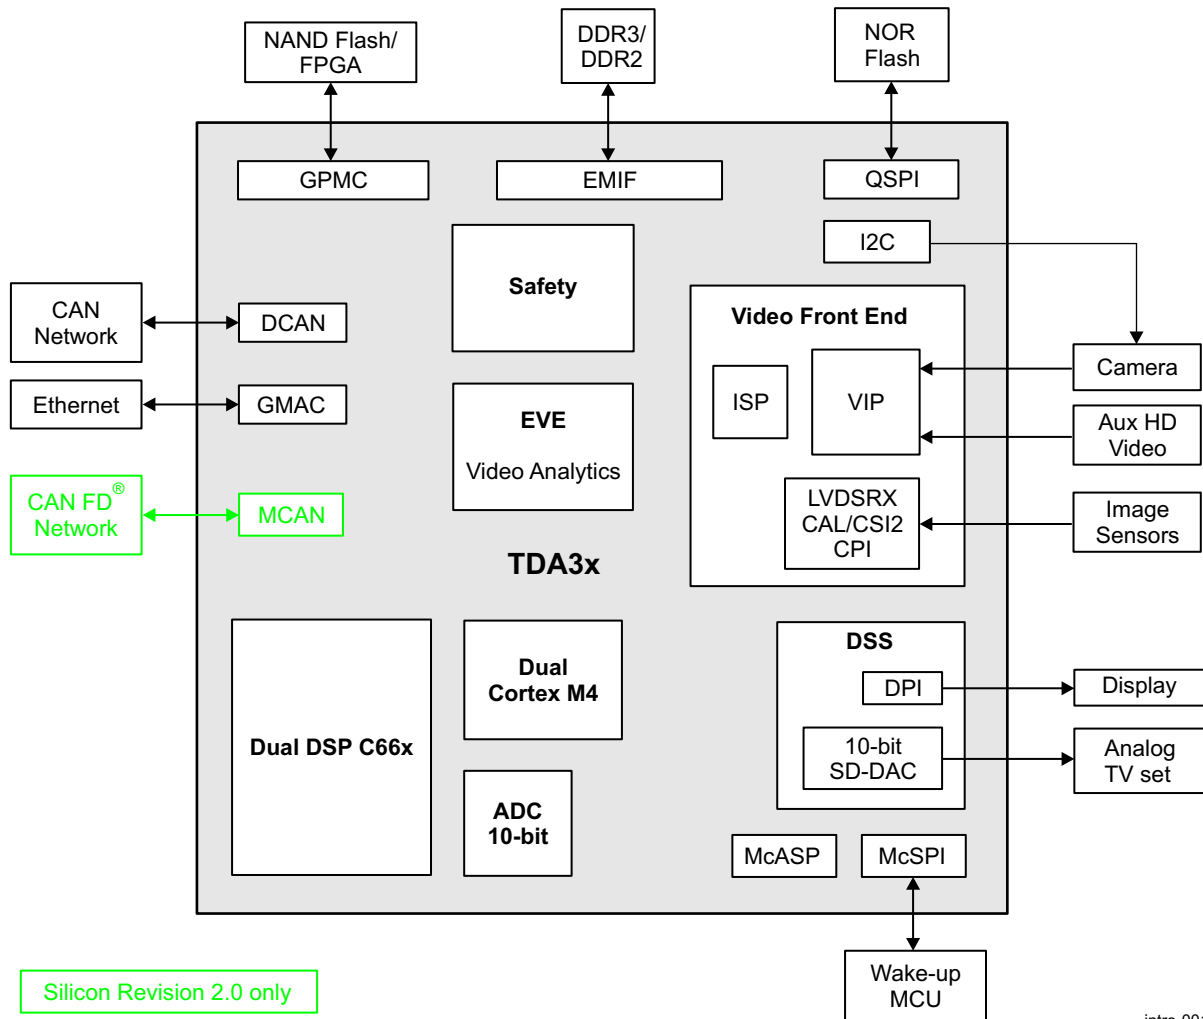

- The device is composed of the following main subsystems:
 - Up to two Digital Signal Processor (DSP) C66x subsystems
 - Embedded Vision Engine (EVE) accelerator subsystem
 - Dual Cortex®-M4 microprocessor unit (MCU) subsystem
 - Video Input capture Port (VIP)
 - Display Subsystem (DSS)
 - Imaging Subsystem (ISS) with Imaging Signal Processor (ISP)
 - Debug Subsystem
- The device provides a rich set of connectivity peripherals, including among others:
 - Camera Parallel Interface (CPI)
 - Camera Serial Interface (MIPI® CSI-2)
 - Display parallel 24-bit output (for MIPI DPI 2.0, or BT.656/BT.1120 support), and one NTSC/PAL Standard Definition DAC (for composite video support)
 - Gigabit Ethernet (GEMAC) subsystem
 - Two DCAN subsystems (in SR1.0 only); One DCAN subsystem (in SR2.0)
 - One MCAN subsystem (in SR2.0 only)
 - One SDIO controller
 - One QSPI module
 - One McASP module (in SR1.0); Three McASP modules (in SR2.0 only)
 - One PWMSS module
- The device also integrates:
 - On-chip memory
 - External memory interfaces
 - Memory management
 - Level 3 (L3_MAIN) and level 4 (L4) interconnects
 - System and serial control peripherals
 - PLLs (Phase Lock Loop) for internal clock generation
- The device includes comprehensive support for functional safety system requirements:
 - Dual core ECC-protected M4
 - ECC protected 32-bit DDR interface
 - Error Detection and Correction:
 - Parity bit per byte on C66x DSP L1 program cache and Single-Error Correction Dual-Error Detection (SECEDED) on L2 memories on the DSP
 - SECEDED on Large L3 on-chip RAM
 - Dedicated Memory management units per CPU (Cortex-M4 MCU, C66x DSP, EDMA) to implement freedom from interference
 - Memory protection units inside Cortex-M4 MCU subsystem to allow freedom from interference

- Memory protection units internal to DSP cache controller to allow freedom from interference
- Firewalls to enable isolation and in-advertent accesses
- Real Time Interrupt (RTI) module supporting a windowed watchdog feature
- Dedicated hardware accelerated CRC block
- Embedded CRC to handle MIPI pixel data on CSI-2 interface
- Two C66x DSP subsystems for redundant calculations
- MISR test schemes for EVE
- Parity protected EVE internal memories on minimum access size granularity
- LBIST controller for testing device processors and PBIST controller for all on-chip memories
- ESM module to enable error monitoring off-chip
- DCC module for online clock monitoring
- Temperature monitoring sensors
- Embedded 8-channel ADC for system monitoring

NOTE: The supported set of features and peripherals is device part number dependent. Refer to device Data Manual, for more information.

1.3.2 MCU Subsystem

The Dual Cortex-M4 MCU subsystem includes the following components:

- Two Cortex-M4 CPUs
- ARMv7E-M and Thumb-2 instruction set architectures
- Hardware division and single-cycle multiplication acceleration
- Dedicated INTC with up to 63 physical interrupt events with 16-level priority
- Two-level memory subsystem hierarchy
 - L1 Unicache RAM
 - 32-KiB shared cache memory
 - L2 ROM + RAM
 - 64-KiB RAM
 - 32-KiB bootable ROM (in SR1.0 only); 16-KiB bootable ROM (in SR2.0)
- ECC on all internal memories
- MMU with protection attributes for address translation
- Integrated power management
- Emulation feature embedded in the Cortex-M4

1.3.3 DSP Subsystem

There can be up to two DSP subsystems in the device. Each DSP subsystem contains the following submodules:

- TMS320C66x VLIW DSP core for audio processing, and general-purpose imaging and video processing. It extends the performance of existing C64x+ and C647x DSPs through enhancements and new features.
 - 32-KiB L1D and 32-KiB L1P cache or addressable SRAM
 - 288-KiB L2 cache
 - 256-KiB configurable as cache or SRAM
 - 32-KiB SRAM
- Enhanced direct memory access (EDMA) engine for video and audio data transfer
- Memory management units (MMU) for address management.
- Interrupt controller (INTC)
- Emulation capabilities

1.3.4 EVE Subsystem

The Embedded Vision Engine (EVE) module is a programmable imaging and vision processing engine allowing late in-development or post-silicon processing requirements to be met by addition of differentiating features in imaging and vision products. EVE also provides full featured debug support.

The EVE subsystem consists of the following main units:

- ARP32 scalar core with 32-KiB direct mapped program cache, and 32-KiB data memory
- VCOP vector core with 16 processing elements, 32-KiB working buffer, and four 16-KiB image buffers
- Integrated EDMA controller and memory management units

1.3.5 Imaging Subsystem

The imaging subsystem (ISS) deals with the processing of pixel data coming from external image sensor or data from memory (image format encoding and decoding can be done to and from memory). ISS is mainly composed of MIPI[®] CSI-2, LVDS-RX, and parallel camera interfaces, an image signal processor (ISP) and block based imaging accelerator (SIMCOP). ISS is tightly coupled with a low-interrupt latency microprocessor subsystem (Cortex-M4 IPU), which runs a real-time operating system (OS) to reach optimal performance, and can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks.

ISS is a key component for Rear View Camera, Front View Stereo Camera, and Surround View Camera applications.

ISS targets the following major use cases:

- Video / Preview
 - Up to 1080p60
 - Up to 2x 1080p30
- Stereo Video / Preview
 - Up to 2x 1080p30
- Zero or negative shutter lag still image capture
- Multi-camera use cases, with capability of up to 4 simultaneous cameras (ISP is time shared)

ISS offers the following main features:

- ISS interfaces:
 - Two Camera Adapter Layer (CAL) modules:
 - CAL_A serves as sensor capture interface supporting MIPI CSI-2 protocol via external MIPI D-PHY with 4 data lanes (up to 1.5 Gbps per lane), and providing data write DMA function
 - CAL_B supporting data read DMA function only, without support for sensor capture
 - 16-bit parallel interface (CPI), with up to 212.8 MPix/s throughput, and supporting BT656, SYNC modes
 - LVDS-RX receiver
 - 128-bit data interface to L3_MAIN system interconnect
- Image Signal Processor (ISP):
 - On-the-fly or memory-to-memory processing
 - Up to 212.8 MPix/s throughput
 - Statistic data collection
 - Image pipe interface (IPIPE) front-end RAW data processing
 - IPIPE back-end RGB and YUV data processing
 - High-ISO video noise filtering (NSF3V)
 - Global and local contrast enhancement accelerator (GLBCE)
 - Two image continuous real-time resizers
 - Chroma noise filter (CNF)
- Still Image Coprocessor (SIMCOP):
 - Memory-to-memory operation
 - Warping accelerator (LDC)
 - Temporal video noise filter (VTNF)
 - Direct memory access (DMA) controller
 - Hardware sequencer
 - Mesh based lens distortion and perspective correction

1.3.6 Video Input Capture

There is one Video Input Port (VIP) module in the device, providing video capture functions. The VIP module supports:

- Two separate 16-bit video ports for parallel RGB/YUV/RAW (or BT656/1120) data, up to 165 MHz
- Up to two separate 8-bit video ports for YUV/RAW (or BT656) data, up to 165 MHz
- Embedded Sync (multiplexed sources) and Discrete Sync (single source) data interface modes
- Color space conversion and scaling:
 - Up to 2047 pixels wide input with scaling
 - Up to 3840 pixels wide input - when chroma up/down sampling without scaling
 - Up to 4095 pixels wide input - without scaling and chroma up/down sampling
 - Maximum input resolution support is further limited by pixel clock and feature-dependent constraints
- Embedded DMA engine, supporting tiled (2D) and raster addressing

1.3.7 Display Subsystem

The display subsystem provides the logic and control signals required to interface the device system memory frame buffer (SDRAM) directly to a display or central applications processor with display compatible inputs. Various pixel processing capabilities are supported, such as: color space conversion, filtering, scaling, blending, color keying, etc. The display subsystem allows low-power display refresh and arbitration between normal and low-priority pipelines. The display subsystem consists of the following components:

- Display controller (DISPC): Reads and displays the encoded pixel data stored in memory and writes the output of one of the overlays or one of the pipelines into the system memory. The display controller supports the following components:
 - Two video pipelines, one graphic pipeline, and one write-back pipeline.
 - Graphic pipeline supports pixel formats such as: ARGB16-4444, RGB16-565, ARGB16-1555, ARGB32-8888, RGBA32-8888, RGB24-888, and BITMAP (1, 2, 4, or 8 bits per pixel). It implements also color-depth expansion.
 - Video pipelines support pixel formats such as: YUV (4:2:0/4:2:2), RGB565, ARGB16-4444, RGB16-565, ARGB16-1555, ARGB32-8888, RGBA32-8888, RGB24-888 and BITMAP (1, 2, 4, or 8 bits per pixel). They provide color conversion from YUV to RGB, and scaling up to 1080p (5-tap).
 - CLUT (1, 2, 4, or 8-bit BITMAP input, 24-bit RGB output) on video and graphics pipelines.
 - Write-back pipeline: YUV or RGB input from either one of video pipeline outputs, graphics pipeline output, or overlay managers outputs. Uses poly-phase filtering for independent horizontal and vertical resampling (upsampling and downsampling). It allows programmable color space conversion of RGB24 into YUV4:2:2-UYVY, YUV4:2:2-YUV2, or YUV4:2:0-NV12 or NV21, and selection of color-depth reduction from RGB24 to RGB16.
 - Own direct memory access (DMA) engine
 - Two overlay managers, receiving the outputs of the video and graphic pipelines, and applying overlay function using rules based on z-order, transparency color keys, and alpha blending values.
- NTSC/PAL Video Encoder (VENC) with the following main features:
 - Output to 10-bit on-chip standard definition video digital-to-analog converter (SD_DAC), supporting sampling rates up to 60 MSPS, and full-scale output voltage (1.2 V_{pp} with a 75Ohm load)
 - Support for square pixel sampling
 - Programmable horizontal synchronization, vertical timing, and waveforms
- Display outputs:
 - One parallel 24-bit RGB888 output, used for BT.656 or BT.1120, or MIPI® DPI 2.0 interface, supporting up to 165 MHz pixel clock video formats defined in CEA-861-E and VESA DMT standards.
 - One composite analog video output (DC or AC coupled), provided by the SD_DAC.
 - Parallel and SD_DAC interfaces can output the same video (composed by a single overlay)

manager in the Display Controller), but not simultaneously.

1.3.8 On-Chip Debug Support

The on-chip debug support has the following features:

- Multiprocessor debugging lets users control multiple CPU cores embedded in the device, such as:
 - Global starting and stopping of individual or multiple processors
 - Each processor can generate triggers that can be used to alter the execution flow of other processors
 - System clocking and power down
 - Interconnection of multiple devices
 - Channel triggering
- The following device cores can be debugged via Code Composer Studio (CCS):
 - Cortex-M4
 - DSP
 - EVE
- Target debugging, using IEEE1149.1 (JTAG®)
- Reduction of power consumption in normal operating mode

The debug subsystem includes:

- Generic TAP for emulation and test control (ICEPick-D)
- Debug access port (DAP)
- Embedded Trace Macro (ETM)
- Trace Port Interface Unit (TPIU)
- Embedded Trace Buffer (ETB)
- Emulation Pin Manager (EPM)
- Cross triggering (XTRIG)

The debug subsystem provides also:

- ICEMelter, for controlling the wake-up and power-down of the emulation power domain
- L3_INSTR CORE instrumentation interconnect
- OCP watch-point (OCP-WP), for monitoring L3 interconnect transaction when target transaction attributes match the user-defined attributes or trigger on external debug event
- Power-management events profiler (PM instrumentation)
- Clock-management events profiler (CM instrumentation)
- Statistics collector (performance probes)

1.3.9 On-Chip Memory

- The device includes one On-Chip Memory Controller (OCMC) with associated RAM with ECC, with total size of up to 512 KiB.

1.3.10 Memory Management

The memory management is performed from:

- Enhanced DMA (EDMA) controller supporting two simultaneous read and two simultaneous write physical channels, and up to 64 programmable logical channels.
- One memory management unit (MMU), with 4KiB, 64KiB, 1MiB, 16MiB programmable page sizes, and 32 entries TLB.

1.3.11 External Memory Interfaces

- One 32-bit DDR memory controller (EMIF):

- Supporting LPDDR2/DDR2/DDR3/DDR3L
- 32-bit data path, one chip-select
- The EMIF controller supports Single bit Error Correction and Dual Error Detection (SECEDED)
 - SECEDED supported in both 32-bit and 16-bit/Narrow mode
 - Programmable address ranges to define SECEDED protected region
 - Parity bits calculated and stored on all writes to SECEDED protected address region
 - Parity bits verified on all reads from SECEDED protected address region
 - Statistics for 1-bit and 2-bit errors
- General-purpose memory controller (GPMC) supporting connection with:
 - Asynchronous SRAM memories
 - Asynchronous and synchronous NOR flash memories
 - NAND flash memories, with up to 16-bit ECC via the Error Location Module (ELM)
 - Pseudo-SRAM devices
- Quad SPI module, supporting 1 to 4 address bytes for SPI NOR flash, and up to 100 MHz single data rate

1.3.12 Power, Reset, and Clock Management

The PRCM module allows efficient control of clocks and power according to the required performance, and reduction of power consumption. The PRCM module is divided into:

- Power and reset management (PRM), based on the SmartReflex™ Class-0 framework with the following features:
 - Adaptive Voltage Scaling (AVS)
 - Dynamic clock gating
 - Dynamic power switching (DPS)
 - Dynamic frequency scaling
- Clock management (CM) for clock generation and distribution, allowing reduction of dynamic consumption.
- Temperature sensor

1.3.13 System and Connectivity Peripherals

The device supports a rich set of peripherals to provide flexible and high-speed interfacing and on-chip programming resources.

1.3.13.1 System Peripherals

- Eight general-purpose timers (two timer modules supporting 1-ms tick generation)
- One 32-kHz synchronization timer
- System control module, which contains registers for the following functions:
 - Static device configuration
 - Debug and observability
 - Status
 - Pad configuration
 - I/O configuration
 - eFuse logic
 - Analog function control
 - System boot decoding logic
- System Mailbox with 2 mailbox message queues
- SpinLock module for hardware semaphore between the MCU and DSP subsystems

- Inter-processor Communication Register
- Multiple general-purpose input/output (GPIO) modules

1.3.13.2 Connectivity Peripherals

- One two-port switch (GEMAC), supporting 10, 100, or 1000 Mbps. It provides up to two external Ethernet ports and one internal CPPI interface port with Industrial Ethernet and 802.1ae support. Included 1.8- or 3.3-V RGMII.
- Two DCAN controllers (DCAN1 and DCAN2) in SR1.0, supporting bitrates up to 1 Mbit/s and compliant to the Controller Area Network (CAN) 2.0B protocol specification.
- One DCAN controller (DCAN) in SR2.0, supporting bitrates up to 1 Mbit/s, and compliant to the Controller Area Network (CAN) 2.0B protocol specification.
- One MCAN controller introduced in SR2.0, supporting CAN FD® (Flexible Data rate) with up to 64 data bytes per frame and bitrates up to 5 Mbit/s. Compliant to ISO 11898-1:2015.
 - The availability of CAN FD feature is device part number dependent. Refer to device Data Manual for more information.

1.3.13.3 Serial Control Peripherals

- Three universal asynchronous receiver/transmitter (UART) modules as serial-communication interfaces, 16C750 compatible
- Four general-purpose multichannel serial peripheral interface (McSPI) modules
- Two I²C controller modules with rates up to 400kbps
- One SDIO controller supporting 4-bit data bus width and SD3.0 physical layer with SDA3.00 standards, with embedded dual voltage I/Os (1.8 or 3V).
- One Multichannel Audio Serial Port (McASP) in SR1.0, supporting up to 16 channels and independent TX/RX clock/sync domains. Supporting DIT for S/PDIF output, and providing connectivity to HD Radio tuners and audio ADC/DAC.
- Three Multichannel Audio Serial Ports (McASP) in SR2.0, each supporting DIT for S/PDIF output, and providing connectivity to HD Radio tuners and audio ADC/DAC. In addition:
 - McASP1 supports up to 16 channels and independent TX/RX clock/sync domains.
 - McASP2 and McASP3 support up to 6 channels each, and independent TX/RX clock/sync domains.

1.4 TDA3x Family

The supported set of features and peripherals is device part number dependent. Refer to device Data Manual, for more information.

1.5 TDA3x Device Identification

[Table 1-1](#) describes the identification registers.

The identification registers include the data registers listed in [Table 1-2](#) and [Table 1-4](#). These registers are read-only accessed ports that are programmed into eFuses FARM FROM.

1.6 TDA3x Package Characteristics Overview

The package option for the device is: 15x15 FCBGA Lidded - ABF.

- Package Type: Lidded
 - Body: 15 × 15 mm
 - Technology: Ball Grid Array (BGA) package
 - Ball pitch: 0.65mm
 - Pins: 367

For more information on packaging refer to device Data Manual.

Memory Mapping

This chapter describes the memory mapping in the device.

2.3 L4 Memory Map	355
2.4 L4_PER Memory Map	358
2.5 IPU Memory Map	363
2.6 DSP Memory Map	365
2.7 EVE Memory Map	366

2.1 Introduction

The memory map has the following features that are shared among the initiators:

- Memory space: General-Purpose Memory Controller (GPMC)
- Register spaces: Level 3 (L3_MAIN) and level 4 (L4) interconnects
- Dedicated spaces: EVE/IPU/DSP subsystems

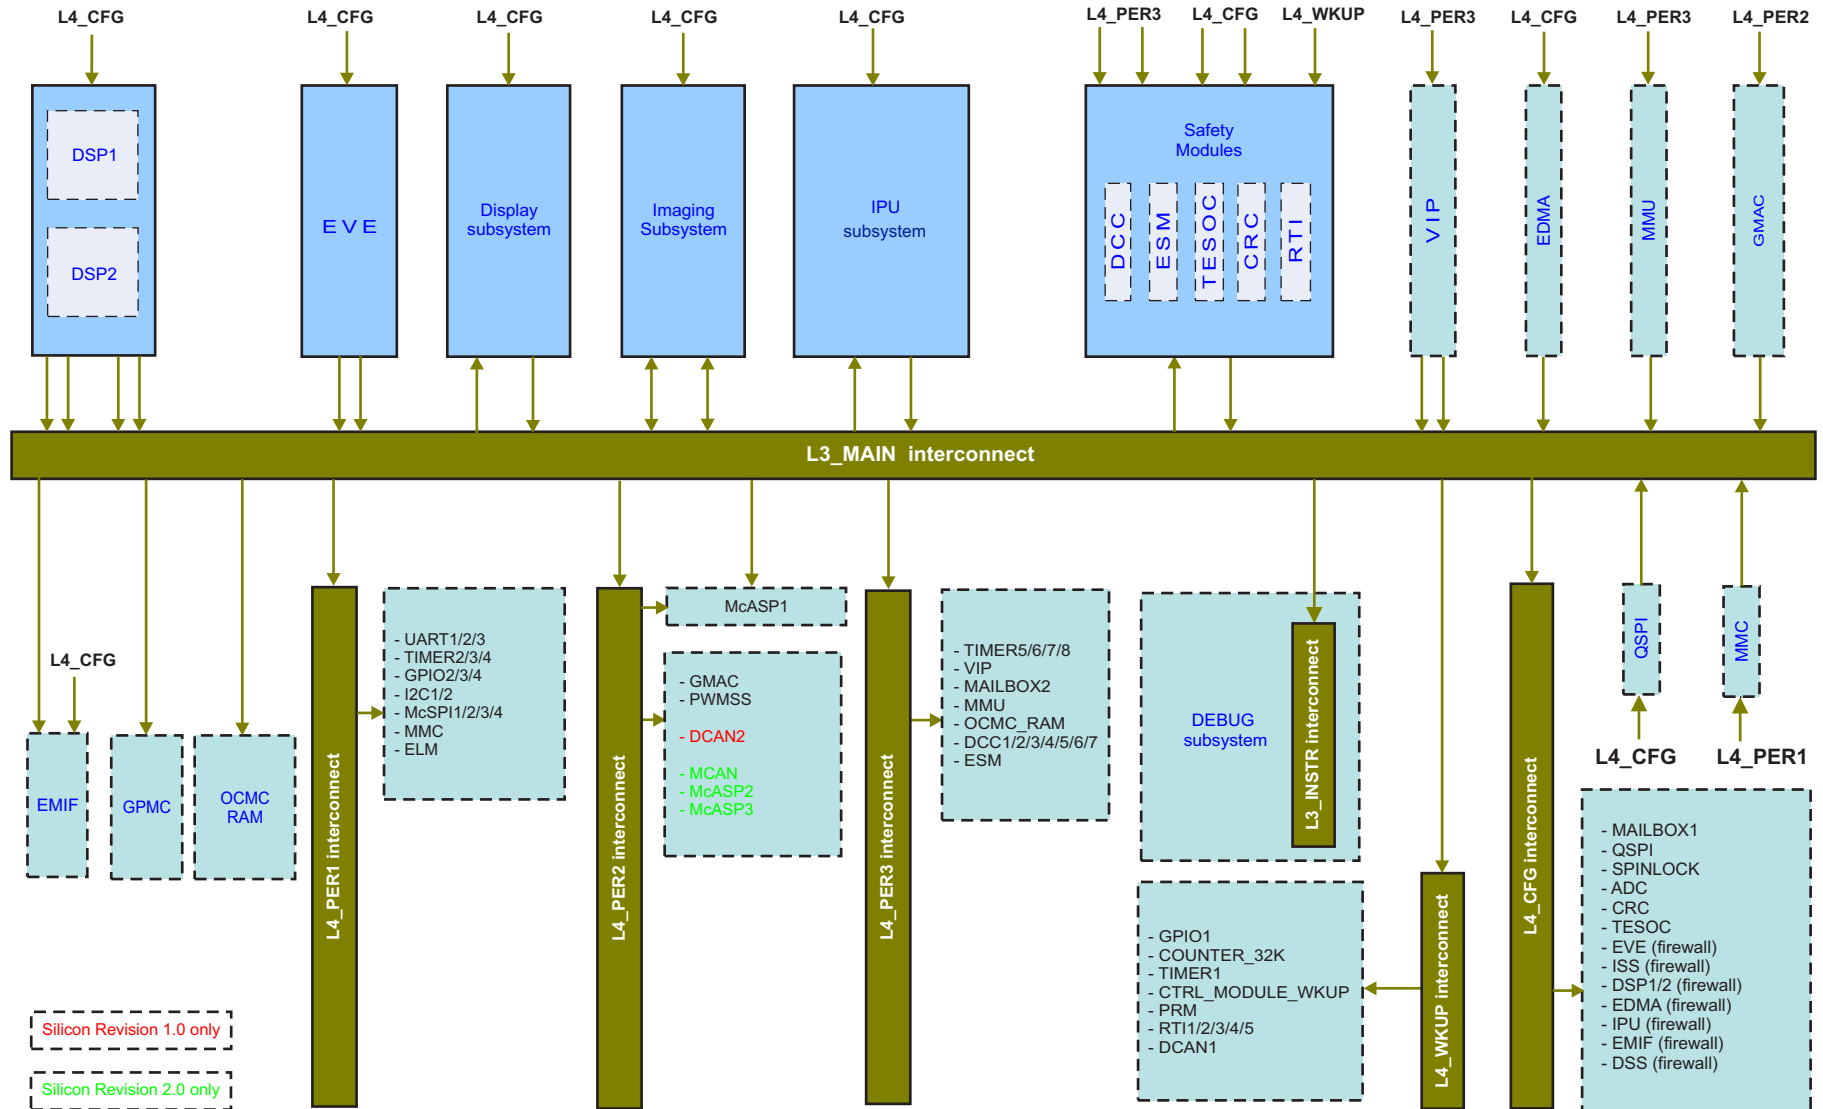

The GPMC and EMIF are dedicated to memory connection. The GPMC is used for NOR and NAND flash, and Static Random Access Memories (SRAMs). The EMIF is used for Synchronous Dynamic Random Access Memories (SDRAMs), such as DDR. For more information, see [Section 11.2, EMIF Controller](#).

The L3_MAIN interconnect allows the sharing of resources, such as peripherals and external or on-chip memories, among all the initiators of the platform. The L4 interconnects control access to the peripherals.

Transfers across the platform between initiators and targets are physically conditioned by the chip interconnect and can be logically conditioned by firewalls. For more information about the intercommunication (L3_MAIN and L4 interconnects) and protection mechanisms implemented in the device, see [Section 10.2, L3_MAIN Interconnect](#), and [Section 10.3, L4 Interconnects](#).

[Figure 2-1](#) shows the interconnect of the device, and the main modules and subsystems in the platform.

Figure 2-1. Interconnect Overview

memmap-001

2.2 L3_MAIN Memory Map

The memory space system is hierarchical: level 1 (L1), level 2 (L2), level 3 (L3_MAIN), and level 4 (L4). L1 and L2 are memories in the IPU and Digital Signal Processor (DSP) subsystems. L3_MAIN handles many types of data transfers, including data exchange with system on-chip/external memories. The chip-level interconnect, which consists of one L3_MAIN and number of L4 interconnects, enables communication among all modules and subsystems.

This section provides a global view of the memory mapping of the device at the L3_MAIN interconnect and describes the boot, GPMC, and SDRAM controller (SDRC) (EMIF) spaces.

The system memory mapping is flexible, with two levels of granularity for target address space allocation:

- L1: The four quarters are labeled Q0, Q1, Q2, and Q3. Each quarter corresponds to a 1-GiB address space (the total low-address space is 4 GiB, 32-bit).
- L2: Each quarter is divided into eight blocks of 32 MiB, with target spaces mapped in the blocks.

This organization allows the decoding of all target spaces based on the 7 most-significant bits (MSBs) of the 32-bit address, that is bits [31:25].

- Boot space:

When booting from the on-chip ROM with the appropriate external sys_boot pin configuration, the lowest 1-MiB memory space [0x0000 0000–0x000F FFFF] is redirected to the on-chip boot ROM address space [0x4000 0000–0x400F FFFF].

When booting from the GPMC, the memory space is part of the GPMC address space. At reset, the 0x0000 0000 address is available on chip-select 0 (CS0) for a memory size of 16 MiB.

For more information about the sys_boot pins configuration, see [Section 11.3, General-Purpose Memory Controller](#), and [Chapter 25, Initialization](#).

- GPMC space:

Eight independent GPMC chip-selects (CS0 to CS7) are available in the first quarter (Q0) of the addressing space to access NOR/NAND flash and SRAM. The chip-selects have a programmable start address and programmable size (up to 128 MiB) in a total memory space of (Q0) 1GiB, but limited now to 512 MiB.

- DDR/SDRAM (EMIF) space:

Q2 addressing space is 1GiB and is dedicated to EMIF.

Q3 addressing space is 1GiB and is dedicated to EMIF.

[Table 2-1](#) describes the global memory map.

2.3 L4 Memory Map

The L4 interconnects handle transfers with peripherals. The L4 interconnect comprises the following interconnects:

- L4_CFG
- L4_WKUP
- L4_PER1
- L4_PER2
- L4_PER3

The L4 interconnect can be configured to tune the access according to the characteristics of each module.

The following sections describe the register mapping of the L4 interconnect. Software configures these registers.

2.3.1 L4_CFG Memory Map

The L4_CFG interconnect is a 12-MiB space composed of the L4_CFG interconnect configuration registers and the module registers.

[Table 2-3](#) describes the mapping of the registers for the L4_CFG interconnect.

NOTE: All memory spaces described as modules provide direct access to module registers outside the L4_CFG interconnect. All other accesses are internal to the L4_CFG interconnect.

2.5 IPU Memory Map

The device implements one IPU subsystem. For more information about IPU, see [Chapter 5, Dual Cortex-M4 IPU Subsystem](#).

[Table 2-8](#) describes the IPU memory mapping.

NOTE: Some of the system (L3) resources, such as EVE and EDMA, are not directly accessible by IPU, as they are overlapping with IPU's own resources in its memory space. In such cases, software must properly configure IPU AMMU / L2 MMU so that IPU can access these system resources.

Figure 3-1. Clock Tree Tool (CTT)

prcm-095

The Clock Tree Tool (CTT) is a Java-based, stand-alone application. The CTT is interactive clock tree configuration software for the device. The CTT lets the user:

- Visualize the device clock tree
- Interact with clock tree elements and view the effect on PRCM registers
- Interact with the PRCM registers and view the effect on the device clock tree
- View a trace of all the device registers affected by the user interaction with clock tree
- Extract registers and register dumps for Code Composer Studio and Lauterbach

The advantage of the CTT is that the user can visualize the clock tree state of the device on power-on reset and then customize the configuration of the clock tree for the specific use case and identify the device register settings associated to that configuration. Furthermore, the user can dump and read in register settings for the specific scenarios.

Being an interactive visual tool, the CTT gives the user a global view of the device clock tree architecture and allows determining the exact register settings to obtain the specific configuration.

3.1 Device Power Management Introduction

Power management is one of the most important design aspects of any system.

The device power-management architecture ensures maximum performance while offering versatile power-management techniques for maximum design flexibility, depending on application requirements.

This introduction contains the following information:

- Power-management architecture building blocks for the device
- State-of-the-art power-management techniques supported by the power-management architecture of the device

3.1.1 Device Power-Management Architecture Building Blocks

To provide a versatile architecture that supports multiple power-management techniques, the power-management framework is built with three levels of resource management: clock, power, and voltage.

These management levels are enforced by defining the managed entities or building blocks of the power-management architecture, called the clock, power, and voltage domains.

A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch). The group forming the domain is managed by a policy manager. For example, a clock for a clock domain is managed by a dedicated clock manager within the power, reset, and clock management (PRCM) module. The clock manager considers the joint clocking constraints of all the modules belonging to that clock domain (and, hence, receiving that clock).

NOTE: In the following sections, the term <module> is used to represent the device IPs (that is, modules or subsystems), other than the PRCM module, that receive clock, reset, or power signals from the PRCM module.

3.1.1.1 Clock Management

The PRCM module manages the gating (that is, switching off) and enabling of the clocks to the device modules. The clocks are managed based on the requirement constraints of the associated modules. The following sections identify the module clock characteristics, management policy, clock domains, and clock domain management. Clock management integration details are described in [Section 3.6, Clock Management Functional Description](#).

3.1.1.1.1 Module Interface and Functional Clocks

Each module within the device has specific clock input characteristics requirements. Based on the characteristics of the clocks delivered to the modules, the clocks are divided into two categories: interface clocks and functional clocks (see [Figure 3-2](#)).

Figure 3-2. Functional and Interface Clocks

The interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the system interconnect interface and registers of the module.
- A typical module has one interface clock, but modules with multiple interface clocks may also exist (that is, when connected to multiple interconnect buses).
- Interface clock management is done at the device level.

- From the standpoint of the PRCM module, an interface clock is identified with an `_ICLK` suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or subsystem.
- A module can have one or more functional clocks. Some functional clocks are mandatory, while others are optional. A module needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the module activity (for example, the clock for the camera).
- From the standpoint of the PRCM module, a functional clock is distributed directly to the related modules through a dedicated clock tree. It is identified with an `_FCLK` suffix.

Some clocks are qualified as permanent clocks. They are functional clocks, that can stay active while the corresponding entity manages them.

NOTE: At the module level, the interface clocks are always fed by the interface clock outputs of the PRCM module. The functional clocks are fed by a PRCM module functional clock output or a PRCM module interface clock output. In the latter case, the functional and interface module clocks inherit the clock-management features (autoidle features) of the PRCM module interface clock.

3.1.1.1.2 Module-Level Clock Management

Each module in the device may also have specific clock requirements. Certain module clocks must be active when operating in specific modes, or they may be gated. Globally, the activation and gating of the module clocks are managed by the PRCM module. Hence, the PRCM module must be aware of when to activate and when to gate the module clocks.

The PRCM module differentiates the clock-management behavior for device modules based on whether the module can initiate transactions on the device interconnect (called master module) or it cannot initiate transactions and only responds to the transactions initiated by the master (called slave module). Thus, two hardware-based power-management protocols are used:

- Master standby protocol: Clock-management protocol between the PRCM and master modules
- Slave idle protocol: Clock-management protocol between the PRCM and slave modules

Master standby protocol

This protocol is used to indicate that a master module must initiate a transaction on the device interconnect and requests specific (functional and interface) clocks for that purpose. The PRCM module ensures that the required clocks are active when the master module requests the PRCM module to enable them. This is called a module wake-up transition and the module is said to be functional after this transition completes.

Similarly, when the master module no longer requires the clocks, it informs the PRCM module, which can then gate the clocks to the module. The master module is then said to be in standby mode.

Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the module. This is done by setting the `<Module>_SYSCONFIG.MIDLEMODE` or `<Module>_SYSCONFIG.STANDBYMODE` bit fields, as described in [Table 3-1](#). The behavior, identified in the STANDBYMODE Bit Value column, must be configured.

Table 3-1. Master Module Standby Mode Settings

STANDBYMODE Bit Value	Selected Mode	Description
0x0	Force-standby	The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully because it does not prevent loss of data at the time the clocks are gated.

Table 3-1. Master Module Standby Mode Settings (continued)

STANDBYMODE Bit Value	Selected Mode	Description
0x1	No-standby	The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active; however, it is not efficient from a power-saving perspective because it never allows the PRCM module output clocks to be gated.
0x2	Smart-standby	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module.
0x3	Smart-standby wake-up-capable mode	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idle. The PRCM module can then gate the clocks to the module. The module may generate (master-related) wake-up events when in standby state. The mode is relevant only if the appropriate module mwake-up output is implemented.

NOTE:

- Smart-standby mode is the preferred mode of operation, while force-standby and no-standby modes are intended for debugging purposes.
- A master module may support all or some of the standby modes listed in [Table 3-1](#). See the power-management section in the module chapter to identify the supported standby mode.

The standby status of a master module is indicated by the CM_<Clock domain>_<Module>_CLKCTRL[x]. STBYST bit in the PRCM module. [Table 3-2](#) describes the master module standby status.

Table 3-2. Master Module Standby Status

STBYST Bit Value	Description
0x0	The module is functional.
0x1	The module is in standby mode.

[Table 3-3](#) lists the enabling conditions for the master module clocks managed by the standby protocol.

Table 3-3. Master Module Clock Enabling Conditions

Relation	Condition
AND	Clock domain is ready.
	OR
	Master module standby request is deasserted. Master module wake-up request is asserted.

Slave idle protocol

This hardware protocol allows the PRCM module to control the state of a slave module. The PRCM module informs the slave module, through assertion of an IDLE request, when its clocks (interface and functional) can be gated. The slave can then acknowledge the request from the PRCM module, and the PRCM module is then allowed to gate the clocks to the module. A slave module is said to be in IDLE state when its clocks are gated by the PRCM module.

Similarly, an idled slave module may need to be woken up because of a service request from a master module or because the slave module receives a wake-up event (for example, an interrupt or a direct memory access [DMA] request). In this situation the PRCM module enables the clocks for the module, and then signals the module to wake up by deasserting the IDLE request.

Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the slave module. This is done by setting the `<Module>_SYSCONFIG.IDLEMODE` or `<Module>_SYSCONFIG.IDLEMODE` bit field, as described in [Table 3-4](#). The behavior, identified in the IDLEMODE Bit Value column, must be configured by software.

Table 3-4. Module Idle Mode Settings

IDLEMODE Bit Value	Selected Mode	Description
0x0	Force-idle	The module unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully because it does not prevent loss of data at the time the clock is switched off.
0x1	No-idle	The module never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The module acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management.
0x3	Smart-idle wake-up-capable mode	The module acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. The mode is relevant only if the appropriate module wakeup output(s) is implemented.

NOTE:

- Smart-idle mode is the preferred mode of operation, while force-idle and no-idle modes are intended for debugging purposes.
- A slave module may support all or some of the idle modes listed in [Table 3-4](#). See the power-management section in the module chapter to identify the supported idle modes.

The idle status of a slave module is indicated by the `CM_<Clock domain>_<Module>_CLKCTRL[x]IDLEST` bit field in the PRCM module. [Table 3-5](#) lists the possible idle statuses for a slave module.

Table 3-5. Slave Module Idle Status

IDLEST Bit Value	Idle Status	Description
0x0	Functional	The module is fully functional. The interface and functional clocks are active.
0x1	In transition	The module is performing a wake-up or a sleep transition.
0x2	Interface idle	The module interface clock is idled. The module may remain functional if using a separate functional clock.
0x3	Full idle	The module is fully idle. The interface and functional clocks are gated.

When configured in smart-idle mode, the slave module may acknowledge the IDLE request of the PRCM module based on the activity of its interface and/or functional clocks. To define which module clocks (that is, interface and/or functional) should be considered when responding to the PRCM module request, software must configure the `<Module>_SYSCONFIG[x]CLOCKACTIVITY` bit field.

The `CLOCKACTIVITY` setting is used internally by the module to determine the part of the module on which the conditions to acknowledge the PRCM module IDLE request are tested. As an example, if the functional clock must remain active when the module is in idle mode, the module must acknowledge a PRCM module IDLE request by considering only the interface clock gating conditions (that is, there is no pending activity on the interconnect).

NOTE: See the power-management section in the module chapter to identify whether this feature is configurable.

Using the CLOCKACTIVITY setting along with smart-idle mode ensures that the clock remains active for the module features that must remain available during the module idle mode. [Table 3-6](#) describes the possible CLOCKACTIVITY settings for a module.

Table 3-6. Slave Module Clock Activity Settings

CLOCKACTIVITY Bit Value	Module Interface Clock	Module Functional Clock	Description
0x0	Gated	Gated	The interface and functional clocks are considered when generating the acknowledgment. This setting also means both clocks may be gated upon a PRCM module IDLE request.
0x1	Active	Gated	The interface clock is not shut down and is not considered when generating the acknowledgment to the PRCM module IDLE request. Only the functional clock is considered.
0x2	Gated	Active	The functional clock is not shut down and is not considered when generating the acknowledgment to the PRCM module IDLE request. Only the interface clock is considered.
0x3	Active	Active	The interface and functional clocks are not shut down. The module can acknowledge the IDLE request without checking the internal functions linked to its clocks.

NOTE:

- The software configuration of the CLOCKACTIVITY settings may not be available for a given module. For some modules, the CLOCKACTIVITY settings can be hardwired.
- A slave module may support all or some of the CLOCKACTIVITY settings listed in [Table 3-6](#).

See the power-management section in the specific module chapter to identify the supported idle feature and settings.

CAUTION

The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings of the module. Software must ensure consistent programming between the CLOCKACTIVITY settings of the module and the clock-gating control bits in the PRCM module. The PRCM module must be configured (where software control is available) not to gate the module clock, which should remain active according to the CLOCKACTIVITY settings of the module.

For idle protocol management on the PRCM module side, the behavior of the PRCM module is configured in the CM_<Clock domain>_<module>_CLKCTRL[1:0] MODULEMODE bit field. Based on the configured behavior, the PRCM module asserts the IDLE request to the module unconditionally (that is, immediately when software requests) or through hardware control when the module idle conditions are satisfied. [Table 3-7](#) describes the configurable behavior of MODULEMODE.

Table 3-7. Slave Module Mode Settings in PRCM

MODULEMODE Bit Value	Selected Mode	Description
0x0	Disabled	The PRCM module unconditionally asserts the module IDLE request. This request applies to the gating of the functional and interface clocks to the module. If acknowledged by the module, the PRCM module can gate all clocks to the module (that is, the module is completely disabled). It can react only to an asynchronous wake-up event (that is, a wake-up event that does not require the module functional clock to be active).

Table 3-7. Slave Module Mode Settings in PRCM (continued)

MODULEMODE Bit Value	Selected Mode	Description
0x1	Auto	This mode applies to a module when the PRCM module manages only its interface clock and not its functional clock. The PRCM module automatically asserts/deasserts the module IDLE request based on the clock domain transitions. If acknowledged by the module, the PRCM module can gate the interface clock to the module.
0x2	Enabled	This mode applies to a module when the PRCM module manages its interface and functional clocks. The functional clock to the module remains active unconditionally, while the PRCM module automatically asserts/deasserts the module IDLE request based on the clock domain transitions. If acknowledged by the module, the PRCM module can gate only the interface clock to the module.
0x3	Reserved	Not available

NOTE: The PRCM module may support all or some of the MODULEMODE module settings listed in [Table 3-7](#). See the CM_<Clock domain>_<module>_CLKCTRL[1:0] MODULEMODE bit field description for the module to identify the supported settings.

NOTE: Modules, which can be configured with DISABLED or AUTO values of ModuleMode, cannot go from IDLE to DISABLED state if ModuleMode is changed from AUTO to DISABLED while module is in IDLE state. Once the CM_<Clock domain>_CLKSTCTRL[1:0] CLKTRCTRL has been set to SW_WKUP, then SW has to poll for PM_<Power domain>_PWRSTST[1:0] PowerStateSt = 0x03 and PM_<Power domain>_PWRSTST[20] InTransition = 0x00 before update MODULEMODE bit field.

[Table 3-8](#) and [Table 3-9](#) list the enabling conditions for the slave module clocks managed by the idle protocol.

Table 3-8. Slave Module Interface Clock Enabling Conditions

Relation		Condition
AND	OR	Clock domain is ready.
		Slave module idle status is 0x0 (fully functional).
		Slave module idle status is 0x1 (in transition).
		Slave module wake-up request is asserted.

Table 3-9. Slave Module Functional Clock Enabling Conditions

Relation		Condition
AND	OR	Clock domain is ready.
		Slave module idle status is 0x0 (fully functional).
		Slave module idle status is 0x1 (in transition).
		Slave module idle status is 0x2 (interface clock is idled).
		Slave module wake-up request is asserted.

The module clock domain must be ready for the optional clocks to the module, and any associated clock-enable control is asserted.

NOTE: A given clock can be used by more than one module. Clock-enabling conditions are then ORed together (that is, the clock is provided as soon as one of the enabling conditions is true). As a consequence, the clock is disabled only when all related enabling conditions are false.

Module wake-up request

In IDLE state, a slave module may have to wake up to generate an interrupt or a DMA request. This can be the result of an external request (for example, to the input/output [I/O] port of a general-purpose input/output [GPIO] module) or an internally generated event (for example, WD_TIMER time up). The slave module, with wake-up capability, sends a wake-up request to the PRCM module. The PRCM module then activates the module clocks and acknowledges the module wake-up request.

In IDLE state, some slave modules may require functional clock(s) to generate a wake-up event. Such requests are called synchronous wake-up events on the PRCM module side, while the events generated when the functional or interface module clocks are gated are called asynchronous wake-up events.

NOTE: See the power-management section in the module chapter to identify whether its wake-up event is synchronous or asynchronous.

The standby and idle clock-management protocols allow the configuration of the module-level clock-management interaction between the PRCM module and individual modules of the device. However, the PRCM module may not necessarily gate the clock to the module immediately after the module switches to standby or idle mode at the end of this interaction. This is because the same clock can be shared by other modules that are active and need this shared clock to complete their activity. As a result, the PRCM module provides a second level of clock management called the clock-domain level, as explained in [Section 3.1.1.1.3, Clock Domain](#).

3.1.1.1.3 Clock Domain

A clock domain is a group of modules fed by clock signals controlled by the same clock manager in the PRCM module (see [Figure 3-3](#)). By gating the clocks in a clock domain, the clocks to all the modules belonging to that clock domain can be cut to lower their active power consumption (that is, the device is on and the clocks to the modules are dynamically switched to ACTIVE or INACTIVE [gated] state). Thus, a clock domain allows control of the dynamic power consumption of the device.

The device is partitioned into multiple clock domains and each clock domain is controlled by an associated clock manager within the PRCM module. This allows the PRCM module to activate and gate individually each device clock domain.

Figure 3-3. Generic Clock Domain

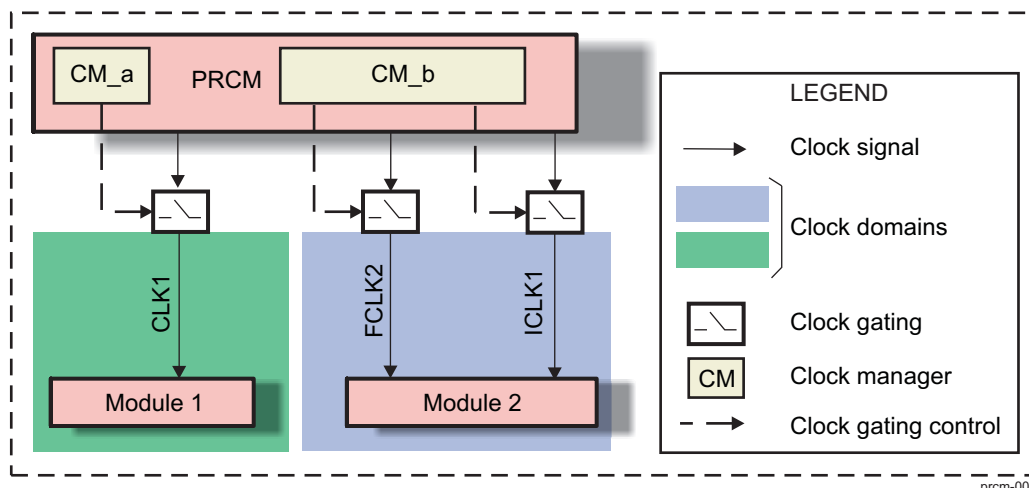

Figure 3-3 is an example of two clock managers: CM_a and CM_b. Each clock manager manages a clock domain. The clock domain of CM_b is composed of two clocks, a functional clock (FCLK2) and an interface clock (ICLK1), while that of CM_a consists of a clock (CLK1) that is used by the module as functional and interface clock. The clocks to Module 2 can be gated independently of the clock to Module 1, thus ensuring power savings when Module 2 is not in use.

The PRCM module lets software check the status of the clock domain functional clocks. The CM_<Clock domain>_CLKSTCTRL[x] CLKACTIVITY_<Clock name>_(G)FCLK bit in the PRCM module identifies the state of the functional clock(s) within the clock domain. Table 3-10 lists the two possible states of the functional clock.

Table 3-10. Clock Domain Functional Clock States

CLKACTIVITY Bit Value	Status	Description
0	Gated	The functional clock of the clock domain is inactive.
1	Active	The functional clock of the clock domain is running.

Similarly, the PRCM module lets software check the status of the clock domain interface clocks. The CM_<Clock domain>_CLKSTCTRL[x] CLKACTIVITY_<Clock name>_(G)ICLK bit in the PRCM module identifies the state of the interface clock(s) within the clock domain. Table 3-11 lists the two possible states of the functional clock.

Table 3-11. Clock Domain Interface Clock States

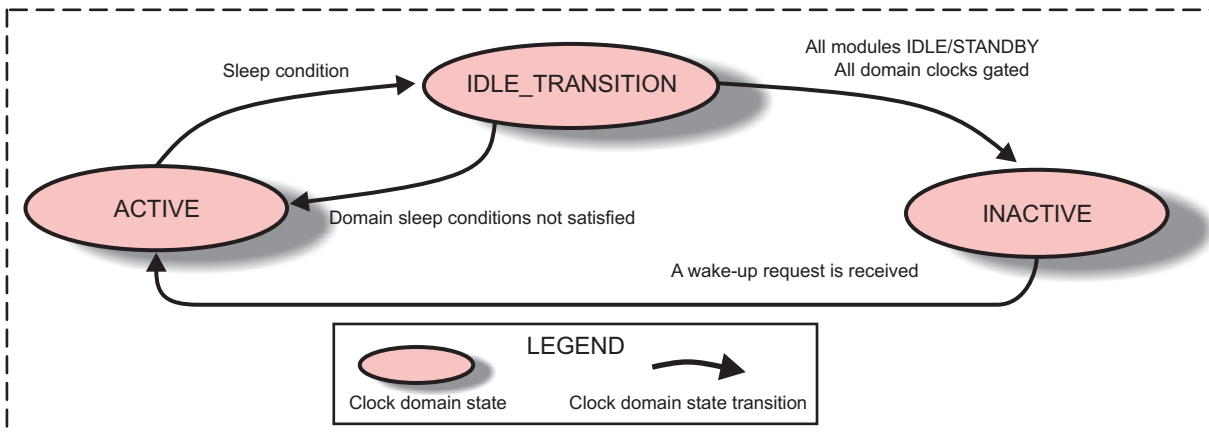

CLKACTIVITY Bit Value	Status	Description
0	Gated	The interface clock of the clock domain is inactive.
1	Active	The interface clock of the clock domain is running.

3.1.1.1.4 Clock Domain-Level Clock Management

The domain clock manager can automatically (that is, based on hardware conditions) and jointly manage the interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings.

A clock domain can switch between three possible states: ACTIVE, IDLE_TRANSITION (IDLEREQ), and INACTIVE (IDLE). Figure 3-4 shows the sleep and wake-up transitions of the clock domain between ACTIVE and INACTIVE states.

Figure 3-4. Clock Domain State Transitions

prcm-003

Table 3-12 defines the clock domain states.

Table 3-12. Clock Domain Clock States

State	Description
ACTIVE	<ul style="list-style-type: none"> Every nondisabled slave module (that is, those whose MODULEMODE value is not set to disabled) is put out of IDLE state. All mandatory functional clocks to the active slave modules (that is, not idled) of the clock domain are provided. All interface clocks to the nondisabled slave modules in the clock domain are provided. All mandatory functional and interface clocks to the active master modules (that is, not in STANDBY state) in the clock domain are provided. Every enabled optional clock to the modules in the clock domain is provided.
IDLE_TRANSITION	<p>This is a transitory state.</p> <ul style="list-style-type: none"> Every master module in the clock domain is in STANDBY state. Every IDLE request to all the slave modules in the clock domain is asserted. The functional clocks to the slave module in enabled state (that is, those whose MODULEMODE values are set to enabled) remain active. Every enabled optional clock to the modules in the clock domain is provided.
INACTIVE	<p>All clocks within the clock domain are gated.</p> <ul style="list-style-type: none"> Every slave module in the clock domain (that is, those whose MODULEMODE value is set to disabled or auto) is in IDLE state and set to disabled or auto mode. Every master module in the clock domain is in STANDBY state. Every optional functional clock in the clock domain is gated.

Each clock domain transition behavior is managed by an associated register bit field in the CM_<Clock domain>_CLKSTCTRL[x] CLKTRCTRL PRCM module.

Table 3-13 describes the clock transition mode settings of the clock domain.

Table 3-13. Clock Domain Clock Transition Mode Settings

CLKTRCTRL Bit Value	Selected Mode	Description
0x0	NO_SLEEP	A clock domain sleep transition is never initiated, regardless of the hardware conditions.
0x1	SW_SLEEP	A software-forced sleep transition. The transition is initiated when the associated hardware conditions are satisfied (see Table 3-15).
0x2	SW_WKUP	A software-forced clock domain wake-up transition is initiated, regardless of the hardware conditions identified in Table 3-14.
0x3	HW_AUTO	Hardware-controlled automatic sleep and wake-up transition is initiated by the PRCM module when the associated hardware conditions are satisfied (see Table 3-14 and Table 3-15).

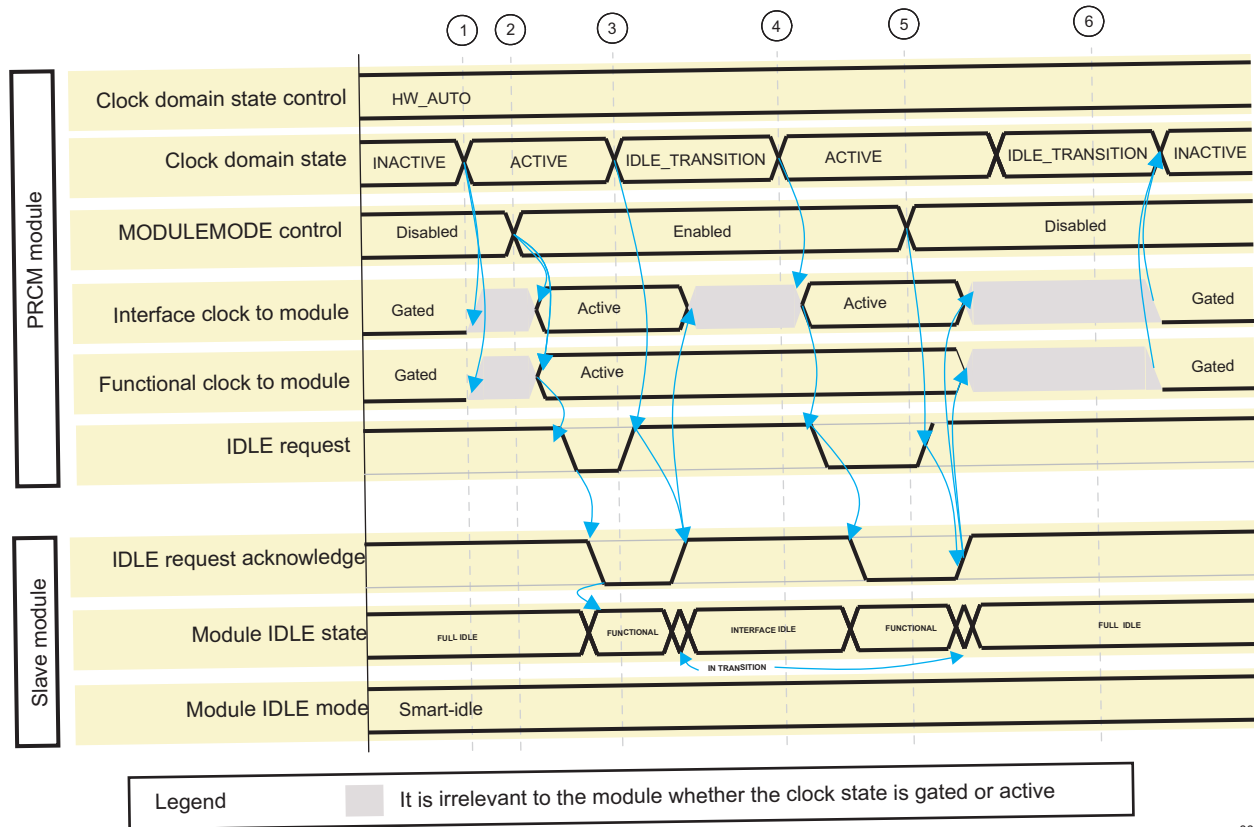

NOTE: Depending on its characteristics, a clock domain may or may not support all the clock transition mode settings described in Table 3-13. See the clock domain clock management section of the specific clock domain to identify the supported clock transition mode settings.

3.1.1.1.5 Clock Domain HW_AUTO Mode Sequences

The sequence diagrams in Figure 3-5 through Figure 3-7 identify the PRCM module hardware-controlled enabling and gating of the functional and interface clocks to the module. They show the changes in the state of the module based on the changes to the clock domain state and module mode settings.

Figure 3-5 shows the behavior of a slave module receiving the interface and functional clocks and having two configurable module modes: disabled and enabled.

Figure 3-5. Clock Domain/Slave Module Clock-Management Interaction Sequence 1

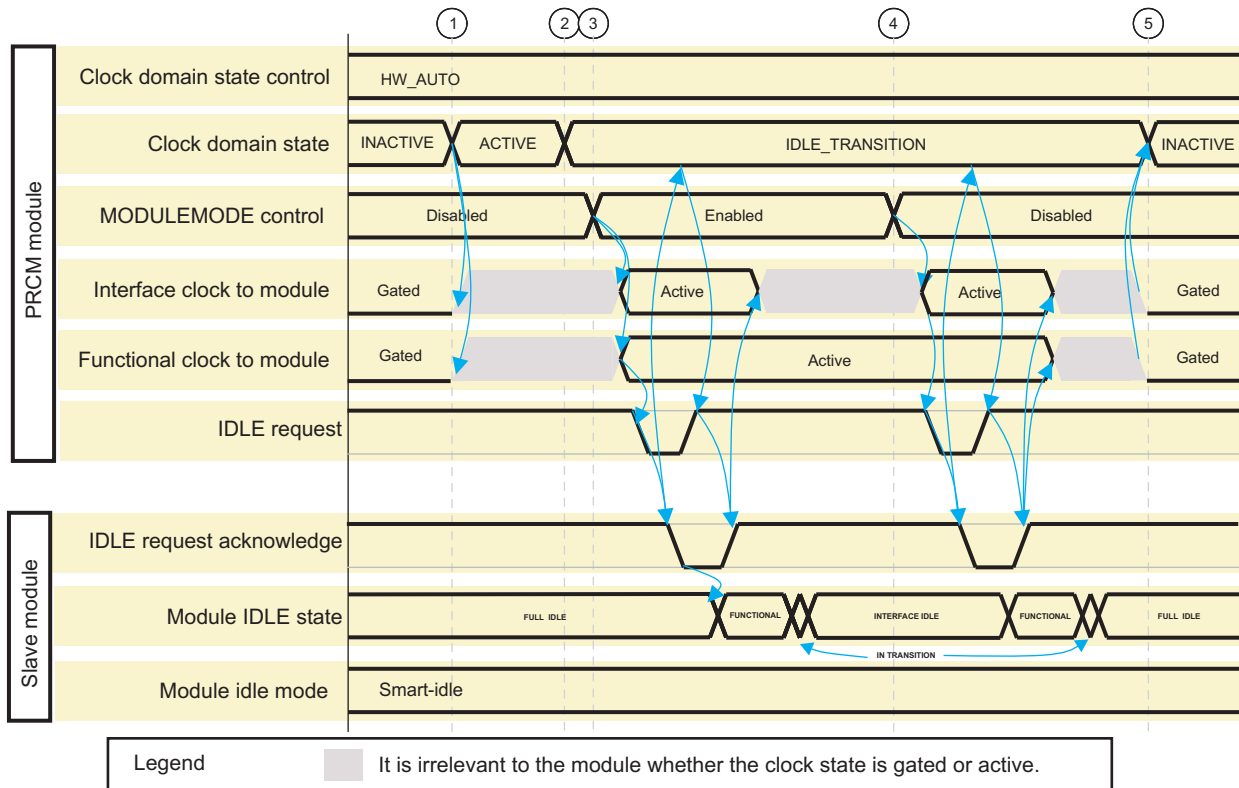

prcm-004

Initially, the clock domain, which includes the slave module, is inactive. The module is in FULL IDLE state and its functional and interface clocks are gated.

1. The clock domain wakes up and changes its state to ACTIVE. Because the MODULEMODE control is still disabled, this event has no effect on the state of the module. The functional and interface clocks can still be restarted automatically, based on the requirements of other modules sharing these clocks.
2. Software changes the module mode to ENABLED. The clocks to the module are automatically restarted. The PRCM module then deasserts a hardware IDLE request signal to the module. The module sends an IDLE request acknowledge to the PRCM module. The module is now effectively awake. The module IDLE state is functional.
3. The clock domain switches to IDLE_TRANSITION state. In turn, the PRCM module requests the module to go into IDLE state by asserting the IDLE request signal. When acknowledged, the clock to the module can be gated, depending on other modules sharing the same clock. The functional clock of the module remains enabled because the module is in enabled mode.
4. The clock domain does not have all conditions to complete the sleep transition and wakes up again. In turn, the interface clock to the module is automatically restarted, and then the module is put out of IDLE state.
5. Software disables the module. The PRCM module requests the module to go to IDLE state by asserting the IDLE request signal. When acknowledged, the clock to the module can be gated, depending on other modules sharing the same clock.
6. The clock domain switches to IDLE_TRANSITION state. When the sleep transition conditions of the clock domain are satisfied, the clocks (functional and interface) are gated. The clock domain then switches to INACTIVE state. This has no effect on the module, which is already in FULL IDLE state.

Figure 3-6 shows the behavior of the same slave module, receiving the interface and functional clocks, when the module mode is changed while the clock domain state is IDLE_TRANSITION.

Figure 3-6. Clock Domain/Slave Module Clock-Management Interaction Sequence 2

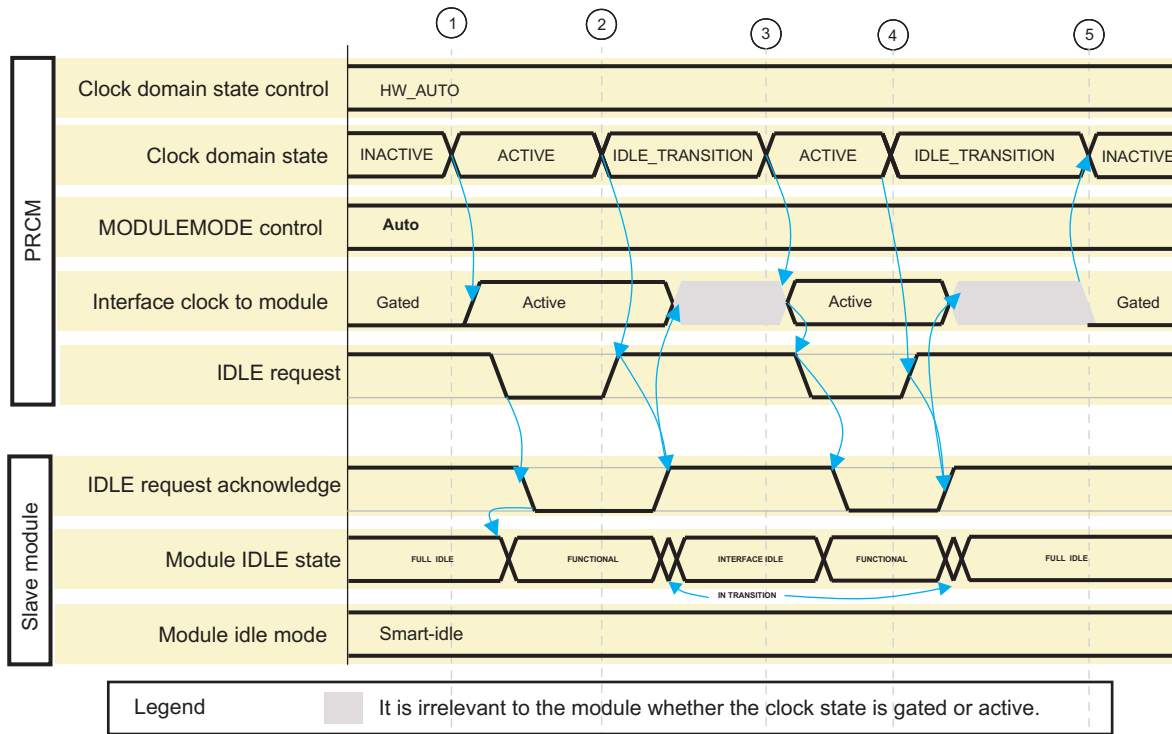

prcm-005

Initially, the clock domain, which includes the slave module, is inactive. The module is in FULL IDLE state and its functional and interface clocks are gated.

1. The clock domain wakes up and changes its state to ACTIVE. Because the MODULEMODE control is disabled, this event has no effect on the state of the module. The functional and interface clocks can still be restarted automatically, based on the requirements of other modules sharing these clocks.
2. The clock domain goes into the IDLE_TRANSITION state. Because the module mode control is disabled, this event has no effect on the module state.
3. Software changes the module mode to ENABLED. The clocks to the module are restarted automatically and then the module is put out of IDLE state. As soon as acknowledged, the module is requested to go back to IDLE state with gating of the interface clock only (that is, the INTERFACE IDLE state). The interface clock to the module can be gated, depending on other modules sharing the same clocks.
4. Software disables the module. The interface clock to the module is restarted automatically. The PRCM module requests the module to go out of IDLE state by asserting the IDLE request signal. As IDLE request acknowledge is de-asserted, PRCM set back the module to IDLE state. When acknowledged, the interface and the functional clocks to the module can be gated, depending on other modules sharing the same clock.
5. When the clock domain sleep transition conditions are satisfied and the functional and interface clocks are gated, the clock domain switches to INACTIVE state. This has no effect on the module, which is already in FULL IDLE state.

Figure 3-7 shows the behavior of a slave module receiving only interface clock and supporting the configurable auto module mode.

Figure 3-7. Clock Domain/Slave Module Clock-Management Interaction Sequence 3

prcm-006

Initially, the clock domain, which includes the slave module, is inactive. The module is in FULL IDLE state and its interface clock is gated.

1. The clock domain wakes up and changes its state to ACTIVE. In turn, the interface clock to the module is automatically restarted. The PRCM module then deasserts a hardware IDLE request signal to the module. The module sends an IDLE request acknowledge to the PRCM module. The module is now effectively awake; that is, the module IDLE state is functional.
2. The clock domain switches to IDLE_TRANSITION state. The PRCM module requests the module to go to IDLE state by asserting the IDLE request signal. When acknowledged, the interface clock to the module can be gated, depending on other modules sharing the same clock.
3. The clock domain does not have all conditions to complete the sleep transition and wakes up again. In turn, the interface clock to the module is automatically restarted, and then the module goes out of IDLE state.
4. This step is the same as Step 2.
5. The clock domain has all conditions to complete the sleep transition. The module is in IDLE state and its clock is gated.

⁽¹⁾ The dynamic, static, and wake-up dependencies are explained in [Section 3.1.1.1.7](#), *Clock Domain Dependency*.

3.1.1.1.7 Clock Domain Dependency

A domain dependency is a binary relationship between two clock domains. A clock domain A is said to depend on a clock domain B when a module in clock domain B provides services to a module in clock domain A. As a result, clock domain B must be active when clock domain A is active so that the module in clock domain B is accessible by the module in clock domain A.

Dependency between two clock domains can also exist if one clock domain serves to ensure communication between two modules (for example, the clock domain of the device interconnect).

Thus, a clock domain can support the types of clock domain dependencies described in the following sections.

[Table 3-16](#) and [Table 3-17](#) detail all the domain dependencies:

- **NA/NA**: if no dependency can exist because no corresponding interconnect path exists in the device
- When cell is different than NA/NA, the cell contains two attributes:
 - First attribute for the presence and control method of a static dependency:
 - **SW**: Static dependency is controlled by a software bit. This is the most generic way of control. Depending on the use case and on latency requirement for accessing target domain, software can enable or not the static dependency. When not enabled, access to those domains is performed using dynamic dependencies.
 - **1**: Static dependency is always enabled (hard-wired). This is relevant for a domain that has an "exact standby" system initiator with the target domain being the domain containing the interconnect module to which the initiator is connected.
 - **0**: Static dependency is never enabled (hard-wired). This is relevant for domains that do not have strong access latency requirements, or for which a static dependency is not desired for specific reasons (for example, dependencies with emulation domain). Access to those domains is performed using dynamic dependencies.
 - **NA**: Nonapplicable (means domain has no system initiator able to access the other domain)
 - Second attribute for the presence and control method of a dynamic dependency:
 - **1..n**: Dynamic dependency is always enabled (hard-wired). The number of corresponding interconnect interfaces is also specified. This is relevant for most of the domain-to-domain direct interconnect connection.
 - **0**: Dynamic dependency is never enabled (hard-wired). This is relevant only when a static

dependency is always enabled between same domains, or when the target domain cannot support the wakeup on access feature.

- **NA:** Non-applicable (means that both domains are not directly linked by an OCP interface)

When a static dependency is hardware-coded between two domains directly linked by one or several interconnect interfaces, then the corresponding dynamic dependency is useless.

Emulation domain (DAP initiator) has no static dependency with any other domain. It has, however, a dynamic dependency with the L3_MAIN2 interconnect. A domain that can access an emulation domain does not have static or dynamic dependency with it.

Domain dependencies are chosen such that any access (even from EMU/DAP) towards a nondisabled target is always completed normally. Using static dependencies allows having minimal access latencies by keeping necessary domains on whenever the initiator is not standby. This may be at the expense of additional power consumption because some domains may stay on while not in use for a long time. By disabling static dependencies, applicative access is still completed normally by waking up, if applicable, the necessary domain on the path from the initiator to the target. Power consumption can be optimized at the expense of additional access latencies.

NOTE: Once the CM_<Clock domain>_CLKSTCTRL[1:0] CLKTRCTRL has been set to SW_WKUP, then SW has to poll for PM_<Power domain>_PWRSTST[1:0] PowerStateSt = 0x03 and PM_<Power domain>_PWRSTST[20] InTransition = 0x00 before update MODULEMODE bit field.

3.1.1.1.7.1 Static Dependency

If clock domain A has a master module that can access a slave module in clock domain B, then clock domain A can have a static dependency with clock domain B. Similarly, a static dependency can also exist between domain A and B if domain B conveys the transactions from a domain A module toward a module in any other domain. For example, CD_DSP can have a static dependency with CD_L3_MAIN1 because this domain has a level 3 (L3) interconnect to carry the transactions from the digital signal processor (DSP) module.

This static dependency consists of forcing clock domain B to stay active as long as there is at least one master module of clock domain A that is not in STANDBY state. If clock domains A and B are initially in GATED state, then clock domain B becomes active as soon as clock domain A becomes active when a wake-up request from the master module is received by the PRCM module.

Similarly, as a result of the static dependency, clock domain B can be gated only if all the master modules of clock domain A that can access the slave modules in clock domain B are in STANDBY state.

The static dependency between a source clock domain and a destination clock domain is configured in the PRCM module by setting the CM_<Source Clock domain>_STATICDEP[x] <Destination Clock domain>_STATDEP bit. As a result, the source clock domain forces the destination clock domain to become active and stay active as long as the source clock domain is active.

The destination domain must be put into forced wake-up (CM_<X>_CLKSTCTRL[1:0] CLKTRCTRL = SW_WKUP) before changing a configurable static dependency.

3.1.1.1.7.2 Dynamic Dependency

When clock domains A and B contain modules directly linked to a common device interconnect, these clock domains can have a dynamic dependency.

A dynamic dependency consists of forcing clock domain B to stay active as long as a module from clock domain A is communicating with the module in clock domain B through the interconnect. Clock domain B becomes active as soon as the communication is initiated. This is automatically managed by the PRCM module by monitoring the communication on the interconnect between the modules of the two clock domains.

Similarly, the inverse condition of this dependency can be stated: Clock domain B can be inactive only if there has not been transactions from clock domain A to clock domain B, identified as a sliding window duration on the interconnect activity status.

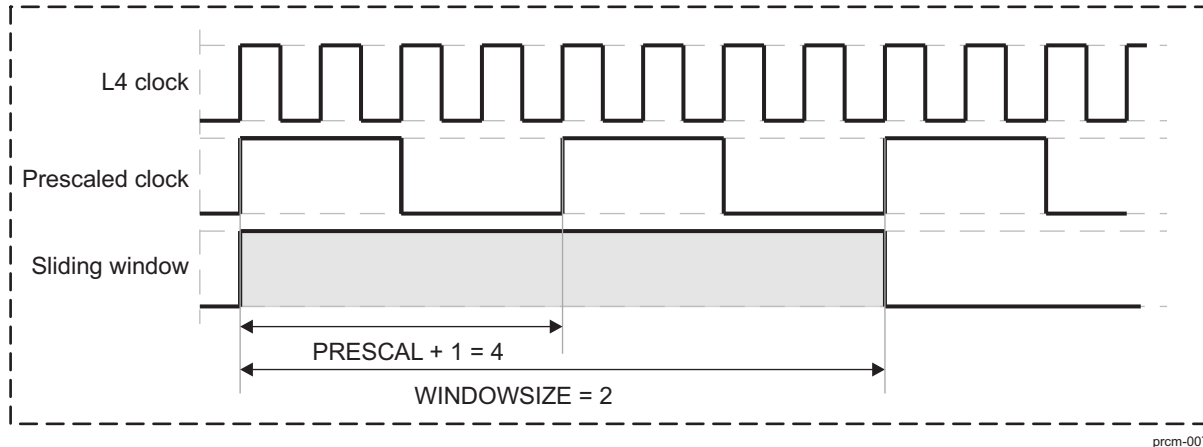

The size of the sliding window is based on the number of cycles of a prescaled level 4 (L4) clock whose frequency is configured by setting the CM_DYN_DEP_PRESCAL[5:0] PRESCAL bit field. The prescaled clock frequency is given as:

$$\text{Prescaled clock frequency} = \text{L4 interface clock frequency} / (\text{PRESCAL} + 1)$$

The size of the sliding window is fixed by setting the CM_<Clock domain>_DYNAMICDEP[27:24] WINDOWSIZE bit field. It is given as:

$$\text{Sliding window duration} = \text{WINDOWSIZE} \times \text{Period of Prescaled clock cycle}$$

Figure 3-8 is an example of the sliding window duration equal to eight clock cycles of an L4 clock when PRESCAL is set to 3 and WINDOWSIZE is set to 2.

Figure 3-8. Sliding Window for Dynamic Dependency

This dynamic dependency is also referred to as the autosleep/autowakeup feature.

NOTE:

- The static dependency between two clock domains can be configured by software (PRCM module registers) or hardwired in the PRCM module.
- The dynamic dependency between two clock domains is hardwired in the PRCM module.

A dynamic dependency is said to be active when both of the following conditions are met:

- There has been one or more transaction on the interconnect within the sliding window duration.

Otherwise, a dynamic dependency is said to be inactive.

The dynamic dependency between a source clock domain and a destination clock domain can be read in the PRCM module from the corresponding read-only `CM_<Source Clock domain>_DYNAMICDEP[x] <Destination Clock domain>_DYNDP` bit.

NOTE: It is recommended to use dynamic dependencies. They give better power results. Static dependencies should be rarely used (in some cases they can be used as they give shorter latency for a system initiator to access slave).

3.1.1.1.7.3 Wake-Up Dependency

A wake-up dependency is a dependency between the clock domain of a module that owns one or several wake-up signals toward the clock domain of another module needed to service the associated wake-up event. As a result of this dependency, the wake-up event to a module activates not only its clock domain but also the clock domain of the servicing module.

NOTE: To ensure that the clock domain of the servicing module remains active, the wake-up signal that triggers a wake-up dependency stays active as long as the source of the event is not serviced.

Wake-up dependencies allow acceleration of the wake-up transition of multiple domains needed to service the wake-up event by initiating their transition in parallel. The static and dynamic dependencies can allow the wake-up of related domains, but the complete wake-up transition of all the associated domains is slower because of the sequential cascading of their wake-up transitions.

In the device, the source event of the wake-up signal to a slave module can be either of following types:

- Interrupt request to the DSP, or image processor unit (IPU) interrupt controller (INTC)
- DMA request to a DMA controller

Upon wake-up by these types of wake-up events, and for as long as they remain asserted, the PRCM module takes the following actions:

- The power domain of the servicing module (for example DSP, IPU, or DMA) is forced to POWER ON state and the clock domain becomes active.
- The power domain of the device interconnect between the servicing module and the module originator of the wake-up event is forced to POWER ON state and the clock domain becomes active.
- The power domain of the slave module originator of the wake-up event is forced to POWER ON state and the clock domain becomes active.
- The slave module originator of the wake-up event is switched from IDLE to ACTIVE state.

On assertion of a wake-up event of a stand-alone master module, and as long as it remains asserted, the PRCM module takes the following action:

- The power domain of the master module originator of the wake-up event is forced to POWER ON state and the clock domain becomes active.

NOTE: For slave modules, the static and dynamic dependencies of a clock domain are not affected by its wake-up dependency settings. For master modules, the static dependencies are not affected.

Hence, in addition to the activation of the clock domains previously described, all clock domains associated by static dependencies are also activated.

However, the clock domains associated with the wake-up clock domain through dynamic dependencies are activated only if a transaction is initiated to these clock domains.

For each wake-up signal coming from a slave module, the type of the corresponding event can be configured in the PM_<Power domain>_<Originator Module>_WKDEP[x] WKUPDEP_<Originator Module>_[IRQ/DMA]_<Servicing Module> bit of the PRCM module, where <Power domain> is the name of the power domain of the originator module of the wake-up event identified as <Originator Module>. <Servicing Module> refers to the module servicing the wake-up event.

NOTE: When only one event type is associated with the wake-up signal of a slave module, the wake-up dependency (WKUPDEP) for the module clock domain is not configurable and may be hardwired in the PRCM module.

For the master modules, there is no configurable wake-up dependency. Their power domain is switched on and their clock domain is activated by the PRCM module when they assert their wake-up signal.

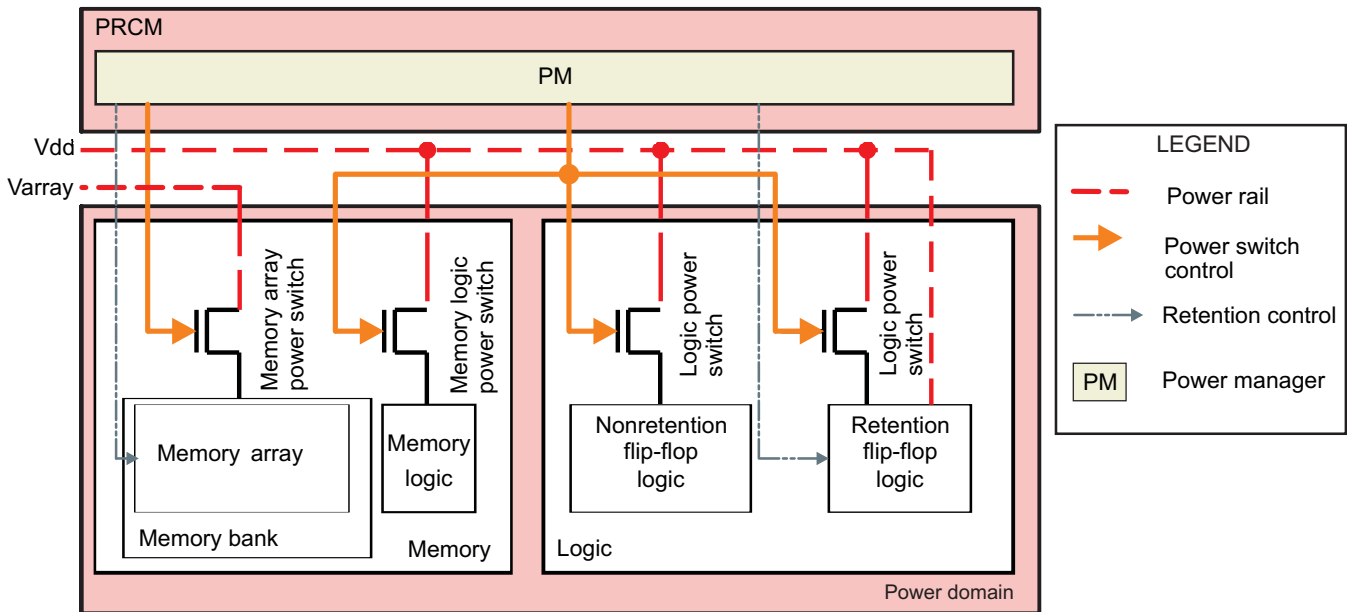

3.1.1.2 Power Management

The PRCM module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device lets the PRCM module turn on and off specific sections of the device without affecting other sections. Power management integration details are described in [Section 3.7, Power Management Functional Description](#).

3.1.1.2.1 Power Domain

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager (see [Figure 3-9](#)). A power domain can be turned on and off without affecting other parts of the device.

Figure 3-9. Generic Power Domain

prcm-008

To minimize device power consumption, the modules are grouped into power domains. A power domain can be split into logic and memory areas.

The memory area contains two entities:

- Memory bank: Composed of memory arrays. It is powered by a dedicated voltage rail and an associated power switch (for example, Varray and memory array power switches).
- Memory logic: Powered by the same voltage source as the logic area of the power domain, but has its dedicated power switch (for example, Vdd and memory logic power switches)

The logic area in the power domain can also be split between retention flip-flops (RFFs) and nonretention flip-flops (DFFs).

Table 3-18 lists the possible states and substates of the logic area in a power domain.

Table 3-18. States of a Logic Area in a Power Domain

State	Substate	Description
ON	ON-ACTIVE	Logic is fully powered and at least one enclosed clock domain is active.
	ON-INACTIVE	Logic is fully powered and all enclosed clock domains are idled.
RETENTION	CSWR (close switch retention)	Logic is fully powered and all enclosed clock domains are idled.
OFF		Logic power switches are off. All the logic (DFF and RFF) is lost except for the context, which has been saved in the scratchpad memory of an always-on power domain.

RETENTION state is useful for quickly switching to low-power idle mode (in which the domain clocks are gated and the domain voltage is less than the on-voltage level) without losing the context, and then quickly switching back to ON-ACTIVE state when necessary. In RETENTION state, power consumption is less than in ON power state.

The behavior of the memory array power switch and memory logic power switch can be selected through software settings in the PRCM module or can be hardwired. Once the behavior is selected, the PRCM module hardware automatically handles these elements to ensure correct power transition sequencing between the power domain states.

Software can also initiate power state changes of the memory array when the associated power domain is in ON power state. This allows the memory array to be turned off and on as needed.

The memory area can be configured to any of the power states listed in [Table 3-19](#).

Table 3-19. States of a Memory Area in a Power Domain

State	Description
ON	The memory array is powered and fully functional.
RETENTION	The memory array is fully powered, but memory is not accessible. The array can be put into retention through an applicable direct retention control signal. Data in memory are always retained.
OFF	The memory array is powered down. Data in memory are lost.

3.1.1.2.2 Module Logic and Memory Context

In case of a power state transition in the logic or memory areas, the context of the module may no longer be valid. This can also be the case when the domain resets are asserted by the device. A specific RM_<Clock Domain Name>_<Module Name>_CONTEXT register provides the status of the device logic and memory context.

- The module logic context consists of simple flip-flops (DFFs) if the module has no logic RFFs.
- If the module has logic retention (full or partial), it is assumed that the context consists of: only RFFs, only DFFs or both RFFs and DFFs.

NOTE: The display subsystem is an exception where the status of DFF and RFF context is given, because only HMDI keys are retained, while most of the display subsystem is not retained.

These context status bits must be cleared by software.

3.1.1.2.3 Power Domain Management

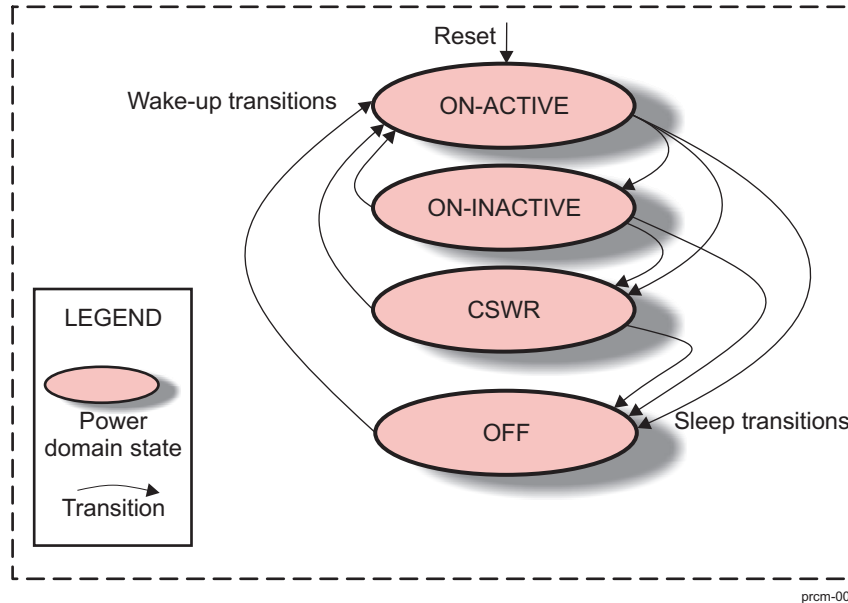

The power manager associated with each power domain is assigned the task of managing the domain power transitions. It ensures that all hardware conditions are satisfied before it can initiate a power domain transition from a source to a target power state (for example, from ON-ACTIVE state to CSWR RETENTION state).

The hardware condition for power domain transition from ON-ACTIVE to any other transition state is:

- All clock domain managers in the power domain are in IDLE state.

[Figure 3-10](#) shows all possible power domain state transitions.

Figure 3-10. Power Domain Transitions

Successive power-down transitions can be performed by lowering the power state from ON-ACTIVE to ON-INACTIVE to RETENTION, and then to OFF and LOWPOWERSTATECHANGE, as long as the hardware condition is satisfied.

However, the power domain wake-up transition from any low-power state (ON-INACTIVE, CSWR or OFF) to ON-ACTIVE state is always direct.

The power domain manager initiates a power domain wake-up transition when the conditions listed in [Table 3-20](#) are satisfied.

Table 3-20. Power Domain Wake-Up Conditions

Relation	Condition
AND	Voltage domain is on.
OR	There is at least a wake-up condition for one enclosed functional clock domain.
	There is a request for clock generation or distribution enclosed in the power domain.
	There is a PRCM module service request (applicable only to power domains, including PRCM module logic).

The power domain manager initiates a domain sleep transition when the conditions listed in [Table 3-21](#) are satisfied.

Table 3-21. Power Domain Sleep Conditions

Relation	Condition
AND	All functional clock domains enclosed in the power domain are idled.
	All clock generation or distribution enclosed in the power domain is quiet, and corresponding input clocks are gated. For example, DPLL, if present, must be in stop mode.
	There is no PRCM module service request (applicable only to power domains, including PRCM module logic).

[Table 3-22](#) lists the control and status features of the PRCM module power domain.

Table 3-22. Power Domain Control and Status Registers

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTCTRL[1:0] POWERSTATE	Control	Selects the target power state of the power domain among OFF, ON-ACTIVE, ON-INACTIVE, and RETENTION
PM_<Power domain>_PWRSTCTRL[x] LOWPOWERSTATECHANGE	Control	Power state change request when domain has already performed a sleep transition. Allows going into deeper low-power state without waking up the power domain.
PM_<Power domain>_PWRSTCTRL[2] LOGICRETSTATE	Control	Selects whether the power domain logic is in CSWR or RETENTION state when the domain transitions to RETENTION state
PM_<Power domain>_PWRSTCTRL[x] <memory bank>_RETSTATE	Control	Selects whether the memory bank in the power domain is in ON, or RETENTION state when the power domain is in RETENTION state. The memory bank cannot be in ON state when the power domain is in RETENTION state.
PM_<Power domain>_PWRSTCTRL[x] <memory bank>_ONSTATE	Control	Selects whether the memory bank is in ON, RETENTION, or OFF state when the power domain is in ON state
PM_<Power domain>_PWRSTST[1:0] POWERSTATEST	Status	Identifies the current state of the power domain. It can be OFF, RETENTION, ON-INACTIVE, or ON-ACTIVE.
PM_<Power domain>_PWRSTST[2] LOGICSTATEST	Status	Identifies the current state of the logic area in the power domain. It can be OFF or ON.
PM_<Power domain>_PWRSTST[20] INTRANSITION	Status	Identifies whether a power state transition in the power domain is in progress or there is no ongoing transition
PM_<Power domain>_PWRSTST[x] <memory bank>_STATEST	Status	Identifies the current power state of the memory bank in the power domain. It can be OFF, RETENTION, or ON.
PM_<Power domain>_PWRSTST[25:24] LASTPOWERSTATEENTERED	Status	Identifies the last (previous) power state of the power domain. It can be OFF, RETENTION, ON-INACTIVE, or ON-ACTIVE.

3.1.1.3 Voltage Management

The PRCM module do not provide controls over the Voltage management. All OPP changes will be handled by Application software directly without any PRCM intervention.

Voltage management integration details are described in [Section 3.8, Voltage Management Functional Description](#).

3.1.1.3.1 Voltage Domain

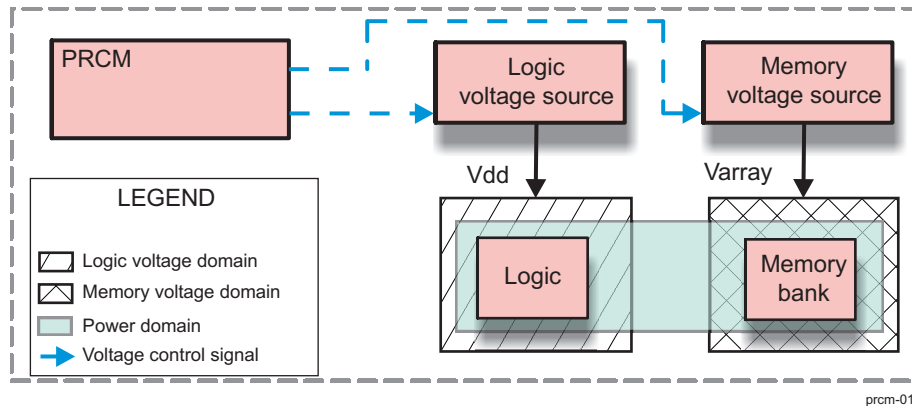

A voltage domain is a section of the device supplied by a dedicated voltage source (that is, an internal LDOs or external switch mode power supply [SMPS]). A voltage domain may or may not be controlled by the PRCM module.

The voltage managers in the PRCM module is one type:

- Dynamically configurable by software to scale the domain voltage level to specific values within the operational voltage range of the device. This is called adaptive voltage scaling (AVS).

[Figure 3-11](#) shows a voltage domain.

Figure 3-11. Generic Voltage Domain

By partitioning the device into independent voltage domains, different operating voltages can be assigned to the different sections of the device (that is, a group of modules or memory banks). The independent voltage control allows voltage scaling of device subsections to ensure that each module or memory bank operates at the optimized operating voltage level based on the application performance requirements.

3.1.1.3.2 Voltage Domain Management

Figure 3-12 shows the different voltage control paths available within a generic logic voltage management block to control the voltage supply to the logic voltage domains of the device.

Figure 3-12. Generic Logic Voltage Management

NOTE: For more information about AVS Class 0 eFuse Voltage registers, see chapter AVS Class 0 Associated Registers in the Control Module.

Figure 3-13 shows the voltage control path available within a generic memory voltage management block to control the voltage supply to the memory voltage domains of the device.

Figure 3-13. Generic Memory Voltage Management

The PRCM hardware supports automatic scaling down of the memory array supply whenever the memory domains transition to RETENTION power state. The device power manager FSM manages the voltage scaling of memory voltage domains through the memory voltage controller (or LDO).

3.1.1.3.3 AVS Overview

Adaptive Voltage Scaling (AVS) Class 0 (also referred to as SmartReflex™) is a power-management technique used to control the operating voltage of a device to reduce its active power consumption.

With SmartReflex, the power supply voltage is adapted to the silicon performance in one way:

- Statically adapted to the manufacturing process of a given device

SmartReflex achieves optimal performance/power trade-off for all devices across the technology process spectrum.

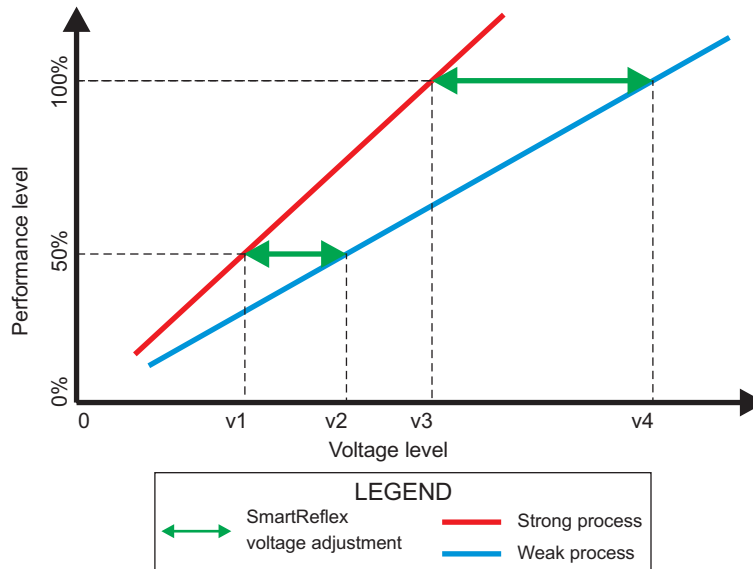

The static correction of the device voltage level (see Figure 3-14) is based on the desired performance level and silicon performance characteristics of the device. As a result of process dispersion, each die has its specific silicon performance. The range of the process distribution defines the weak devices (low-performance silicon) and the strong devices (high-performance silicon).

A weak device is a device with the lowest performance tolerated for a process distribution; that is, at the typical voltage, the inherent maximum frequency is the lowest frequency of the chip distribution. Considered as the worst case, weak devices are used to constrain the target frequency of all the chips (OPP definition).

A strong device is a device with the highest performance tolerated for a process distribution. The inherent maximum frequency at the typical voltage is greater than the targeted frequency.

Figure 3-14 shows that with the SmartReflex voltage-control architecture, it is possible to compensate for the device silicon characteristics and obtain optimal performance characteristics. Based on the device characteristics, the device voltage level can be adjusted for specific performance level.

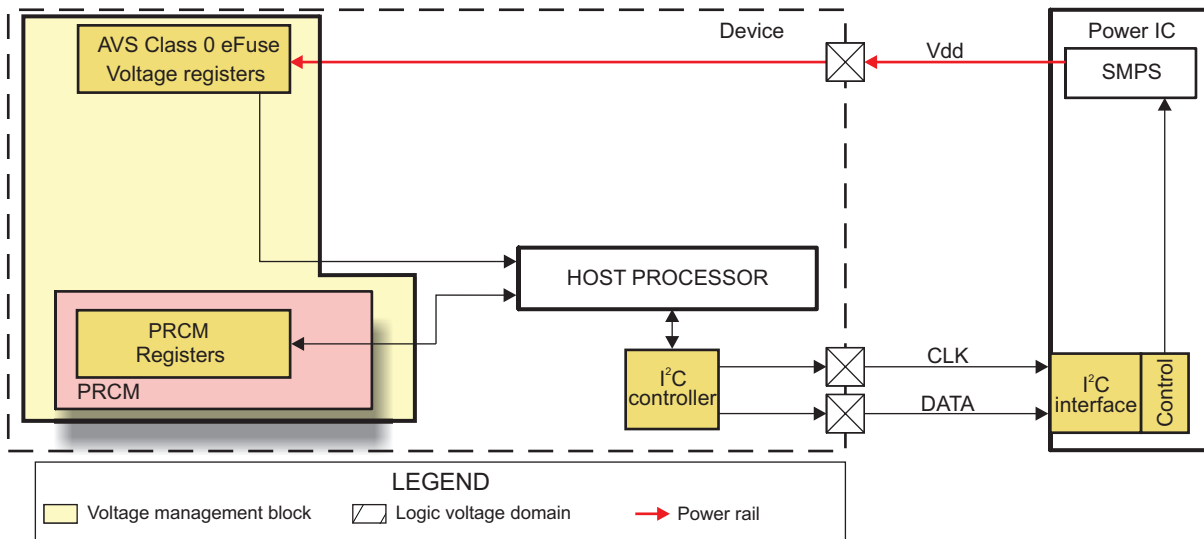

Figure 3-14. SmartReflex Static Voltage Adjustment

prcm-013

Figure 3-15 is a functional overview of the SmartReflex voltage-control architecture of the device connected to an external power IC.

Figure 3-15. SmartReflex Voltage Control Functional Overview

prcm-015

SmartReflex voltage control consists of the following modules:

- Host Processor
- I²C interface
- SMPS

The device supports one operational mode for SmartReflex voltage control:

- Class 0, Manufacturing Test Calibration

3.1.1.3.3.1 AVS Class 0 (SmartReflex™) Voltage Control

Adaptive Voltage Scaling (AVS) Class 0 (also referred to as SmartReflex) is a procedure for lowering the voltage on certain device power rails. AVS Class 0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory. This value is written in the device eFuse where it can be read through dedicated registers. These registers reside in the control module.

3.1.2 Power-Management Techniques

The following sections describe the power-management techniques supported by the device.

NOTE: The values in [Figure 3-16](#) through [Figure 3-18](#), which show the power-management techniques, are hypothetical. They do not represent valid test results on the device.

3.1.2.1 Standby Leakage Management

Standby leakage management (SLM) is a power-management technique that reduces standby power consumption by reducing power leakage.

With SLM, the device switches into low-power system modes automatically or in response to user requests during system standby (that is, in situations when no application is started and system activity is negligible or limited).

When applying SLM, the system remains in the lowest static power mode compatible with the system response time requirement.

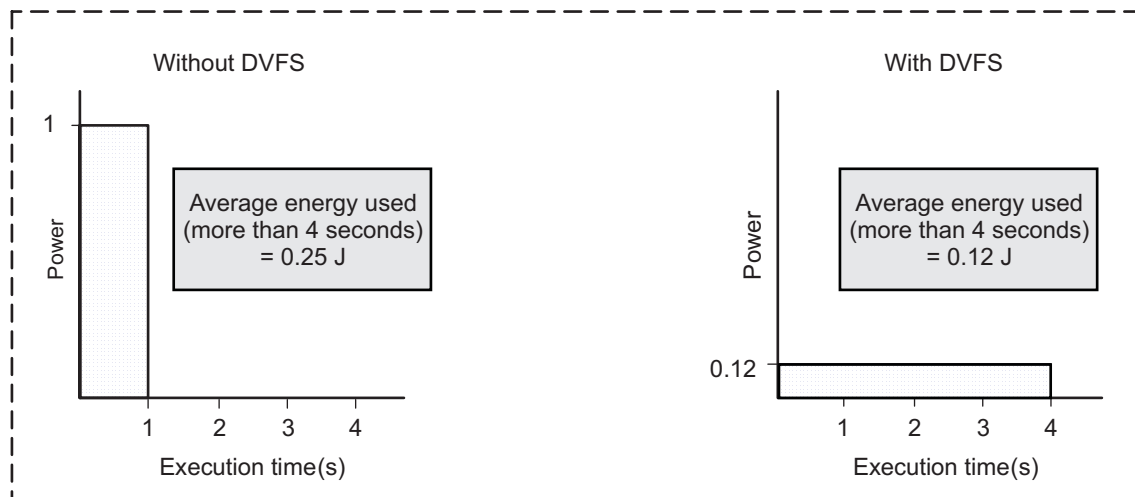

This technique trades static power consumption for wake-up latency.

3.1.2.2 Dynamic Voltage and Frequency Scaling

Dynamic voltage and frequency scaling (DVFS) consists of minimizing the idle time of the system. The DVFS technique uses dynamic selection of the optimal operating frequency and voltage to allow a task to be performed in the required length of time. This reduces the active power consumption (power consumed while executing a task) of the device while still meeting task requirements.

NOTE: The values in [Figure 3-16](#) are hypothetical. They are meant only to clarify the concept and do not represent valid test results on the device.

Figure 3-16. Comparison of Energy Consumed With/Without DVFS

prcm-016

Figure 3-16 shows the DVFS technique by comparing a process executed at maximum frequency and operating voltage without applying DVFS to the same process executed at optimal frequency and voltage using DVFS, based on the task requirements. If a task that must terminate in 4 seconds is performed at maximum operating frequency (see the left side of the figure), it terminates in 1 second, and the remaining 3 seconds are spent in idle mode.

With DVFS (see the right side of the figure), the operating frequency is reduced to optimal level; the task takes the full 4 seconds to complete, but power consumption is reduced. In addition, the voltage can be reduced further to save power so the dynamic and leakage power consumption are reduced.

DVFS requires control over the clock frequency and the operating voltage of the device elements. By intelligently switching the individual elements of the device to their OPPs, the power consumption of the device for a given task can be minimized.

For practical reasons related to the development of the device (flow, tools), DVFS can be used only for a few discrete steps, not over a continuum of voltage and frequency values. Each step, or OPP, is composed of a voltage (V) and frequency (F) pair. For an OPP, the frequency corresponds to the maximum frequency allowed at a voltage, or reciprocally; the voltage corresponds to the minimum voltage allowed for a frequency.

When applying DVFS, a processor or system always runs at the lowest OPP that meets the performance requirement at a given time. The user determines the optimal OPP for a given task and then switches to that OPP to save power.

3.1.2.3 Dynamic Power Switching

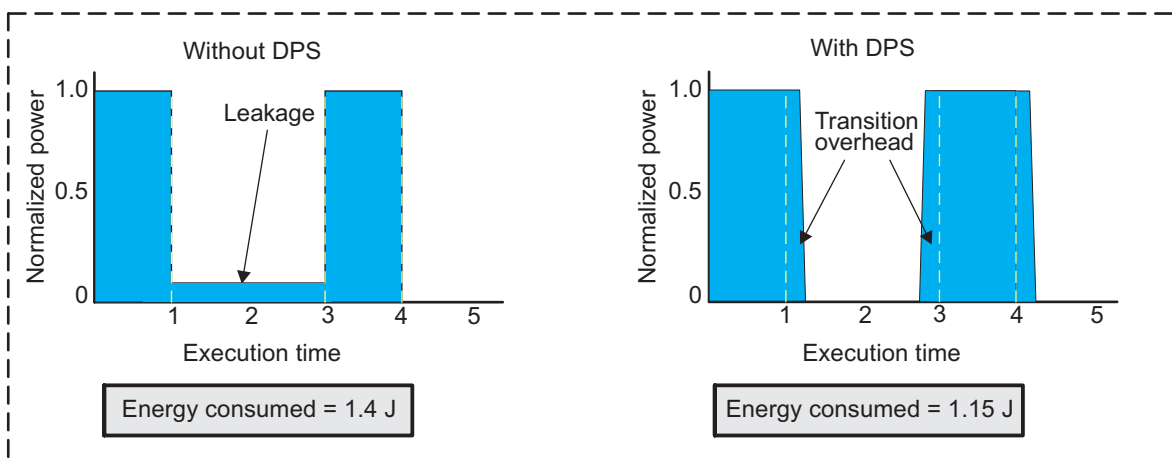

Like DVFS, dynamic power switching (DPS) is a power-management technique intended to reduce the active power consumption of a device. However, whereas DVFS reduces dynamic and leakage power consumption, DPS reduces only leakage power consumption, at the expense of a slight overhead in dynamic power consumption.

With DPS, the system switches dynamically between high- and low-consumption system power modes during system active time. When DPS is applied, a processor or system runs at the highest OPP (maximum frequency and voltage) to complete its tasks quickly, followed by an automatic switch to a low-power mode for minimum power consumption. DPS is useful when a real-time application is waiting for an event. The system can switch into a low-power system mode if the wake-up latency conditions allow it.

This technique consists of maximizing the idle period of the system to reduce its power consumption.

NOTE: The values in Figure 3-17 are hypothetical. They are meant only to clarify the concept and do not represent valid test results on the device.

Figure 3-17. Comparison of Energy Consumed With/Without DPS

prcm-017

Figure 3-17 compares the behavior of power consumption for the same operation of the device without DPS (see the left side of the figure) and with DPS (see the right side of the figure). When operating without DPS, the device has a constant leakage current in idle mode. By using DPS, the system reduces the leakage current to 0. However, the transitions between system power modes may require storing the information before entering a low-power inactive state and restoring the information after a wake-up event (see **Figure 3-17**). This results in additional dynamic power consumption, referred to as transition overhead (see **Figure 3-17**). Transition overhead must be considered for a DPS operation.

For efficient deployment of DPS techniques, it is necessary to predict dynamically the performance requirement of the applications running on the processor. The DPS controller must account for the overhead of wake-up latencies related to domain switching and ensure that they do not significantly affect the performance of the device. Even with transition overhead, the user can identify an optimal idle-time limit, after which the DPS is useful for dynamic power saving.

3.1.2.4 Adaptive Voltage Scaling

With SmartReflex, power-supply voltage is adapted to silicon performance, statically (based on performance points predefined in the manufacturing process of a given device).

AVS achieves the optimal performance/power trade-off for all devices across the technology process spectrum. This ensures optimal power consumption for a given OPP.

3.1.2.5 Combining Power-Management Techniques

The power-management techniques previously described have specific features and are most effective when used under the specific operating conditions of the device. Hence, the best active power savings are obtained by combining the DVFS, DPS, SLM, and AVS techniques. For a given operating state, one or more of the power-saving techniques can be applied to ensure optimal operation with maximum power saving.

AVS must be used at boot time to adapt the voltage to the process characteristics (strong/weak) of the device. AVS can also ensure the maximum available application performance of the device at a given OPP.

When medium application performance is required, or when application performance requirements vary, DVFS can be applied. The voltage and frequency can be scaled to match the closest OPP that meets the performance requirement.

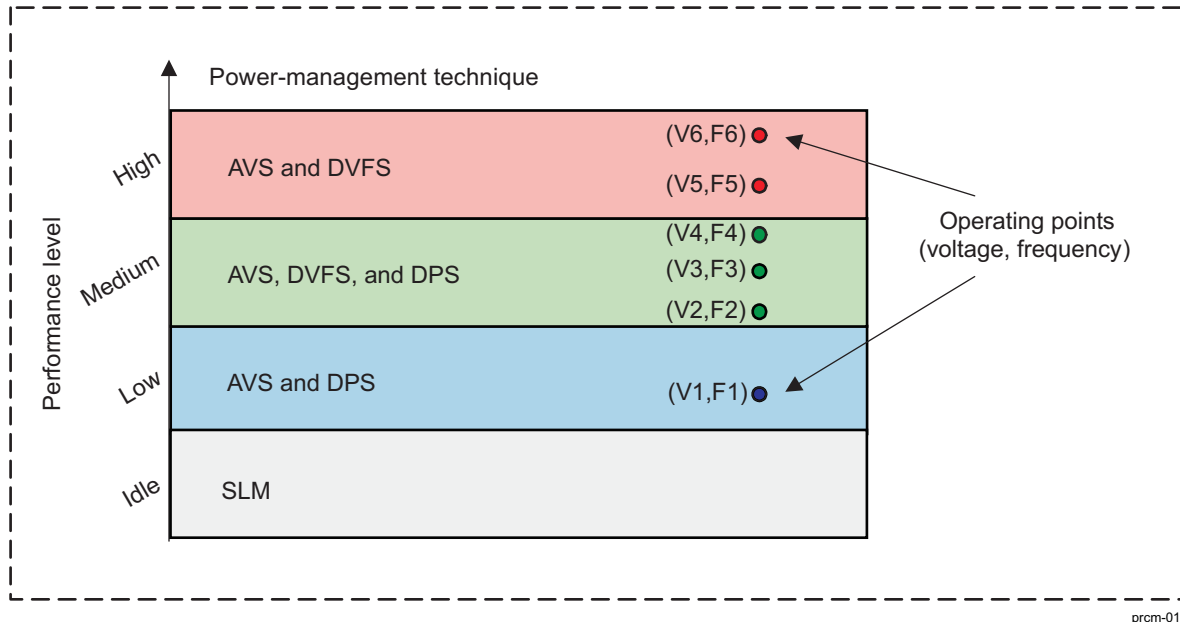

When application performance requirements fall between two OPPs, or when a low application performance is required that is below the lowest performance OPP, DPS can be applied to switch to low-power mode.

When combining DVFS and DPS, the operating frequency must not be scaled to match the performance requirement without scaling the voltage. Lower operating frequency increases task completion time and reduces idle time. This prevents DPS or reduces its efficiency (DPS becomes more effective as idle time increases). Unless DPS cannot be applied for other reasons, for a given operating point of DVFS the operating frequency must always be set to the maximum allowed at a given voltage. This ensures optimal process completion time and application of DPS.

If DPS cannot be applied in a given context, scaling the frequency while keeping the voltage constant does not save energy; it does, however, reduce peak power consumption. This can have a positive effect on temperature dissipation and battery life.

SLM must be used when no applications are running and performance requirement drops to 0.

NOTE: The OPPs shown in **Figure 3-18** are only for indication and clarity of text. They do not correspond to validated OPPs of the device.

Figure 3-18. Performance Level and Applied Power-Management Techniques

3.1.2.5.1 DPS Versus SLM

DPS and SLM are similar concepts: they consist of switching the system between high- and low-power consumption modes. However, their operating timescales differ, principally in the latency allowed for mode transitions.

DPS is generally used in an applicative context (tasks are started). Therefore, mode transitions are related to system performance requirements or the processor load. DPS transition latencies must be small (typically between 10 and 100 μ s) compared to the time constraints or deadlines of the application so that they do not degrade application performance. DPS requires performance prediction to ensure that transition latencies do not deteriorate device performance to the point that real-time application deadlines are missed or the user experience degrades too much for an interactive application.

SLM is not used in an applicative context (no task started). Mode transitions are related more to system responsiveness, and the transition latencies must be small compared to user sensitivity so that they do not degrade the user experience. For SLM, transition latencies are typically 1-10 ms or more.

DPS and SLM also differ in the type of wake-up event used to exit low-power idle mode. For DPS, wake-up events are application-related (timer, DMA request, peripheral interrupt, etc.); for SLM, wake-up events are user-related (touch screen, key pressed, peripheral connections, etc.).

3.2 PRCM Subsystem Overview

3.2.1 Introduction

The power-management framework of the device significantly reduces dynamic power consumption and static leakage current. This framework incorporates support for state-of-the-art power-management techniques. It ensures optimal device operation with significantly reduced power consumption. The power-management framework (PMFW) of the device is handled by the PRCM which is a logical module composed of the following three physical submodules:

- PRM: Handles device-level power and reset management. It also handles some clocks in the device. This module always remains on, unless no power is supplied to the device pads.
- CM_CORE_AON: Handles device-level clock management of the DSP1, DSP2, COREAON, CORE, IPU, L4PER, DSS, L3INIT, ISS, CAM, CUSTEFUSE, EVE1, EMU and WKUPAON power domains. This module always remains on, unless no power is supplied to the device pads.
- CM_CORE: Handles device-level clock management of the MMR block.

The device supports the power-management techniques with the following features:

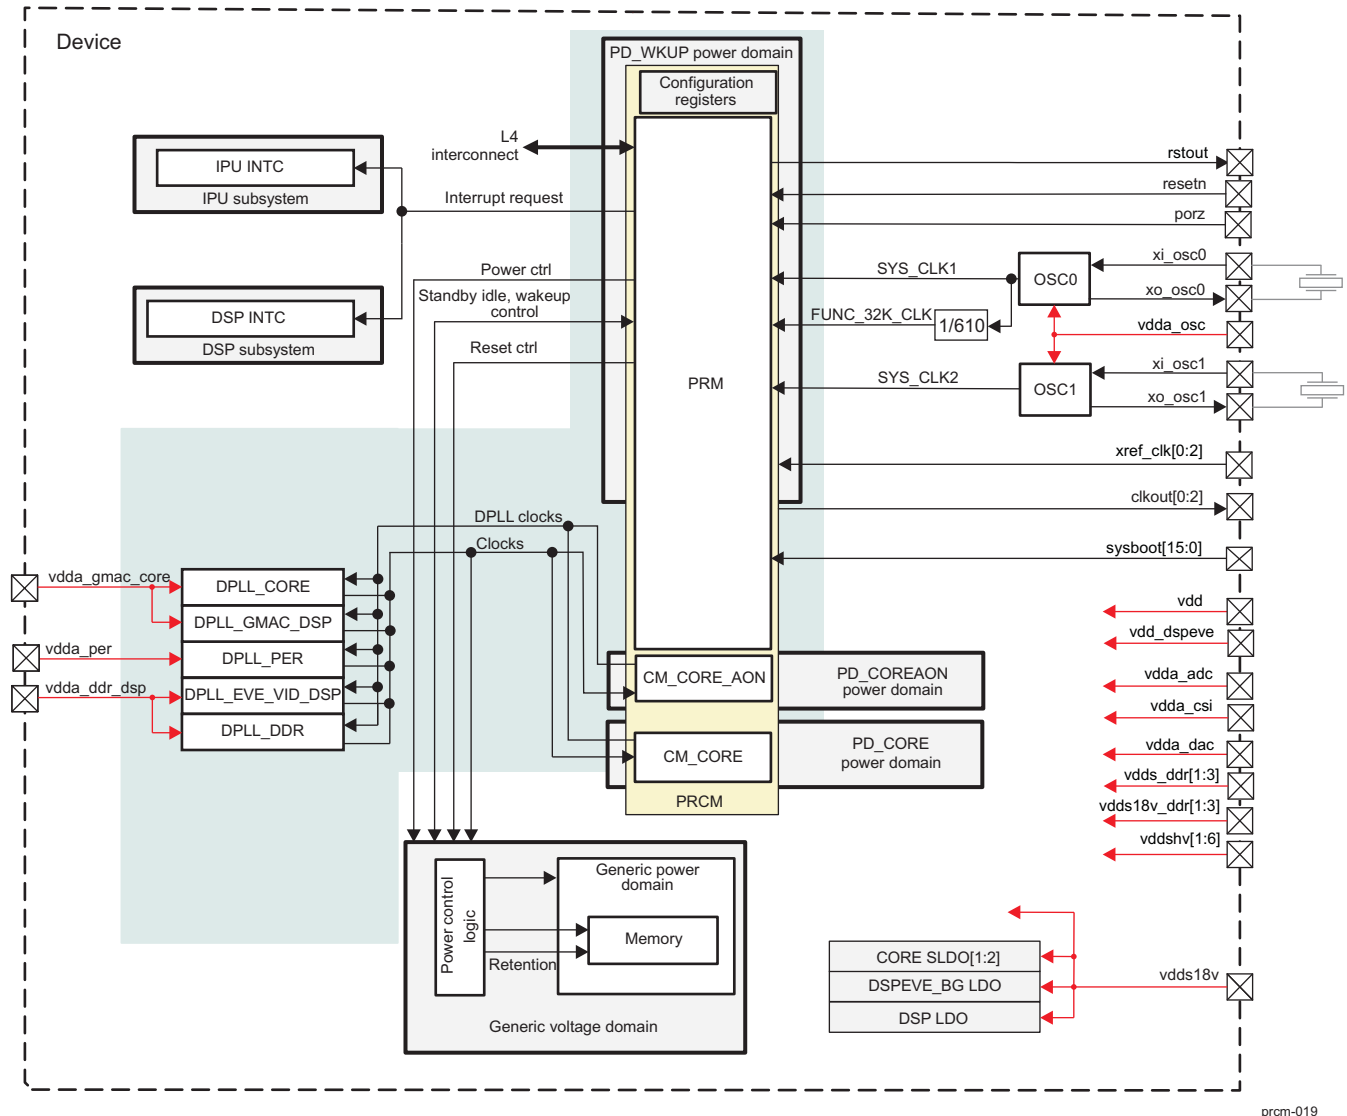

- Partitioning of the device into voltage, power, clock, and reset domains
- Domain isolation that allows any combination of domain ON/OFF states
- Clock tree with selective clock-gating conditions
- Hardware-controlled reset sequencing management
- Power, reset, and clock control hardware mechanism to manage sleep and wake-up dependencies of the power domains
- Support for hardware-controlled autogating of module clocks
- Memory retention capability for preserving memory contents in low-power sleep mode
- DVFS support for the processor and peripherals

The PMFW interfaces with all the components of the device for power, clock, and reset management through associated control signals. It integrates enhanced features to let the device adapt energy consumption dynamically according to changing application and performance requirements. The innovative hardware architecture allows a substantial reduction in leakage current.

The power-management modules are fully configurable through their L4 interface ports.

[Figure 3-19](#) is an overview of the power-management modules and their internal connections with a generic power domain.

Figure 3-19. PMFW Overview

prcm-019

NOTE: The device I/O logic maps the module signals to the different pads of the device. For more information, see the *Pad Configuration Registers* and sections in [Chapter 14, Control Module](#) and the device Data Manual.

3.2.2 Power-Management Framework Features

The power-management modules:

- Manage independent power domains
- Control scalable logic voltage domains and selectable voltage modes for memory voltage domains
- Handle standby, idle, and wake-up procedures for the modules of the device
- Allow software and partial hardware control
- Monitor and handle wake-up events
- Control system clock and reset input sources
- Manage and distribute clocks and resets with high control granularity
- Handle power-up sequences

- Have debug and emulation features
- Control RFFs of device modules to support DPS

3.3 PRCM Subsystem Environment

The modules of the PMFW receive the external reset, clock, and power signals. See [Figure 3-19](#).

The following sections describe the interfaces for external clock, reset, and power sources.

3.3.1 External Clock Signals

[Table 3-23](#) lists the external clock pins, signal names, their direction, associated module, and description of the signals. If the signal is input to the device, the module is the destination module for the signal; if the signal is an output from the device, the module is the source module of the signal.

Table 3-23. External Clock Signals

3.3.2 External Boot Signals

The PRM receives SYSBOOT[15:0] information from external pins sys_boot[15:0]. They are used to configure the boot mode of the device. For more information, see [Chapter 25, Initialization, Section 25.2.4, Sysboot Configuration](#) and the device *Data Manual*.

[Table 3-24](#) lists the external boot configuration pins, signal names, their direction, the associated modules, description, and reset values of the signals. If the signal is input to the device, the module is the destination module for the signal; if the signal is an output from the device, the module is the source module of the signal.

3.3.3 External Reset Signals

The PRM drives the SYS_WARM_OUT_RST reset output signal which is directly mapped as rstoutn device pin. The PRM asserts SYS_WARM_OUT_RST output upon the assertion of any source of global reset (warm or cold). This reset signal keeps external peripherals under reset while the device is in global reset.

Table 3-25 lists the external reset pins, signal names, their direction, associated module, and description of the signals. If the signal is input to the device, the module is the destination module for the signal; if the signal is an output from the device, the module is the source module of the signal.

⁽¹⁾ I = Input; O = Output; I/O = bidirectional

3.3.4 External Voltage Inputs

Table 3-26 lists the external voltage sources related to the PRCM module.

NOTE: Table 3-26 lists only the voltage sources that are directly managed by the PRCM module or received by parts of the PRCM module (for example, DPLLs, LDOs, etc.). It does not give the device voltage sources not directly associated with the PRCM module. Please refer to the device *Data Manual* for all power pins.

	VDDA_LDO_CORE[1:2]	No	VDDS supply for core SLDO

3.4 PRCM Subsystem Integration

The internal configuration registers of the power-management modules can be accessed for configuration and control through their respective L4_WKUP interconnect. In addition to the L4 interconnect, the internal module interface contains the following interfaces and signals:

- A set of signals for idle/wake-up control for each module
- Clocks and reset signals for the modules
- Power control signals (switches and memories) to the power domains
- Interrupts to the IPU and DSP INTCs
- Phase-locked loop (PLL) control commands for recalibration and bypass of the digital phase-locked loops (DPLLs)

Figure 3-19 shows details of the control interface to a generic power domain.

3.4.1 Device Power-Management Layout

The PMFW sees the device split into voltage domains, power domains, and clock domains. Table 3-27 provides the device-level view with module association to the clock, power, and voltage domains.

The PRM part of the PRCM module is in the PD_WKUPAON power domain, which is continuously active. It is composed of the logic that must be permanently supplied to manage domain power-state transitions and detect wake-up events.

The CM_CORE_AON part of the PRCM module is in the PD_COREAON power domain, which is an always-on power domain, while the CM_CORE part of the PRCM module is in the PD_CORE power domain, which can be activated and deactivated according to the requirements of the executing applications.

3.4.2.2 Resets

The PMFW modules are reset by independent reset signals (see Table 3-29).

NOTE: The **Default Mapping** column in [Table 3-30 PMFW Hardware Requests](#) shows the default mapping of module IRQ source signals. These module IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module, respectively.
For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).
For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

3.5 Reset Management Functional Description

3.5.1 Overview

In the device, the reset scheme is managed by the PRM, device-level reset manager.

3.5.1.1 Reset Management Functional Description

The PRM handles the device power-on and warm reset pads: porz, resetn, and rstoutn. The PRM:

- Extends the reset duration beyond the porz pad release
- Provides the reset duration period after the resetn pad assertion
- Routes the device pad resets

The PRM is functionally sensitive to the device POR.

3.5.1.1.1 Power-On Reset

The PRM receives the device POR on the porz reset pad of the device. It extends the duration of the POR module until at least stable 32-kHz clock and SYS_CLK1 are provided to it. The 32-kHz clock and SYS_CLK1 of the device are propagated once the PRCM releases the internal POR.

3.5.1.1.2 Warm Reset

The device warm reset can be received from an external source or the device PRM module as a result of an internal event.

The PRCM can generate the global reset used by the domain Reset Managers from these warm reset input sources:

- SYS_WARM_IN_RST
- GLOBAL_SW_WARM_RST

3.5.1.2 PRM Reset Management Functional Description

The PRM module manages the resets to all power domains inside the device.

NOTE: The PRM module has no knowledge or control over resets generated locally within a module (for example, through the <Module name>_SYSCONFIG[x] SOFTRESET configuration register bit). A software reset has the same effect on the module logic as a hardware reset.

All PRM reset outputs are asynchronously asserted, while the deassertion is synchronous to the SYS_CLK1 clock. The reset managers in PRM use this clock to stall, or delay, deassertion of reset upon source deactivation.

In each power domain one or more reset domains are defined by a unique reset signal that originates from the reset manager and is connected to one or more modules of the device. All the connected modules of the reset domain are reset simultaneously when the reset signal is asserted. Independent control of these reset domains allows sequencing of the release of resets and ensures a safe reset of the entire power domain.

3.5.2 General Characteristics of Reset Signals

Reset signals can be categorized based on four criteria:

- Scope: Global or local reset
- Occurrence: Cold or warm reset
- Source type: Software-controlled or hardware-triggered reset
- Retention type: Retention reset or nonretention reset

3.5.2.1 Scope

A reset signal can be categorized according to its scope (the area of the device affected by the reset):

- Global reset: Affects the entire logic of the device; all modules are reset. Generally, occurs when the device powers up (POR) or an abnormal operation is detected (watchdog timeout, thermal shutdown, etc.)
- Local reset: Affects one power domain, reset domain, or module.

3.5.2.2 Occurrence

A reset signal can be categorized depending on when the reset occurs:

- Cold reset: Occurs on device power up (POR), or in certain emulation modes. Also, it can be software-initiated. Upon cold reset, it is assumed the device is being powered up, and therefore, everything in the device is being reset. That is, cold resets must be considered as global resets.
- Warm reset: Warm reset types are not necessarily applied globally within device. Also, a module can use a warm reset to reset a subset of its logic. This is often done to speed up reset recovery time; that is, the time to transition to a safe operating state, compared to the time required upon receipt of a cold reset. Warm reset events include software-triggered reset per power domain, watchdog time-out, externally triggered and emulation initiated.

Modules that behave differently in cold reset and warm reset have two reset signals: RST and PWRON_RST. These reset signals reconstruct warm reset and cold reset in modules that require them.

The following modules are reset upon global cold reset events and not upon global warm reset events:

- All DPLLs associated with the PRCM module
- EMIF
- Control module: CTRL_MODULE_CORE, CTRL_MODULE_WKUP

NOTE: For information about the PRCM module registers affected by the global warm reset, see the register description in [Section 3.12](#), *PRCM Register Manual*.

NOTE: The DPLLs state will change after warm reset even though their registers are not warm reset-sensitive, refer to [Section 3.5.6.8](#), *Global Warm Reset Sequence* for more details.

3.5.2.3 Source Type

A reset can be categorized depending on whether it is software-controlled or hardware-triggered:

- Software reset: Triggered by setting a bit in a configuration register of the PRCM module
- Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

3.5.2.4 Retention Type

The power domain manager in PRM controls the assertion of two types of local cold reset sources, retention and nonretention reset. They are identified by the naming convention <PowerDomain>_DOM_RET_RST and <PowerDomain>_DOM_RST, respectively.

Upon transitioning a power domain to the ON-ACTIVE power state from the OFF power state:

- Retention type reset source is always asserted.
- Nonretention type reset source is always asserted.

Upon transitioning a power domain to the ON-ACTIVE power state from the RETENTION power state:

- Retention type reset source is never asserted.
- Nonretention type reset source is optionally asserted. The software-selectable option enables the PRM to support two retention mechanisms: CSWRET. Nonretention type reset source has the following behavior:
 - It is not asserted if the power domain state transitions from the CSWR-RETENTION state.

3.5.3 Reset Sources

The reset sources triggering the reset managers in the PRM are described in this section.

3.5.3.1 Global Reset Sources

Table 3-31 lists the global reset sources of the device. The global reset source signals received by the reset manager trigger the reset of all the device modules. For all hardware reset signals, the source of the reset is identified; for the software reset signals, the bit triggering the reset is identified.

Table 3-31. Global Reset Sources

Type ⁽¹⁾	Name	Source/Control	Description
H/C	SYS_PWRON_RST	porz input pin	The entire device is held in reset during porz pin assertion. porz pin is typically asserted by external PMIC at POR. PMIC keeps porz asserted until all voltage rails are ramped-up and stable. PRM extends device internal reset after porz release. Refer to Power Supply Sequences in Device Data Manual.
H/W	SYS_WARMIN_RST	resetn input pin	Warm reset from external device. Internal warm reset is triggered by the active (falling) edge of this signal and is extended with RstTime1.
S/C	GLOBAL_COLD_SW_RST	PRM_RSTCTRL[1] RST_GLOBAL_COLD_SW	Global software cold reset
S/W	GLOBAL_WARM_SW_RST	PRM_RSTCTRL[0] RST_GLOBAL_WARM_SW	Global software warm reset
H/W	TSHUT_CORE_RST	Device thermal sensor, placed close to the ISS and DSP	Asserted when measured temperature is greater than shutdown temperature threshold
H/W	ICEPICK_RST	ICEPick™ module	ICEPick warm reset. It is used only in emulation mode.
H/C	ICEPICK_POR_RST	ICEPick module	ICEPick cold reset. It is used only in emulation mode.
H/W	RTI_DWD_RST	RTI digital watchdog reset	Can be selected among RTI[1:5] in Control Module register CTRL_CORE_CONTROL_IO_2

⁽¹⁾ H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

3.5.3.2 Local Reset Sources

In addition to the global reset sources the device can have a number of local reset sources for each power domain. The local reset sources can be cold or warm reset sources. They can be software-controlled or hardware-triggered. Table 3-32 identifies the possible types of hardware-triggered local cold reset sources. Some power domains can support one or both of these local cold reset sources. The table does not list the software-triggered local warm reset sources that are listed in the reset management section of the respective power domains. A local reset source signal received by the reset manager resets only a specific part of the device (for example, some modules/subsystems within the power domain).

Table 3-32. Local Reset Sources

Type ⁽¹⁾	Name	Source/Control	Description
H/C	<Power domain>_RET_RST	PRCM	Asserted only for a power domain state transition from OFF to ON-ACTIVE state
H/C	<Power domain>_RST	PRCM	Asserted for any power domain transition to ON-ACTIVE state

⁽¹⁾ H = Hardware reset, C = Cold reset

3.5.4 Reset Logging

A reset of the device is logged in the reset status registers RM_<power domain>_RSTST and in global register [PRM_RSTST](#).

RM_<power domain>_RSTST are reset asynchronously on assertion of a global cold reset. However, a reset status bit is always logged when the reset is released to the domain.

For this reason, after the assertion of a global cold reset, the reset status register is cleared to 0. When the domain reset is released, the register bit to log the global cold reset (the [PRM_RSTST\[0\]](#) GLOBAL_COLD_RST bit) is updated to 1. For the same reason, the reset status register of domains released from reset by software is updated only when software releases the domain reset.

The assertion of a global cold reset prevents logging any other source of reset until after the release of the domain reset. This is valid in the following situations:

- A source of reset other than global cold reset is asserted before, during, or after the active period of a global cold source of reset and before the release of the domain reset signal.
- A source of reset other than global cold reset is asserted and then released, but a global cold reset source is asserted before the release of the domain reset signal.

3.5.5 Reset Domains

A power domain can receive power-on reset (PWRON_RST) and/or normal reset (RST) signals. These signals reset nonretention logic and behave as follows:

- On any global or local cold reset, RST and PWRON_RST are asserted.
- On any global or local warm reset, only RST is asserted.
- On wakeup from OFF, PWRON_RST are asserted.

A power domain can receive two additional retention logic reset signals: power-on retention reset (PWRON_RET_RST) and/or retention reset (RET_RST). These signals behave as follows:

- On any global cold reset, RET_RST and PWRON_RET_RST are asserted.
- On any global cold reset or wakeup from OFF state to ON-ACTIVE state, RET_RST and PWRON_RET_RST are asserted.
- On any global warm reset, only RET_RST is asserted.

This section discusses the trigger sources and attributes for all reset domains of the device. For an explanation of each reset trigger source of the device, see [Section 3.5.3, Reset Sources](#).

[Table 3-33](#) identifies the associated power and rest domains for each module.

NOTE: The DPLLs state will change after warm reset even though they are not warm reset-sensitive, refer to [Section 3.5.6.8, Global Warm Reset Sequence](#) for more details.

3.5.6 Reset Sequences

3.5.6.1 IPU1 Subsystem Power-On Reset Sequence

Figure 3-20 shows the power-on reset sequence of the IPU1 subsystem.

Figure 3-20. IPU1 Power-On Reset Sequence

The assumptions on power-on reset assertion are:

- The IPU subsystem is held in reset by the PRCM module and the following are asserted:
 - IPU1_PWRON_RST
 - IPU1_RET_RST
 - IPU1_CPU0_RST
 - IPU1_CPU1_RST
 - IPU1_RST

The power-on reset sequence is:

1. Device power-on reset is released. CTRL_CORE_IPU_WAKEUP[0] IPU_WKUP_EN reset value is set to 1 to allow starting up the IPU. This includes initiating the IPU's reset release sequence, as well as setting the MODULEMODE to HW AUTO.
2. The PRCM module releases IPU1_PWRON_RST once the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) reaches its limit and the IPU1_GFCLK is running. Upon deassertion of the POR signal, the IPU subsystem starts the CPU and CACHE_MMU_IPU initialization sequence.
3. When the reset sequence of Step 2 completes and the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the IPU1_RST and IPU1_RET_RST signals.
4. The PRCM module releases IPU_CPU0_RST, which causes IPU_C0 to start executing code from IPU_BOOTROM.
5. The PRCM module releases IPU_CPU1_RST to IPU_C1. IPU_C1 is in wait-for-event state until boot ROM code wakes it up to execute code.

NOTE: IPU or other device core can disable IPU subsystem by clearing CTRL_CORE_IPU_WAKEUP[0] IPU_WKUP_EN to 0.

3.5.6.2 DSP1 Subsystem Power-On Reset Sequence

Figure 3-21 shows the power-on reset sequence of the DSP1 subsystem.

Figure 3-21. DSP1 Subsystem Power-On Reset Sequence

The power-on reset to DSP1 is applied when PD_DSP1 is powered. The assumptions after power-on reset assertion are:

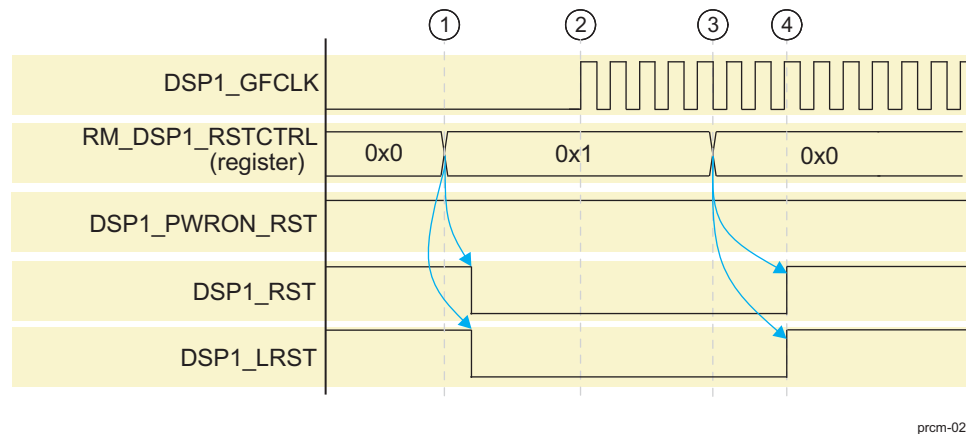

- PD_DSP1 is on
- The PRCM module provides DSP1_GCLK functional clock to the DSP subsystem, and it has been enabled by IPU software control.

The Power-On Reset sequence is:

1. Software clears the [RM_DSP1_RSTCTRL\[1\]](#) RST_DSP1 bit. This causes the PRCM module to release the DSP1_PWRON_RST used inside DSP1 mainly to reset the emulation logic and the DSP1_RST used to reset all logic inside DSP1. Then software can download data into TCM memory while keeping the CPU under reset.
2. When the memory is initialized, software clears the [RM_DSP1_RSTCTRL\[0\]](#) RST_DSP1_LRST bit. This release DSP1_LRST to the local CPU inside DSP subsystem.

3.5.6.3 DSP1 Subsystem Software Warm Reset Sequence

[Figure 3-22](#) shows the software warm reset sequence of the DSP1 subsystem.

Figure 3-22. DSP1 Subsystem Software Warm Reset Sequence

Before asserting the software reset to the DSP subsystem, the IPU software must ensure that:

- The DSP CPUs are in IDLE state ([CM_DSP1_DSP1_CLKCTRL\[17:16\]](#) IDLEST).
- The DSP subsystem is in STANDBY state ([CM_DSP1_DSP1_CLKCTRL\[18\]](#) STBYST).
- The functional clock to the DSP subsystem has been gated by the PRCM module ([CM_DSP1_CLKSTCTRL\[8\]](#) CLKACTIVITY_DSP1_GFCLK)

The software reset sequence is:

1. IPU software sets the [RM_DSP1_RSTCTRL\[1\]](#) RST_DSP1 = 0 and [RM_DSP1_RSTCTRL\[0\]](#) RST_DSP1_LRST = 1. This causes the PRCM module to assert DSP1_RST, DSP1_LRST to the DSP subsystem. The DSP1_PWRON_RST remains deasserted.
2. The IPU software enables the functional clock to the DSP subsystem.
3. The IPU software clears the [RM_DSP1_RSTCTRL\[1\]](#) RST_DSP1 and [RM_DSP1_RSTCTRL\[0\]](#) RST_DSP1_LRST bits. This causes the PRCM module to release DSP1_RST and DSP1_LRST to the DSP subsystem.

3.5.6.4 DSP2 Subsystem Power-On Reset Sequence

Figure 3-23 shows the power-on reset sequence of the DSP2 subsystem.

Figure 3-23. DSP2 Subsystem Power-On Reset Sequence

prcm-025a

The power-on reset to DSP2 is applied when PD_DSP2 is powered. The assumptions after power-on reset assertion are:

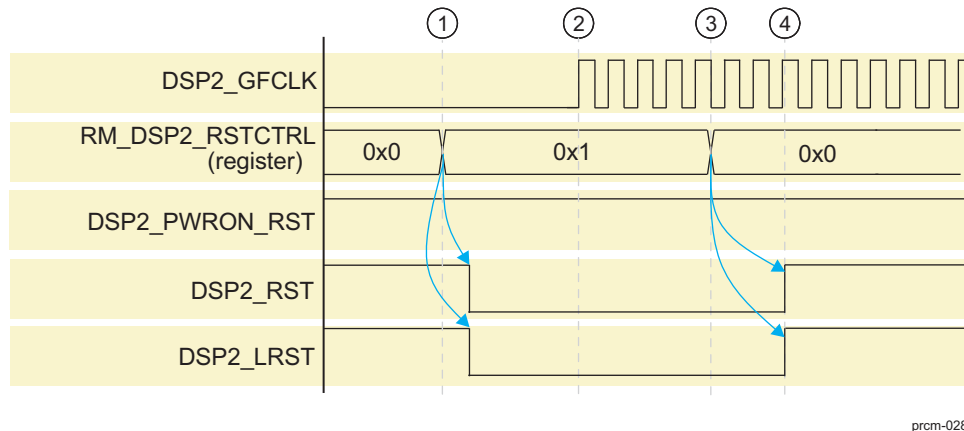

- PD_DSP2 is on.
- The PRCM module provides DSP2_GCLK functional clock to the DSP subsystem, and it has been enabled by IPU software control.

The Power-On Reset sequence is:

1. Software clears the [RM_DSP2_RSTCTRL\[1\]](#) RST_DSP2 bit. This causes the PRCM module to release the DSP2_PWRON_RST used inside DSP2 mainly to reset the emulation logic and the DSP2_RST used to reset all logic inside DSP2. Then software can download data into TCM memory while keeping the CPU under reset.
2. When the memory is initialized, software clears the [RM_DSP2_RSTCTRL\[0\]](#) RST_DSP2_LRST bit. This releases DSP2_LRST to the local CPU inside DSP subsystem.

3.5.6.5 DSP2 Subsystem Software Warm Reset Sequence

Figure 3-22 shows the software warm reset sequence of the DSP2 subsystem.

Figure 3-24. DSP2 Subsystem Software Warm Reset Sequence

Before asserting the software reset to the DSP subsystem, the IPU software must ensure that:

- The DSP CPUs are in IDLE state ([CM_DSP2_DSP2_CLKCTRL\[17:16\] IDLEST](#)).
- The DSP subsystem is in STANDBY state ([CM_DSP2_DSP2_CLKCTRL\[18\] STBYST](#)).
- The functional clock to the DSP subsystem has been gated by the PRCM module ([CM_DSP2_CLKSTCTRL\[8\] CLKACTIVITY_DSP2_GFCLK](#))

The software reset sequence is:

1. IPU software sets the [RM_DSP2_RSTCTRL\[1\] RST_DSP2](#) = 0 and [RM_DSP2_RSTCTRL\[0\] RST_DSP2_LRST](#) = 1. This causes the PRCM module to assert [DSP2_RST](#), [DSP2_LRST](#) to the DSP subsystem. The [DSP2_PWRON_RST](#) remains deasserted.
2. The IPU software enables the functional clock to the DSP subsystem.
3. The IPU software clears the [RM_DSP2_RSTCTRL\[1\] RST_DSP2](#) and [RM_DSP2_RSTCTRL\[0\] RST_DSP2_LRST](#) bits. This causes the PRCM module to release [DSP2_RST](#) and [DSP2_LRST](#) to the DSP subsystem.

3.5.6.6 EVE Subsystem Power-On Reset Sequence

Figure 3-25 shows the power-on reset sequence of the EVE subsystem.

Figure 3-25. EVE Subsystem Power-On Reset Sequence

The power-on reset to EVE is applied when [PD_EVE](#) is powered. The assumptions on power-on reset assertion are:

- The PRCM module provides the [EVE1_GFCLK](#) functional clock to the EVE subsystem, and it has been enabled by IPU software control.

The power-on reset sequence is:

1. Software clears the `RM_EVE1_RSTCTRL[1]` RST_EVE bit. This causes the PRCM module to release the `EVE_PWRON_RST` and the `EVE_RST` signals. Then software can download data into TCM memory while keeping the sequencer CPUs under reset.
2. When the TCM memory is initialized, software clears the `RM_EVE1_RSTCTRL[0]` RST_EVE_LRST bit. This release `EVE_LRST` to the local CPU inside EVE subsystem.

3.5.6.7 EVE Subsystem Software Warm Reset Sequence

Figure 3-26 shows the software warm reset sequence of the EVE subsystem.

Figure 3-26. EVE Subsystem Software Warm Reset Sequence

For doing the software reset of EVE the IPU software must ensure that EVE CPU is in IDLE state and EVE is in STANDBY state and the functional clock to EVE has been gated.

The software warm reset sequence is:

1. IPU software sets the `RM_EVE1_RSTCTRL[1]` RST_EVE bit. This causes the PRCM module to release the `EVE_RST`, `EVE_LRST` to the EVE subsystem. The `EVE_PWRON_RST` remains deasserted.
2. The IPU software enables the functional clock to the EVE subsystem.
3. The IPU software clears the `RM_EVE1_RSTCTRL[1]` RST_EVE = 0 and `RM_EVE1_RSTCTRL[0]` RST_EVE_LRST = 1. This causes the PRCM module to release `EVE_RST` and `EVE_LRST` to the EVE subsystem.

3.5.6.8 Global Warm Reset Sequence

This section describes the global warm reset sequence.

Figure 3-27 shows the global warm reset sequence.

Figure 3-27. Global Warm Reset Sequence

prcm-032

The assumptions are:

- All the logic and memory voltage sources are at their nominal voltage levels.
- The device is active:
 - All resets are released.
 - CORE DPLL is locked.

The steps of a global warm reset sequence are:

1. On assertion of any global warm reset source the PRM signals the EMIF that a global warm reset event has occurred. The EMIF initiates the transition to IDLE state. The PRCM module delays global warm reset to the device for a minimum of 16 L3 clock cycles so that the EMIF switches to IDLE state and switches the external SDRAM to self-refresh mode.
2. The reset managers in the PRM assert the following resets:
 - The external warm reset SYS_WARM_OUT_RST (rstoutn pin).
 - All power domain warm resets are asserted.
 - The PRM and CM registers, sensitive to warm reset, are asynchronously reset.
 - DPLL hardware resets are not asserted.
 - DPLL_CORE transitions to bypass mode once the EMIF switches to IDLE state.
 - DPLL_PER, DPLL_EVE_VID_DSP, and DPLL_DDR transition to idle bypass low-power mode. Then as clock signals are no more requested, they are gated and these DPLLs goes to stop mode.
 - DPLL_GMAC_DSP configuration is not changed.
 - CM gates the clocks that are not needed, as per their default reset setting in the associated registers.

3. The device warm reset (internal and rstoutn pin) duration is set up by the [PRM_RSTTIME\[9:0\]](#) RSTTIME1 bit field. It defines the global warm reset duration in number of FUNC_32K_CLK clock cycles. Default value loaded after POR is 6 clock cycles.
4. The CORE power domain is released from reset (that is, warm reset-sensitive modules in the CORE power domain).
5. The PRCM module switches the EMIF from IDLE state back to ACTIVE state.

NOTE:

- The PD_DSP and PD_EVE power domains are held under reset after global warm reset by assertion of the software source of the reset.
 - The following are held under reset after global warm reset until the PRCM module enables their interface clock:
 - PD_L4PER
 - PD_L3INIT
 - PD_DSS
 - PD_CAM
-

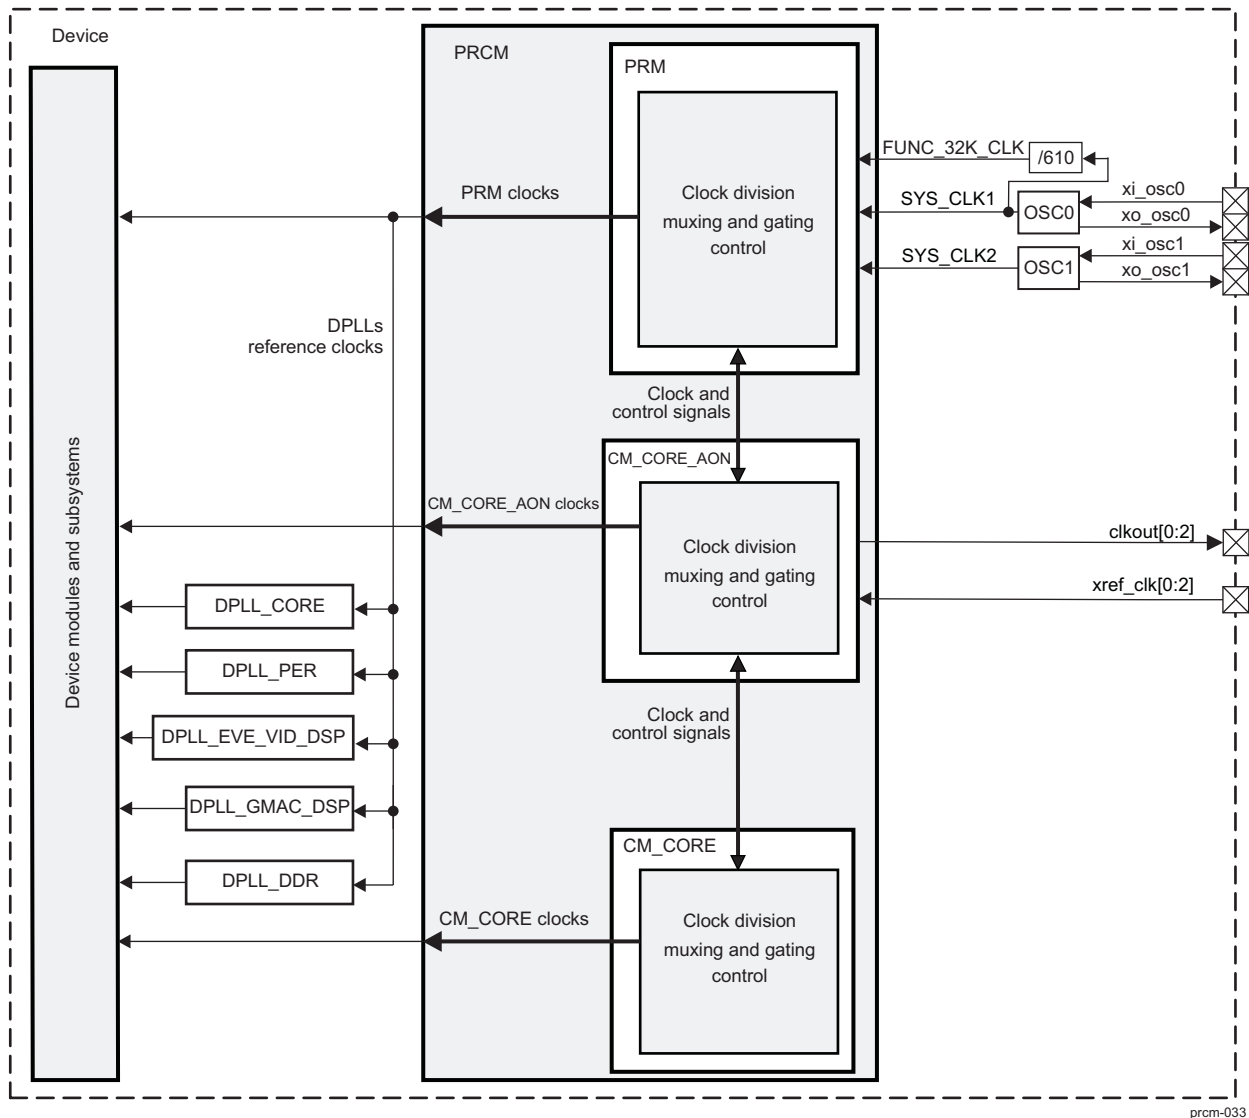

3.6 Clock Management Functional Description

3.6.1 Overview

The PRCM module provides the control for clock generation, division, distribution, synchronization, and gating. It distributes the clock sources to all modules in the device. For information about the clock-management functional architecture of the device, see [Section 3.1.1.1, Clock Management](#).

The PRCM module provides clocks to the internal DPLLs for internal high-frequency clock generation. Clock division and gating are handled by the PRM, CM_CORE_AON, and CM_CORE sections of the PRCM module. [Figure 3-28](#) shows the high-level clock-management scheme in the device.

Figure 3-28. PRCM Module Clock Manager Overview

prcm-033

3.6.2 External Clock Inputs

3.6.2.1 High-Frequency System Clock Input

The system clocks SYS_CLK1 and SYS_CLK2, are the main source clocks of the device. SYS_CLK1 and SYS_CLK2 are received from internal oscillators (OSC0 and OSC1) of the PRCM module. They are supplied as the reference clock to the DPLLs and as functional clock to several modules.

3.6.2.2 External Reference Clock Input

The external reference clocks `xref_clk[0:2]` are received directly from external reference clock source for the device. They are supplied as the functional clock to the TIMERS, and as reference clock to the McASP and other peripherals.

3.6.3 Internal Clock Sources/Generators

The PRCM module clock sources/generators are split into the following parts:

- PRM clock source that receives system clocks `SYS_CLK1` and `SYS_CLK2` inputs.
- `CM_CORE_AON` and `CM_CORE` clock sources that distribute high-frequency clocks
- DPLL clock generators that synthesize high-frequency clocks for the device

Table 3-36. Internal Clock Sources

Clock Name	Source	Frequency	Note
<code>SYS_CLK1</code>	<code>OSC0</code>	19.2 MHz, 20 MHz, or 27 MHz	See Section 3.6.3.1, PRM Clock Source
<code>SYS_CLK2</code>	<code>OSC1</code>	19.2 – 32 MHz	See Section 3.6.3.1, PRM Clock Source
<code>FUNC_32K_CLK</code>	<code>SYS_CLK1/610</code>	32.786 kHz ⁽¹⁾	See Section 3.6.3.1, PRM Clock Source
<code>RCOSC_32K_CLK</code>	On-die RC Oscillator	32 kHz ⁽²⁾	Section 3.6.3.2.2, CM_CORE_AON_CLKOUTMUX Overview
<code>FUNC_96M_AON_CLK</code>	<code>DPLL_PER</code>	96 MHz	See Section 3.6.3.5, DPLL_PER Description
<code>FUNC_192M_CLK</code>	<code>DPLL_PER</code>	192 MHz	See Section 3.6.3.5, DPLL_PER Description
<code>FUNC_128M_CLK</code>	<code>DPLL_PER</code>	128 MHz	See Section 3.6.3.5, DPLL_PER Description
<code>CORE_CLK</code>	<code>DPLL_CORE</code>	532 MHz	See Section 3.6.3.6, DPLL_CORE Description

⁽¹⁾ Because `FUNC_32K_CLK` is derived from the `SYS_CLK1`, and `SYS_CLK1` can be one of three different clock rates, `FUNC_32K_CLK` will also have three different rates. `FUNC_32K_CLK` will be close to its nominal frequency only at `SYS_CLK1` rate of 20 MHz.

⁽²⁾ Resistor-Capacitor (RC) oscillator frequency will depend on PVT variation. See Data Manual for more details.

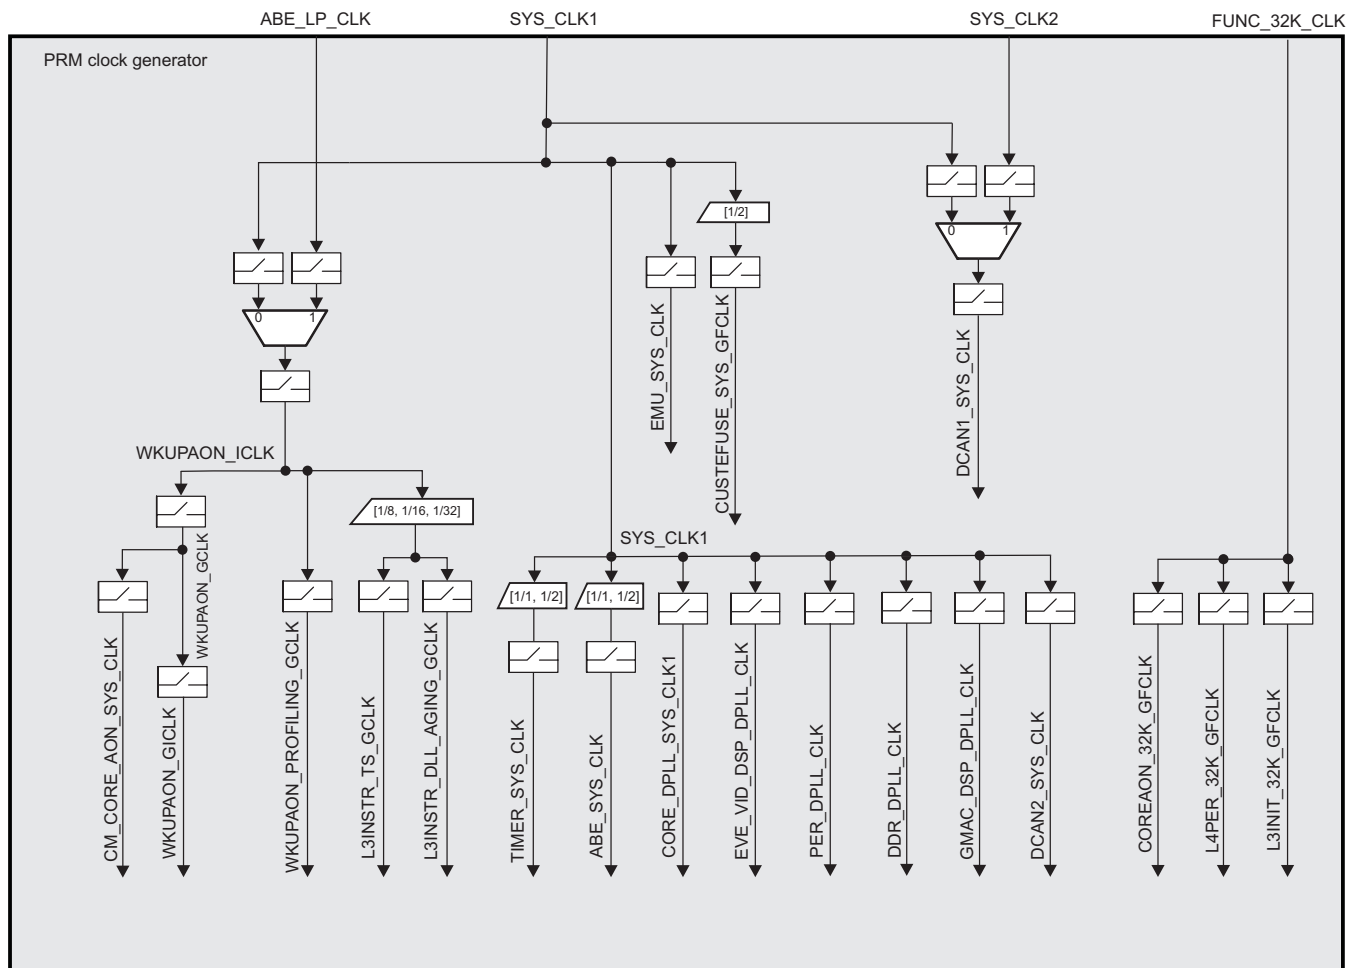

3.6.3.1 PRM Clock Source

The PRM clock source receives the `SYS_CLK1` and `SYS_CLK2` clocks from external input pins. The PRM manages the low-frequency clocks associated with these input clocks. The PRM sources various versions (through gating controls) of these externally sourced clocks to supply:

- PRCM-managed DPLLs with a reference clock, which is permanently supplied with always-on buffers
- The DSS with a reference clock, which is permanently supplied with always-on buffers
- The various timers and watchdog timers with clocks supplied by always-on buffers
- The clocks for the CM clock generator and the CORE power domain
- Timer functional clocks
- The bandgap and control module for thermal sensor feature

[Figure 3-29](#) is a logical representation of the PRM clock source.

NOTE: For clock signals control (gating/ungating management), see Section 3.1.1.1, *Clock Management*.

The PRM provides a 32-kHz gated and ungated clock for use by portions of the PD_WKUPAON power domain and some peripherals outside the PD_WKUPAON power domain.

It also provides the system clock to the DSS, a gated and buffered version to the WKUPAON_GICLK interconnect clock, and the DPLLs controlled by the PRCM module.

3.6.3.2 CM Clock Source

The clock manager (CM) is primarily responsible for generating interface and functional clocks from the internal clocks provided by DPLL_CORE and DPLL_PER. The CM is physically divided into two independent entities: CM_CORE_AON, which is placed in the PD_COREAON always-on power domain, and CM_CORE, which is placed in the PD_CORE switchable power domain. The split is done to provide control over various entities, such as modules, DPLLs, and clocks, during low-power use case scenarios when the PD_CORE power domain can be switched to RETENTION state.

3.6.3.2.1 CM_CORE_AON Clock Generator

CM_CORE_AON receives system clocks (SYS_CLK1 and SYS_CLK2) from the PRM, which serve as its functional clocks. CM_CORE_AON provides a gated clock to

- PD_CAM
- PD_CORE
- PD_CUSTEFUSE
- PD_DSP1
- PD_DSP2
- PD_DSS
- PD_EMU
- PD_EVE
- PD_IPU
- PD_L3INIT

- PD_MMAON

and DPLLs:

- DPLL_DDR
- DPLL_GMAC_DSP
- DPLL_EVE_VID_DSP
- DPLL_PER
- DPLL_CORE

and their associated HSDividers.

3.6.3.3.1 Programming Guide For Control Module

DPLL management and clock control is partly exported to the device Control Module. Below are listed the software guidelines for functions managed by Control Module.

- All control module registers relating to clock selection and clock division must be programmed prior to locking the corresponding DPLL and enabling the corresponding module in PRCM
- IPU clock selection in PRCM defaults to selecting CORE_IPU_ISS_BOOST_CLK (from DPLL_CORE H22) as the source. If desired to select DPLL_ABE_X2_CLK (from H12 of DPLL_DDR), the IPU clock mux select in [CM_IPU1_IPU1_CLKCTRL](#)[24] CLKSEL must be programmed to 0
- TENABLEDIV is required to be pulsed for latching HSDIVIDER values
 - for HSDIVIDER values coming from PRCM, TENABLEDIV is driven by respective DPLL sources.
 - for HSDIVIDER values coming from control module (DBG_TRC_EXPT_CLK_DIV, DBG_ATB_CLK_DIV, TESOC_HSDIV, DBG_STM_EXPT_CLK_DIV, VID_PIX_CLK_HSDIV, and MCAN_CLK_HSDIV (SR2.0)), TENABLEDIV has an override control from the control module registers [CTRL_CORE_PRCM_CLKDIV_CONTROL1](#), [CTRL_CORE_PRCM_CLKDIV_CONTROL2](#), and [CTRL_CORE_SMA_SW_17](#).
- For Debug Subsystem clocks (ATB_CLK, STM_EXPT_CLK, and TRCEXPT_CLK), that get the HSDIVIDER values from control module, the programming sequence is as follows:
 - ROM code locks DPLL_CORE and/or DPLL_PER.
 - To program HSDIVIDERS for DebugSS clocks, the HSDIVIDER values must be programmed first in the control module.
 - Corresponding TENABLEDIV_OVR must be programmed to 1 (TENABLEDIV controlled from the control module)
 - Corresponding TENABLEDIV_CTRL must be programmed to 1 and then 0 again.
- For TESOC_EXT_CLK and VID_PIX_CLK clocks, clock enable bits must be set. That is, TESOC_HSDIV_EN and VID_PIX_CLK_HSDIV_EN in [CTRL_CORE_PRCM_CLKDIV_CONTROL2](#) register.
- CTRLCLK of CAMERARX is driven by FUNC_96M_FCLK coming from DPLL_PER. This implies either of the following modules has to be enabled: I2C1 or I2C2.
- The following sequence must be followed to select SYS_CLK2 (SR2.0) as input clock to DPLL_CORE during run time:
 - Ensure DPLL_CORE is in BYPASS mode
 - Set [CM_CLKSEL_DPLL_CORE](#)[23] DPLL_BYP_CLKSEL to 1 to select the BYP_CLK_M2 input of DPLL

3. Switch the SYS_CLK mux to select SYS_CLK2. That is, set bit [CTRL_CORE_SMA_SW_16\[0\]](#) CORE_DPLL_INPUT_CLK_SELECTION to 1
4. Program new DPLL parameters to match SYS_CLK2 clock speed
5. Switch DPLL_CORE input back to REF_CLK. Clear bit [CM_CLKSEL_DPLL_CORE\[23\]](#) DPLL_BYP_CLKSEL to 0
6. Initiate the DPLL lock

3.6.3.4 Generic DPLL Overview

To generate high-frequency clocks, the device supports multiple on-chip DPLLs controlled by the PRCM and Control module.

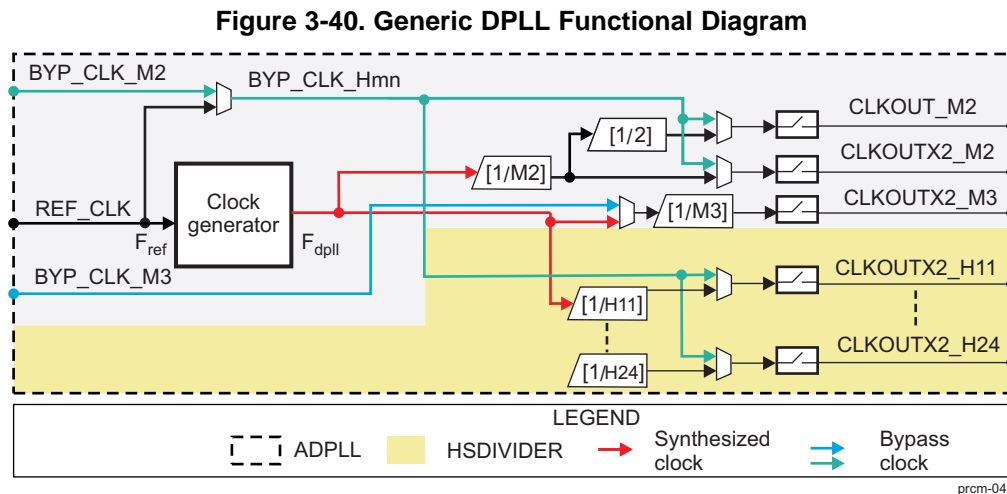

- DPLL_CORE
- DPLL_PER
- DPLL_EVE_VID_DSP
- DPLL_GMAC_DSP
- DPLL_DDR

NOTE: Dual Clock Comparator (DCC) modules are used to determine the accuracy of DPLL output clocks. For more information about *Dual Clock Comparator*, see [Section 24.1, Safety Modules Overview](#).

All DPLLs support the features described in the following sections, unless otherwise identified.

3.6.3.4.1 DPLLs Output Clocks Parameters

Figure 3-40 shows the functional architecture of a generic DPLL.

The DPLL has three input clocks:

- REF_CLK: Used to generate the synthesized clock but can also be used as the bypass clock for some outputs of the DPLL whenever the DPLL enters bypass mode. It is mandatory for the DPLL clock synthesis.
- BYP_CLK_M2: Selectable bypass clock for the output of an M2 post-divider (optional)
- BYP_CLK_M3: Selectable bypass clock for the output of an M3 post-divider (optional)

The DPLL provides the bypass clock used by HSDIVIDER: BYP_CLK_Hmn, which is output by the multiplexer between the BYP_CLK_M2 and REF_CLK clock signals.

The DPLL can be programmed to be locked at any frequency given by one of the following equation:

- $F_{dpll} = F_{ref} \times 2 \times xM / (N + 1)$

Where:

- F_{dpll} is the DPLL lock frequency.
- F_{ref} is the REF_CLK frequency. F_{ref} is also known as CLKINP.
- M is the software-configured multiplication ratio binary value.
- N is the software-configured division ratio binary value.

NOTE: It is preferred to minimize the value for N parameter (it minimizes lock time and jitter). Then M should be chosen to provide correct frequency (with lowest delta as possible).

It internally generates three main clocks: CLKOUT_M2, CLKOUTX2_M2, and CLKOUTX2_M3 as shown in [Table 3-44](#).

Table 3-44. CLKOUT_M2, CLKOUTX2_M2, and CLKOUTX2_M3 Frequencies With DPLL State

Output	Equation	DPLL Mode
CLKOUT_M2	$F_{dpll} / (2 \times M2)$	Locked (typical case)
	F_{ref} or BYP_CLK_M2	Before lock or during relock
	$F_{dpll} / M2$	DC corrector logic is used (DCC_EN bit is set) with M2 set to 0x1.
CLKOUTX2_M2	$F_{dpll} / M2$	Locked (typical case)
	F_{ref} or BYP_CLK_M2	Before lock or during relock
	$F_{dpll} / M2$	DC corrector logic is used (DCC_EN bit is set).
CLKOUTX2_M3	$F_{dpll} / M3$ or $BYP_CLK_M3/M3$	Locked (typical case)
	0	Before lock or during relock
	$F_{dpll} / M3$ or $BYP_CLK_M3/M3$	DC corrector logic is used (DCC_EN bit is set).

Where:

- M2 is the software-configured division ratio binary value.
- M3 is the software-configured division ratio binary value.
- CLKOUT_M2 and CLKOUTX2_M2 bypass clock input can be switched when the DPLL is not in locked state by using the M2 bypass clock select control bit.
- CLKOUTX2_M3 output clock can be switched when the DPLL is in locked state by using the M3 clock select control bit.

NOTE:

- A value of 0 for M2 and M3 division ratios is not allowed. They are set to 1 after reset.
- CLKOUT_M2 is generated based on a fixed divide-by-2 ratio, except in bypass mode.

The DPLL can contain one or two HSDIVIDER modules to produce more clocks with divided ratio based on the DPLL synthesized clock frequency. HSDIVIDER1 provides four extra post-dividers from H11 to H14 (the output clocks are CLKOUTX2_H11 through CLKOUTX2_H14). HSDIVIDER2 provides four extra post-dividers from H21 through H24 (the output clocks are CLKOUTX2_H21 through CLKOUTX2_H24). The HSDIVIDER output clock frequency is given by the equations in [Table 3-45](#).

Table 3-45. CLKOUTX2_Hmn Frequencies With DPLL State

Equation	DPLL Mode
$CLKOUTX2_Hmn = F_{dpll} / Hmn$	Locked
$CLKOUTX2_Hmn = BYP_CLK_Hmn$	Before lock or during relock

Where:

- F_{dpll} is the DPLL lock frequency.
- Hmn is the software-configured division ratio binary value.
- n is in the range from 1 to 4.
- m is equal to 1 or 2.

NOTE: Hmn division ratio is set to 1 after reset.

All clock outputs of the DPLL can be gated. The PRCM module provides the DPLL with a clock-gating control signal to enable or disable the clock. DPLL provides the PRCM module with a clock activity status signal to let the PRCM module hardware know when the clock is effectively running or effectively gated. The PRCM module provides a CM_IDLEST_DPLL_dpll_name[0] ST_DPLL_CLK status bit, which indicates the lock state or nonlock state of the DPLL.

3.6.3.4.2 Enable Control, Status, and Low-Power Operation Mode

The DPLL has a manual mode control bit field, which allows the setting of the different operating modes of the DPLL. When the DPLL is switched to lock mode, the current values of the multiplication ratio (M) and the division ratio (N) are latched in the DPLL. The DPLL then starts the lock or relock sequence to synthesize the corresponding output frequency clock.

The status of the synthesized clock output of the DPLL is represented by the CLKOUT status bit. It can be gated or active.

The DPLLs can be switched to low-power operation mode (also called LPMODE) to optimize DPLL power consumption when the input and output clock frequencies are low. This mode can be software-enabled using the low-power mode control bit of the DPLL.

It must be enabled only if both of the following operating conditions are satisfied:

- $F_{\text{ref}} / (N + 1)$ is less than or equal to 1 MHz.
- $F_{\text{ref}} \times M / (N + 1)$ is less than or equal to 100 MHz.

Where:

- F_{ref} is the REF_CLK frequency.
- M is the software-configured multiplication ratio binary value.
- N is the software-configured division ratio binary value.

3.6.3.4.3 DPLL Power Modes

DPLL supports several power modes. Each mode results in a tradeoff between power savings and relock time. The PRCM module allows only a few modes for each DPLL, depending on the use of the DPLL.

Table 3-46 lists the DPLL power modes.

Table 3-46. DPLL Power Modes

Power Mode	CLKOUT State	Logic Current (mA)	Analog Current (mA)	Freq Lock Time	Phase Lock Time
Low-power stop	Clock stopped	0.065 (leakage)	0.009 (leakage)	$2.5 \mu\text{s} + 70 \times (N+1) / F_{\text{ref}}$	$2.5 \mu\text{s} + 120 \times (N+1) / F_{\text{ref}}$
Fast-relock stop	Clock stopped	0.065 (leakage)	0.009 (leakage)	$2.5 \mu\text{s} + 70 \times (N+1) / F_{\text{ref}}$	$2.5 \mu\text{s} + 120 \times (N+1) / F_{\text{ref}}$
Low-power bypass	Bypass clock/clock stopped	0.065 (leakage)	0.009 (leakage)	$2.5 \mu\text{s} + 70 \times (N+1) / F_{\text{ref}}$	$2.5 \mu\text{s} + 120 \times (N+1) / F_{\text{ref}}$
Fast-relock bypass	Bypass clock/clock stopped	0.065 (leakage)	0.5 (leakage)	$0.05 \mu\text{s} + 70 \times (N+1) / F_{\text{ref}}$	$0.05 \mu\text{s} + (120 \times (N+1) / F_{\text{ref}})$

Table 3-46. DPLL Power Modes (continued)

Power Mode	CLKOUT State	Logic Current (mA)	Analog Current (mA)	Freq Lock Time	Phase Lock Time
Lock	Synthesized clock	0.95 (active)	3 (active)	N/A	N/A

Where:

- F_{ref} is the REF_CLK frequency.

A DPLL power mode can be achieved on a software request (manual) and/or automatically (automatic), depending on the specific hardware conditions.

A DPLL can switch from one mode to another as a result of the following:

- Software-programmed transition (manual): Software configures the dedicated DPLL manual mode control feature for the next desired DPLL mode. It must ensure that the transition can be performed based on the clock activity on the device.
- Combined software-programmed and hardware-conditions-based transition (auto): This mode allows the DPLL to automatically transition to a low-power state (that is, any state other than the LOCK state) when the output clocks are gated or the destination clock domain is inactive, and to switch back to the LOCK state when the output clock is needed (that is, the clock is ungated or the clock domain becomes active). The desired low-power state for the automatic transition is configured in the dedicated Auto Mode Control parameter of the DPLL.

NOTE: With $T_{ref} = 1 / F_{ref} = (N + 1) / CLKINP$; ($F_{ref} = CLKINP / (N + 1)$):

T_{ref} is the REF_CLK period.

This formula indicates that a smaller N divider value provides a smaller time for switching the clock after an M2 post-divider change.

A compromise is necessary between the clock switching latency and power consumption.

Having a smaller N value:

- Requires a higher M2 post-divider value to obtain the same target frequency.
 - Results in a higher DPLL lock frequency, and then higher power consumption.
-

NOTE:

- A manual transition can be performed from any power mode to any other power mode.
 - An automatic transition can be performed from lock mode to any low-power mode.
-

NOTE: When the DPLL is in Low-Power bypass mode, Auto-idle mode is disabled and no clock is requested, the DPLL makes a transition to Low-power stop mode.

3.6.3.4.4 DPLL Recalibration

Each time the DPLL is reset or performs a lock sequence (following a change in the value of multiplier M or divider N), it performs a recalibration of the output frequency, based on voltage and temperature conditions. In lock mode, the DPLL maintains a steady lock frequency output by compensating for voltage and temperature changes within a certain range. However, if the voltage or temperature drifts outside the range or shows a significant or fast change, the DPLL may not be able to track and compensate it. It would need a recalibration, which is signaled by assertion of a recalibration flag.

NOTE:

- The recalibration mechanism is active only while the DPLL is in lock mode. When the DPLL is in off or bypass mode (low-power or fast-relock), it does not assert the recalibration flag.
- If the DPLL drifts out of the operating range limits while not locked, and then when it tries to relock, it fails to lock within the normal delay and recalibrates automatically before eventually locking. The only difference between this case and a standard relock is the recalibration delay.

During recalibration, the DPLL loses lock and output clock switches to the bypass clock.

The DPLL can automatically start recalibration when the recalibration flag is asserted, or recalibration can be triggered by software control. The trigger setting of the recalibration can be configured by the corresponding registers of the DPLL in the PRCM module. The software-controlled recalibration mode is selected by default.

Software-controlled recalibration: The DPLL continues its tracking mechanism as long as the recalibration is not triggered by software (that is, by enabling the recalibration-enable control parameter). If the DPLL reaches upper or lower bounds of the DCO control code and software has still not triggered recalibration, the DPLL stops its tracking mechanism. The output clock remains active, but frequency and jitter are not ensured to meet the requirement.

Automatic recalibration: The DPLL immediately starts the recalibration as soon as the recalibration flag is asserted.

NOTE: Automatic recalibration of the DPLL can start at any time. While relocking, the DPLL switches to bypass mode, which introduces a frequency change. For modules that are sensitive to frequency change while operating, this can introduce operational instability. For example, the external memory EMIF controller is sensitive to a frequency change on the DPLL because its embedded DLL relocks on a frequency change. Any EMIF access during this DLL relock period can be corrupted. It is, therefore, important to stall EMIF access during DPLL recalibration.

To allow software to recalibrate the DPLL at the correct time depending on the device activity, the PRCM module can generate a wake-up event on the processor power domain, followed by an interrupt on the processor subsystem when the DPLL recalibration flag is asserted.

Table 3-47 lists the DPLL recalibration and control parameters.

3.6.3.4.5 DPLL Output Power Down

The DCO clock LDO (DCOCLKLDO) of the DPLL can be powered down if all output dividers of the DPLL are powered down. The PRCM module automatically reenables the power to the LDO when an output divider is powered up or the DPLL switches to bypass mode.

3.6.3.6.5 Fractional M-factor (SR2.0)

DPLL_CORE supports fractional synthesis, that is, the frequency multiplication factor M can be programmed as fractional. The fractional part of M-factor is programmed in the 18-bit CTRL_CORE_SMA_SW_22[17:0] CORE_DPLL_REGMF_CONTROL register. Similarly to REGM, REGMF value is loaded into DPLL at the rising edge of TENABLE signal. Fractional synthesis is typically associated with additional jitter overhead. Refer to the device-specific Data Manual for DPLL jitter characteristics.

The allowed range of M for fractional synthesis to operate is $M = 20$ and $M = 2042$.

The integer-only division takes place when CORE_DPLL_REGMF_CONTROL is programmed to 0x0.

3.6.4.12.3 Clock Domain Dependency

CD_L3_INSTR has no static, dynamic, or module wake-up dependency with any other clock domain of the device.

For aging, DLL requires a low-frequency clock that must run as long as the CORE power domain is on. To match this requirement, the DLL_AGING module has been created and instantiated in this clock domain, which is the last to transition in low-power state.

3.7.1.1 Power Domain Modes

The PD_WKUPAON power domain is an always-on power domain and does not switch to RETENTION state. There is no logic power state control or status bit field for this power domain.

The PD_WKUPAON power domain has memory bank (DCAN_MEM) which is related to DCAN1.

3.7.1.1.1 Logic and Memory Area Power Modes

[Table 3-230](#) lists the power modes supported by the memory area of the power domain. A memory area power mode is identified with respect to a power state of the power domain. The Logic On, Logic Retention, and Logic Off columns in the table identify the power states of the power domain. The values in these columns identify the supported power state of the memory area (identified in the Memory Bank column) or the module memory inside the memory area (identified in the Module Memory column).

3.7.2 PD_DSP1 Description

PD_DSP1 contains the following reset domains:

- DSP1_RST
- DSP1_PWRON_RST
- DSP1_RET_RST
- DSP1_SYS_RST

PD_DSP1 contains the CD_DSP1 clock domain.

[Table 3-231](#) lists the logic retention capability for each module of the power domain.

3.7.3 PD_DSP2 Description

PD_DSP2 contains the following reset domains:

- DSP2_RST
- DSP2_PWRON_RST
- DSP2_RET_RST
- DSP2_SYS_RST

PD_DSP2 contains the CD_DSP2 clock domain.

Table 3-236 lists the logic retention capability for each module of the power domain.

3.7.5 PD_IPU Description

PD_IPU contains the following reset domains:

- IPU1_PWRON_RST
- IPU1_RST
- IPU1_RET_RST
- IPU1_CPU0_RST
- IPU1_CPU1_RST

PD_IPU contains the CD_IPU1 clock domain.

3.8 Voltage-Management Functional Description

This section describes the voltage domains and voltage control architecture. It also explains the interactions between the device and the external power IC.

NOTE: For more information about the device power pads connection, see the device data manual.

3.8.1 Overview

The voltage-management architecture of the device is based on voltage sources managed by the PRCM module. They define the voltage domains within the device (see Section 3.1.1.3, *Voltage Management*). This partition of the voltage domains ensures independent voltage control of each voltage domain through dedicated LDO. The following voltage domains are managed by the PRCM module:

- VDD_CORE_L
- VDD_DSPEVE_L

NOTE: For the association of the device power supply pin to the power domain, see Table 3-26.

The PRCM module supports the AVS technique for all power domains VDD_CORE_L and VDD_DSPEVE_L voltage domains.

At boot time, the device is set with VDD_CORE_L at OPP_NOM.

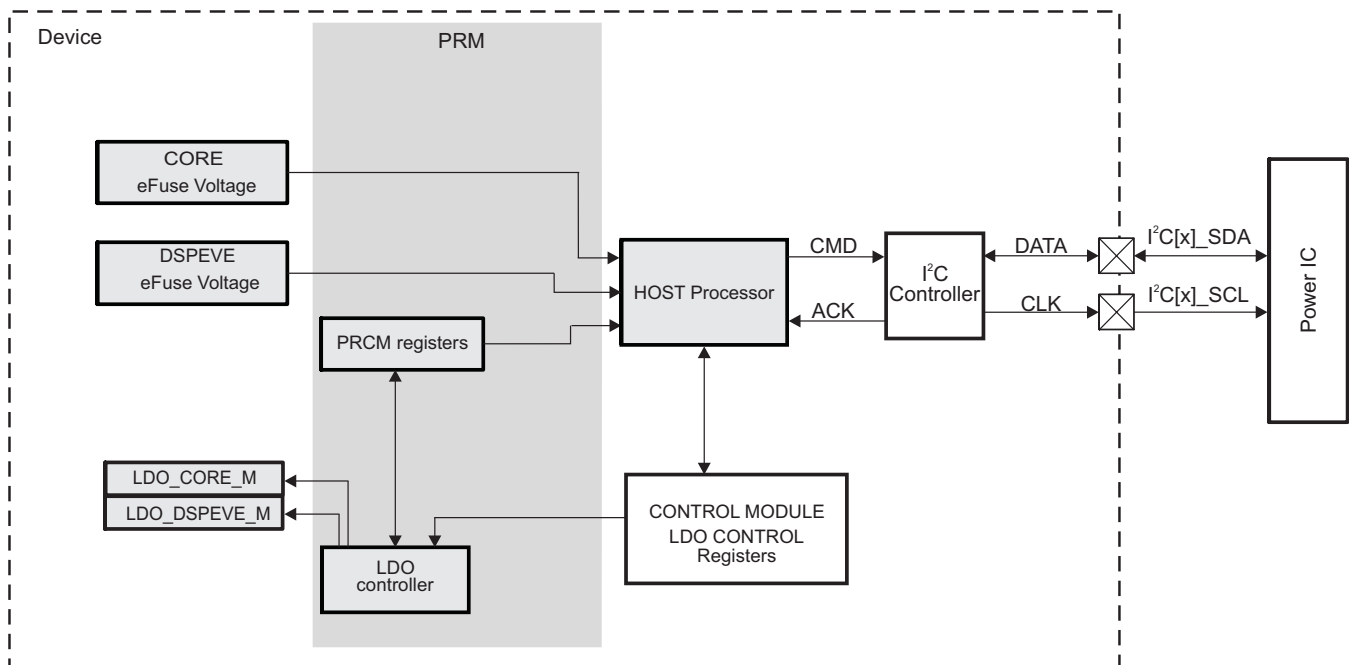

3.8.2 Voltage-Control Architecture

The PRM is split over several blocks that manage the different voltage sources.

- A device PRCM for managing the I/O wake-up control and system clock control sequencing during device sleep and wake-up transitions.
- LDO regulator controllers for memory arrays voltage management, and WAKEUP logic.
- BANDGAPs reference voltage sleep control

Figure 3-68 shows the architecture for PRM voltage control.

Figure 3-68. PRM Voltage Control Architecture

prcm-088

3.8.3 Internal LDOs Control

3.8.3.1 VDD_CORE_L and VDD_DSPEVE_L Control

3.8.3.1.1 Adaptive Voltage Scaling

As explained in [Section 3.1.2.4, Adaptive Voltage Scaling](#), the SmartReflex technology. With SmartReflex, the power supply voltage can be adapted to the silicon performance statically (for example, adapted to the manufacturing process of a given device) or dynamically.

3.8.3.2 Memory LDOs

Embedded SRAM LDOs are used to supply power to the split-rail memory arrays. The PRM generates the controls used to select LDO operating mode: on-active, on-retention, or off.

Split-rail type SRAMs are used in the device to implement the larger memories. These SRAMs feature memory array and periphery logic, which are on separate supplies to allow independent power management. Proper memory operation, however, requires the SRAM array voltage never to be operated at a level lower than the SRAM periphery logic.

Memory LDO can switch to on and retention mode:

- On (active) mode: 1.15 V is the normal voltage reference used through all functional OPPs whenever memories must be functional. When logic voltage level VDD_x_L becomes higher than the associated memory voltage level VDD_x_M, the LDO operates in tracking mode and follows its respective VDD_x_M or VDD_x_ABB voltage level.
- Retention mode: 0.6 V is set when software allows and when all memory banks belonging to the LDO memory voltage are in RETENTION or OFF state. In this mode, the output voltage is generated from the corresponding VDD_WKUP_L logic voltage source.

[Section 3.8.3.4, Memory LDOs Transitions](#), describes the state transition conditions and sequences for the memory LDOs.

NOTE: The voltage levels associated with the different modes may depend on the device characteristics.

3.8.3.3 BANDGAP Control

BANDGAPs provides voltage reference for internal LDOs. The PRCM module automatically controls the switching between ON and OFF states of the BANDGAPs, based on the power state of the device. It is completely transparent to user software.

BANDGAPs startup time is 100µs. The [PRM_BANDGAP_SETUP\[7:0\]](#) STARTUP_COUNT bit field must be set accordingly.

3.8.3.4 Memory LDO Transitions

The transition trigger condition for on-to-retention mode is:

- At least all memory banks associated with the LDO are in RETENTION state.

The transition sequence is:

1. Transition trigger conditions are true (that is, satisfied).
2. Switch LDO reference to:
 - Retention mode value if on-to-retention mode transition
3. Start counter for LDO stabilization.
4. When counter expires, voltage transition is complete.

3.8.3.5 VDD_WKUP_L Transitions

The ON-to-SLEEP transition trigger conditions are:

- Power domain states: Device is in low-power state (STANDBY).
- Clock states: Only the 32K clock is active in CD_WKUPAON.

The SLEEP-to-ON transition trigger conditions are:

- Any device wake-up event other than emulation wake-up event

The EMULATION-to-ON transition trigger conditions are:

- Power domain states: device is in active mode.
- Clock states: any clock other than 32K clock is active in PD_WKUPAON.
- PD_EMU in OFF state.

The EMULATION-to-SLEEP transition trigger conditions are:

- Power domain states: Device is in low-power state (STANDBY).
- Clock states: Only the 32K clock is active in CD_WKUPAON.
- PD_EMU in OFF state.

The SLEEP or ON-to-EMULATION transition trigger condition is:

- Any wake-up event on PD_EMU

The transition sequence is:

1. Transition trigger conditions are met.
2. VDD_WKUP_L initiates the transition.
3. Starts a counter for VDD_WKUP_L transition.
4. VDD_WKUP_L transition completes.

3.9 Device Low-Power States

The device low-power states are the result of any valid combination of power domain states in which all the power domains are no longer in ACTIVE state. In such a situation the PRCM module hardware can trigger events to further lower the consumption of the device and the system.

These device low-power states are characterized by the system power consumption, wake-up latency, and required functionality.

The low-power state is:

- **"STANDBY"** : Any combination of logic voltage domain states (SLEEP or RETENTION) other than ACTIVE state.

Once the PRCM module hardware detects any valid combination of power domain states, and if a proper programming model of the PRCM module is set, the PRCM module automatically triggers the transition into the device low-power mode.

3.9.1 Device Wake-Up Source Summary

The wake-up events can be asynchronous or synchronous. Synchronous wake-up events require the 32-kHz clock or the system clock to be active, while asynchronous wake-up events do not require an active clock.

The *Modules Attributes* subsection of each clock domain in [Section 3.6, Clock Management Functional Description](#), describes the wake-up capability support for each module of the corresponding power domain.

While the device is in STANDBY mode, additional asynchronous wakeup events from other domains are able to wake up the device.

[Table 3-272](#) identifies which modules in which power domains can be configured to generate a wake-up while the device is in a low-power mode.

Table 3-272. Wake-Up Sources During Device Low Power Mode

Device Power Mode name	VD_CORE VOLTAGE STATE	VD_DSPEVE VOLTAGE STATE	Domain containing wake-up source	Wakeup sources

⁽¹⁾ Only modules able to generate asynchronous wake-up have to be taken into account, and only when domain is in INACT or CSWRET state.

3.9.2 Wakeup Upon Global Warm Reset

When global warm reset is the source of the device wakeup, the sequence is modified as follows:

- The PRCM module releases its reset line. In parallel, the device reset manager counts for global reset extension (set up by the [PRM_RSTTIME\[9:0\]](#) RSTTIME1 bit field). The PRCM module holds the other asserted resets until the global reset counter overflows.

The hardware blocks and modifies the [CM_MPU_CLKSTCTRL\[1:0\]](#) CLKTRCTRL bit fields. [CM_SHADOW_FREQ_CONFIG1\[0\]](#) FREQ_UPDATE and

3.9.3 Global Warm Reset During a Device Wake-Up Sequence

If a global warm reset occurs before the PRCM module completes the voltage stabilization count, the global warm reset is applied immediately. As a consequence, the sequence described in [Section 3.9.2, Wakeup Upon Global Warm Reset](#), is performed.

If the global warm reset occurs after the PRCM module completes voltage stabilization (during phase 1 of automatic restore):

- Global warm reset is delayed and applied after phase 1 restore completes.
- Phase 2 of restore is discarded.
- IPU boots after the warm reset sequence completes.

If the global warm reset occurs during phase 2 of automatic restore:

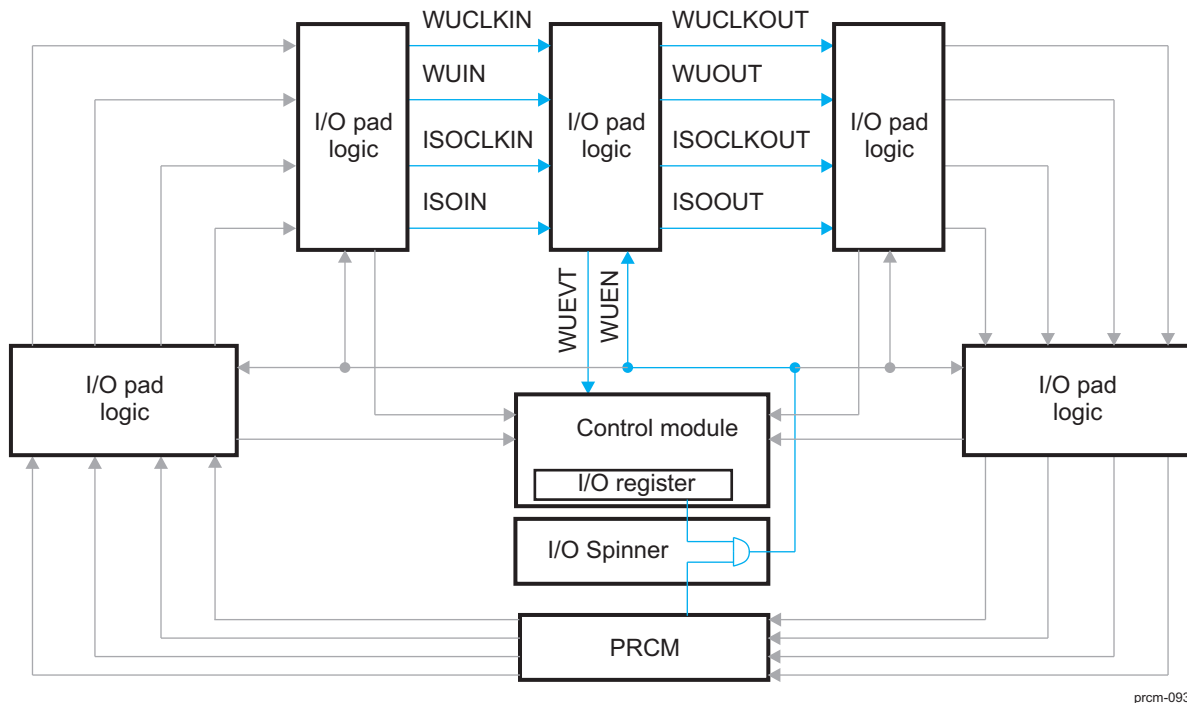

- Global warm reset is applied immediately.
- Phase 2 of restore is discarded.
- IPU boots after the warm reset sequence completes.

3.9.4 I/O Management

Figure 3-69 is an overview of the power-management modules and their internal connections with a generic power domain.

ISOIN, ISOCLKIN, WUCLKIN, WUIN, ISOOUT, ISOCLKOUT, WUCLKOUT and WUOUT connections are built with daisy chaining approach and are all VDD_WKUP_L level signals driven by PRM. WUEN and WUEVNT are VDD level signals driven by the control module and/or IO control module. ISOOVR and ISOBYPASS (for DDR IO only) are VDD level signals driven by the PRM.

Figure 3-69. I/O Pads Daisy-Chain Configuration

NOTE: ISOBYPASS control from PRM is routed to all the EMIF i/f IOs and ISOOVR control from PRM is routed to all the remaining IOs. These control signals are routed using ALWON VDD buffers. The ISOOVR pin on EMIF IOs is tied to 0 using ALWON tie-off cells. PRM also provides an output status "IO_ISO_ACTIVE" which is set when EMIF IOs are isolated or transitioning between isolation and functional mode, and which is cleared when EMIF IOs are functional.

it is required that the ISOCLKIN is forced to 1 during global power-on reset (PRM_PWRON_RST_n = 0).

3.9.4.1 Isolation / Wakeup Sequence

Enabling Wake-Up Feature:

- Program Control module MMR to assert "WKEN" for each IO (To enable Wakeup feature of IO)
- Write the bit [PRM_IO_PMCTRL\[8\] WUCLK_CTRL](#) to 1 to assert high the signal WUCLKIN.
- Write the bit [PRM_IO_PMCTRL\[8\] WUCLK_CTRL](#) to 0 to assert low the signal WUCLKIN.
- This will latch WKEN, Latch the current pad input value.
- The PRCM register [PRM_IO_PMCTRL\[9\] WUCLK_STATUS](#) logs the signal WUCLK of the last pad of the IO ring.(Should be 0).

Device goes into sleep mode (There is no need to put IO in ISOLATION and hence no need to toggle ISOCLKIN and ISOIN (As core supply is still ON)) :

- WKUP event is generated by one of the IOs

- WUOUT of the last IO is asserted HIGH.
- Because of #9, PRM interrupt is generated towards MPU/Host processor
- MPU/Host processor disables the WUKP feature of each IO and power up the required domains.

DISABLING WKUP feature:

- Write the bit [PRM_IO_PMCTRL\[8\] WUCLK_CTRL](#) to 1 to assert high the signal WUCLKIN.
- Write the bit [PRM_IO_PMCTRL\[8\] WUCLK_CTRL](#) to 0 to assert low the signal WUCLKIN.
- The PRCM register [PRM_IO_PMCTRL\[9\] WUCLK_STATUS](#) logs the signal WUOUT of the last pad of the IO ring.

3.9.4.1.1 Software-Controlled I/O Isolation

The [PRM_IO_PMCTRL\[4\] ISOOVR_EXTEND](#) bit allows extending the non-EMIF I/O isolation. This feature can be used by software to restore modules driving output, such as GPIO, while non-EMIF I/Os are still isolated. Once software completes the relevant module restore, it clears the bit and hardware performs full-isolation-to-EMIF on the hardware-controlled I/O transition.

The [PRM_IO_PMCTRL\[5\] IO_ON_STATUS](#) bit is available for software to check completion of the EMIF on transition.

3.10.3.2 Forced Memory Area State Change With Power Domain ON

This procedure initiates a forced memory area state change while the power domain is ON.

Table 3-286. Forced Memory Area State Change With Power Domain ON

Step	Register/Bit Field/Programming Model	Value
Configure memory area target power state. Not all memory area states are programmable.	PM_<Power Domain name>_PWRSTCTRL[x] <Memory Bank name>_ONSTATE	0x0: OFF 0x1: RETAINED 0x3: ON

Table 3-286. Forced Memory Area State Change With Power Domain ON (continued)

Step	Register/Bit Field/Programming Model	Value
Get memory area current state.	PM_<Power Domain name>_PWRSTST[x] <Memory Bank name>_STATEST	0x0: OFF 0x1: RETAINED 0x3: ON

3.10.3.3 Forced Power Domain Low-Power State Transition

Table 3-287. Forced Power Domain Low-Power State Transition

Step	Register/Bit Field/Programming Model	Value
Select target low-power state of the power domain. Not all states are programmable.	PM_<Power Domain name>_PWRSTCTRL[1:0] POWERSTATE	0x0: OFF 0x1: RETENTION
Force power domain low-power state transition.	PM_<Power Domain name>_PWRSTCTRL[4] LOWPOWERSTATECHANGE	0x1: Force change

17:16	IDLEST	Module idle status. [warm reset insensitive] 0x0: Module is fully functional, including OCP 0x1: Module is performing transition: wakeup, or sleep, or sleep abortion 0x2: Module is in Idle mode (only OCP part). It is functional if using separate functional clock 0x3: Module is disabled and cannot be accessed	R	0x3
15:2	RESERVED		R	0x0
1:0	MODULEMODE	Control the way mandatory clocks are managed. 0x0: Module is disabled by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 0x1: Module is managed automatically by HW according to clock domain transition. A clock domain sleep transition put module into idle. A wakeup domain transition put it back into function. If CLKTRCTRL=3, any OCP access to module is always granted. Module clocks may be gated according to the clock domain state. 0x2: Reserved 0x3: Reserved	RW	0x0

Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 0x1: Module is managed automatically by HW according to clock domain transition. A clock domain sleep transition put module into idle. A wakeup domain transition put it back into function. If CLKTRCTRL=3, any OCP access to module is always granted. Module clocks may be gated according to the clock domain state. 0x2: Reserved 0x3: Reserved	RW	0x0
