These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

ORDERING INFORMATION

| T _A | PACKAGE ⁽¹⁾ | PART NUMBER |
|----------------|-------------------------|-------------|
| –40°C to 85°C | 28-pin HTSSOP PowerPAD™ | TLC5941PWP |
| –40°C to 85°C | 32-pin 5 mm x 5 mm QFN | TLC5941RHB |
| –40°C to 85°C | 28-pin PDIP | TLC5941NT |

- (1) For the most current package and ordering information, see the Package Option Addendum at the end of this document, or see the TI Web site at www.ti.com.

ABSOLUTE MAXIMUM RATINGS.

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

PRINCIPLES OF OPERATION

SERIAL INTERFACE

The TLC5941 has a flexible serial interface, which can be connected to microcontrollers or digital signal processors in various ways. Only 3 pins are needed to input data into the device. The rising edge of SCLK signal shifts the data from the SIN pin to the internal register. After all data is clocked in, a high-level pulse of XLAT signal latches the serial data to the internal registers. The internal registers are level-triggered latches of XLAT signal. All data are clocked in with the MSB first. The length of serial data is 96 bit or 192 bit, depending on the programming mode. Grayscale data and dot correction data can be entered during a grayscale cycle. Although new grayscale data can be clocked in during a grayscale cycle, the XLAT signal should only latch the grayscale data at the end of the grayscale cycle. Latching in new grayscale data immediately overwrites the existing grayscale data. Figure 12 shows the timing chart. More than two TLC5941s can be connected in series by connecting an SOUT pin from one device to the SIN pin of the next device. An example of cascading two TLC5941s is shown in Figure 13. The SOUT pin can also be connected to the controller to receive status information from TLC5941 as shown in Figure 22.

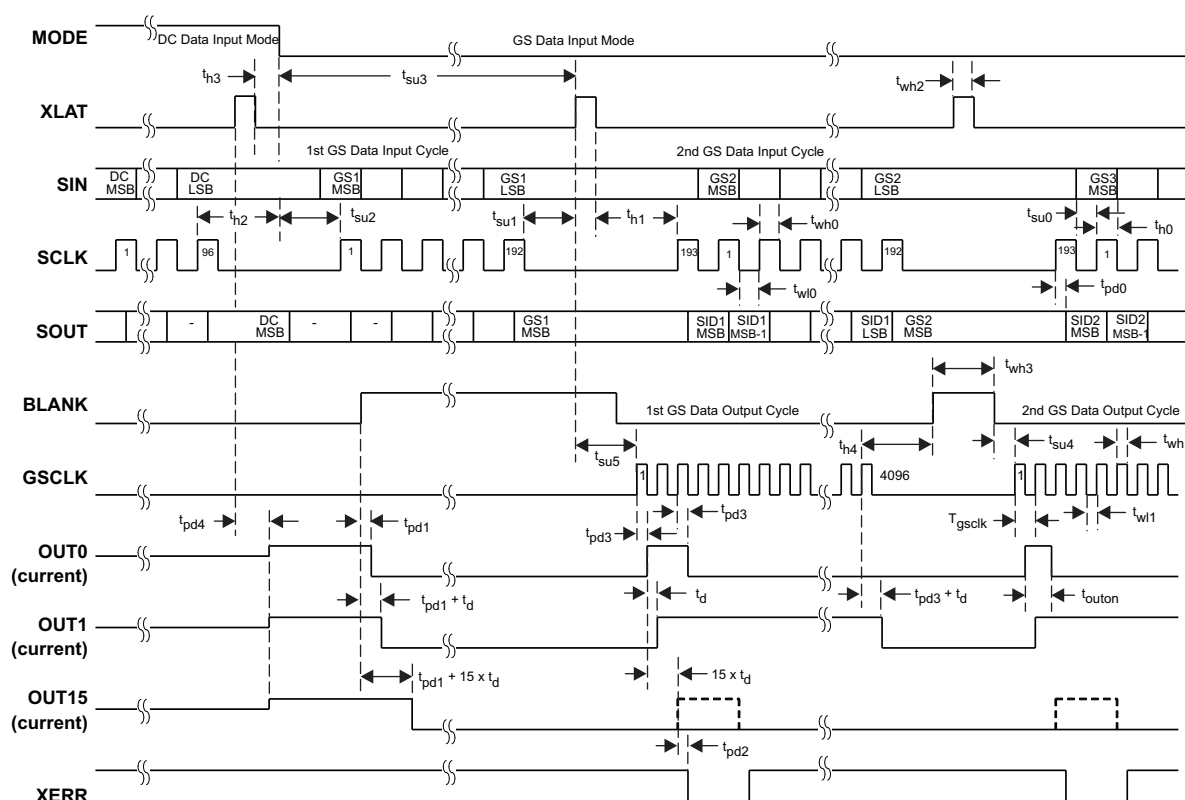

Figure 12. Serial Data Input Timing Chart

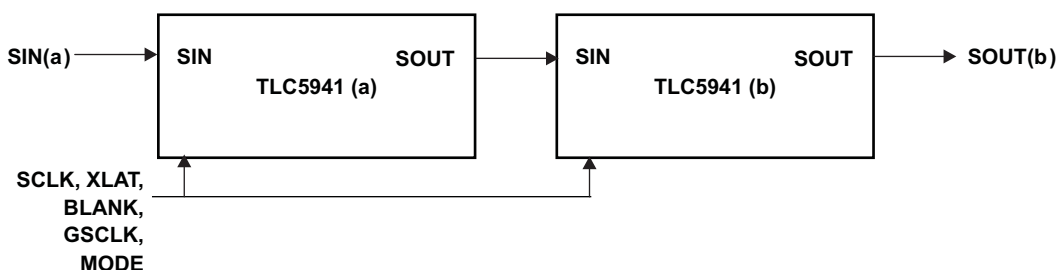

Figure 13. Cascading Two TLC5941 Devices

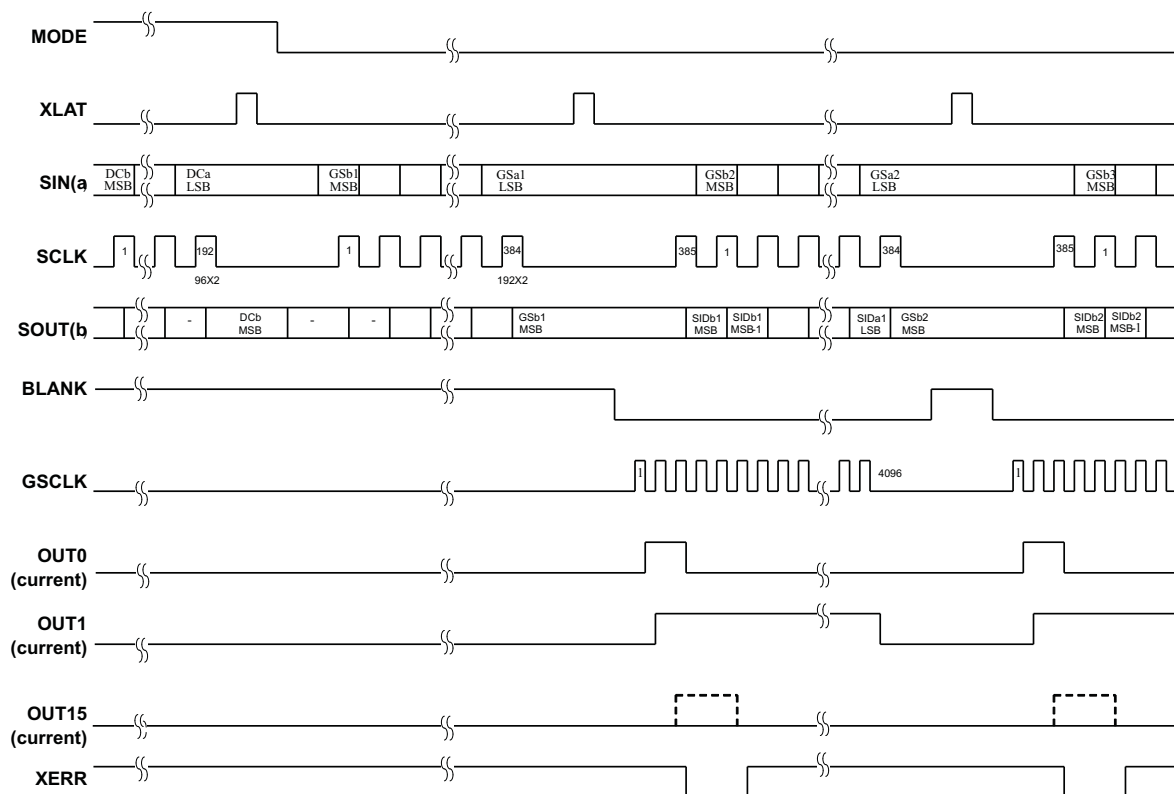

Figure 14. Timing Chart for Two Cascaded TLC5941 Devices

ERROR INFORMATION OUTPUT

The open-drain output XERR is used to report both of the TLC5941 error flags, TEF and LOD. During normal operating conditions, the internal transistor connected to the XERR pin is turned off. The voltage on XERR is pulled up to V_{CC} through an external pullup resistor. If TEF or LOD is detected, the internal transistor is turned on, and XERR is pulled to GND. Because XERR is an open-drain output, multiple ICs can be ORed together and pulled up to V_{CC} with a single pullup resistor. This reduces the number of signals needed to report a system error (see Figure 22).

To differentiate LOD and TEF signal from XERR pin, LOD can be masked out with BLANK = HIGH.

Table 2. XERR Truth Table

| ERROR CONDITION | | ERROR INFORMATION | | SIGNALS | |
|-------------------|--------------------|-------------------|-----|---------|------|
| TEMPERATURE | OUTn VOLTAGE | TEF | LOD | BLANK | XERR |
| $T_J < T_{(TEF)}$ | Don't Care | L | X | H | H |
| $T_J > T_{(TEF)}$ | Don't Care | H | X | | L |
| $T_J < T_{(TEF)}$ | $OUTn > V_{(LED)}$ | L | L | L | H |
| | $OUTn < V_{(LED)}$ | L | H | | L |
| $T_J > T_{(TEF)}$ | $OUTn > V_{(LED)}$ | H | L | | L |
| | $OUTn < V_{(LED)}$ | H | H | | L |

TEF: THERMAL ERROR FLAG

The TLC5941 provides a temperature error flag (TEF) circuit to indicate an overtemperature condition of the IC. If the junction temperature exceeds the threshold temperature (160°C typical), TEF becomes H and XERR pin goes to low level. When the junction temperature becomes lower than the threshold temperature, TEF becomes L and XERR pin becomes high impedance. TEF status can also be read out from the TLC5941 status register.

LOD: LED OPEN DETECTION

The TLC5941 has an LED-open detection circuit that detects broken or disconnected LED's. The LED open detector pulls the XERR pin to GND when an open LED is detected. XERR and the corresponding error bit in the Status Information Data is only active under the following open LED conditions.

1. OUTn is on and the time tpd2 (1 μ s typical) has passed.
2. The voltage of OUTn is < 0.3V (typical)

The LOD status of each output can be also read out from the SOUT pin. See the [STATUS INFORMATION OUTPUT](#) section for details. The LOD error bits are latched into the Status Information Data when XLAT returns to a low after a high. Therefore, the XLAT pin must be pulsed high then low while XERR is active in order to latch the LOD error into the Status Information Data for subsequent reading via the serial shift register.

DELAY BETWEEN OUTPUTS

The TLC5941 has graduated delay circuits between outputs. These circuits can be found in the constant current driver block of the device (see the functional block diagram). The fixed-delay time is 20ns (typical), OUT0 has no delay, OUT1 has 20ns delay, and OUT2 has 40ns delay, etc. The maximum delay is 300ns from OUT0 to OUT15. The delay works during switch on and switch off of each output channel. These delays prevent large inrush currents which reduces the bypass capacitors when the outputs turn on.

OUTPUT ENABLE

All OUTn channels of the TLC5941 can be switched off with one signal. When BLANK is set high, all OUTn channels are disabled, regardless of logic operations of the device. The grayscale counter is also reset. When BLANK is set low, all OUTn channels work under normal conditions. If BLANK goes low and then back high again in less than 300ns, all outputs programmed to turn on still turn on for either the programmed number of grayscale clocks, or the length of time that the BLANK signal was low, which ever is lower. For example, if all outputs are programmed to turn on for 1ms, but the BLANK signal is only low for 200ns, all outputs still turn on for 200ns, even though some outputs are turning on after the BLANK signal has already gone high.

Table 3. BLANK Signal Truth Table

| BLANK | OUT0 - OUT15 |
|-------|------------------|
| LOW | Normal condition |
| HIGH | Disabled |

SETTING MAXIMUM CHANNEL CURRENT

The maximum output current per channel is programmed by a single resistor, $R_{(IREF)}$, which is placed between IREF pin and GND pin. The voltage on IREF is set by an internal band gap $V_{(IREF)}$ with a typical value of 1.24 V. The maximum channel current is equivalent to the current flowing through $R_{(IREF)}$ multiplied by a factor of 31.5. The maximum output current can be calculated by Equation 6:

$$I_{max} = \frac{V_{(IREF)}}{R_{(IREF)}} \times 31.5 \quad (6)$$

where:

$$V_{(IREF)} = 1.24 \text{ V}$$

$R_{(IREF)}$ = User-selected external resistor.

I_{max} must be set between 5 mA and 80 mA. The output current may be unstable if I_{max} is set lower than 5 mA. Output currents lower than 5 mA can be achieved by setting I_{max} to 5 mA or higher and then using dot correction.

Figure 3 shows the maximum output current I_O versus $R_{(IREF)}$. $R_{(IREF)}$ is the value of the resistor between IREF terminal to GND, and I_O is the constant output current of OUT0 to OUT15. A variable power supply may be connected to the IREF pin through a resistor to change the maximum output current per channel. The maximum output current per channel is 31.5 times the current flowing out of the IREF pin.

POWER DISSIPATION CALCULATION

The device power dissipation needs to be below the power dissipation rate of the device package to ensure correct operation. Equation 7 calculates the power dissipation of device:

$$P_D = (V_{CC} \times I_{CC}) + \left(V_{OUT} \times I_{MAX} \times N \times \frac{DC_n}{63} \times d_{PWM} \right) \quad (7)$$

where:

V_{CC} : device supply voltage

I_{CC} : device supply current

V_{OUT} : TLC5941 OUTn voltage when driving LED current

I_{MAX} : LED current adjusted by $R_{(IREF)}$ Resistor

DC_n : maximum dot correction value for OUTn

N: number of OUTn driving LED at the same time

d_{PWM} : duty cycle defined by BLANK pin or GS PWM value

OPERATING MODES

The TLC5941 has two operating modes defined by MODE as shown in Table 4. The GS and DC registers are set to random values that are not known just after power on. The GS and DC values must be programmed before turning on the outputs. Please note that when initially setting GS and DC data after power on, the GS data must be set before the DC data is set. Failure to set GS data before DC data may result in the first bit of GS data being lost. XLAT must be low when the MODE pin goes high-to-low or low-to-high to change back and forth between GS mode and DC mode.

Table 4. TLC5941 Operating Modes Truth Table

| MODE | INPUT SHIFT REGISTER | OPERATING MODE |
|----------|----------------------|--------------------------------|
| GND | 192 bit | Grayscale PWM Mode |
| V_{CC} | 96 bit | Dot Correction Data Input Mode |

SETTING DOT CORRECTION

The TLC5941 has the capability to fine-adjust the output current of each channel (OUT0 to OUT15) independently. This is also called dot correction. This feature is used to adjust the brightness deviations of LEDs connected to the output channels OUT0 to OUT15. Each of the 16 channels can be programmed with a 6-bit word. The channel output can be adjusted in 64 steps from 0% to 100% of the maximum output current I_{\max} . The TEST pin must be connected to VCC to ensure proper operation of the dot correction circuitry. Equation 8 determines the output current for each output n:

$$I_{\text{OUTn}} = I_{\max} \times \frac{\text{DCn}}{63} \quad (8)$$

where:

I_{\max} = the maximum programmable output current for each output.

DCn = the programmed dot correction value for output n (DCn = 0 to 63).

n = 0 to 15

Figure 15 shows the dot correction data packet format which consists of 6 bits x 16 channel, total 96 bits. The format is Big-Endian format. This means that the MSB is transmitted first, followed by the MSB-1, etc. The DC 15.5 in Figure 15 stands for the 5th-most significant bit for output 15.

Figure 15. Dot Correction Data Packet Format

When MODE is set to VCC, the TLC5941 enters the dot correction data input mode. The length of input shift register becomes 96bits. After all serial data are shifted in, the TLC5941 writes the data in the input shift register to DC register when XLAT is high, and holds the data in the DC register when XLAT is low. The DC register is a level triggered latch of XLAT signal. Since XLAT is a level-triggered signal, SCLK and SIN must not be changed while XLAT is high. After XLAT goes low, data in the DC register is latched and does not change. BLANK signal does not need to be high to latch in new data. When XLAT goes high, the new dot-correction data immediately becomes valid and changes the output currents if BLANK is low. XLAT has setup time (tsu1) and hold time (th1) to SCLK as shown in Figure 12.

To input data into the dot correction register, MODE must be set to V_{CC} . The internal input shift register is then set to 96-bit width. After all serial data are clocked in, a rising edge of XLAT is used to latch the data into the dot correction register. Figure 16 shows the dc data input timing chart.

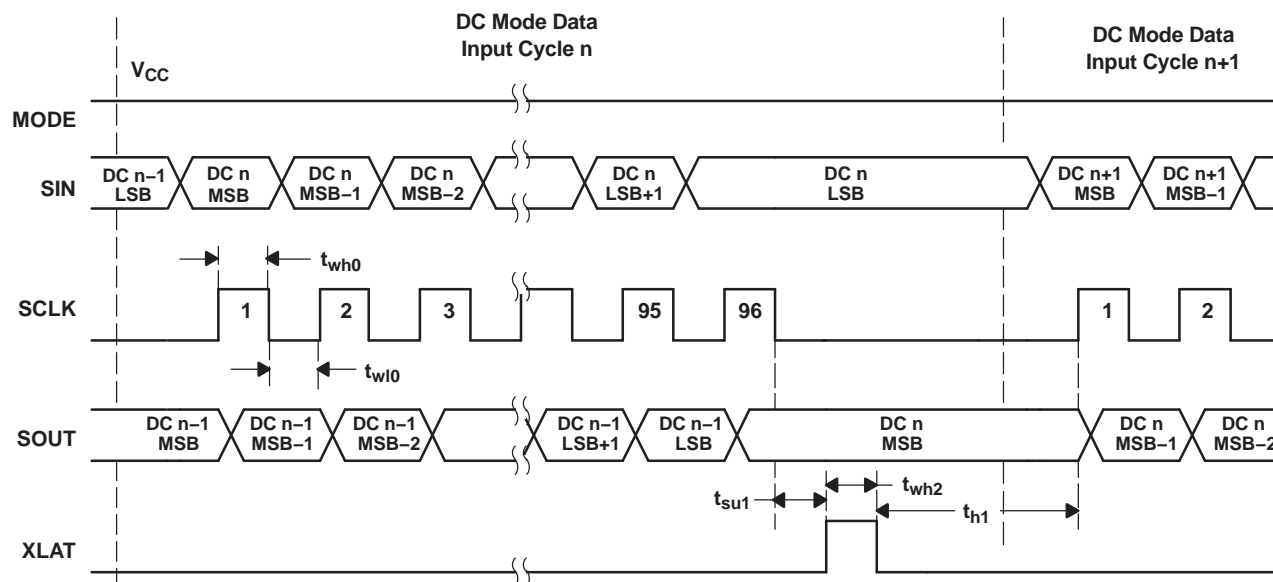

Figure 16. Dot Correction Data Input Timing Chart

SETTING GRAYSCALE

The TLC5941 can adjust the brightness of each channel OUT_n using a PWM control scheme. The use of 12 bits per channel results in 4096 different brightness steps, from 0% to 100% brightness. Equation 9 determines the brightness level for each output n:

$$\text{Brightness in \%} = \frac{\text{GS}_n}{4095} \times 100 \quad (9)$$

where:

GS_n = the programmed grayscale value for output n (GS_n = 0 to 4095)

n = 0 to 15

Grayscale data for all OUT_n

The input shift register enters grayscale data into the grayscale register for all channels simultaneously. The complete grayscale data format consists of 16 x 12 bit words, which forms a 192-bit wide data packet (see Figure 17). The data packet must be clocked in with the MSB first.

Figure 17. Grayscale Data Packet Format

When MODE is set to GND, the TLC5941 enters the grayscale data input mode. The device switches the input shift register to 192-bit width. After all data is clocked in, a rising edge of the XLAT signal latches the data into the grayscale register (see Figure 18). New grayscale data immediately becomes valid at the rising edge of the XLAT signal; therefore, new grayscale data should be latched at the end of a grayscale cycle when BLANK is high. The first GS data input cycle after dot correction requires an additional SCLK pulse after the XLAT signal to complete the grayscale update cycle. All GS data in the input shift register is replaced with status information data (SID) after updating the grayscale register.

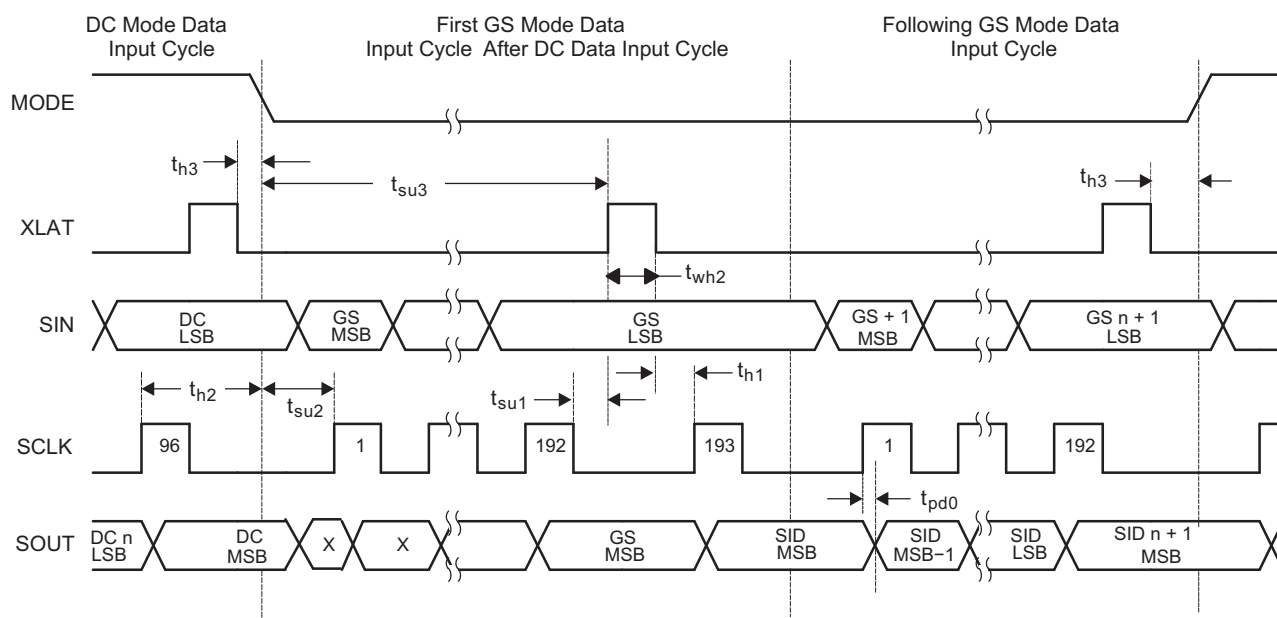

Figure 18. Grayscale Data Input Timing Chart

STATUS INFORMATION OUTPUT

The TLC5941 does have a status information register, which can be accessed in grayscale mode (MODE = GND). After the XLAT signal latches the data into the GS register, the input shift register data is replaced with status information data (SID) of the device (see [Figure 18](#)). LOD, TEF, and dot-correction register data can be read out at the SOUT pin. The status information data packet is 192 bits wide. Bits 0 – 15 contain the LOD status of each channel. Bit 16 contains the TEF status. Bits 24 – 119 contain the data of the dot-correction register. The remaining bits are reserved. The complete status information data packet is shown in [Figure 19](#).

SOUT outputs the MSB of the SID at the same time the SID are stored in the SID register, as shown in [Figure 20](#). The next SCLK pulse, which will be the clock for receiving the MSB of the next grayscale data, transmits MSB-1 of SID. If output voltage is < 0.3 V (typical) when the output sink current turns on, LOD status flag becomes active. The LOD status flag is an internal signal which pulls XERR pin down to low when the LOD status flag becomes active. The delay time, tpd2 (1 μ s maximum), is from the time of turning on the output sink current to the time LOD status flag becomes valid. The timing for each channels LOD status to become valid is shifted by the 30-ns (maximum), channel-to-channel turn-on time. After the first GSCLK goes high, OUT0 LOD status is valid; tpd3 + tpd2 = 60 nS + 1 μ s = 1.06 μ s. OUT1 LOD status is valid; tpd3 + td + tpd2 = 60 ns + 30 ns + 1 μ s = 1.09 μ s. OUT2 LOD status is valid; tpd3 + 2*td + tpd2 = 1.12 μ s, and so on. It takes 1.51 μ s maximum (tpd3 + 15*td + tpd2) from the first GSCLK rising edge until all LOD become valid; *tsuLOD* must be > 1.51 μ s (see [Figure 20](#)) to ensure that all LOD data are valid.

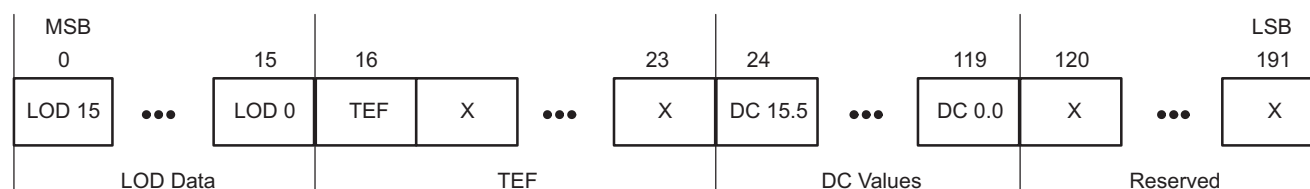

Figure 19. Status Information Data Packet Format

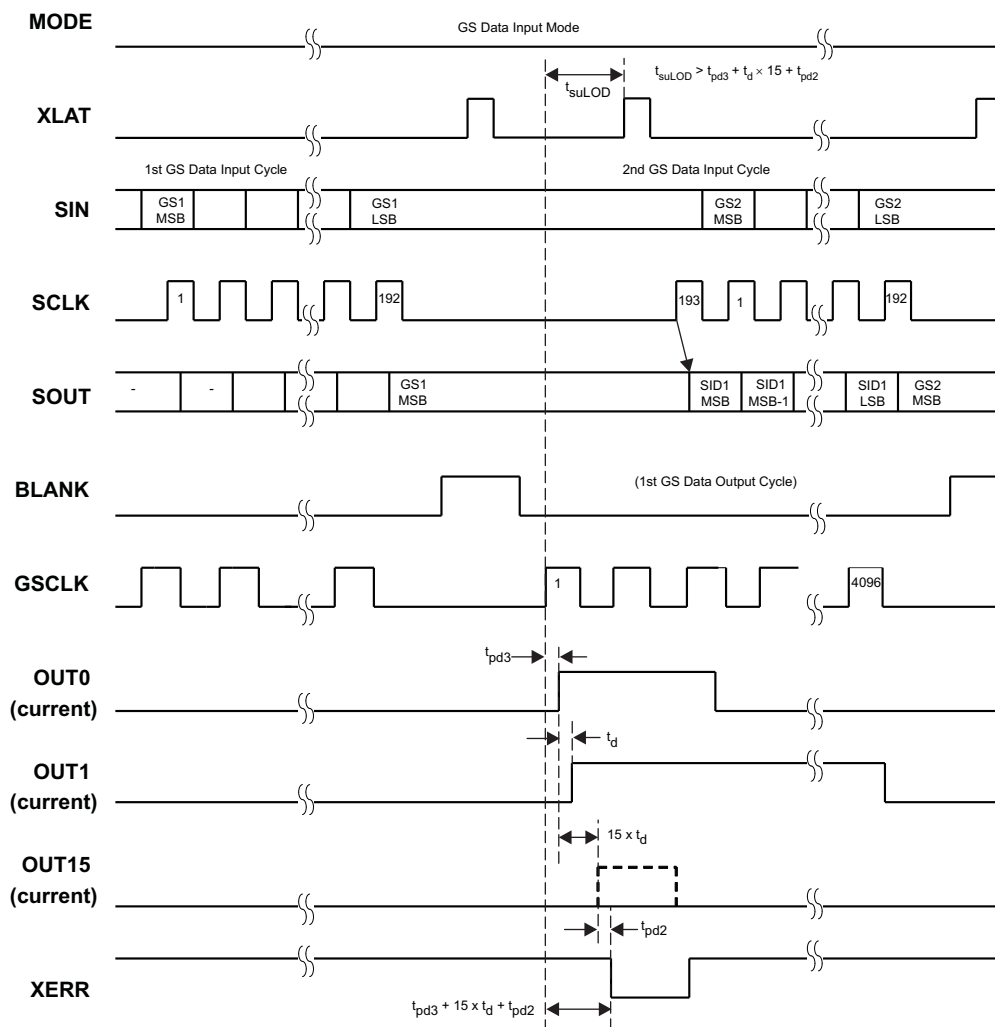

Figure 20. Readout Status Information Data (SID) Timing Chart

The LOD status of each output can be read out from the SOUT pin. The LOD error bits are latched into the Status Information Data when XLAT returns to a low after a high. Therefore, the XLAT pin must be pulsed high then low while XERR is active in order to latch the LOD error into the Status Information Data for subsequent reading via the serial shift register.

GRAYSCALE PWM OPERATION

The grayscale PWM cycle starts with the falling edge of BLANK. The first GSCLK pulse after BLANK goes low increases the grayscale counter by one and switches on all OUTn with grayscale value not zero. Each following rising edge of GSCLK increases the grayscale counter by one. The TLC5941 compares the grayscale value of each output OUTn with the grayscale counter value. All OUTn with grayscale values equal to the counter values are switched off. A BLANK=H signal after 4096 GSCLK pulses resets the grayscale counter to zero and completes the grayscale PWM cycle (see [Figure 21](#)). When the counter reaches a count of FFFh, the counter stops counting and all outputs turn off. Pulling BLANK high before the counter reaches FFFh immediately resets the counter to zero.

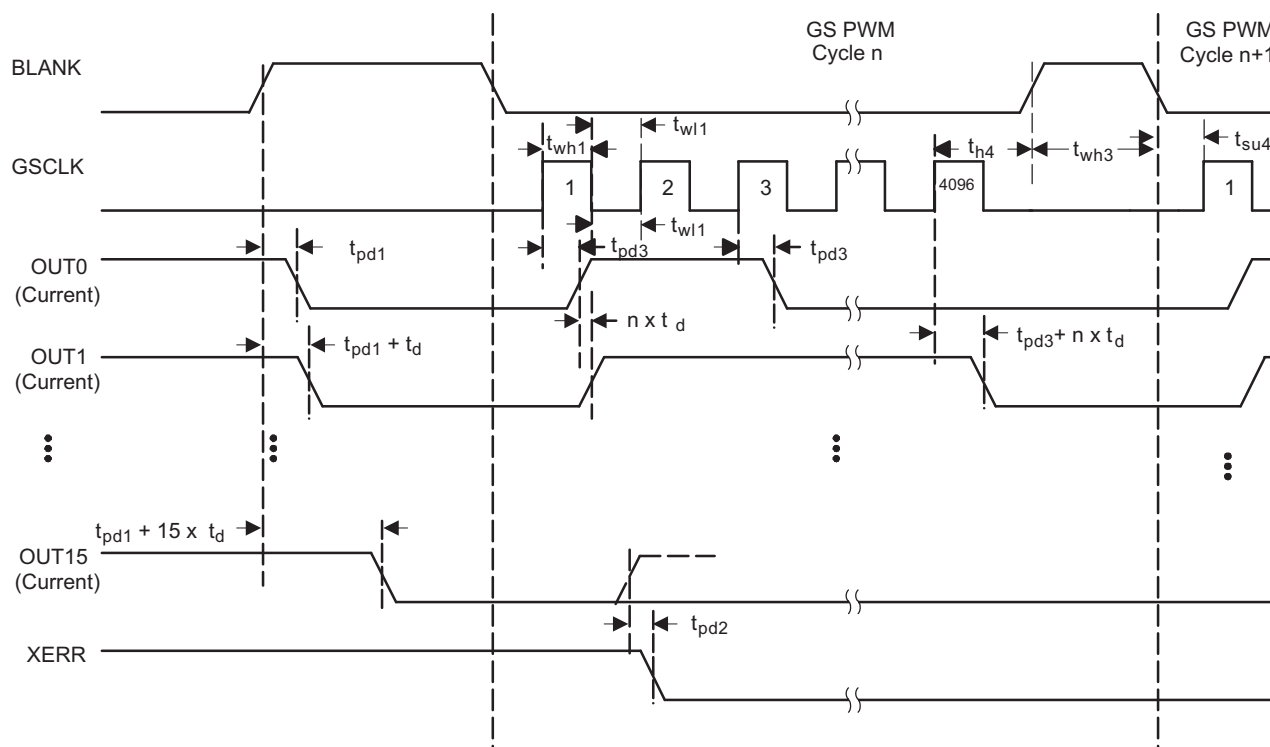

Figure 21. Grayscale PWM Cycle Timing Chart

Output On Time

The amount of time that each output is turned on is a function of the grayscale clock frequency and the programmed grayscale PWM value. The on-time of each output can be calculated using [Equation 10](#).

$$T_{on_n} = \frac{GS_n}{f_{(GSCLK)}} + t_{on_err} \quad (10)$$

Where

- T_{on_n} is the time that OUTn turns on and sinks current
- GS_n is OUTn's programmed grayscale PWM value between 0 and 4095
- t_{on_err} is the Output on time error defined in the Switching Characteristics Table

When using [Equation 10](#) with very high GSCLK frequencies and very low grayscale PWM values, the resulting T_{on} time may be negative. If T_{on} is negative, the output does not turn on. For example, using $f_{(GSCLK)} = 30$ MHz, $GS_n = 1$, and the typical $t_{on_err} = 50$ nS, [Equation 10](#) calculates that OUTn turns on for -16.6 nS. This output may not turn on under these conditions. Increasing the PWM value or reducing the GSCLK clock frequency ensures turn-on.

SERIAL DATA TRANSFER RATE

Figure 22 shows a cascading connection of n TLC5941 devices connected to a controller, building a basic module of an LED display system. There is no TLC5941 limitation to the maximum number of ICs that can be cascaded. The maximum number of cascading TLC5941 devices depends on the application system and is in the range of 40 devices. Equation 11 calculates the minimum frequency needed:

$$\begin{aligned} f_{(\text{GSCLK})} &= 4096 \times f_{(\text{update})} \\ f_{(\text{SCLK})} &= 193 \times f_{(\text{update})} \times n \end{aligned} \quad (11)$$

where:

$f_{(\text{GSCLK})}$: minimum frequency needed for GSCLK

$f_{(\text{SCLK})}$: minimum frequency needed for SCLK and SIN

$f_{(\text{update})}$: update rate of whole cascading system

n : number cascaded of TLC5941 device

Application Example

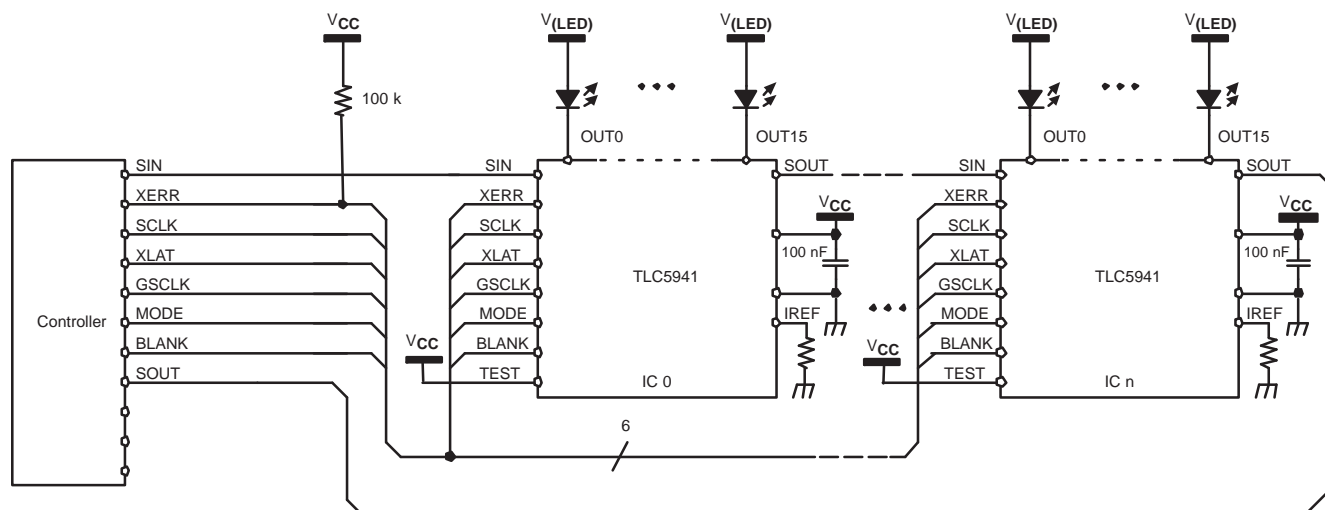

Figure 22. Cascading Devices

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

⁽⁶⁾ Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

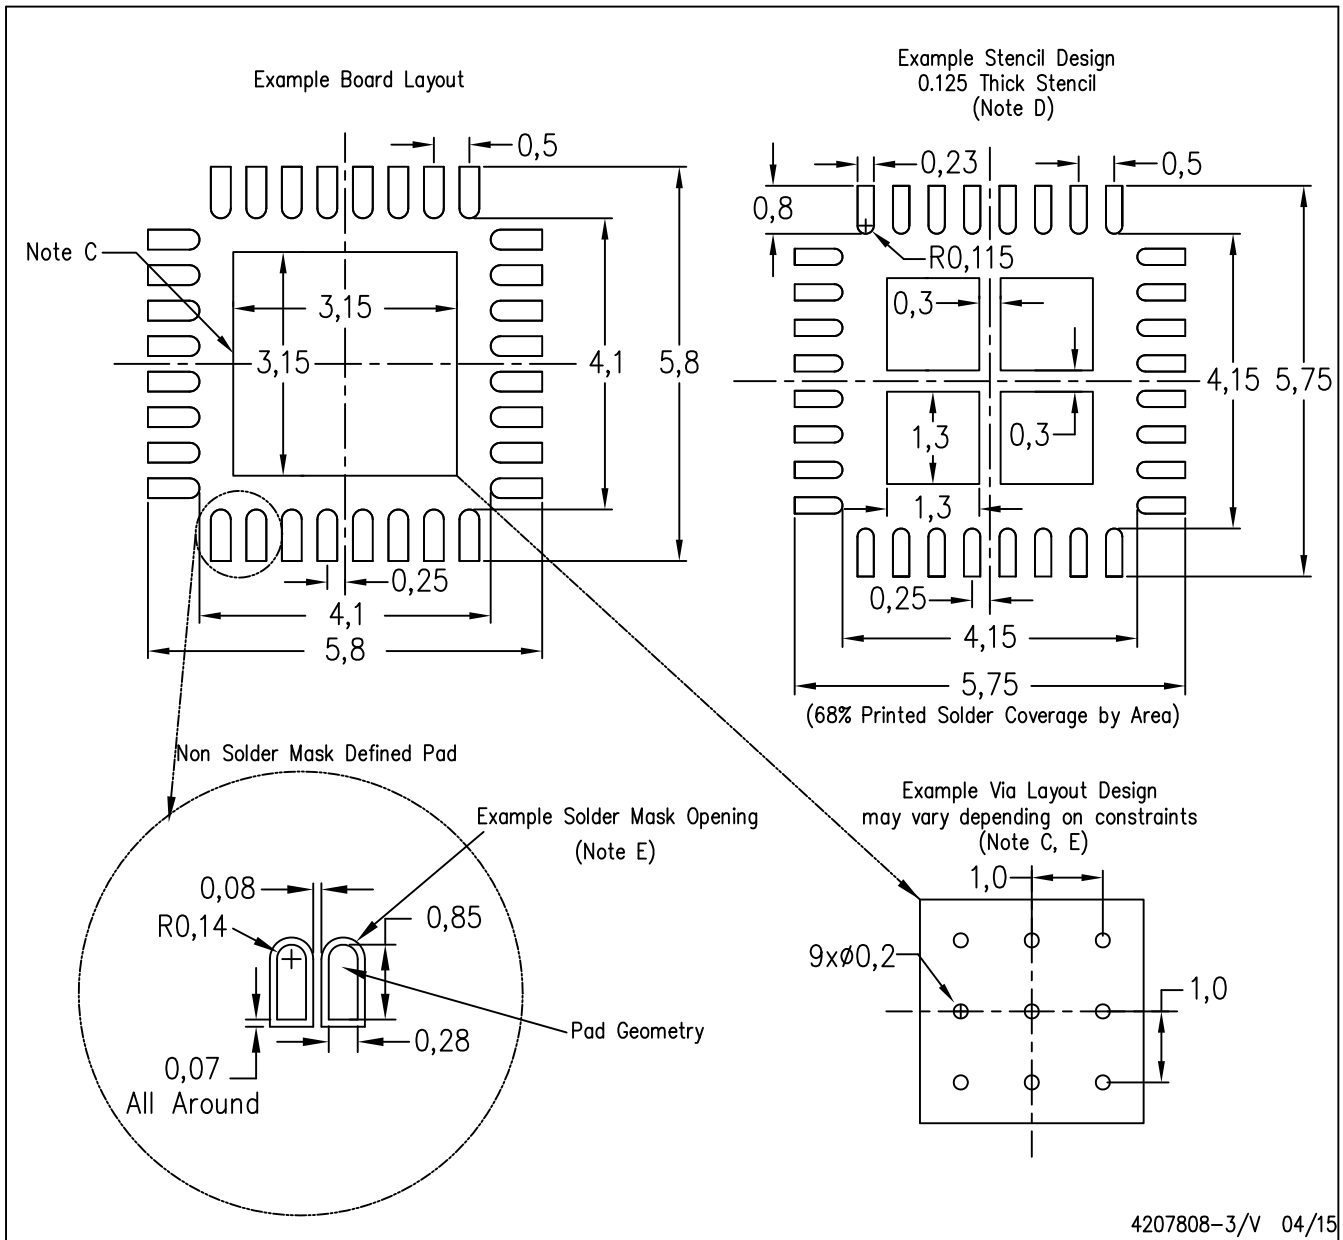

Exposed Thermal Pad Dimensions
