| B11/GPIO21 <sup>(3)</sup> | 49          | 34    | -     | -     | -   |     | -   |                            |               |                  |                  | GPI021           |
| TempSensor <sup>(4)</sup> | -           | -     | -     | -     | -   | -   | C12 |                            |               |                  |                  |                  |

- (1) A6 and C6 is double bonded as pin # 4.
- (2) Optional external reference voltage for on-chip COMPDACs/GPDACs. There is an internal capacitance to VSSA on this pin whether used for ADC input or COMPDAC/GPDAC reference. If used as a VDAC reference, place at least a 1-μF capacitor on this pin.
- (3) The GPIOs on these analog pins support full digital input and output functionality and are referred to as AGPIOs. By default, the AGPIOs are unconnected; that is, the analog and digital functions are both disabled. For configuration details, see the *Digital Inputs and Outputs on ADC Pins (AGPIOs)* section.
- (4) Internal connection only; does not come to a device pin.

**Table 15-3. Analog Signal Descriptions**

| Signal Name | Description   |
|-------------|---|
| AIOx        | Digital input on ADC pin                            |
| GPI0x       | Digital input/output pin with ADC functionality     |
| Ax          | ADC A Input   |
| Bx          | ADC B Input   |
| Cx          | ADC C Input   |
| CMPx_DACH   | Comparator subsystem high DAC output                |
| CMPx_DACL   | Comparator subsystem low DAC output                 |
| CMPx_HNy    | Comparator subsystem high comparator negative input |
| CMPx_HPy    | Comparator subsystem high comparator positive input |

**Table 15-3. Analog Signal Descriptions (continued)**

| Signal Name | Description   |
|-------------|---|
| CMPx_LNy    | Comparator subsystem low comparator negative input  |
| CMPx_LPy    | Comparator subsystem low comparator positive input  |
| DACx_OUT    | Buffered DAC Output   |
| TempSensor  | Internal temperature sensor   |
| VDAC        | Optional external reference voltage for on-chip COMPDACs. This pin has a higher capacitance compared to the other analog pins. <i>See the Per-Channel Parasitic Capacitance</i> table for details. This capacitance is present whether the pin is being used for ADC input or COMPDAC/GPDAC reference and cannot be disabled. If this pin is being used as a reference for the on-chip COMPDAC/GPDACs, place at least a 1- $\mu$ F capacitor on this pin. |

**Table 15-4. Reference Summary**

| Module       | Reference Option                        | Configured Where? | Register  | Driverlib Function      | Notes  |   |
|--------------|---|-------------------|---|-------------------------|--|---|
| ADC          | Internal or External                    | Analog System     | AnalogSubsysRegs.<br>ANAREFCTL.bit.<br>ANAREFSEL    | ADC_setVREF             | Both options require use of the VREFHI pin                     |   |

### 15.1.6 Lock Registers

Setting one of the bits in the lock registers prevents further writes to the associated analog subsystem configuration register. This lock can only be cleared by a device reset.

## 15.2 Analog Subsystem Registers

This section describes the Analog Subsystem Registers.

### 15.2.1 ASBSYS Base Address Table

**Table 15-5. ASBSYS Base Address Table**

| Bit Field Name   |                    | DriverLib Name    | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|------------------|--------------------|-------------------|--------------|------|-----|-----|-----|--------------------|
| Instance         | Structure          |                   |              |      |     |     |     |                    |
| AnalogSubsysRegs | ANALOG_SUBSYS_REGS | ANALOGSUBSYS_BASE | 0x0005_D700  | YES  | -   | -   | -   | YES                |

## 15.2.2 ANALOG\_SUBSYS\_REGS Registers

Table 15-6 lists the memory-mapped registers for the ANALOG\_SUBSYS\_REGS registers. All register offset addresses not listed in Table 15-6 should be considered as reserved locations and the register contents should not be modified.

**Table 15-6. ANALOG\_SUBSYS\_REGS Registers**

| Offset | Acronym        | Register Name  | Write Protection | Section            |
|--------|----------------|--|------------------|--------------------|
| 5Eh    | CONFIGLOCK     | Lock Register for all the config registers.  | EALLOW           | <a href="#">Go</a> |
| 60h    | TSNSCTL        | Temperature Sensor Control Register  | EALLOW           | <a href="#">Go</a> |
| 68h    | ANAREFCTL      | Analog Reference Control Register  | EALLOW           | <a href="#">Go</a> |
| 70h    | VMONCTL        | Voltage Monitor Control Register   | EALLOW           | <a href="#">Go</a> |
| 82h    | CMPPMXSEL      | Bits to select one of the many sources on CompHP inputs. Refer to Pimux diagram for details. | EALLOW           | <a href="#">Go</a> |
| 84h    | CMPLPMXSEL     | Bits to select one of the many sources on CompLP inputs. Refer to Pimux diagram for details. | EALLOW           | <a href="#">Go</a> |
| 86h    | CMPHNMXSEL     | Bits to select one of the many sources on CompHN inputs. Refer to Pimux diagram for details. | EALLOW           | <a href="#">Go</a> |
| 87h    | CMPLNMXSEL     | Bits to select one of the many sources on CompLN inputs. Refer to Pimux diagram for details. | EALLOW           | <a href="#">Go</a> |
| 88h    | ADCDACLOOPBACK | Enable loopback from DAC to ADCs   |                  | <a href="#">Go</a> |
| 8Eh    | LOCK           | Lock Register  | EALLOW           | <a href="#">Go</a> |
| 102h   | AGPIOCTRLA     | AGPIO Control Register   | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 15-7 shows the codes that are used for access types in this section.

**Table 15-7. ANALOG\_SUBSYS\_REGS Access Type Codes**

| Access Type              | Code       | Description                            |
|--------------------------|------------|--|
| Read Type                |            |  |
| R                        | R          | Read                                   |
| R-0                      | R<br>-0    | Read<br>Returns 0s                     |
| Write Type               |            |  |
| W                        | W          | Write                                  |
| W1S                      | W<br>1S    | Write<br>1 to set                      |
| WOnce                    | W<br>Once  | Write<br>Write once                    |
| WSonce                   | W<br>Sonce | Write<br>Set once                      |
| Reset or Default Value   |            |  |

| Register Array Variables |            |  |

**Table 15-7. ANALOG\_SUBSYS\_REGS Access Type Codes (continued)**

| Access Type | Code | Description  |
|-------------|------|--|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 15.2.2.1 CONFIGLOCK Register (Offset = 5Eh) [Reset = 0h]

CONFIGLOCK is shown in [Figure 15-5](#) and described in [Table 15-8](#).

Return to the [Summary Table](#).

Lock Register for all the config registers.

## 16.1 Introduction

The ADC module is a successive approximation (SAR) style ADC. The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (s/h) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see [Section 16.3](#)).

### 16.1.2 Features

Each ADC has the following features:

- Ratiometric external reference set by VREFHI and VREFLO pins
- Single-ended signal conversions
- Input multiplexer with up to 16 channels
- 16 configurable SOCs
- 16 individually addressable result registers
- Multiple trigger sources
  - S/W - software immediate start
  - All ePWMs - ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2
  - ADCINT1/2
- Four flexible PIE interrupts
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from setpoint calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture

---

#### Note

Not every channel may be pinned out from all ADCs. Check the datasheet for your device to determine which channels are available.

---

### 16.1.3 Block Diagram

Figure 16-1 shows the block diagram for the ADC core and ADC wrapper.

Figure 16-1. ADC Module Block Diagram

## 16.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. [Table 16-1](#) summarizes the basic ADC options and their level of configurability. The subsequent sections discuss these configurations.

**Table 16-1. ADC Options and Configuration Levels**

| Options                     | Configurability                             |
|-----------------------------|---|
| Clock                       | Per module <sup>(1)</sup>                   |
| Resolution                  | Not configurable (12-bit only)              |
| Signal mode                 | Not configurable (single-ended only)        |
| Reference voltage source    | Either external or internal for all modules |
| Trigger source              | Per SOC <sup>(1)</sup>                      |
| Converted channel           | Per SOC                                     |
| Acquisition window duration | Per SOC <sup>(1)</sup>                      |
| EOC location                | Per module                                  |
| Burst Mode                  | Per module <sup>(1)</sup>                   |

(1) Writing these values differently to different ADC modules could cause the ADCs to operate asynchronously. See [Section 16.13.1](#) for guidance on when the ADCs are operating synchronously or asynchronously.

### 16.2.1 Clock Configuration

The base ADC clock is provided directly by the system clock (SYSCLK). SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. The ADCCLK is used to clock the converter.

The core requires approximately 10.5 ADCCLK cycles to process a voltage into a conversion result. It is necessary for the user to determine the required duration of the acquisition window, see [Section 16.13.2](#).

---

#### Note

To determine an appropriate value for ADCCTL2.PRESCALE, see your device-specific datasheet to determine the maximum SYSCLK and ADCCLK frequency.

---

### 16.2.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. This ADC supports a resolution of 12 bits.

### 16.2.3 Voltage Reference

#### 16.2.3.1 External Reference Mode

The ADC modules share VREFHI and VREFLO inputs. In external reference mode these pins are used as a ratiometric reference to determine the ADC conversion input range.

See [Section 16.13.6](#) for information on how to supply the reference voltage.

---

#### Note

- On devices with no external VREFLO signals, VREFLO is internally connected to the device analog ground, VSSA.
  - See your device-specific datasheet to determine the allowable voltage range for VREFHI and VREFLO.
  - The external reference mode requires an external capacitor on the VREFHI pin. See your device-specific datasheet for the specific value required.
- 

#### 16.2.3.2 Internal Reference Mode

In internal reference mode the device drives a voltage out onto the VREFHI pin. The VREFHI and VREFLO pins then set the ADC conversion range.

The internal reference voltage can be configured to be either 2.5V or 1.65V. When a 1.65V internal reference voltage is selected, the effective ADC conversion input range will be VREFLO to 3.3V.

---

#### Note

The internal reference mode also requires an external capacitor on the VREFHI pin. See your device-specific datasheet for the specific value required.

---

#### 16.2.3.3 Selecting Reference Mode

The voltage reference mode should be configured by using either SetVREF or ADC\_setVREF function provided in C2000Ware. Using any of these functions ensures that the correct trim is loaded in the ADC trim registers. This function must be called at least once after a device reset. Do not configure the voltage reference mode by directly writing to the ANAREFCTL register.

### 16.2.4 Signal Mode

The ADC supports single-ended signaling.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCIN<sub>x</sub>), referenced to VREFLO.

### 16.2.5 Expected Conversion Results

Based on a given analog input voltage, the ideal expected digital conversion is given in [Table 16-2](#). Fractional values are truncated.

**Table 16-2. Analog to 12-bit Digital Formulas**

| Analog Input                              | Digital Result  |
|---|---|
| when ADCIN <sub>y</sub> ≤ VREFLO          | ADCRESULT <sub>x</sub> = 0  |
| when VREFLO < ADCIN <sub>y</sub> < VREFHI | ADCRESULT <sub>x</sub> = 4096 $\left( \frac{\text{ADCIN}_y - \text{VREFLO}}{\text{VREFHI} - \text{VREFLO}} \right)$ |
| when ADCIN <sub>y</sub> ≥ VREFHI          | ADCRESULT <sub>x</sub> = 4095   |

### 16.2.6 Interpreting Conversion Results

Based on a given ADC conversion result, the ideal corresponding analog input is given in [Table 16-3](#). This corresponds to the center of the possible range of analog voltages that could have produced this conversion result.

**Table 16-3. 12-Bit Digital-to-Analog Formulas**

| Digital Value                          | Analog Equivalent   |
|--|---|
| when ADCRESULT <sub>y</sub> = 0        | ADCIN <sub>x</sub> ≤ VREFLO   |
| when 0 < ADCRESULT <sub>y</sub> < 4095 | ADCIN <sub>x</sub> = (VREFHI - VREFLO) $\left( \frac{\text{ADCRESULT}_y}{4096} \right) + \text{VREFLO}$ |
| when ADCRESULT <sub>y</sub> = 4095     | ADCIN <sub>x</sub> ≥ VREFHI   |

### 16.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper will ensure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and/or acquisition window as desired. Configuring multiple SOCs to use the same trigger will allow the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel will allow for oversampling.

Figure 16-2. SOC Block Diagram

### 16.3.1 SOC Configuration

Each SOC has its own configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, and acquisition (sample) window duration.

### 16.3.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCB from each ePWM module

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

### 16.3.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in their ability to drive an analog signal quickly and effectively. In order to achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

$$\text{Acquisition window} = (\text{ACQPS} + 1) \cdot (\text{System Clock (SYSCLK) cycle time})$$

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The datasheet will specify a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

### 16.3.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see [Figure 16-3](#)) can be found in the device-specific datasheet.

**Figure 16-3. Single-Ended Input Model**

These input models should be used along with actual signal source impedance to determine the acquisition window duration. See [Section 16.13.2](#) for more information.

### 16.3.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. This is summarized in [Table 16-4](#).

**Table 16-4. Channel Selection of Input Pins**

| Input Mode   | CHSEL | Input   |
|--------------|-------|---------|
| Single-Ended | 0     | ADCIN0  |
|              | 1     | ADCIN1  |
|              | 2     | ADCIN2  |
|              | 3     | ADCIN3  |
|              | 4     | ADCIN4  |
|              | 5     | ADCIN5  |
|              | 6     | ADCIN6  |
|              | 7     | ADCIN7  |
|              | 8     | ADCIN8  |
|              | 9     | ADCIN9  |
|              | 10    | ADCIN10 |
|              | 11    | ADCIN11 |
|              | 12    | ADCIN12 |
|              | 13    | ADCIN13 |
|              | 14    | ADCIN14 |
|              | 15    | ADCIN15 |

## 16.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

### 16.4.1 Single Conversion from ePWM Trigger

To configure ADCA to perform a single conversion on channel ADCINA1 when the ePWM timer reaches its period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 16 SOCs could be used.

Assuming a 100 ns sample window is desired with a SYSCLK frequency of 100 MHz, then the acquisition window duration should be  $100 \text{ ns} / 10 \text{ ns} = 10$  cycles. The ACQPS field should therefore be set to  $10 - 1 = 9$ .

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 will convert ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 9;     //SOC5 will use sample duration of 10 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;  //SOC5 will begin conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches its period and generates the SOCB signal, the ADC will begin sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 will begin sampling when SOC5 gains priority (see [Section 16.5](#)). The ADC control logic will sample ADCINA1 with the specified acquisition window width of 100 ns. Immediately after the acquisition is complete, the ADC will begin converting the sampled voltage to a digital value. When the ADC conversion is complete, the results will be available in the ADCRESULT5 register (see [Section 16.12](#) for exact sample, conversion, and result latch timings).

### 16.4.2 Oversampled Conversion from ePWM Trigger

To configure the ADC to oversample ADCINA1 4 times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

As configured, when ePWM3 matches its period and generates the SOCB signal, the ADC will begin sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 will begin sampling when SOC5 gains priority (see [Section 16.5](#)). Once the conversion is complete for SOC5, SOC6 will begin converting ADCINA1 and the results for SOC5 will be placed in the ADCRESULT5 register. All four conversions will eventually be completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

---

#### Note

It is possible, but unlikely, that the ADC could begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See [Section 16.5](#) to understand how the next SOC to be converted is chosen.

---

### 16.4.3 Multiple Conversions from CPU Timer Trigger

This example will show how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 will be used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and their required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in [Table 16-5](#), where a SYCLK of 100 MHz is assumed (10 ns cycle time).

**Table 16-5. Example Requirements for Multiple Signal Sampling**

| Signal Name | Acquisition Window Requirement (ns) | Acquisition Window SYSCLK Cycles | ACQPS Register Value |
|-------------|-------------------------------------|----------------------------------|----------------------|
| Signal 1    | >240 ns                             | 240 ns/10 ns = 24                | 24 – 1 = 23          |
| Signal 2    | >883.333 ns                         | 883.333 ns/10 ns = 89 (round up) | 89 – 1 = 88          |
| Signal 3    | >220 ns                             | 220 ns/10 ns = 22                | 22 – 1 = 21          |
| Signal 4    | >585 ns                             | 585 ns/10 ns = 59 (round up)     | 59 – 1 = 58          |

Next decide which ADC pins to connect to each signal. This will be highly dependent on application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see [Table 16-6](#)).

**Table 16-6. Example Connections for Multiple Signal Sampling**

| Signal Name | ADC Pin | CHSEL Register Value |
|-------------|---------|----------------------|
| Signal 1    | ADCINA5 | 5                    |
| Signal 2    | ADCINA0 | 0                    |
| Signal 3    | ADCINA3 | 3                    |
| Signal 4    | ADCINA2 | 2                    |

With the information tabulated, it is easy to generate the SOC configurations:

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;         //SOC0 will use sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;        //SOC0 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;          //SOC1 will convert ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;         //SOC1 will use sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;        //SOC1 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;          //SOC2 will convert ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;         //SOC2 will use sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;        //SOC2 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;          //SOC3 will convert ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;         //SOC3 will use sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;        //SOC3 will begin conversion on CPU1 Timer 2
    
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 will eventually be sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) will be in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) will be in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

---

### Note

It is possible, but unlikely, that the ADC could begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See [Section 16.5](#) to understand how the next SOC to be converted is chosen.

---

#### 16.4.4 Software Triggering of SOCs

At any point, whether or not the SOCs have been configured to accept a specific trigger, a software trigger can set the SOCs to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger could be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;           //set SOC flags for SOC0 to SOC3
```

#### 16.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the order in which they are converted. The default priority method is round robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the SOCPRIORITY register is written. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round robin priority method is given in [Figure 16-4](#).

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOCs. When configured as high priority, an SOC will interrupt the round robin wheel after any current conversion completes and insert itself in as the next conversion. After its conversion completes, the round robin wheel will continue where it was interrupted. If two high priority SOC's are triggered at the same time, the SOC with the lower number will take precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in [Figure 16-5](#).

- A** After reset, SOC0 is highest priority SOC ; SOC7 receives trigger ; SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ; SOC8 is now highest priority SOC .
- C** SOC2 & SOC12 triggers rcvd . simultaneously ; SOC12 is first on round robin wheel ; SOC12 configured channel is converted while SOC2 stays pending .
- D** RRPOINTER changes to point to SOC 12 ; SOC2 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 2 ; SOC3 is now highest priority SOC .

Figure 16-4. Round Robin Priority Example

Example when SOC PRIORITY = 4

- A** After reset, SOC4 is 1<sup>st</sup> on round robin wheel ;  
SOC7 receives trigger ;  
SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ;  
SOC8 is now 1<sup>st</sup> on round robin wheel .
- C** SOC2 & SOC12 triggers rcvd. simultaneously ;  
SOC2 interrupts round robin wheel and SOC 2 configured channel is converted while SOC 12 stays pending .
- D** RRPOINTER stays pointing to 7 ;  
SOC12 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 12 ;  
SOC13 is now 1<sup>st</sup> on round robin wheel .

Figure 16-5. High Priority Example

## 16.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOCs one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOCs that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOCs are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper will not set all round-robin SOCs to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOCs. The first SOC to be set will be that with the highest priority based on the round-robin pointer, and subsequent SOCs will be set until BURSTSIZE SOCs have been set.

---

### Note

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received.

---

### 16.6.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations could be configured for each SOC as desired.

```

AdcaRegs.BURSTCTL.BURSTEN = 1;           //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;         //CPU1 Timer 2 will trigger burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;        //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICL.bit.SOCPRIORITY = 12; //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;      //SOC12 will convert ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;     //SOC12 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;      //SOC13 will convert ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;     //SOC13 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;      //SOC14 will convert ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;     //SOC14 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;      //SOC15 will convert ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;     //SOC15 will use sample duration of 20 SYSCLK cycles
    
```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 will be converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 will be converted once their SOCs gain priority. The results for SOC12 and SOC13 will be in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round robin pointer will give highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 will be set as pending and eventually be converted. The results for SOC14 and SOC15 will be in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers will continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions could be achieved using a similar approach.

### 16.6.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOC's is presented in Figure 16-6.

Example when  $SOC_{PRIORITY} = 4$ ,  $BURSTEN = 1$ , and  $BURSTSIZE = 1$

- A After reset, SOC4 is 1<sup>st</sup> on round robin wheel; BURSTTRIG trigger is received; SOC4 & SOC5 are set and configured channels converted immediately.
- B RRPOINTER changes to point to SOC5; SOC6 is now 1<sup>st</sup> on round robin wheel.
- C BURSTTRIG & SOC1 triggers rcvd. simultaneously; SOC1, SOC6, and SOC7 are set; SOC1 interrupts round robin wheel and SOC1 configured channel is converted while SOC6 and SOC7 stay pending.
- D RRPOINTER stays pointing to 5; SOC6/SOC7 configured channels are now converted.
- E RRPOINTER changes to point to SOC7; SOC8 is now 1<sup>st</sup> on round robin wheel, waiting for BURSTTRIG.

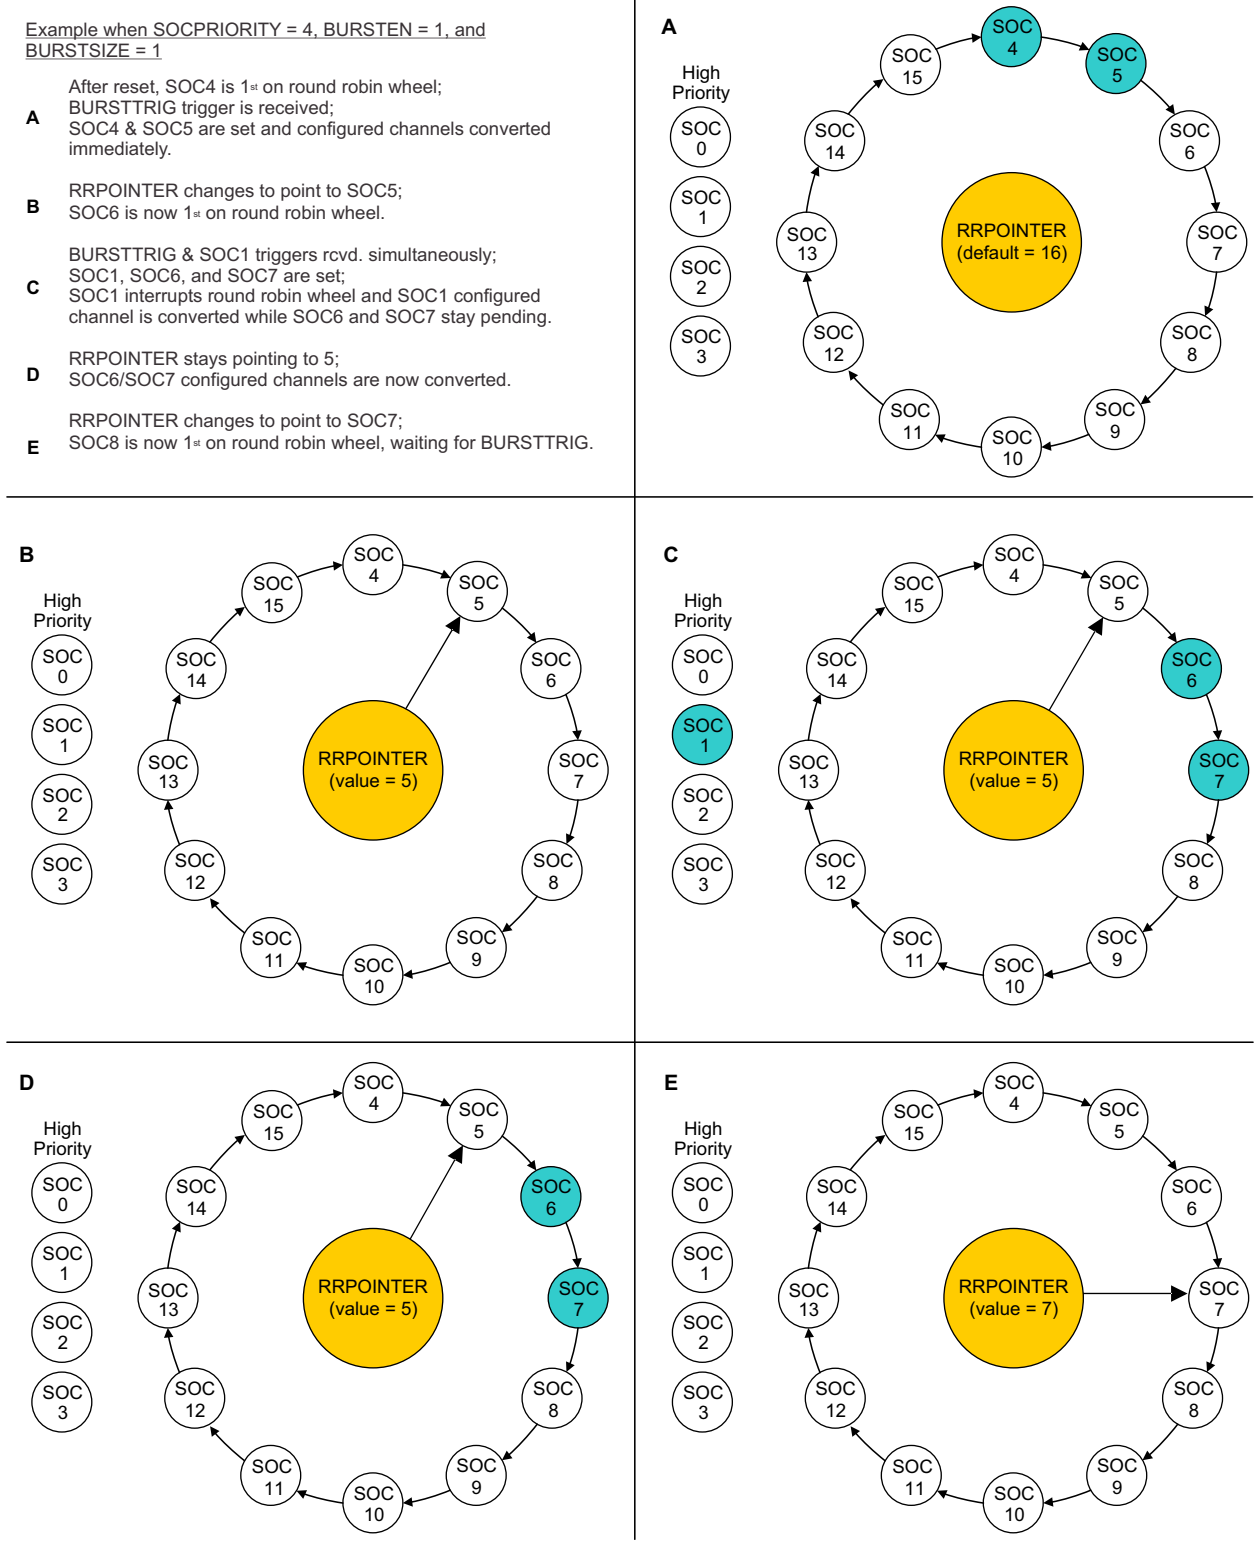

Figure 16-6. Burst Priority Example

## 16.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See [Section 16.12](#) for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the PIE.

### Note

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 16-7 shows a block diagram of the ADC interrupt structure.

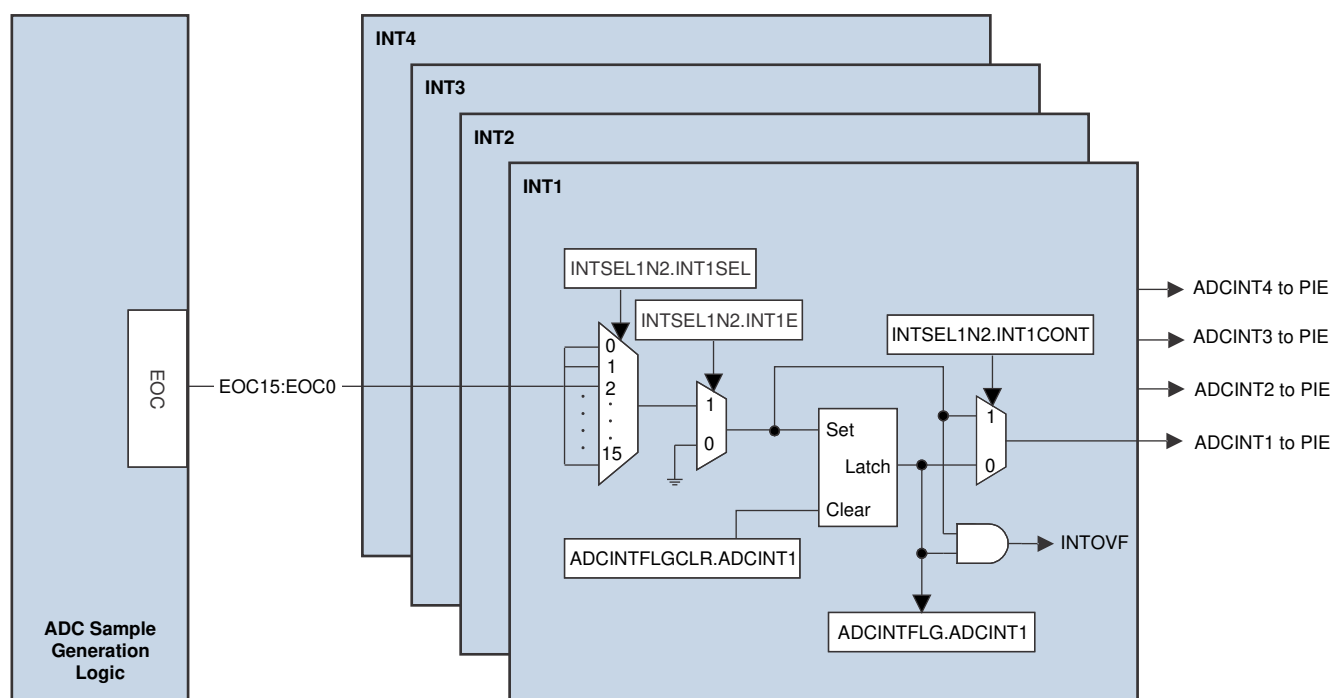

Figure 16-7. ADC EOC Interrupts

### 16.7.1 Interrupt Overflow

If the EOC signal would set a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts will not be passed on to the PIE module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; it does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow could occur, the application should check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;      //clear INT1 flag for ADC-A

// Check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)     //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1   //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1   //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// Check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

### 16.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts will not be issued to the PIE. By activating this mode ADC interrupts will always reach the PIE. The ADCINTOVF register will still be set if an interrupts occur while ADCINTFLG is still set regardless of this configuration.

### 16.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when they become available. However, the timing of the early interrupt may be too early and the application may need to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt will be generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 will not have any effect on the interrupt generation.

### 16.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. Each PPB can simultaneously remove an offset associated with the ADCIN channel, subtract out a reference value, flag a zero-crossing point, and flag a high or low compare limit. Furthermore, the zero-crossing and compare flags can trip a PWM and/or generate an interrupt. A PPB is also capable of recording the delay between when the SOC associated with the PPB is triggered and when it actually begins to be sampled. Figure 16-8 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

Figure 16-8. ADC PPB Block Diagram

### 16.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block will automatically add or subtract the value in the OFFCAL register from the raw conversion result and store it in the ADCRESULT register.

---

#### Note

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
  - It is possible to point multiple PPBs to the same SOC. In this case, the OFFCAL value that will actually be applied will be that of the PPB with the highest number.
  - In particular, care needs to be taken when using the PPB on SOC0, as all the PPB point to this SOC by default. This may cause unintentional overwriting of offset correction of a lower numbered PPB by a higher numbered PPB.
- 

### 16.8.2 PPB Error Calculation

In many applications, an error from a setpoint or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these function automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block will automatically subtract the value in the OFFREF register from the ADCRESULT value and store it in the ADCPPBxRESULT register. This subtraction will produce a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

---

#### Note

- not write a value larger than 12 bits to the OFFREF register.
  - Since the PPBxRESULT register is unique for each PPB, it is possible to point multiple PPBs to the same SOC and get different results for each PPB.
  - Writing a 0 to the OFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.
- 

### 16.8.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against a high and low limit or whenever ADCPPBxRESULT changes sign. Based on these comparisons, it can generate a trip to the PWM and/or an interrupt automatically, lowering the sample to ePWM latency and reducing software overhead. This functionality also enables safety conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zerocrossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit will be set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT register is gated by EOC and not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR

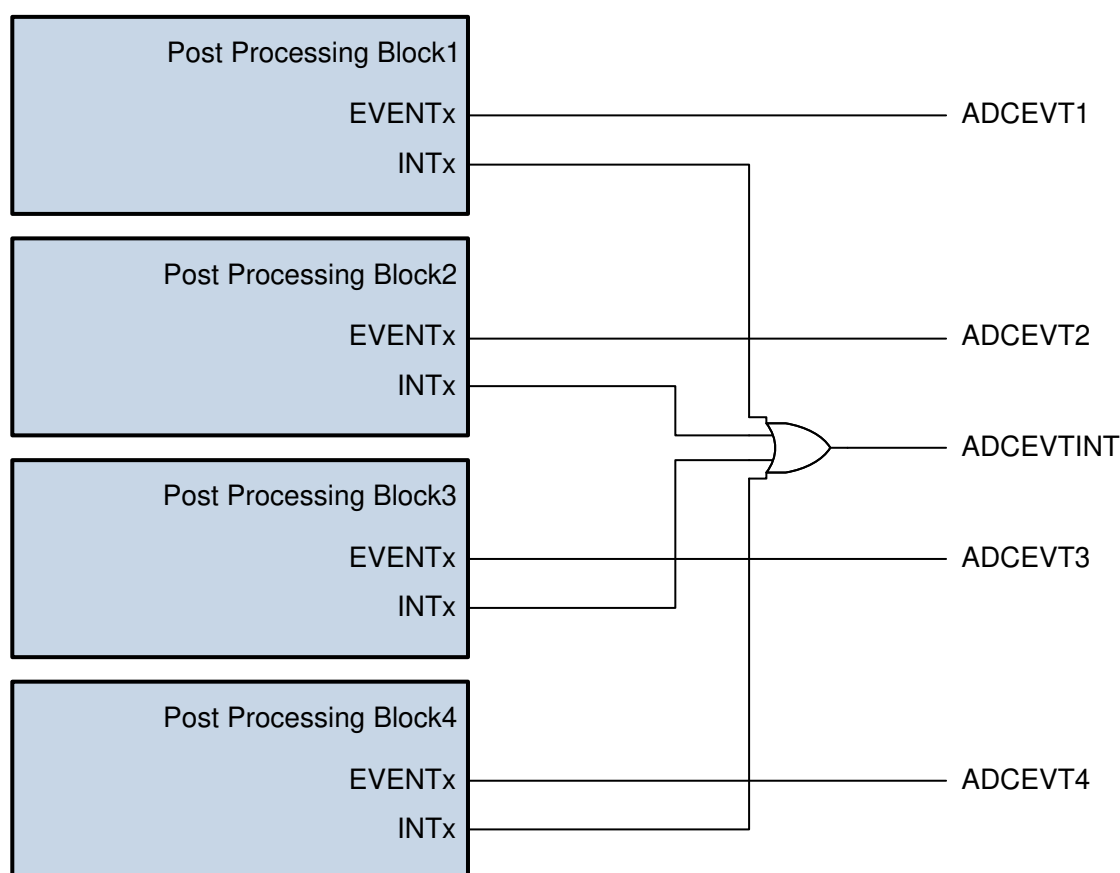

register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCINTSEL register has corresponding bits which allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in [Figure 16-9](#).

#### Note

- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR will have to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and/or zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

**Figure 16-9. ADC PPB Interrupt Event**

#### 16.8.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops will collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field will contain the number of SYSCLK cycles between when the associate SOC was triggered and when it began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

**Note**

If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register may overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

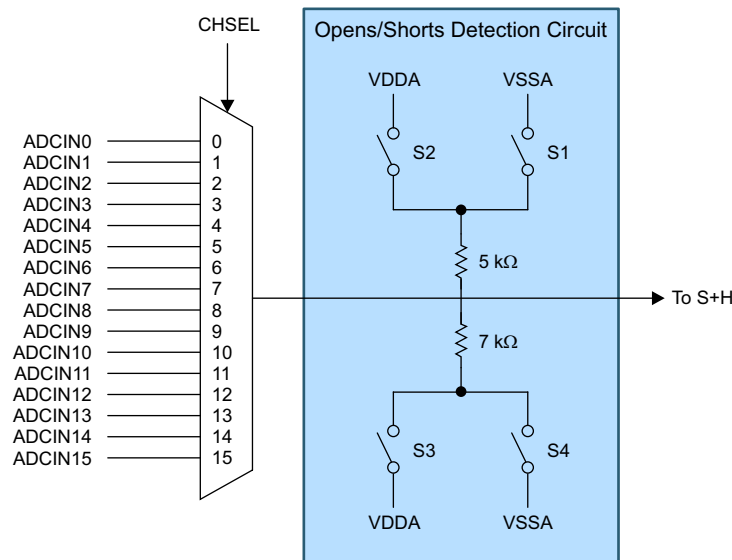

The sample delay capture will not function if the associated SOC is triggered via software. It will, however, correctly record the delay if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

**16.9 Opens/Shorts Detection Circuit (OSDETECT)**

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 16-10.

**Note**

- The divider resistance tolerances can vary widely, hence this feature should not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum will be needed.

**Figure 16-10. Opens/Shorts Detection Circuit**

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This will cause the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 16-7.

**Table 16-7. DETECTCFG Settings**

| ADCOSDETECT.<br>DETECTCFG | Source Voltage | S4     | S3     | S2     | S1     | Drive Impedance |
|---------------------------|----------------|--------|--------|--------|--------|-----------------|
| 0                         | Off            | Open   | Open   | Open   | Open   | Open            |
| 1                         | Zero Scale     | Closed | Open   | Open   | Closed | 5K    7K        |
| 2                         | Full Scale     | Open   | Closed | Closed | Open   | 5K    7K        |
| 3                         | 5/12 VDDA      | Open   | Closed | Open   | Closed | 5K    7K        |
| 4                         | 7/12 VDDA      | Closed | Open   | Closed | Open   | 5K    7K        |
| 5                         | Zero Scale     | Open   | Open   | Open   | Closed | 5K              |
| 6                         | Full Scale     | Open   | Open   | Closed | Open   | 5K              |
| 7                         | Zero Scale     | Closed | Open   | Open   | Open   | 7K              |

### 16.9.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance  $R_S$ , shunt capacitor  $C_P$ , the equivalent OSDETECT resistance  $R_{OSDETECT}$  and voltage  $V_{OSDETECT}$  is shown in Figure 16-11 and can be used as a basis to calculate the signal level going in to the sampling capacitor.  $R_{OSDETECT}$  and  $V_{OSDETECT}$  are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 16-7 for the different configuration settings. Refer to Figure 16-11 when deriving the input signal to S/H if signal source  $V_S$  is driving while the OSDETECT feature is enabled.

**Figure 16-11. Input Circuit Equivalent with OSDETECT Enabled**

The input impedance  $R_S$  and  $C_P$  may be integral parts of the signal source or these could have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature as this would affect the conversion results. For instance, driving an input signal when this feature is enabled would connect signal  $V_S$  to the OSDETECT circuit through  $R_S$  and affecting the ADC results. Larger  $C_P$  values (in the order greater than hundreds of pF) would require using higher ACQPS to ensure that signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 16-7.
3. Initiate a conversion and inspect the conversion result.

You must interpret the results based on what is driving on the input side and what are the values of  $R_S$  and  $C_P$ . If the  $V_S$  signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

### 16.9.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal will be pulled towards the sourced voltages. An input with good drive strength (pin not open) will be minimally affected. However, if the pin is open, the sampled voltages will be close to the source voltages specified in [Table 16-7](#).

### 16.9.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal will be pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) will be pulled toward each sourced voltage. However, if the pin is shorted, the signal will remain at the same voltage.

## 16.10 Power-Up Sequence

Upon device power-up or system level reset, the ADC will be powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data manual for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as it occurs after all the ADCs have begun powering up.

## 16.11 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are embedded into TI reserved OTP memory as part of C-callable functions.

- The `Device_cal()` function copies the trim values for ADC from OTP memory to their respective trim registers.
- The trim functions in `Device_cal()` are callable in C2000ware as `ADC_setOFFSETTRIM()`, `ADC_setINLTRIM()`. These functions fetch trim values from the TI reserved OTP memory source locations where the values are stored during test process as well as the analog module register destinations where the trim values are copied to.

Until the appropriate factory trim is loaded, the ADC (and other modules) will not be assured to operate within data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) will not be assured to operate within data sheet specifications.

The boot ROM will call the calibration functions, so trim values should be initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user can call the calibration functions (defined in the headerfiles).

### 16.11.1 ADC Zero Offset Calibration

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO. The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIM register. The value contained in this register will be applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results will not be affected and the full dynamic range of the ADC will be maintained for any trim value.

Using the `GetAdcOffsetTrimOTP(Uint16)` function, the ADCOFFTRIM register can be loaded with the factory calibrated offset error correction. You can modify the ADCOFFTRIM register to compensate for additional offset error induced by the application environment if desired, but this is not typically necessary to achieve data sheet specified performance.

---

#### Note

Regardless of the converter resolution, the size of each ADCOFFTRIM step is  $(VREFHI - VREFLO) / 65536$ .

---

Use the following procedure to re-calibrate the ADC offset in 12-bit, single-ended mode:

1. Set ADCOFFTRIM to +112 steps (0x70). This adds an artificial offset to account for negative offset that may reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example,  $32 * 16$  conversions = 512 conversions).
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIM to 112 – result from step 3.

## 16.12 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must ensure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the datasheet. The conversion time is approximately 10.5

### 16.12.1 ADC Timing Diagrams

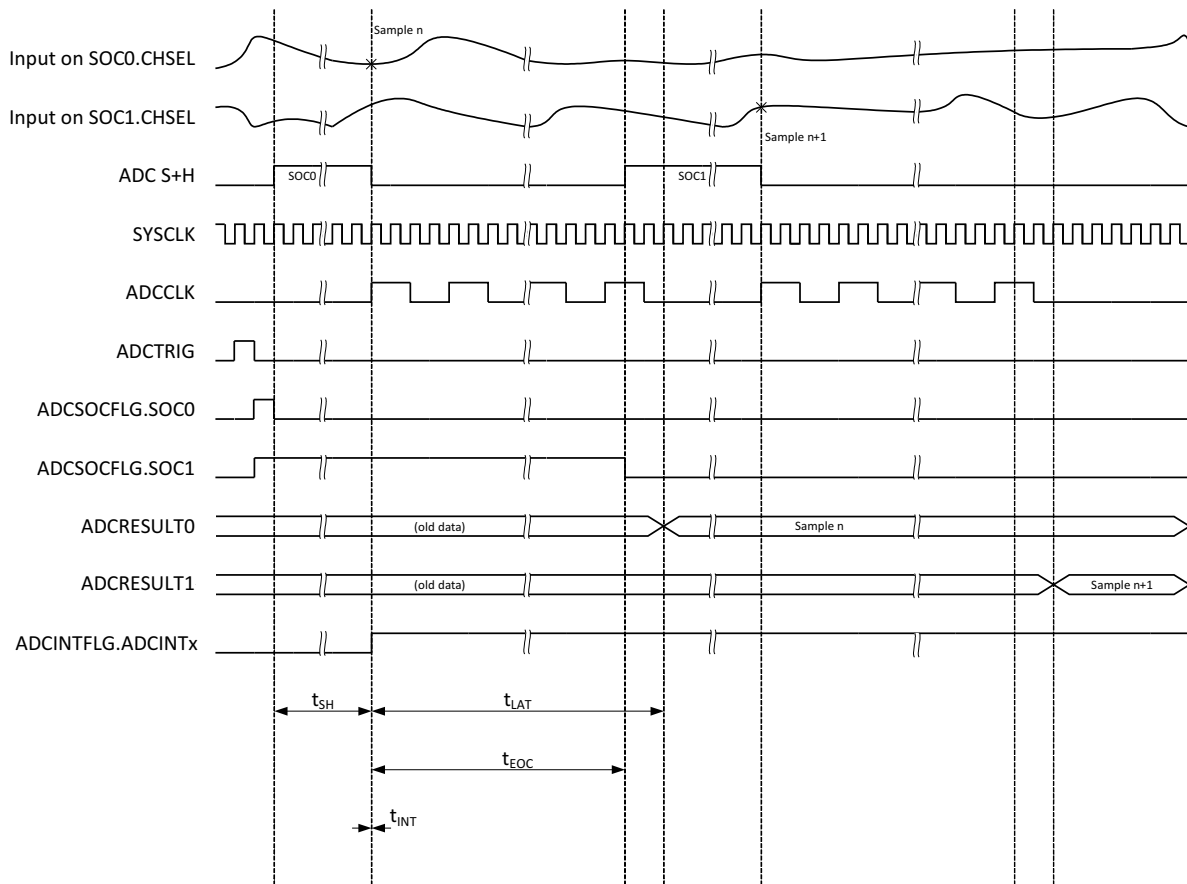

The following diagrams show the ADC conversion timings for two SOC's given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOC's are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

Table 16-8 describes the parameters in the following timing diagrams. Table 16-9 lists the ADC timings.

**Table 16-8. ADC Timing Parameter Descriptions**

| Parameter | Description  |
|-----------|--|
| $t_{SH}$  | <p>The duration of the S+H window.</p> <p>At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by <math>(ACQPS + 1)</math> SYSCLK cycles. ACQPS can be configured individually for each SOC, so <math>t_{SH}</math> will not necessarily be the same for different SOC's.</p> <p><b>Note:</b> The value on the S+H capacitor will be captured approximately 5ns before the end of the S+H window regardless of device clock settings.</p>   |
| $t_{LAT}$ | <p>The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register.</p> <p>If the ADCRESULTx register is read before this time, the previous conversion results will be returned.</p>   |
| $t_{EOC}$ | <p>The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. The subsequent sample can start before the conversion results are latched.</p>  |
| $t_{INT}$ | <p>The time from the end of the S+H window until an ADCINT flag is set (if configured).</p> <p>If the INTPULSEPOS bit in the ADCCTL1 register is set, <math>t_{INT}</math> will coincide with the conversion results being latched into the result register.</p> <p>If the INTPULSEPOS bit is 0, <math>t_{INT}</math> will coincide with the end of the S+H window. If <math>t_{INT}</math> triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to ensure the read occurs after the results latch (otherwise, the previous results will be read)</p> <p>If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there will be a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR or trigger the DMA at exactly the time the sample is ready.</p> |

**Figure 16-12. ADC Timings for 12-bit Mode in Early Interrupt Mode**

## 16.13 Additional Information

The following sections contain additional practical information.

### 16.13.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device should be operated synchronously. The device datasheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To ensure synchronous operation, all ADCs on the device should operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration).

#### 16.13.1.1 Basic Synchronous Operation

The following example configures two SOC's each on ADCA and ADCC with identical trigger select and ACQPS values. This will result in synchronous operation between ADCA and ADCC. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

```

Example: Basic Synchronous Operation
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
    
```

**Figure 16-14. Example: Basic Synchronous Operation**

Several things should be noted from [Figure 16-14](#). First, while the ACQPS values must be the same for SOC's with the same number, different ACQPS values can be used for SOC's with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high priority SOC's are to be used, the priority must be configured the same on all ADCs.

### 16.13.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCC while using three SOCs and two trigger sources. Figure 16-15 demonstrates that any combination of relative trigger timings still results in synchronous operation.

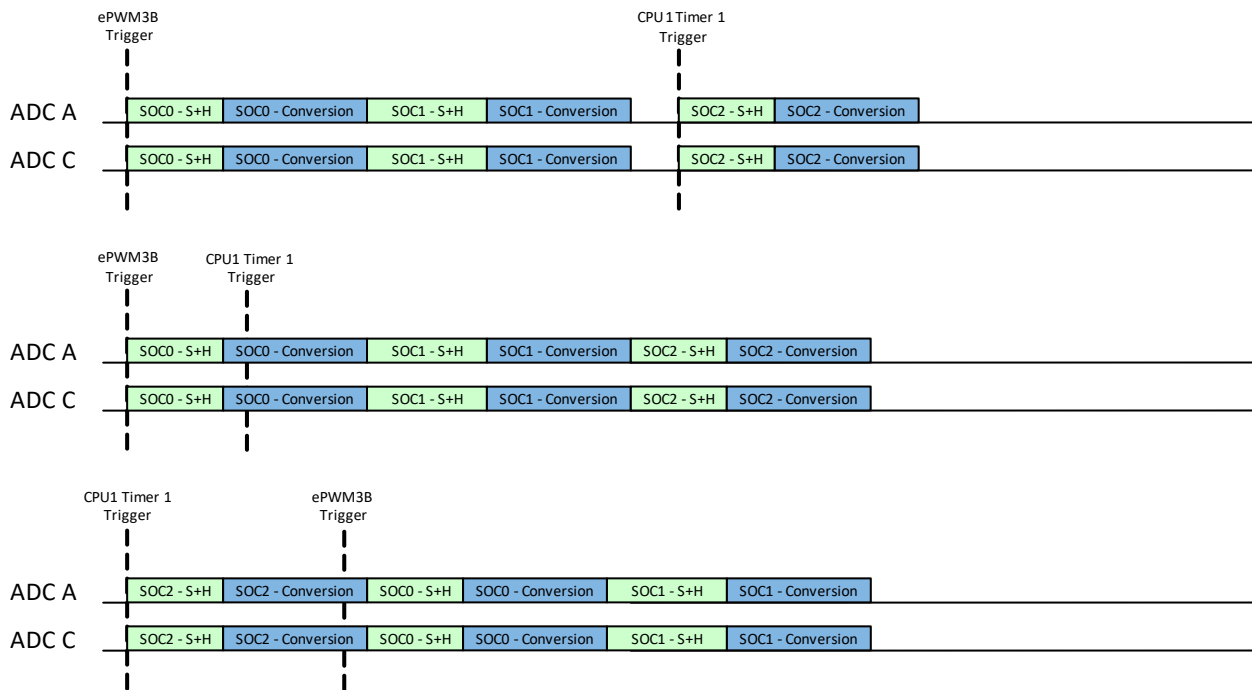

**Example: Synchronous Operation With Multiple Trigger Sources**

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0; //SOC2 will convert ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 will begin conversion on CPU Timer1
AdccRegs.ADCSOC2CTL.bit.CHSEL = 2; //SOC2 will convert ADCINC2
AdccRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 will begin conversion on CPU Timer1
    
```

**Figure 16-15. Example: Synchronous Operation with Multiple Trigger Sources**

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so it will likely result in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

### 16.13.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOC's than the other ADCs while still operating synchronously.

**Example: Synchronous Operation With Uneven SOC Numbers**

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;    //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;  //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0;     //SOC0 will convert ADCINCO
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;    //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;  //SOC0 will begin conversion on ePWM3 SOCB

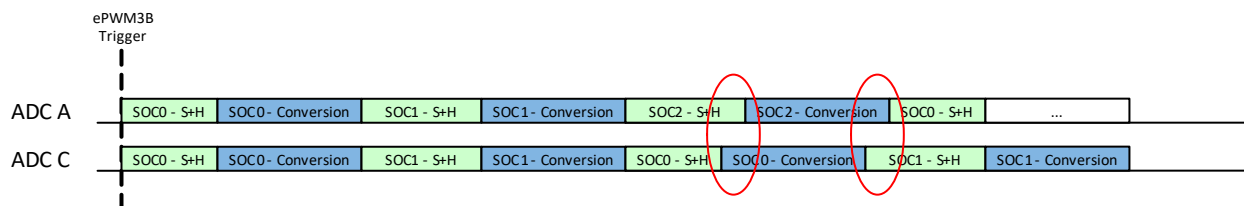

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;    //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;  //SOC1 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1;     //SOC1 will convert ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30;    //SOC1 will use sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10;  //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;     //SOC2 will convert ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;    //SOC2 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10;  //SOC2 will begin conversion on ePWM3 SOCB
    
```

**Figure 16-16. Example: Synchronous Operation with Uneven SOC Numbers**

Note that if the trigger comes again before all SOC's have completed their conversions, ADCC will begin converting immediately on SOC0 while ADCA will not start converting SOC0 again until SOC2 is complete. This will result in asynchronous operation, so care must be taken to not overflow the trigger.

**Figure 16-17. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow**

### 16.13.1.4 Non-overlapping Conversions

If conversion timings can be guaranteed to not overlap by the user, then it is not necessary to configure all SOC0s identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources which are always 180 degrees out-of-phase, then SOC0 could be used for both ADCA and ADCC with different trigger sources and different ACQPS values.

**Example: Operation with Non-overlapping Conversions**

```
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 9; //SOC0 will begin conversion on ePWM3 SOCA
```

Figure 16-18. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions

### 16.13.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor will be charged to within 1/2 LSB or 1/4 LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to ensure adequate settling performance. See TI application reports [ADC Input Circuit Evaluation for C2000 MCUs](#) and [Charge-Sharing Driving Circuits for C2000 ADCs](#) for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_s + R_{on}) \cdot C_h + R_s \cdot (C_s + C_p) \tag{2}$$

And the number of time constants needed is given by the equation:

$$k = \ln \left( \frac{2^n}{\text{settling error}} \right) - \ln \left( \frac{C_s + C_p}{C_H} \right) \tag{3}$$

So the total S+H time should be set to at least:

$$t = k \cdot \tau \tag{4}$$

Where the following parameters are provided by the ADC input model in the device data manual:

- n = ADC resolution (in bits)
- R<sub>ON</sub> = ADC sampling switch resistance (in Ohms)
- C<sub>H</sub> = ADC sampling capacitor (in pF)

- $C_p$  = ADC channel parasitic input capacitance (in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- $R_s$  = ADC driving circuit source impedance (in Ohms)
- $C_s$  = capacitance on ADC input pin (in pF)

For example, assuming the following parameters:

- $n$  = 12-bits
- $R_{ON}$  = 500 $\Omega$
- $C_H$  = 12.5pF
- $C_p$  = 12.7pF
- settling error =  $\frac{1}{4}$  LSB
- $R_s$  = 180 $\Omega$
- $C_s$  = 150pF

The time constant would be calculated as:

$$\tau = (180\Omega + 500\Omega) \cdot 12.5\text{pF} + 180\Omega \cdot (150\text{pF} + 12.7\text{pF}) = 8.5\text{ns} + 29.3\text{ns} = 37.8\text{ns} \quad (5)$$

And the number of required time constants would be:

$$k = \ln\left(\frac{2^{12}}{0.25}\right) - \ln\left(\frac{150\text{pF} + 12.7\text{pF}}{12.5\text{pF}}\right) = 9.70 - 2.57 = 7.13 \quad (6)$$

So the S+H time should be set to at least:

$$37.8\text{ns} \cdot 7.13 = 270\text{ns}$$

If SYSCLK = 100 MHz, then each SYSCLK is 10 ns. S+H duration should be 270 ns/10 ns = 27.0 SYSCLKs, so ACQPS for this input should be set to at least CEILING(27.0) – 1 = 26.

While this gives a rough estimate of the required acquisition window, a better method would be to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

---

#### Note

The device datasheet will specify a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

---

### 16.13.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, it is easy to achieve simultaneous sampling. This is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The example below demonstrates simultaneous sampling based on an ePWM3 event. ADCINA3 and ADCINC5 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;           //SOC0 will convert ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;         //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;       //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;         //SOC0 will convert ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;         //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;       //SOC0 will begin conversion on ePWM3 SOCB
    
```

When the ePWM3 trigger is received, all ADCs will begin converting in parallel immediately. All results will be in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples will not happen at exactly the same time.

### 16.13.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all C28x CPUs, C28x DMAs, and CLAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

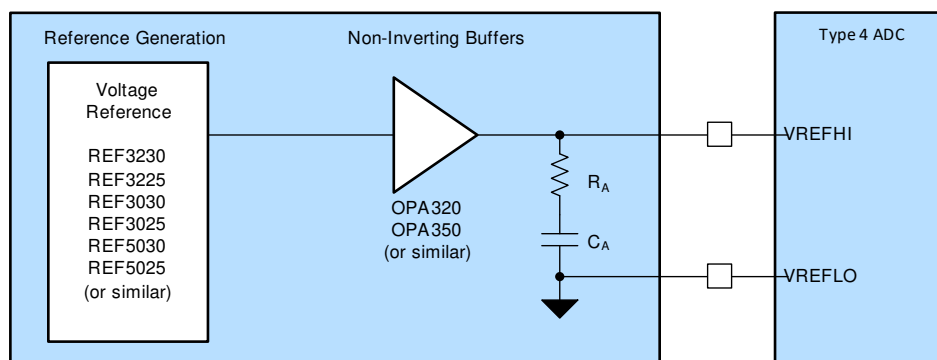

### 16.13.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN12 on ADCC and on CMPSS2\_HP5 input by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the ADC\_getTemperatureC() function in F28003x ADC driverlib file.

### 16.13.6 Designing an External Reference Circuit

Figure 16-19 shows the basic organization of the external voltage reference generation circuitry. The reference voltage should then be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the reference pin. A capacitor between the high and low reference pins should be placed on the PCB as close to the pins as practical to help absorb high frequency currents. A series resistor (typically <math><1\Omega</math>) in series with this capacitor may be necessary to ensure op-amp stability.

**Figure 16-19. ADC Reference System**

## 16.14 Software

### 16.14.1 ADC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/adc

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 16.14.1.1 ADC ePWM Triggering Multiple SOC

FILE: adc\_ex10\_multiple\_soc\_epwm.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

##### *External Connections*

- A0, A1, A2 and C2, C3, C4 pins should be connected to signals to be converted.

##### *Watch Variables*

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcCResult0* - Digital representation of the voltage on pin C2
- *adcCResult1* - Digital representation of the voltage on pin C3
- *adcCResult2* - Digital representation of the voltage on pin C4

#### 16.14.1.2 ADC Burst Mode

FILE: adc\_ex11\_burst\_mode\_epwm.c

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

##### *External Connections*

- A0, A1, A2, A3, A4

##### *Watch Variables*

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcAResult3* - Digital representation of the voltage on pin A3
- *adcAResult4* - Digital representation of the voltage on pin A4

#### 16.14.1.3 ADC Burst Mode Oversampling

FILE: adc\_ex12\_burst\_mode\_oversampling.c

This example sets up ePWM1 to periodically trigger SOC0 and SOC1 on ADCA (to sample A0 and A1). Additionally, the ADC burst mode is also triggered using ePWM1. The burst SOCs are used to accumulate multiple conversions to oversample A2 over multiple ePWM periods.

##### *External Connections*

- A0, A1, A2

#### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

#### 16.14.1.4 ADC SOC Oversampling

FILE: `adc_ex13_soc_oversampling.c`

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA including multiple SOC's that all convert A2 to achieve oversampling on A2.

ADCA Interrupt ISRs are used to read results of ADCA.

#### External Connections

- A0, A1, A2 should be connected to signals to be converted.

#### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

#### 16.14.1.5 ADC PPB PWM trip (*adc\_ppb\_pwm\_trip*)

FILE: `adc_ex14_ppb_pwm_trip.c`

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block(PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases:

- one-shot
- cycle-by-cycle
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

#### External Connections

- A2 should be connected to a signal to convert
- Observe the following signals on an oscilloscope
  - ePWM1(GPIO0 - GPIO1)
  - ePWM2(GPIO2 - GPIO3)
  - ePWM3(GPIO4 - GPIO5)

#### Watch Variables

- *adcA2Results* - Digital representation of the voltage on pin A2

#### 16.14.1.6 ADC Software Triggering

FILE: `adc_ex1_soc_software.c`

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

### External Connections

- A0, A1, C2, and C3 should be connected to signals to convert

### Watch Variables

- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1
- *myADC1Result0* - Digital representation of the voltage on pin C2
- *myADC1Result1* - Digital representation of the voltage on pin C3

#### 16.14.1.7 ADC ePWM Triggering

FILE: `adc_ex2_soc_epwm.c`

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

### External Connections

- A0 should be connected to a signal to convert

### Watch Variables

- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

#### 16.14.1.8 ADC Temperature Sensor Conversion

FILE: `adc_ex3_temp_sensor.c`

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the `ADC_getTemperatureC()` function.

### Watch Variables

- *sensorSample* - The raw reading from the temperature sensor
- *sensorTemp* - The interpretation of the sensor sample as a temperature in degrees Celsius.

#### 16.14.1.9 ADC Synchronous SOC Software Force (`adc_soc_software_sync`)

FILE: `adc_ex4_soc_software_sync.c`

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

### External Connections

- A2, A3, C2, C3 pins should be connected to signals to convert

### Watch Variables

- *myADC0Result0* : a digital representation of the voltage on pin A2
- *myADC0Result1* : a digital representation of the voltage on pin A3
- *myADC1Result0* : a digital representation of the voltage on pin C2
- *myADC1Result1* : a digital representation of the voltage on pin C3

#### 16.14.1.10 ADC Continuous Triggering (`adc_soc_continuous`)

FILE: `adc_ex5_soc_continuous.c`

This example sets up the ADC to convert continuously, achieving maximum sampling rate.

### External Connections

- A0 pin should be connected to signal to convert

### Watch Variables

- *adcAResults* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is the minimum possible based on the ADC speed.

#### 16.14.1.11 ADC Continuous Conversions Read by DMA (*adc\_soc\_continuous\_dma*)

FILE: `adc_ex6_soc_continuous_dma.c`

This example sets up two ADC channels to convert simultaneously. The results will be transferred by the DMA into a buffer in RAM.

##### External Connections

- A3, C3 pins should be connected to signals to convert

##### Watch Variables

- *myADC0DataBuffer*: a digital representation of the voltage on pin A3
- *myADC1DataBuffer*: a digital representation of the voltage on pin C3

#### 16.14.1.12 ADC PPB Offset (*adc\_ppb\_offset*)

FILE: `adc_ex7_ppb_offset.c`

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

##### External Connections

- A2, C2 pins should be connected to signals to convert

##### Watch Variables

- *myADC0Result* : a digital representation of the voltage on pin A2
- *myADC0PPBResult* : a digital representation of the voltage on pin A2, minus 100 LSBs of automatically added offset
- *myADC1Result* : a digital representation of the voltage on pin C2
- *myADC1PPBResult* : a digital representation of the voltage on pin C2 plus 100 LSBs of automatically added offset

#### 16.14.1.13 ADC PPB Limits (*adc\_ppb\_limits*)

FILE: `adc_ex8_ppb_limits.c`

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

##### External Connections

- A0 should be connected to a signal to convert

##### Watch Variables

- None

#### 16.14.1.14 ADC PPB Delay Capture (*adc\_ppb\_delay*)

FILE: `adc_ex9_ppb_delay.c`

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
  - ePWM2, with period 9999, triggering SOC1 to convert on pin A2
- Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
- After the program runs, the memory will contain:

*conversion* : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

## 16.15 ADC Registers

This section describes the Analog-to-Digital Converter Registers.

### 16.15.1 ADC Base Address Table

**Table 16-10. ADC Base Address Table**

| Bit Field Name |                 | DriverLib Name  | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------------|-----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure       |                 |              |      |     |     |     |                    |
| AdcaResultRegs | ADC_RESULT_REGS | ADCARESULT_BASE | 0x0000_0B00  | YES  | YES | YES | YES | -                  |
| AdcbResultRegs | ADC_RESULT_REGS | ADCBRESULT_BASE | 0x0000_0B20  | YES  | YES | YES | YES | -                  |
| AdccResultRegs | ADC_RESULT_REGS | ADCCRESULT_BASE | 0x0000_0B40  | YES  | YES | YES | YES | -                  |
| AdcaRegs       | ADC_REGS        | ADCA_BASE       | 0x0000_7400  | YES  | -   | -   | YES | YES                |
| AdcbRegs       | ADC_REGS        | ADCB_BASE       | 0x0000_7480  | YES  | -   | -   | YES | YES                |
| AdccRegs       | ADC_REGS        | ADCC_BASE       | 0x0000_7500  | YES  | -   | -   | YES | YES                |

### 16.15.2 ADC\_RESULT\_REGS Registers

Table 16-11 lists the memory-mapped registers for the ADC\_RESULT\_REGS registers. All register offset addresses not listed in Table 16-11 should be considered as reserved locations and the register contents should not be modified.

**Table 16-11. ADC\_RESULT\_REGS Registers**

| Offset | Acronym       | Register Name                               | Write Protection | Section            |
|--------|---------------|---|------------------|--------------------|
| 0h     | ADCRESULT0    | ADC Result 0 Register                       |                  | <a href="#">Go</a> |
| 1h     | ADCRESULT1    | ADC Result 1 Register                       |                  | <a href="#">Go</a> |
| 2h     | ADCRESULT2    | ADC Result 2 Register                       |                  | <a href="#">Go</a> |

| 16h    | ADCPPB4RESULT | ADC Post Processing Block 4 Result Register |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 16-12 shows the codes that are used for access types in this section.

**Table 16-12. ADC\_RESULT\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |

**Table 16-12. ADC\_RESULT\_REGS Access Type Codes (continued)**

| Access Type | Code | Description   |
|-------------|------|---|
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 16.15.2.1 ADCRESULT0 Register (Offset = 0h) [Reset = 0h]

ADCRESULT0 is shown in [Figure 16-20](#) and described in [Table 16-13](#).

Return to the [Summary Table](#).

ADC Result 0 Register

**Figure 16-20. ADCRESULT0 Register**

|        |    |    |    |    |    |   |   |
|--------|----|----|----|----|----|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| RESULT |    |    |    |    |    |   |   |
| R-0h   |    |    |    |    |    |   |   |
| 7      | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| RESULT |    |    |    |    |    |   |   |
| R-0h   |    |    |    |    |    |   |   |

**Table 16-13. ADCRESULT0 Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description  |
|------|--------|------|-------|--|
| 15-0 | RESULT | R    | 0h    | ADC Result 0<br>16-bit ADC result. After the ADC completes a conversion of SOC0, the digital result is placed in this bit field.<br>Reset type: SYSRSn |

### 16.15.2.2 ADCRESULT1 Register (Offset = 1h) [Reset = 0h]

ADCRESULT1 is shown in [Figure 16-21](#) and described in [Table 16-14](#).

Return to the [Summary Table](#).

ADC Result 1 Register

**Figure 16-21. ADCRESULT1 Register**

|        |    |    |    |    |    |   |   |
|--------|----|----|----|----|----|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| RESULT |    |    |    |    |    |   |   |
| R-0h   |    |    |    |    |    |   |   |

Complex bit access types are encoded to fit into small table cells. [Table 16-34](#) shows the codes that are used for access types in this section.

**Table 16-34. ADC\_REGS Access Type Codes**

| Access Type              | Code    | Description                            |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read                                   |
| R-0                      | R<br>-0 | Read<br>Returns 0s                     |
| Write Type               |         |  |
| W                        | W       | Write                                  |
| W1S                      | W<br>1S | Write<br>1 to set                      |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value |
| Register Array Variables |         |  |

**Table 16-34. ADC\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description  |
|-------------|------|--|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 16.15.3.1 ADCCTL1 Register (Offset = 0h) [Reset = 0h]

ADCCTL1 is shown in [Figure 16-40](#) and described in [Table 16-35](#).

Return to the [Summary Table](#).

**Table 16-48. ADCSOCFRC1 Register Field Descriptions**

| Bit | Field | Type    | Reset | Description   |
|-----|-------|---------|-------|---|
| 15  | SOC15 | R-0/W1S | 0h    | <p>SOC15 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC15 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC15 flag bit to 1. This will cause a conversion to start once priority is given to SOC15.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC15 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 14  | SOC14 | R-0/W1S | 0h    | <p>SOC14 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC14 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC14 flag bit to 1. This will cause a conversion to start once priority is given to SOC14.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC14 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 13  | SOC13 | R-0/W1S | 0h    | <p>SOC13 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC13 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC13 flag bit to 1. This will cause a conversion to start once priority is given to SOC13.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC13 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |

**Table 16-48. ADCSOCFRC1 Register Field Descriptions (continued)**

| Bit | Field | Type    | Reset | Description   |
|-----|-------|---------|-------|---|
| 12  | SOC12 | R-0/W1S | 0h    | <p>SOC12 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC12 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC12 flag bit to 1. This will cause a conversion to start once priority is given to SOC12.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC12 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 11  | SOC11 | R-0/W1S | 0h    | <p>SOC11 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC11 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC11 flag bit to 1. This will cause a conversion to start once priority is given to SOC11.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC11 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 10  | SOC10 | R-0/W1S | 0h    | <p>SOC10 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC10 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC10 flag bit to 1. This will cause a conversion to start once priority is given to SOC10.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC10 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 9   | SOC9  | R-0/W1S | 0h    | <p>SOC9 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC9 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC9 flag bit to 1. This will cause a conversion to start once priority is given to SOC9.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC9 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>      |

**Table 16-48. ADCSOCFRC1 Register Field Descriptions (continued)**

| Bit | Field | Type    | Reset | Description  |
|-----|-------|---------|-------|--|
| 8   | SOC8  | R-0/W1S | 0h    | <p>SOC8 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC8 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC8 flag bit to 1. This will cause a conversion to start once priority is given to SOC8.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC8 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 7   | SOC7  | R-0/W1S | 0h    | <p>SOC7 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC7 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC7 flag bit to 1. This will cause a conversion to start once priority is given to SOC7.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC7 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 6   | SOC6  | R-0/W1S | 0h    | <p>SOC6 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC6 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC6 flag bit to 1. This will cause a conversion to start once priority is given to SOC6.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC6 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 5   | SOC5  | R-0/W1S | 0h    | <p>SOC5 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC5 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC5 flag bit to 1. This will cause a conversion to start once priority is given to SOC5.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC5 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |

**Table 16-48. ADCSOCFRC1 Register Field Descriptions (continued)**

| Bit | Field | Type    | Reset | Description  |
|-----|-------|---------|-------|--|
| 4   | SOC4  | R-0/W1S | 0h    | <p>SOC4 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC4 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC4 flag bit to 1. This will cause a conversion to start once priority is given to SOC4.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC4 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 3   | SOC3  | R-0/W1S | 0h    | <p>SOC3 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC3 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC3 flag bit to 1. This will cause a conversion to start once priority is given to SOC3.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC3 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 2   | SOC2  | R-0/W1S | 0h    | <p>SOC2 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC2 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC2 flag bit to 1. This will cause a conversion to start once priority is given to SOC2.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC2 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |
| 1   | SOC1  | R-0/W1S | 0h    | <p>SOC1 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC1 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC1 flag bit to 1. This will cause a conversion to start once priority is given to SOC1.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC1 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |

**Table 16-48. ADCSOCFRC1 Register Field Descriptions (continued)**

| Bit | Field | Type    | Reset | Description  |
|-----|-------|---------|-------|--|
| 0   | SOC0  | R-0/W1S | 0h    | <p>SOC0 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC0 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC0 flag bit to 1. This will cause a conversion to start once priority is given to SOC0.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC0 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p> |

### 16.15.3.15 ADCSOCOVF1 Register (Offset = Eh) [Reset = 0h]

ADCSOCOVF1 is shown in [Figure 16-54](#) and described in [Table 16-49](#).

Return to the [Summary Table](#).

ADC SOC Overflow 1 Register

**Table 16-96. ADCPPB4OFFREF Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description   |
|------|--------|------|-------|---|
| 15-0 | OFFREF | R/W  | 0h    | <p>ADC Post Processing Block 4 Offset Correction. This bit field can be used to either calculate the feedback error or convert a unipolar signal to bipolar by subtracting a reference value. This 16-bit unsigned value is subtracted from the ADCRESULT register before being passed through an optional two's complement function and stored in the ADCPPB4RESULT register. This subtraction is not saturated.</p> <p>0000h No change. The ADCRESULT value is passed on.<br/>           0001h ADCRESULT - 1 is passed on.<br/>           0002h ADCRESULT - 2 is passed on.<br/>           ...<br/>           8000h ADCRESULT - 32,768 is passed on.<br/>           ...<br/>           FFFFh ADCRESULT - 65,535 is passed on.</p> <p>NOTE: In 12-bit mode the size of this register does not change from 16-bits. It is the user's responsibility to ensure that only a 12-bit value is written to this register when in 12-bit mode.<br/>           Reset type: SYSRSn</p> |

### 16.15.3.63 ADCPPB4TRIPHI Register (Offset = 5Ch) [Reset = 0h]

ADCPPB4TRIPHI is shown in [Figure 16-102](#) and described in [Table 16-97](#).

Return to the [Summary Table](#).

ADC PPB4 Trip High Register

**Figure 16-102. ADCPPB4TRIPHI Register**

## **Buffered Digital-to-Analog Converter (DAC)**

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

|                                  |             |
|----------------------------------|-------------|
| <b>17.1 Introduction</b> .....   | <b>1962</b> |
| <b>17.2 Using the DAC</b> .....  | <b>1963</b> |
| <b>17.3 Lock Registers</b> ..... | <b>1964</b> |
| <b>17.4 Software</b> .....       | <b>1965</b> |
| <b>17.5 DAC Registers</b> .....  | <b>1966</b> |

## 17.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. For driving even higher loads than typical, a trade-off can be made between load size and output voltage swing. For the load conditions of the buffered DAC, see the device-specific data manual. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

### 17.1.1 DAC Related Collateral

#### Foundational Materials

- [C2000 Academy - Analog Subsystem](#)
- [High Speed, Digital to Analog Converters Basics Application Report](#)
- [Real-Time Control Reference Guide](#)
  - Refer to the DAC section
- [Understanding Data Converters Application Report](#)

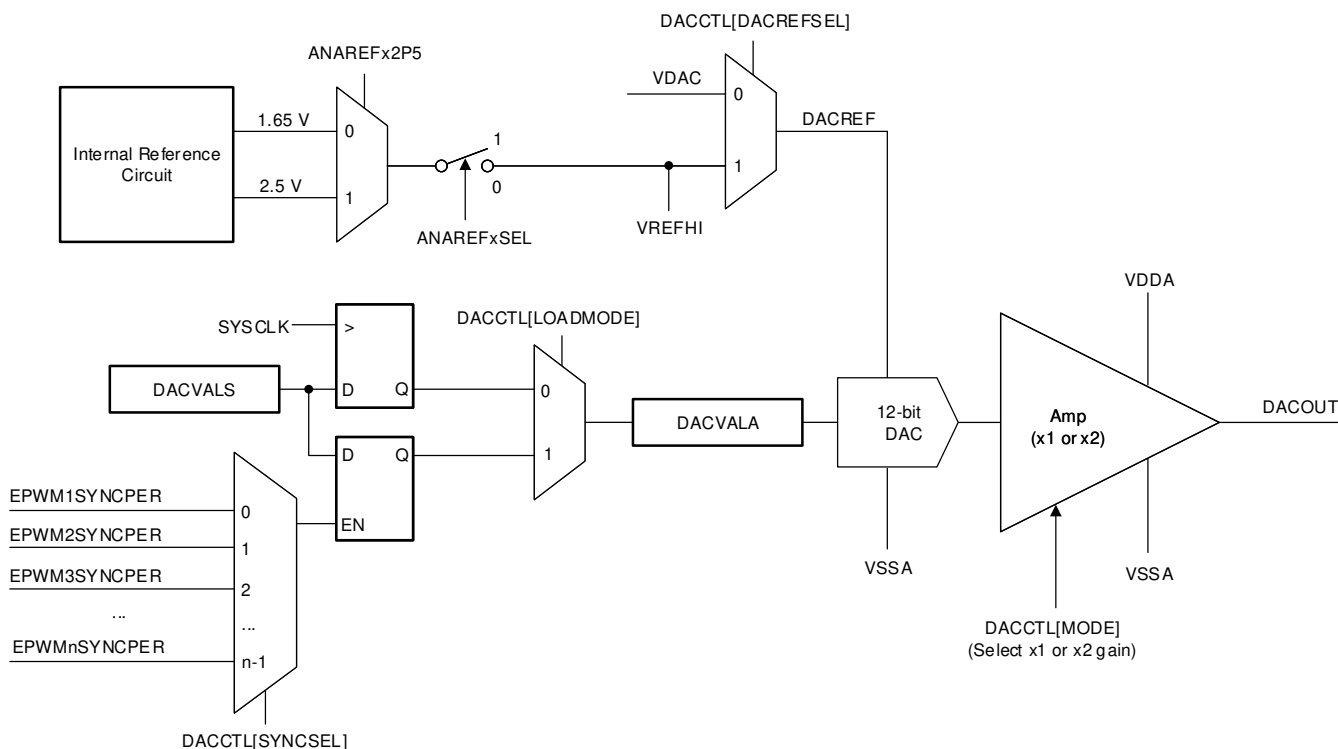

### 17.1.2 Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- x1 and x2 gain modes when using internal VREFHI
- Ability to synchronize with EPWMSYNCPER

### 17.1.3 Block Diagram

The block diagram for the buffered DAC is shown in [Figure 17-1](#).

**Figure 17-1. DAC Module Block Diagram**

## 17.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDACC and VREFHI. The x2 gain mode is only available when VREFHI is set as DACREF and internal reference mode is used (see the *Analog Subsystem* chapter on how to switch to internal reference mode). Even though the buffered DAC has an x2 gain mode, the maximum output voltage from the buffered DAC will not be greater than VDDA. [Table 17-1](#) lists the gain mode combinations supported by the buffered DAC. In this table, x = A or B, X = Don't Care, VDACC/VREFHI = 2.5v, VDDA = 3.3v, and DACVAL = 4095.

**Table 17-1. DAC Supported Gain Mode Combinations**

| DACREFSEL | ANAREFSEL | ANAREF2P5 | Reference Source | Reference Voltage (V) | Mode | Maximum DAC Output (V) | Support Status |
|-----------|-----------|-----------|------------------|-----------------------|------|------------------------|----------------|
| 0         | X         | X         | External         | VDACC                 | 0    | 2.5                    | Supported      |
| 0         | X         | X         | External         | VDACC                 | 1    | 2.5                    | Not Supported  |
| 1         | 0         | 0         | Internal         | 1.65                  | 0    | 1.65                   | Not Supported  |
| 1         | 0         | 0         | Internal         | 1.65                  | 1    | 3.3                    | Supported      |
| 1         | 0         | 1         | Internal         | 2.5                   | 0    | 2.5                    | Supported      |
| 1         | 0         | 1         | Internal         | 2.5                   | 1    | 3.3                    | Not Supported  |
| 1         | 1         | X         | External         | VREFHI                | 0    | 2.5                    | Supported      |
| 1         | 1         | X         | External         | VREFHI                | 1    | 2.5                    | Not Supported  |

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS will no longer be updated with register writes. Enabling the clock to the buffered DAC restores it to the state before the clock was disabled.

The ideal output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (7)$$

The output buffer of the buffered DAC may exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data manual.

### 17.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device-specific data manual.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS should be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device-specific data manual.

### 17.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25v (for 2.5v reference voltage). DAC offset error is calibrated at 2.5v reference voltage and loaded into the DAC offset trim register as part of the Device\_cal() function. If the DAC is used at any reference voltage other than 2.5v, the offset trim must be adjusted to ensure the offset error performance stays within the device-specific data manual limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call DAC\_tuneOffsetTrim() found in C2000Ware to adjust the offset.

### 17.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the Time-Base Submodule section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER will be held at level high and DACVALA will be loaded immediately from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, it is recommended to configure the EPWM first before setting DACCTL [LOADMODE] to 1.

---

#### Note

The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCl and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

---

## 17.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access will be locked out until the device is reset.

## 17.4 Software

### 17.4.1 DAC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/dac

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 17.4.1.1 Buffered DAC Enable

FILE: buffdac\_ex1\_enable.c

This example generates a voltage on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

##### External Connections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB3.

##### Watch Variables

- None.

#### 17.4.1.2 Buffered DAC Random

FILE: buffdac\_ex2\_random.c

This example generates random voltages on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

##### External Connections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB3.

##### Watch Variables

- None.

#### 17.4.1.3 Buffered DAC Sine (*buffdac\_sine*)

FILE: buffdac\_ex3\_waveform.c

This example generates a sine wave on the buffered DAC output, DACOUTA/ADCINA0 (HSEC Pin 9) and uses the default DAC reference setting of VDAC.

When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB3.

Run the included .js file to add the watch variables. This example uses the SGEN module. Documentation for the SGEN module can be found in the SGEN library directory.

The generated waveform can be adjusted with the following variables while running:

- *waveformGain* : Adjust the magnitude of the waveform. Range is from 0.0 to 1.0. The default value of 0.8003 centers the waveform within the linear range of the DAC
- *waveformOffset* : Adjust the offset of the waveform. Range is from -1.0 to 1.0. The default value of 0 centers the waveform
- *outputFreq\_hz* : Adjust the output frequency of the waveform. Range is from 0 to maxOutputFreq\_hz
- *maxOutputFreq\_hz* : Adjust the max output frequency of the waveform. Range - See SGEN module documentation for how this affects other parameters

The generated waveform can be adjusted with the following variables/macros but require recompile:

- *samplingFreq\_hz* : Adjust the rate at which the DAC is updated. Range - See SGEN module documentation for how this affects other parameters
- *SINEWAVE\_TYPE* : The type of sine generated. Range - LOW\_THD\_SINE, HIGH\_PRECISION\_SINE

The following variables give additional information about the generated waveform: See SGEN module documentation for details

- *freqResolution\_hz*
- *maxOutput\_1sb* : Maximum value written to the DAC.
- *minOutput\_1sb* : Minimum value written to the DAC.
- *pk\_to\_pk\_1sb* : Magnitude of generated waveform.
- *cpuPeriod\_us* : Period of cpu.
- *samplingPeriod\_us* : The rate at which the DAC is updated. Note that *samplingPeriod\_us* has to be greater than the DAC settling time.
- *interruptCycles* : Interrupt duration in cycles.
- *interruptDuration\_us* : Interrupt duration in uS.
- *sgen* : The SGEN module instance.
- *DataLog* : Circular log of writes to the DAC.

## 17.5 DAC Registers

This section describes the Buffered Digital to Analog Converter registers.

### 17.5.1 DAC Base Address Table

**Table 17-2. DAC Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| DacaRegs       | DAC_REGS  | DACA_BASE      | 0x0000_5C00  | YES  | YES | YES | YES | YES                |
| DacbRegs       | DAC_REGS  | DACB_BASE      | 0x0000_5C10  | YES  | YES | YES | YES | YES                |

## 17.5.2 DAC\_REGS Registers

Table 17-3 lists the memory-mapped registers for the DAC\_REGS registers. All register offset addresses not listed in Table 17-3 should be considered as reserved locations and the register contents should not be modified.

**Table 17-3. DAC\_REGS Registers**

| Offset | Acronym  | Register Name               | Write Protection | Section            |
|--------|----------|-----------------------------|------------------|--------------------|
| 0h     | DACREV   | DAC Revision Register       |                  | <a href="#">Go</a> |
| 1h     | DACCTL   | DAC Control Register        | EALLOW           | <a href="#">Go</a> |
| 2h     | DACVALA  | DAC Value Register - Active |                  | <a href="#">Go</a> |
| 3h     | DACVALS  | DAC Value Register - Shadow |                  | <a href="#">Go</a> |
| 4h     | DACOUTEN | DAC Output Enable Register  | EALLOW           | <a href="#">Go</a> |
| 5h     | DACLOCK  | DAC Lock Register           | EALLOW           | <a href="#">Go</a> |
| 6h     | DACTRIM  | DAC Trim Register           | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 17-4 shows the codes that are used for access types in this section.

**Table 17-4. DAC\_REGS Access Type Codes**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| Read Type                |            |  |
| R                        | R          | Read   |
| R-0                      | R<br>-0    | Read<br>Returns 0s   |
| Write Type               |            |  |
| W                        | W          | Write  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 17.5.2.1 DACREV Register (Offset = 0h) [Reset = 0h]

DACREV is shown in [Figure 17-2](#) and described in [Table 17-5](#).

Return to the [Summary Table](#).

DAC Revision Register

**Figure 17-2. DACREV Register**

## 18.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes one ramp generator. The ramp generator ramps down only. Comparators are denoted "H" or "L" within each module where "H" and "L" represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin (see the *Analog Subsystem* chapter for mux options available to the CMPSS). The negative input can be driven by an external pin or by the programmable reference 12-bit DAC. Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required. A ramp generator circuit is optionally available to control the reference 12-bit DAC value for the high comparator in the subsystem.

### 18.1.1 CMPSS Related Collateral

#### Foundational Materials

### 18.1.2 Features

Each CMPSS includes:

- Two analog comparators
- Two programmable reference 12-bit DACs
- One decrementing ramp generator
- Two digital filters, max filter clock prescale =  $2^{16}$
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to extend clear signal with EPWMBLANK
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDAC

### 18.1.3 Block Diagram

The block diagram for the CMPSS is shown in [Figure 18-1](#).

- CTRIPx(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *Enhanced Pulse Width Modulator (ePWM)* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.

Figure 18-1. CMPSS Module Block Diagram

## 18.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 18-2.

Figure 18-2. Comparator Block Diagram

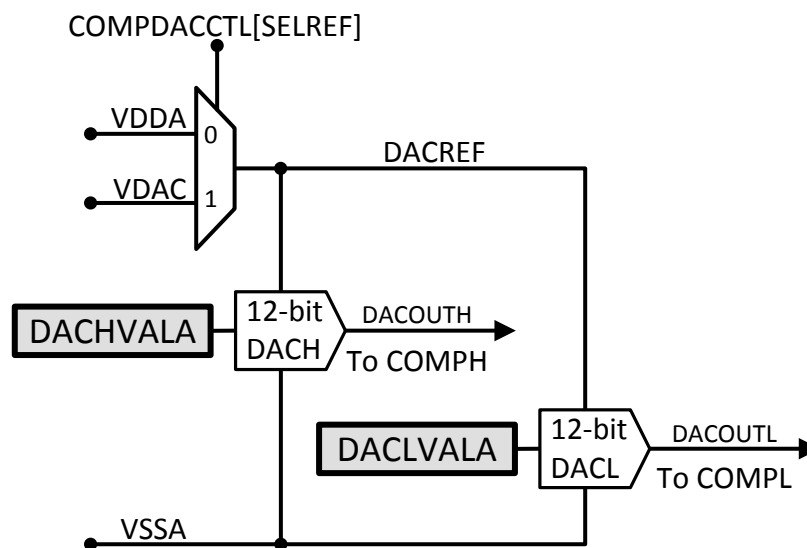

| Voltages              | Output |
|-----------------------|--------|
| Voltage A > Voltage B | 1      |
| Voltage A < Voltage B | 0      |

### 18.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of its respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high reference 12-bit DAC (DACH) can optionally source its DACHVALA value from the ramp generator instead of DACHVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high voltage reference is VDDA by default, but it can be configured to be VDAC. The reference 12-bit DAC is illustrated in [Figure 18-3](#).

**Figure 18-3. Reference DAC Block Diagram**

The ideal output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (8)$$

---

**Note**

The CMPSS instance should be enabled before programming the reference DAC values.

---

## 18.4 Ramp Generator

This section discusses the characteristics of the ramp generator and its behavior.

### 18.4.1 Ramp Generator Overview

The ramp generator produces a falling ramp input for the high reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most significant 12 bits of the RAMPSTS countdown register as its input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling ramp rate configurable with RAMPDECVALA..

The ramp generator is enabled by setting DACSOURCE = 1. On setting DACSOURCE = 1, the value of RAMPSTS is loaded from RAMPMAXREFS and the register remains static until the selected EPWMSYNCPER signal is received. After receiving the selected EPWMSYNCPER signal, the value of RAMPDECVALA. is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a EPWMSYNCPER event, the RAMPDLYA register which serves as a delay counter can be used to hold off the RAMPSTS subtraction. On receiving a EPWMSYNCPER event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. The RAMPSTS subtraction will only begin when RAMPDLYA is zero.

### 18.4.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, EPWMSYNCPER and COMPHSTS.

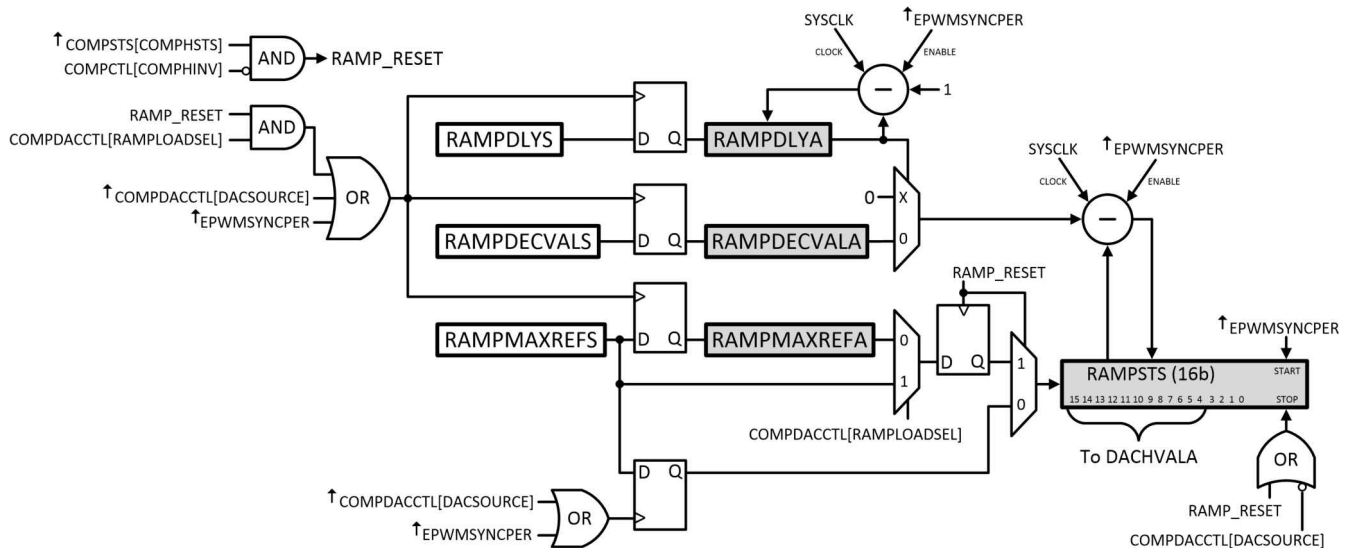

On the rising edge of DACSOURCE, RAMPMAXREFA, RAMPDECVLA and RAMPDLYA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS.

On the rising edge of the selected EPWMSYNCPER, RAMPMAXREFA, RAMPDECVLA and RAMPDLYA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS and starts decrementing when RAMPDLYA counter reaches zero.

On the rising edge of COMPHSTS with RAMPLOADSEL = 1, RAMPMAXREFA, RAMPDECVLA and RAMPDLYA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS and stops decrementing.

On the rising edge of COMPHSTS with RAMPLOADSEL = 0, RAMPSTS is loaded with RAMPMAXREFA and stops decrementing.

Additionally, if the value of RAMPSTS reaches zero, the RAMPSTS register will remain static at zero until the next EPWMSYNCPER is received. These state changes are illustrated in the ramp generator block diagram in [Figure 18-4](#).

**Figure 18-4. Ramp Generator Block Diagram**

### 18.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of EPWMSYNCPER and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before EPWMSYNCPER rising edge. RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on EPWMSYNCPER rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as EPWMSYNCPER rising edge. EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

Case 3: COMPHSTS rising edge occurs one or more cycles after EPWMSYNCPER rising edge but before RAMPDLYA reaches 0. RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from EPWMSYNCPER rising edge. RAMPSTS does not decrement.

This behavior is also illustrated in [Figure 18-5](#).

Figure 18-5. Ramp Generator Behavior

## 18.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than  $SAMPWIN / 2$  and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 18-6.

**Figure 18-6. Digital Filter Behavior**

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
    
```

### 18.5.1 Filter Initialization Sequence

To ensure proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
  - Set SAMPWIN for the number of samples to monitor in the FIFO window.
  - Set THRESH for the threshold required for majority qualification.
  - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch via COMPSTSCLR if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

## 18.6 Using the CMPSS

### 18.6.1 LATCHCLR, EPWMSYNCPER and EPWMBLANK Signals

The LATCHCLR signal holds the digital filter, synchronization block and the latch output in reset (0) after the required delays. It is activated in software using xLATCHCLR(x= "H" or "L"). It can also be activated by EPWMSYNCPER when xSYNCCLREN(x= "H" or "L") is set. If a longer LATCHCLR signal is required, the EPWMBLANK signal can be used to extend it by setting BLANKEN.

EPWMSYNCPER and EPWMBLANK (BLANKWDW) come from the Time-Base and Digital Compare submodules of the EPWM, respectively. For a detailed description of how these two signals are generated, refer to the respective submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACCTL [SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER will be held at level high and DACxVALA will be loaded immediately from DACxVALS irrespective of the value of COMPDACCTL [SWLOADSEL]. Due to this, it is recommended to configure the EPWM first before setting COMPDACCTL [SWLOADSEL] to 1.

---

#### Note

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCL and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

---

### 18.6.2 Synchronizer, Digital Filter and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter will add a delay of 2 sysclks. The latch adds 1 sysclk delay.

### 18.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data manual, the comparator offset error is referred to as **Input referred offset error** and compdac offset error is referred to as **Static offset error**. See the device specific data manual for their values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, it is recommended that the CMPSS be calibrated to ensure trips happen at the expected levels. The flow below outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis should be disabled for calibration. It can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult so it is recommended to use the latch with non-zero filter settings depending on how noisy the signal on the non-inverting input is.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFFF.
  - Optional: Instead of setting the starting compdac value to max, it can be set to **Vtarget + Static offset error + Margin**. Where **Vtarget** is the approximate DC voltage on the non-inverting input, **Static offset error** is the compdac offset error specification and **Margin** is some amount of guard band. This can lead to a faster calibration but will only work if **Vtarget** is known. Alternatively if **Vtarget** is unknown, the ADC can be used to convert it.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
  - Optional: The trip code can be double checked by:
    - a. Increasing compdac value by 1.
    - b. Clear latch.
    - c. Wait for possible latch set.
    - d. Latch should be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

### 18.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and will continue to trip from voltages on its inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA would no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on their current states.

Enabling the clock to the CMPSS restores it to the state before the clock was disabled.

## 18.7 Software

### 18.7.1 CMPSS Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/cmpss

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 18.7.1.1 CMPSS Asynchronous Trip

FILE: cmpss\_ex1\_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO14/OUTPUTXBAR3 pin and CTRIPH to GPIO13/EPWM7B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO13 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,

- Trip signal(GPIO14) output is low
- PWM7B(GPIO13) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,

- Trip signal(GPIO14) output turns high
- PWM7B(GPIO13) gets tripped and outputs as high

#### External Connections

- Give input on CMPIN1P (The pin is shared with ADCINA2)
- Outputs can be observed on GPIO14 and GPIO13 using an oscilloscope

#### Watch Variables

- None

#### 18.7.1.2 CMPSS Digital Filter Configuration

FILE: cmpss\_ex2\_digital\_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO14/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,

- GPIO14 output is low

When a high input(higher than VDD/2) is provided to CMPIN1P,

- GPIO14 output turns high

## 18.8 CMPSS Registers

This section describes the CMPSS Registers.

### 18.8.1 CMPSS Base Address Table

**Table 18-1. CMPSS Base Address Table**

| Bit Field Name |            | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|------------|----------------|--------------|------|-----|-----|-----|--------------------|

The sigma delta filter module (SDFM) is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma ( $\Delta\Sigma$ ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

### 19.1.2 Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Different configurable modulator clock modes supported:
  - Mode 0: Modulator clock rate equals the modulator data rate.
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
    1. Two independent Higher Threshold comparators (used to detect over-value condition)
    2. Two independent Lower Threshold comparators (used to detect under-value condition)
    3. One independent Threshold-Crossing comparator (used to measure duty cycle/frequency with eCAP)
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32

Four independent configurable primary filter (data filter) units per SDFM module:

- Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
- OSR value for data filter unit (DOSR) programmable from 1 to 256
- Ability to enable or disable (or both) individual filter module
- Ability to synchronize all four independent filters of an SDFM module by using the Main Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- Data filter unit has a programmable mode FIFO to reduce interrupt overhead. The FIFO has the following features:
  - The primary filter (data filter) has a 16-deep x 32-bit FIFO.
  - The FIFO can interrupt the CPU after programmable number of data-ready events.
  - FIFO Wait-for-Sync feature: Ability to ignore data-ready events until the PWM synchronization signal (SDSYNC) is received. Once the SDSYNC event is received, the FIFO is populated on every data-ready event.
  - Data filter output can be represented in either 16 bits or 32 bits.
- PWMx.SOCA/SOCB can be configured to serve as SDSYNC source on a per-data-filter-channel basis.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.
- Configurable Input Qualification available for both SD-Cx and SD-Dx
- Ability to use one filter channel clock (SD-C1) to provide clock to other filter clock channels.
- Configurable digital filter available on comparator filter events to blankout comparator events caused by spurious noise

### 19.1.3 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

Figure 19-2 shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in Section 19.12.

Figure 19-2. Sigma Delta Filter Module (SDFM) Block Diagram

Each filter module shown in Figure 19-3 has a primary (data) filter and a secondary (comparator) filter pair that receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

Figure 19-3. Block Diagram of One Filter Module

## 19.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, the following GPIO input qualification can be used. Other GPIO qualifications are not supported.

- If GPIO Input qualification is ASYNC, make sure to check the SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware of the following caution message.

### CAUTION

The SDFM clock inputs (SDx\_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions should be taken on these signals to ensure a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

### Note

The SDFM module expects SD-Dx to change on the falling edge of SD-Cx and strobes for SD-Dx on the rising edge. But some SD-modulators in the market change SD-Dx on the rising edge and expect SDFM to strobe for data on the falling edge. In such cases, the GPIO inversion feature (GPxINV) is used on SD-Cx pin to change polarity and make it compatible with the SDFM.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

### 19.3 Input Qualification

Impulse noise sources such as EMI, crosstalk, and so on, has the possibility of corrupting SDCLK and SDDATA bit streams, resulting in corrupted SDFM filtered data. This impulse noise effects could be mitigated when using the input qualification feature which synchronizes SDCLK / SDDATA signals with PLLCLK. By default, both SDCLK and SDDATA bit stream are not synchronized. SDCLK can be synchronized to PLLCLK by setting SDCTLPARAMx.SDCLKSYNC = 1 and SDDATA can be synchronized to PLLCLK by setting SDCTLPARAMx.SDDATASYNC = 1. [Figure 19-4](#) shows optional Input Qualification option on SDCLK and SDDATA lines.

**Figure 19-4. Input Qualification on SD-Cx and SD-Dx**

## 19.4 Input Control Unit

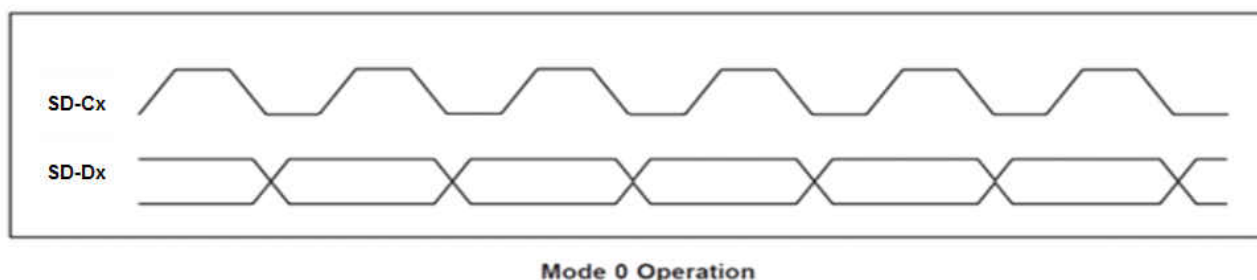

The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in Mode 0. [Table 19-1](#) and [Figure 19-5](#) show how SDCTLPARMx.MOD bits can be configured in Mode 0.

**Table 19-1. Modulator Clock Modes**

| Modulator Mode [MOD] | Description   |
|----------------------|---|
| 0                    | The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock. |
| 1                    | Reserved  |
| 2                    | Reserved  |
| 3                    | Reserved  |

### Note

In order to achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

**Figure 19-5. Different Modulator Modes Supported**

## 19.5 SDFM Clock Control

In systems, the modulator clock could be generated using PWMs. Assuming all the SD-CLKs see the same delay on board traces, you could potentially use just one clock to clock multiple filters, thereby saving on the number of pins used for SDFM. In order to enable this Filter1 SDCLK (SD-C1) can possibly be fed to other filter channels if required. SDCTLPARAMx.SDCLKSEL register bit field can be configured to select filter channel SDCLK. See [Figure 19-6](#) to view this feature.

Figure 19-6. SDFM Clock Control

### 19.6 Sinc Filter

Both comparator filter and data filter available in SDFM have the Sinc<sup>N</sup> filter as its core. The Sinc<sup>N</sup> filter is essentially a low-pass filter that converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc<sup>N</sup> architecture consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 19-7. The Z-transfer function of the Sinc filter of order N is shown in Figure 19-8.

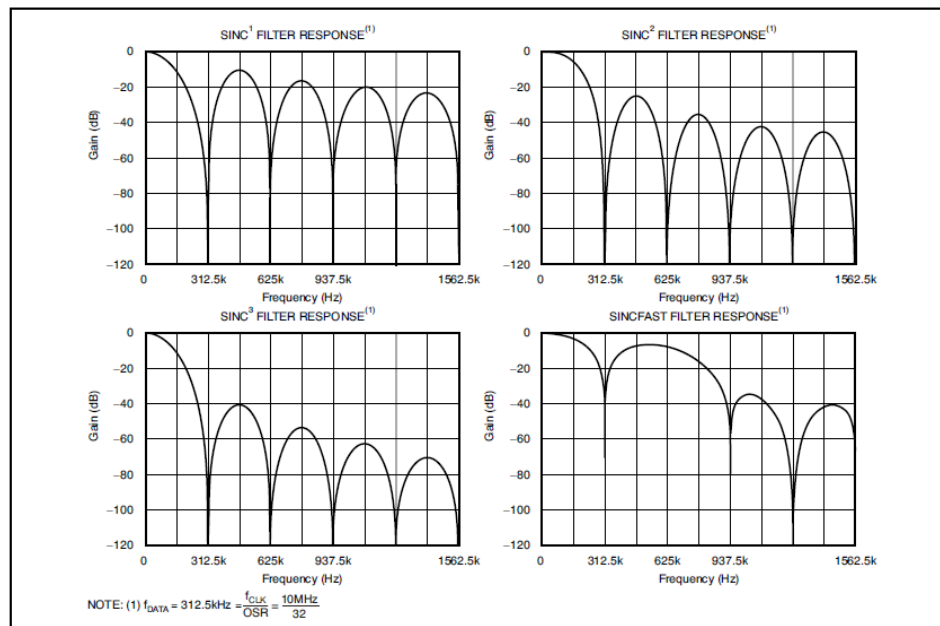

Figure 19-7. Simplified Sinc Filter Architecture

$$H(Z) = \left[ \frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^N$$

**N** = Order of Sinc filter  
**OSR** = Over Sampling Ratio

**Figure 19-8. Z-Transform of Sinc Filter of Order N**

Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution (or) ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator datasheet to determine the effective resolution for a given Sinc filter configuration. [Figure 19-9](#) shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10 MHz.

**Figure 19-9. Frequency Response of Different Sinc Filters**

The order of different sinc filter is shown in [Table 19-2](#).

**Table 19-2. Order of Sinc Filter**

| Filter Type | Order of Sinc Filter |
|-------------|----------------------|
| Sinc1       | 1                    |
| Sinc2       | 2                    |
| Sinc3       | 3                    |
| SincFast    | 3                    |

### 19.6.1 Data Rate and Latency of the Sinc Filter

The data rate of the sinc filter (filter throughput) represented in samples/sec is calculated by the following formula:

$$\text{Data rate of Sinc filter} = \frac{\text{Modulator data rate}}{\text{OSR}} \quad (9)$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency is calculated by the following formula:

$$\text{Latency of Sinc filter} = \frac{\text{Order of Sinc filter}}{\text{Data rate of Sinc filter}} \quad (10)$$

#### Example configuration:

|                          |                                       |
|--------------------------|---------------------------------------|
| Sinc filter type         | = sinc3                               |
| Modulator data rate      | = 10 MHz                              |
| OSR                      | = 256                                 |
| Data rate of Sinc Filter | = 10 MHz / 256 = 39.1 K samples / sec |
| Sinc filter latency      | = 76.8 $\mu$ s                        |
| Sinc filter type         | = sinc2                               |
| Modulator data rate      | = 10 MHz                              |
| OSR                      | = 256                                 |
| Data rate of Sinc Filter | = 10 MHz / 256 = 39.1 K samples / sec |
| Sinc filter latency      | = 51.2 $\mu$ s                        |

### 19.7 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDFPARMx.FEN = 1 enables the data filter. The data filter output is represented in 26-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. [Table 19-3](#) shows the different full scale values that the data filter can store using different OSRs.

See [Section 19.6.1](#) to understand how to calculate data rate and latency of data filter.

**Table 19-3. Peak Data Values for Different DOSR/Filter Combinations**

| DOSR | Sinc1       | Sinc2             | Sinc3                     | SincFast            |
|------|-------------|-------------------|---------------------------|---------------------|
| x    | x           | x <sup>2</sup>    | x <sup>3</sup>            | 2x <sup>2</sup>     |
| 4    | -4 to 4     | -16 to 16         | -64 to 64                 | -32 to 32           |
| 8    | -8 to 8     | -64 to 64         | -512 to 512               | -128 to 128         |
| 16   | -16 to 16   | -256 to 256       | -4096 to 4096             | -512 to 512         |
| 32   | -32 to 32   | -1024 to 1024     | -32,768 to 32,768         | -2048 to 2048       |
| 64   | -64 to 64   | -4096 to 4096     | -262,144 to 262,144       | -8192 to 8192       |
| 128  | -128 to 128 | -16,384 to 16,384 | -2,097,152 to 2,097,152   | -32,768 to 32,768   |
| 256  | -256 to 256 | -65,536 to 65,536 | -16,777,216 to 16,777,216 | -131,072 to 131,072 |

### 19.7.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

#### 32-bit data filter representation:

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits do not have any bearing on the output of the data filter in this configuration.

#### 16-bit data filter representation:

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

For example, for the data filter configuration below:

- Filter type = Sinc3
- OSR = 128
- SDDPARMx.DR = 0

The data filter with a 26-bit signed output value can be in the range of  $-16,777,216$  to  $16,777,216$ . But, 16-bit signed output supports values only from  $-32,768$  to  $32,767$ . Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. Table 19-4 shows the configuration settings of shift control bits for different OSR and filter types.

**Table 19-4. Shift Control Bit Configuration Settings**

| OSR        | Sinc1 | Sinc2 | SincFast | Sinc3 |
|------------|-------|-------|----------|-------|
| 1 to 31    | 0     | 0     | 0        | 0     |
| 32 to 40   | 0     | 0     | 0        | 1     |
| 41 to 50   | 0     | 0     | 0        | 2     |
| 51 to 63   | 0     | 0     | 0        | 3     |
| 64 to 80   | 0     | 0     | 0        | 4     |
| 81 to 101  | 0     | 0     | 0        | 5     |
| 102 to 127 | 0     | 0     | 0        | 6     |
| 128 to 161 | 0     | 0     | 1        | 7     |
| 162 to 181 | 0     | 0     | 1        | 8     |
| 182 to 203 | 0     | 1     | 2        | 8     |
| 204 to 255 | 0     | 1     | 2        | 9     |
| 256        | 0     | 2     | 3        | 10    |

#### CAUTION

Configuring shift control bits incorrectly will result in getting incorrect 16-bit data filter output.

### 19.7.2 Data FIFO

Each primary (data) filter channel has a 16-level deep, 32-bit FIFO.

FIFOs can be configured to collect a programmable number of data filter samples before issuing data-ready interrupt. This reduces the number of data-ready interrupts generated and resulting interrupt overhead for managed data flow.

By default, FIFO operation is disabled. FIFOs can be enabled by setting SDFIFOCTLx.FFEN = 1. When FIFO is enabled, each data-ready event from the data filter will populate the FIFO, and the status of the FIFO at any given time is updated in the SDFIFOCTLx.SDFFST bit field.

### Setting up FIFO to interrupt after receiving programmable number of data ready events:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Configure SDFIFOCTLx.SDFFIL bit field to any value between 0 to 16
- Configure SDFM data ready event to interrupt on FIFO interrupt (SDFFINT) (Set SDFFINTx = 1)
- Select data-ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

When the SDFIFOCTLx.SDFFST  $\geq$  SDFIFOCTLx.SDFFIL condition is met, the SDIFLG.SDFFINTx bit is set and an interrupt is generated on the DRINTx. SDIFLG.SDFFINTx flag can be cleared by setting the SDIFLGCLR.SDFFINTx bit field.

### Wait for Sync feature:

The FIFO wait for sync feature can be used to ignore data-ready events from the data filter until the SDSYNC (from PWM) event is triggered.

By default, the Wait for Sync feature is disabled. This feature can be enabled by setting SDSYNcx.WTSYNcEN = 1

### When the wait for sync feature is disabled:

FIFOs get populated on every data ready event until the FIFO gets full (or) when SDFIFOCTLx.SDFFST  $\geq$  SDFIFOCTLx.SDFFIL.

### When the wait for sync feature enabled:

FIFOs will not be get populated on every data ready event until it receives a SDSYNC event. On a SYSYNC event, it sets SDSYNcx.WTSYNFLG = 1 and data ready events from primary filter will start populating FIFO until either the FIFOs get full (or) when SDFIFOCTLx.SDFFST  $\geq$  SDFIFOCTLx.SDFFIL. WTSYNFLG can be cleared either automatically (or) manually.

When WTSYNFLG = 0, FIFOs contents are frozen and subsequent data ready events don't get populate FIFO until next SDSYNC event.

### WTSYNFLG automatic clear mode:

By default, this mode is enabled. When SDSYNcx.WTSClREN = 1, WTSYNFLG is automatically cleared on SDFFINT event.

### WTSYNFLG manual clear mode:

Setting SDSYNcx.WTSYNCLR = 1 can be used to clear WTSYNFLG manually.

### Clearing FIFO contents:

FIFO contents can be cleared by any of the following methods:-

- Disabling FIFO clear FIFO contents. This can be done by clearing SDFIFOCTLx.FFEN = 0.
- Disabling Primary filter clear FIFO contents. This can be done by either clearing SDDFPARMx.FEN = 0 (or) by clearing SDMFILEN.MFE = 0.
- FIFO contents can also be automatically cleared upon receiving the SDSYNC event. By default, this feature is disabled and this feature can be enabled by setting FIFO Clear-on-SDSYNC enable (SDSYNcx.FFSYNcCLREN = 1).

**Note:** The above feature is only enabled when wait for sync feature is enabled (SDSYNcx.WTSYNcEN = 1).

### FIFO debug access behavior:

Debug access of SDDATFIFOx registers does not affect FIFO pointers. On a CPU / CLA / DMA access to SDDATFIFOx register, FIFO read pointers would be advanced to next available entry in FIFO.

### 19.7.3 SDSYNC Event

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting `SDDFPARMx.SDSYNCEN = 1`. Each primary filter can be synchronized from any of the available PWMx. SOCA / SOCB signals (see [Table 19-5](#)). The `SDSYNcx.SDSYNCSSEL` bits allow the user to configure which PWM signal provides the SDSYNC pulse to the primary filter. [Figure 19-10](#) shows how the PWM signals are connected to SDFM.

**Table 19-5. SDSYNcx.SYNCSSEL**

| SYNCSSEL[5:2] | SDSYNcx.SYNCSSEL[1:0] |           |      |      |
|---------------|-----------------------|-----------|------|------|
|               | 0                     | 1         | 2    | 3    |
| 0             | PWM1.SOCA             | PWM1.SOCB | Rsvd | Rsvd |
| 1             | PWM2.SOCA             | PWM2.SOCB | Rsvd | Rsvd |
| 2             | PWM3.SOCA             | PWM3.SOCB | Rsvd | Rsvd |
| 3             | PWM4.SOCA             | PWM4.SOCB | Rsvd | Rsvd |
| 4             | PWM5.SOCA             | PWM5.SOCB | Rsvd | Rsvd |
| 5             | PWM6.SOCA             | PWM6.SOCB | Rsvd | Rsvd |
| 6             | PWM7.SOCA             | PWM7.SOCB | Rsvd | Rsvd |
| 7             | PWM8.SOCA             | PWM8.SOCB | Rsvd | Rsvd |
| 8             | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 9             | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 10            | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 11            | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 12            | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 13            | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 14            | Rsvd                  | Rsvd      | Rsvd | Rsvd |
| 15            | Rsvd                  | Rsvd      | Rsvd | Rsvd |

**Figure 19-10. SDSYNC Event**

---

### Note

Ensure that ONLY ONE SDSYNC event will be generated per PWM timer period. Using PWM in up-count or down-count mode would automatically ensure that you get ONLY SDSYNC event. But, if up-down count mode is used, then make sure that only one SDSYNC event per PWM cycle is generated; otherwise, the filter synchronizer will corrupt SDFM timing by providing two pulses per PWM cycle.

---

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type will be incorrect. [Table 19-6](#) shows the number of incorrect samples on the following conditions:

- When Sinc filter is enabled / configured for first time.
- When Sinc filter is disabled / re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

**Table 19-6. Number of Incorrect Samples Tabulated**

| Filter Type | Number of Incorrect Samples After the Filter is Enabled and Configured |
|-------------|--|
| Sinc1       | No incorrect sample  |
| Sinc2       | The first sample of the Sinc2 filter is incorrect                      |
| SincFast    | The first two samples of the SincFast filter are incorrect             |
| Sinc3       | The first two samples of the Sinc3 filter are incorrect                |

### CAUTION

SDFM comparator interrupts should be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (CEVT1 and CEVT2) should be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and five SD-Cx clock cycles.

## 19.8 Comparator (Secondary) Filter Unit

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

---

### Note

The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

---

The comparator filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is disabled and setting SDCPARMx.CEN = 1 enables the comparator filter. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as '0' and a high input signal as '1'. The resulting calculations give only positive values for the output of the comparator filter. [Table 19-7](#) shows the different full-scale values that the comparator filter can store using different OSRs.

**Table 19-7. Peak Data Values for Different OSR/Filter Combinations**

| OSR | Sinc1   | Sinc2               | Sinc3               | SincFast             |
|-----|---------|---------------------|---------------------|----------------------|
| x   | 0 to x  | 0 to x <sup>2</sup> | 0 to x <sup>3</sup> | 0 to 2x <sup>2</sup> |
| 4   | 0 to 4  | 0 to 16             | 0 to 64             | 0 to 32              |
| 8   | 0 to 8  | 0 to 64             | 0 to 512            | 0 to 128             |
| 16  | 0 to 16 | 0 to 256            | 0 to 4096           | 0 to 512             |
| 32  | 0 to 32 | 0 to 1024           | 0 to 32,768         | 0 to 2048            |

See [Section 19.6.1](#) to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is memory-mapped and can be read in the SDCDATAx register. This register, SDCDATAx, is updated every COSR number of SD-Cx cycles. The comparator filter digital output is connected to digital comparators explained below.

Figure 19-11. Comparator Unit Structure

### 19.8.1 Higher Threshold (HLT) Comparators

- High threshold comparator can be used to detect over-value condition.
- When comparator data  $\geq$  higher threshold register, a high threshold event is generated.
- Higher threshold comparator events except for COMPHZx can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has three High Threshold comparators:
  - **Higher Threshold 1 (HLT1) Comparator :**
    - When comparator data  $\geq$  (SDFLTxCMPH1.HLT), HLT1 comparator generates COMPH1 event.
    - The COMPH1 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold 2 (HLT2) Comparator**
    - When comparator data  $\geq$  (SDFLTxCMPH2.HLT), HLT2 comparator generates COMPH2 event.
    - The COMPH2 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold (HTLZ) Comparator**
    - When comparator data  $\geq$  (SDFLT1CMPHZ.CMPHZ), it can generate a Higher Threshold (B) event (COMPHZx) and sets the corresponding SDSTATUS.HZx flag. But, this event cannot be configured to generate SDFM interrupt (SDx\_ERR). The COMPHZ signals from HTLZ comparator are connected to CLB XBAR.

### 19.8.2 Lower Threshold (LLT) Comparators

- The low threshold comparator can be used to detect under-value condition.
- When comparator data  $\leq$  Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events : CPU interrupt, CLA task, PWM trip.
- Lower threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of Threshold crossing
- This device has two low threshold comparators.
  - **Lower Threshold 1 (LLT1) Comparator**
    - When comparator data  $\leq$  (SDFLTxCMPL1.LLT), the LLT1 comparator generates COMPL1 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.
  - **Lower Threshold 2 (LLT2) Comparator**
    - When comparator data  $\leq$  (SDFLTxCMPL2.LLT), LLT2 comparator generates COMPL2 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.

### 19.8.3 Digital Filter

The digital filter works on a window of FIFO samples ( $SAMPWIN + 1$ ) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than  $SAMPWIN / 2$ .

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every CLKPRESCALE system clocks. Old data from the FIFO is discarded.

A conceptual model of the digital filter is shown in Figure 19-12.

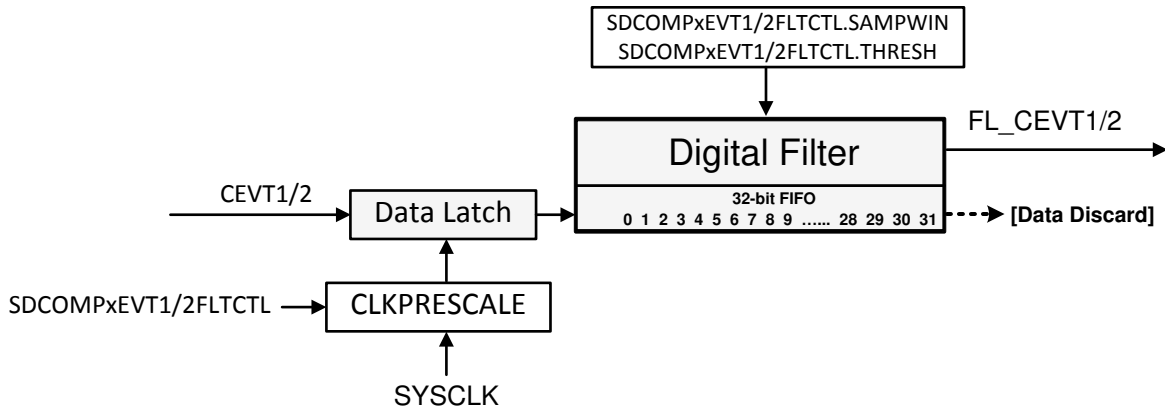

Figure 19-12. Digital Filter

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}

```

#### Filter Initialization Sequence

To ensure proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure the digital filter parameters for operation:
  - Set SAMPWIN for the number of samples to monitor in the FIFO window.
  - Set THRESH for the threshold required for majority qualification.
  - Set CLKPRESCALE for the digital filter clock prescale value.
2. Initialize the sample values in the digital FIFO window by setting FILINIT = 1.

## 19.9 Theoretical SDFM Filter Output

The following equations can be used to derive a theoretical filter output of an SDFM filter output for both a comparator filter and a data filter.

$$\text{Density of ones in bitstream} = \frac{\text{Input Voltage} + V_{\text{clipping}}}{2 \times V_{\text{clipping}}} \quad (11)$$

Where:

- $V_{\text{clipping}}$  = maximum differential voltage input range of modulator
- Input voltage = Differential input voltage applied to the modulator

$$\begin{aligned} \text{Comparator Filter Output (Theoretical)} = \\ \text{Density of ones in bitstream} \times \text{Maximum Filter Output (FilterType, COSR)} \end{aligned} \quad (12)$$

$$\text{FilterOutput} = \left\{ \frac{\text{absolute}(\text{Input voltage})}{V_{\text{clipping}}} \right\} \times \text{Maximum Filter Output (FilterType, DOSR)} \quad (13)$$

$$\text{Data Filter Output}_{32\text{bit}}(\text{Theoretical}) = \begin{cases} \text{FilterOutput} & \text{if Input Voltage is +ve voltage} \\ 2\text{'s complement} & \text{if input voltage is -ve voltage} \\ \text{of FilterOutput} & \end{cases} \quad (14)$$

$$\begin{aligned} \text{Data Filter Output}_{16\text{bit}}(\text{Theoretical}) = \\ \text{Data Filter Output}_{32\text{bit}}(\text{Theoretical}) \gg \text{Shift value}(\text{FilterType, OSR}) \end{aligned} \quad (15)$$

For example, when using the AMC1306x25 modulator:

|                      |  |                  |
|----------------------|--|------------------|
| AMC1306x25           | Vclipping =<br>Input voltage (AINP - AINN) =                         | 320 mV<br>100 mV |
| SDFM filter settings | Filter type =<br>Comparator OSR (COSR) =<br>Data filter OSR (DOSR) = | 3<br>32<br>100   |

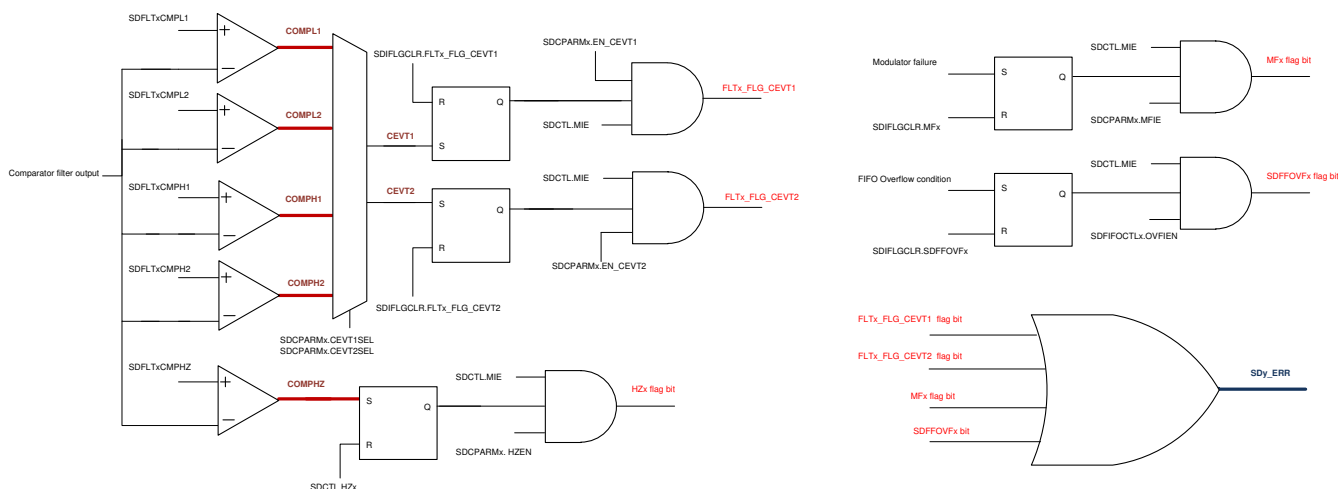

|  |   |         |
|--|---|---------|
| Density of ones in bitstream   | Using <a href="#">Equation 11</a>                                 | 0.65625 |
| Comparator filter output<br>Filter type = Sinc3<br>COSR = 32                           | Using <a href="#">Equation 12</a>                                 | 21504   |
| Data filter output (32-bit)<br>Filter type = Sinc3<br>DOSR = 100                       | Using <a href="#">Equation 13</a> and <a href="#">Equation 14</a> | 312500  |
| Data filter output (32-bit)<br>Filter type = Sinc3<br>DOSR = 100<br>(Right shift by 5) | Using <a href="#">Equation 15</a>                                 | 9765    |

## 19.10 Interrupt Unit

Each SDFM can generate five CPU interrupts such as SDFM Error (SDy\_ERR) and SDFM data ready (SDy\_DRINT1 / SDy\_DRINT2, SDy\_DRINT3, SDy\_DRINT4) interrupts for each filter module.

### 19.10.1 SDFM (SDyERR) Interrupt Sources

Figure 19-13 shows the structure of SDy\_ERR interrupt. SDy\_ERR interrupt can be triggered by any of these 16 events.

**Figure 19-13. SDFM Error (SD\_ERR) Interrupt Sources**

#### 1. Comparator Event1 (CEVT1)

CEVT1 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator Event1 interrupt (SDCPARMx.EN\_CEV1 = 1)

On a CEVT1 event, SDIFLG.FLTx\_FLG\_CEV1 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 2. Comparator Event2 (CEVT2)

CEVT2 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator event1 interrupt (SDCPARMx.EN\_CEV2 = 1)

On a CEVT2 event, SDIFLG.FLTx\_FLG\_CEV2 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

### 3. Modulator Failure (MFx) event

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

### 4. FIFO overflow (SDFFOVx) event

The number of filter data available in FIFO at any given point can be tracked in SDFIFOCTLx.SDFFST. If the number of words received in FIFO is greater than Max FIFO depth (16), SDFFOVx event is generated. SDFFOVx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt, only if below configurations are made:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO overflow interrupt (Set SDFIFOCTLx.OVFIEN = 1) and
- Enable Main interrupt enable (Set SDCTL.MIE = 1)

On a SDFFOVx event, all subsequent data (primary) filter data is lost and is not stored in FIFO. SDIFLG.SDFFOVx flag bit is set on a FIFO overflow event and this bit can be cleared if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 19.10.2 Data Ready (DRINT) Interrupt Sources

Figure 19-14 shows the structure of interrupt SDy\_DRINTx interrupt. Each SDy\_DRINTx interrupt is triggered by corresponding Data Filter channel.

Figure 19-14. SDFM Data Ready (SDy\_DRINTx) Interrupt

## 1. Data Acknowledge (AFx)

When the primary filter is ready with a new filter data, AFx event is generated. AFx events from each filter can generate its own SDy\_DRINTx interrupt. This event can be configured to trigger SDy\_DRINTx interrupt only if below configurations are made:

- Enable individual filter interrupts (SDDFPARMx.AE = 1)
- Select data-ready interrupt source AFx (DRINTx = AFx) (SDFIFOCTLx.DRINTSEL = 0)

On an AFx event, the SDIFLG.AFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 2. Four FIFO Data ready interrupt (SDFINTx)

FIFO Data Ready event is generated whenever SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met. FIFO data ready events from each filter can generate its own SDy\_DRINTx interrupt. This event can be configured to trigger SDy\_DRINTx interrupt only if below configurations are made:

Table 19-8 shows how the DRINTx output is selected.

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1) and
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Select data-Ready interrupt source is SDFINTx (DRINTx = SDFINTx) (SDFIFOCTLx.DRINTSEL = 1)

**Table 19-8. SDFM Data-Ready Interrupt (SDy\_DRINTx) Output Selection**

| DRINTSEL | AE | FFIEN | FFEN | DRINTx  |
|----------|----|-------|------|---------|
| 0        | 0  | x     | X    | 0       |
| 0        | 1  | x     | X    | AFx     |
| 1        | x  | 0     | X    | 0       |
| 1        | x  | x     | 0    | 0       |
| 1        | x  | 1     | 1    | SDFINTx |

## 19.11 Software

### 19.11.1 SDFM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/sdfm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 19.11.1.1 SDFM Filter Sync CPU

FILE: `sdfm_ex1_filter_sync_cpuread.c`

In this example, SDFM filter data is read by CPU in SDFM ISR routine. The SDFM configuration is shown below:

- SDFM used in this example - SDFM1
- Input control mode selected - MODE0
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - HLT = 0x7FFF (Higher threshold setting)
  - LLT = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 128
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 7 bits for Sinc3 filter with OSR = 128
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available.

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO46-GPIO61

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 19.11.1.2 SDFM Filter Sync CLA

FILE: `sdfm_ex2_filter_sync_claread.c`

In this example, SDFM filter data is read by CLA in Cla1Task1. The SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000(Lower threshold setting)

- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO46-GPIO61

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 19.11.1.3 SDFM Filter Sync DMA

FILE: `sdfm_ex3_filter_sync_dmaread.c`

In this example, SDFM filter data is read by DMA. The SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO46-GPIO61

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 19.11.1.4 SDFM PWM Sync

FILE: `sdfm_ex4_pwm_sync_cpuread.c`

In this example, SDFM filter data is read by CPU in SDFM ISR routine. The SDFM configuration is shown below:

- SDFM1 is used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000 (Lower threshold setting)

#### Data filter settings

- All the 4 filter modules enabled
- Sinc3 filter selected
- OSR = 256
- All the 4 filters are synchronized by using PWM (Master Filter enable bit)
- Filter output represented in 16 bit format
- In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256

#### Interrupt module settings for SDFM filter

- All the 4 higher threshold comparator interrupts disabled
- All the 4 lower threshold comparator interrupts disabled
- All the 4 modulator failure interrupts disabled
- All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO46-GPIO61

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 19.11.1.5 SDFM Type 1 Filter FIFO

FILE: `sdfm_ex5_type1_filter_fifo_cpuread.c`

This example configures SDFM1 filter in type 1 to demonstrate data read through CPU in FIFO & non-FIFO mode. Data filter is configured in mode 0 to select SINC3 filter with OSR of 256. Filter output is configured for 16-bit format and data shift of 10 is used.

This example demonstrates the FIFO usage if enabled. FIFO length is set at 16 and data ready interrupt is configured to be triggered when FIFO is full. In this example, SDFM filter data is read by CPU in SDFM Data Ready ISR routine.

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams (SD1-D1, SD1-C1) to (GPIO16, GPIO17)

- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO48, GPIO49)

#### Watch Variables

- *filter1Result* - Output of filter 1

#### 19.11.1.6 SDFM Filter Sync CLA

FILE: `sdfm_ex6_FIFO_freeze_claread.c`

In this example, SDFM FIFO will not be filled until a SDSYNC event. On a SDSYNC event, SDFM data filter output will start filling FIFO and stop filling after programmable number 'N' of FIFO is filled.

SDy-C1 (Filter1 channel clock) is internally configured to connected SDy-C2 / SDy-C3 / SDy-C4 SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000 (Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO46-GPIO61

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

## 19.12 SDFM Registers

This section describes the Sigma Delta Filter Module registers.

### 19.12.1 SDFM Base Address Table

**Table 19-9. SDFM Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| Sdfm1Regs      | SDFM_REGS | SDFM1_BASE     | 0x0000_5E00  | YES  | YES | YES | YES | YES                |
| Sdfm2Regs      | SDFM_REGS | SDFM2_BASE     | 0x0000_5E80  | YES  | YES | YES | YES | YES                |

### 19.12.2 SDFM\_REGS Registers

Table 19-10 lists the memory-mapped registers for the SDFM\_REGS registers. All register offset addresses not listed in Table 19-10 should be considered as reserved locations and the register contents should not be modified.

**Table 19-10. SDFM\_REGS Registers**

| Offset | Acronym     | Register Name                                   | Write Protection | Section            |
|--------|-------------|---|------------------|--------------------|
| 0h     | SDIFLG      | SD Interrupt Flag Register                      |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. [Table 19-11](#) shows the codes that are used for access types in this section.

**Table 19-11. SDFM\_REGS Access Type Codes**

| Access Type              | Code  | Description  |
|--------------------------|-------|--|
| Read Type                |       |  |
| R                        | R     | Read   |
| R-0                      | R-0   | Read Returns 0s  |
| Write Type               |       |  |
| W                        | W     | Write  |
| W1S                      | W1S   | Write 1 to set   |
| WOnce                    | WOnce | Write Set once   |
| Reset or Default Value   |       |  |
| -n                       |       | Value after reset or the default value   |
| Register Array Variables |       |  |
| i,j,k,l,m,n              |       | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |       | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 19.12.2.1 SDIFLG Register (Offset = 0h) [Reset = 0h]

SDIFLG is shown in [Figure 19-15](#) and described in [Table 19-12](#).

Return to the [Summary Table](#).

SD Interrupt Flag Register

**Figure 19-15. SDIFLG Register**

|                    |                    |                    |                    |                    |                    |                    |                    |

### 19.12.2.2 SDIFLGCLR Register (Offset = 2h) [Reset = 0h]

SDIFLGCLR is shown in [Figure 19-16](#) and described in [Table 19-13](#).

Return to the [Summary Table](#).

SD Module Interrupt Flag Clear Bits:

Writing a "1" will clear the respective flag bit in the SDIFLG register.

Writes of "0" are ignored.

Note: If user writes a "1" to clear a bit on the same cycle that the hardware is trying to set the bit to "1", then hardware has priority and the bit will not be cleared.

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital to analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 4 with added register protection capability. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

Further information can be found in the [Flexible PWMs Enable Multi-Axis Drives, Multi-Level Inverters Technical Brief](#).

## 20.1 Introduction

This chapter includes an overview and information about each submodule:

- Time-Base Submodule
- Counter Compare Submodule
- Action Qualifier Submodule
- Dead-Band Generator Submodule
- PWM Chopper (PC) Submodule
- Trip Zone Submodule
- Event Trigger Submodule
- Digital Compare Submodule

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map**

Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.

- **Delayed Trip Functionality**

Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform will not take place immediately. Instead, they will synchronize to the next TBCLK.

- **Dead-Band Generator Submodule Enhancements**

Shadowing of the DBCTL register to allow dynamic configuration changes.

- **One Shot and Global Load of Registers**

The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. It also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and ensuring that all registers are loaded at the same time.

- **Trip Zone Submodule Enhancements**

Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip zone submodule to support certain power converter switching techniques like valley switching.

- **Digital Compare Submodule Enhancements**

Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.

- **PWM SYNC Related Enhancements**

The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High Resolution Dead-Band Capability**

High resolution capability is added to dead-band RED and FED in half-cycle clocking mode.

- **Dead-Band Generator Submodule Enhancements**

The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed

- **High Resolution Extension available on ePWMxB outputs**

Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in [Section 20.15](#).

- **Counter Compare Submodule Enhancements**

The ePWM Type 2 allows Interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.

- **Event Trigger Submodule Enhancements**

Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. It allows software initialization of event counters on SYNC event.

- **Digital Compare Submodule Enhancements**

Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.

- **Simultaneous Writes to TBPRD and CMPx Registers**

This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.

- **Shadow to Active Load on SYNC of TBPRD and CMP Registers**

This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

### Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution**

Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.

- **Enhanced Interrupt and SOC Generation**

Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.

- **High Resolution Period Capability**

Provides the ability to enable high-resolution period. This is discussed in more detail in the device-specific *High-Resolution Pulse Width Modulator (HRPWM)* document..

- **Digital Compare Submodule**

The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

### Note

The name of the sync signal that goes to the CMPSS has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see [Table 20-2](#).

## 20.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 20-1](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 20.15](#). See the device-specific data manual to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

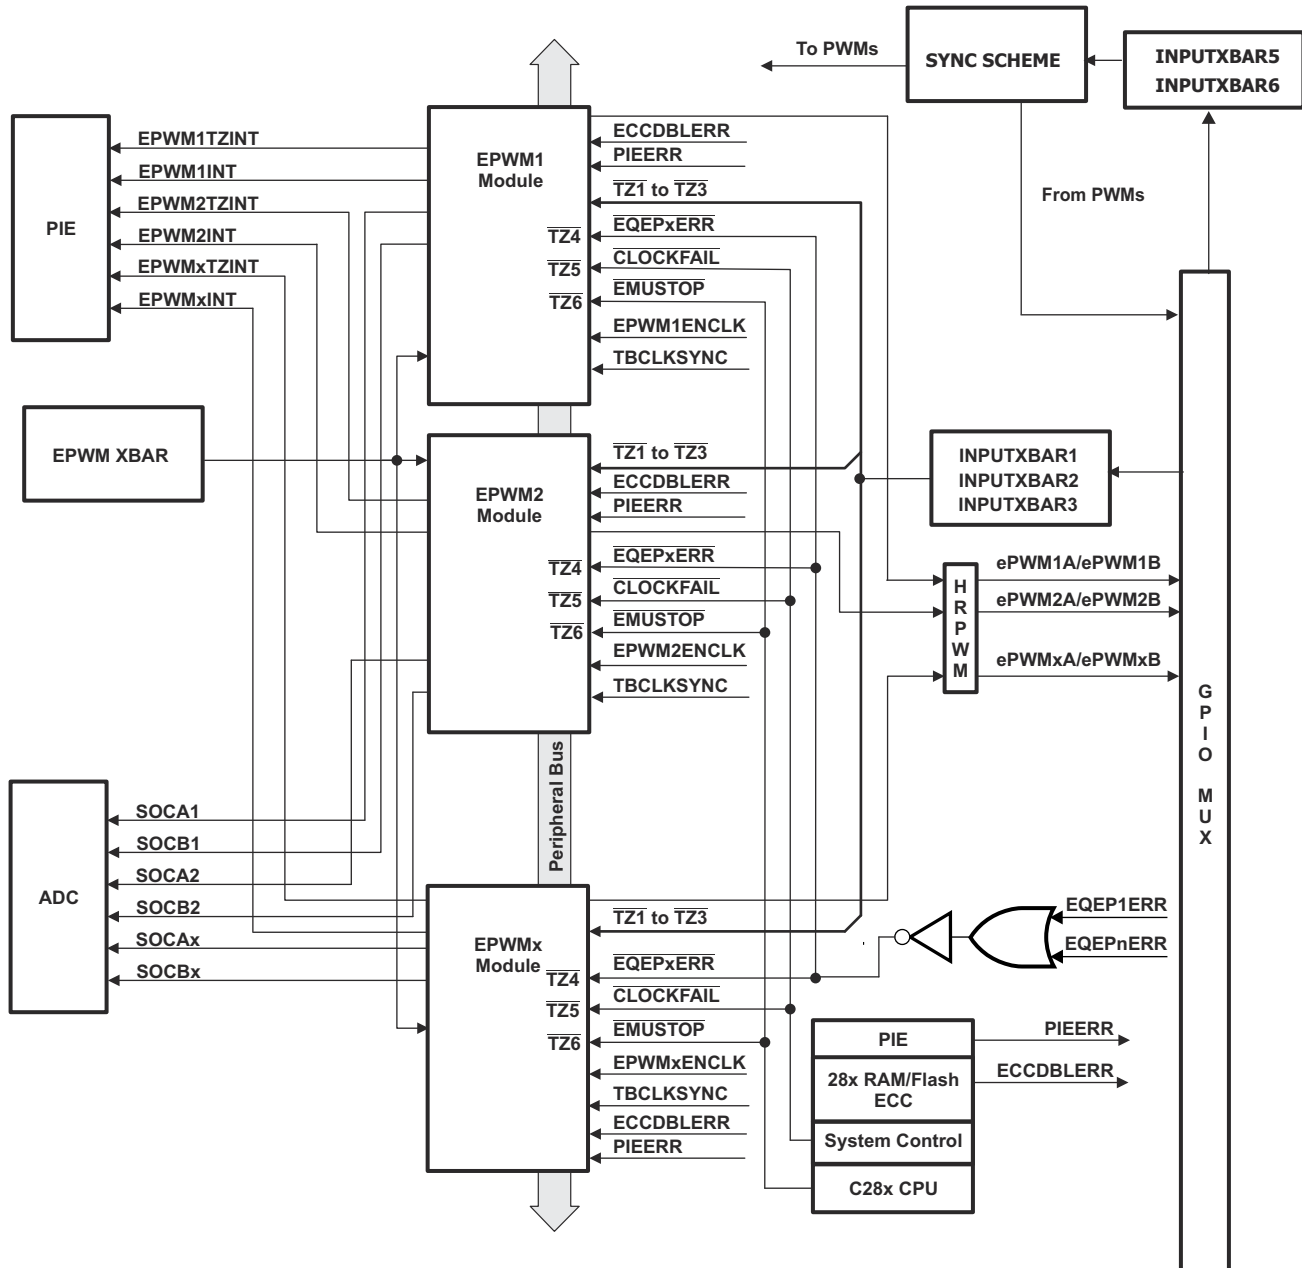

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.

- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 20-1. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in Figure 20-1. See Section 20.4.3.3 for the synchronization scheme for a particular device. Each ePWM module consists of eight submodules and is connected within a system by way of the signals shown in Figure 20-2.

Copyright © 2017, Texas Instruments Incorporated

A. This signal exists only on devices with an eQEP submodule.

Figure 20-1. Multiple ePWM Modules

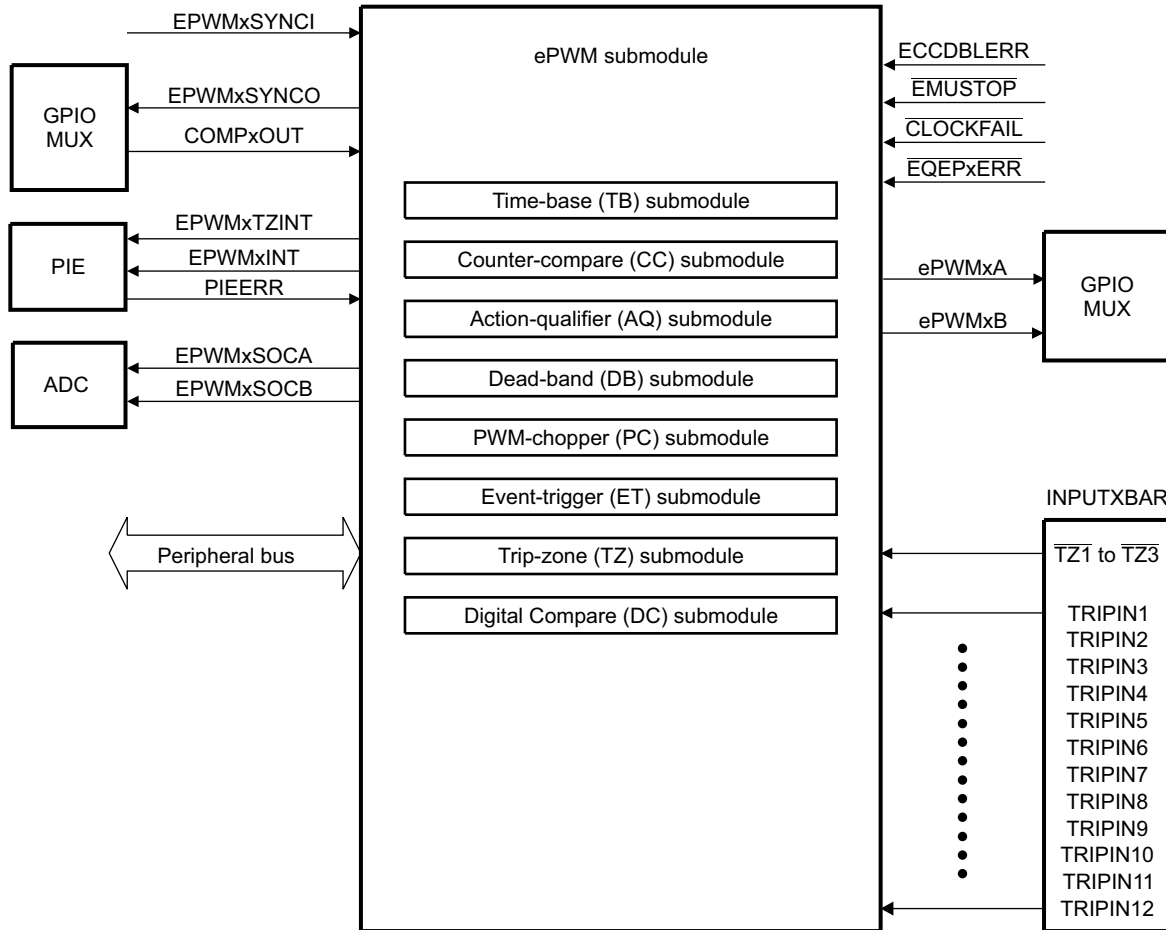

Figure 20-2. Submodules and Signal Connections for an ePWM Module

Figure 20-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**

The PWM output signals are made available external to the device through the GPIO peripheral described in the *System Control and Interrupts* chapter.

- **Trip-zone signals (TZ1 to TZ6)**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The TZ1 to TZ3 trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 20-51. TZ4 is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module). TZ5 is connected to the system clock fail logic, and TZ6 is connected to the EMUSTOP output from the CPU. This allows you to configure a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals**

Each ePWM module can be synchronized with other ePWM modules or other peripherals, using EPWMSYNClNSEL. Each ePWM module can also generate a synchronization output signal. The source of the EPWMxSYNCO can be selected and enabled by EPWMSYNCOOUTEN and TBCTL2.OSHTSYNCPERMODE. For more information, see Section 20.4.3.3.

Each ePWM module also generates another PWMSYNCPER signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. It is configured using the HRPCTL register but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see their respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT)**

Output signals from the comparator module can be fed through the Input X-BAR to one or all of the 12 trip inputs [TRIPIN1 - TRIPIN12] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

**Figure 20-3. ePWM Modules and Critical Internal Signal Interconnects**

## 20.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR must be used. Some examples of when an external signal may be needed are TZx, TRIPx, and EXTSYNCLIN. Any GPIO on the device can be configured as an input. The GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals. Additionally, some TRIPx (TRIP4-12 excluding TRIP6) signals must be routed through the ePWM X-Bar in addition to the Input X-Bar.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *GPIO* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

## 20.3 ePWM Modules Overview

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

[Table 20-1](#) lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in [Section 20.5](#) for relevant details.

**Table 20-1. Submodule Configuration Parameters**

| Submodule             | Configuration Parameter or Option   |
|-----------------------|---|
| Time Base (TB)        | <ul style="list-style-type: none"> <li>• Scale the time-base clock (TBCLK) relative to the ePWM clock (EPWMCLK).</li> <li>• Configure the PWM time-base counter (TBCTR) frequency or period.</li> <li>• Set the mode for the time-base counter:               <ul style="list-style-type: none"> <li>– count-up mode: used for asymmetric PWM</li> <li>– count-down mode: used for asymmetric PWM</li> <li>– count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>• Configure the time-base phase relative to another ePWM module.</li> <li>• Synchronize the time-base counter between modules through hardware or software.</li> <li>• Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>• Simultaneous writes to the TBPRD registers on all PWM's corresponding to the configuration on EPWMXLINK.</li> <li>• Configure how the time-base counter will behave when the device is halted by an emulator.</li> <li>• Specify the source for the synchronization output of the ePWM module</li> <li>• Configure one shot and global load of registers in this module.</li> </ul> |
| Counter Compare (CC)  | <ul style="list-style-type: none"> <li>• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB</li> <li>• Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> <li>• Specify the programmable delay for interrupt and SOC generation with additional comparators</li> <li>• Simultaneous writes to the CMPA, CMPB, CMPC, CMPD registers on all PWM's corresponding to the configuration on EPWMXLINK.</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>   |
| Action Qualifier (AQ) | <ul style="list-style-type: none"> <li>• Specify the type of action taken when a time-base counter-compare, trip-zone submodule, or comparator event occurs:               <ul style="list-style-type: none"> <li>– No action taken</li> <li>– Output EPWMxA and/or EPWMxB switched high</li> <li>– Output EPWMxA and/or EPWMxB switched low</li> <li>– Output EPWMxA and/or EPWMxB toggled</li> </ul> </li> <li>• Force the PWM output state through software control</li> <li>• Configure and control the PWM dead band through software</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>  |

**Table 20-1. Submodule Configuration Parameters (continued)**

| Submodule            | Configuration Parameter or Option  |
|----------------------|--|
| Dead Band (DB)       | <ul style="list-style-type: none"> <li>• Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>• Specify the output rising-edge-delay value</li> <li>• Specify the output falling-edge delay value</li> <li>• Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.</li> <li>• Option to enable half-cycle clocking for double resolution.</li> <li>• Allow ePWMxB phase shifting with respect to the ePWMxA output.</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>   |
| PWM Chopper (PC)     | <ul style="list-style-type: none"> <li>• Create a chopping (carrier) frequency.</li> <li>• Pulse width of the first pulse in the chopped pulse train.</li> <li>• Duty cycle of the second and subsequent pulses.</li> <li>• Bypass the PWM chopper module entirely. In this case the PWM waveform is passed through without modification.</li> </ul>   |
| Trip Zone (TZ)       | <ul style="list-style-type: none"> <li>• Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events.</li> <li>• Specify the trip action taken when a fault occurs: <ul style="list-style-type: none"> <li>– Force EPWMxA and/or EPWMxB high</li> <li>– Force EPWMxA and/or EPWMxB low</li> <li>– Force EPWMxA and/or EPWMxB to a high-impedance state</li> <li>– Configure EPWMxA and/or EPWMxB to ignore any trip condition.</li> </ul> </li> <li>• Configure how often the ePWM will react to each trip-zone signal: <ul style="list-style-type: none"> <li>– One-shot</li> <li>– Cycle-by-cycle</li> </ul> </li> <li>• Enable the trip-zone to initiate an interrupt.</li> <li>• Bypass the trip-zone module entirely.</li> <li>• Programmable option for cycle-by-cycle trip clear</li> <li>• If desired, independently configure trip actions taken when time-base counter is counting down.</li> </ul> |
| Event Trigger (ET)   | <ul style="list-style-type: none"> <li>• Enable the ePWM events that will trigger an interrupt.</li> <li>• Enable ePWM events that will trigger an ADC start-of-conversion event.</li> <li>• Specify the rate at which events cause triggers (every occurrence or every 2nd or up to 15th occurrence)</li> <li>• Poll, set, or clear event flags</li> </ul>  |
| Digital Compare (DC) | <ul style="list-style-type: none"> <li>• Enables comparator (COMP) module outputs and trip zone signals which are configured using the Input X-BAR to create events and filtered events</li> <li>• Specify event-filtering options to capture TBCTR counter, generate blanking window, or insert delay in PWM output or time-base counter based on captured value.</li> </ul>  |

## 20.4 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 20-4 illustrates the time-base module's place within the ePWM.

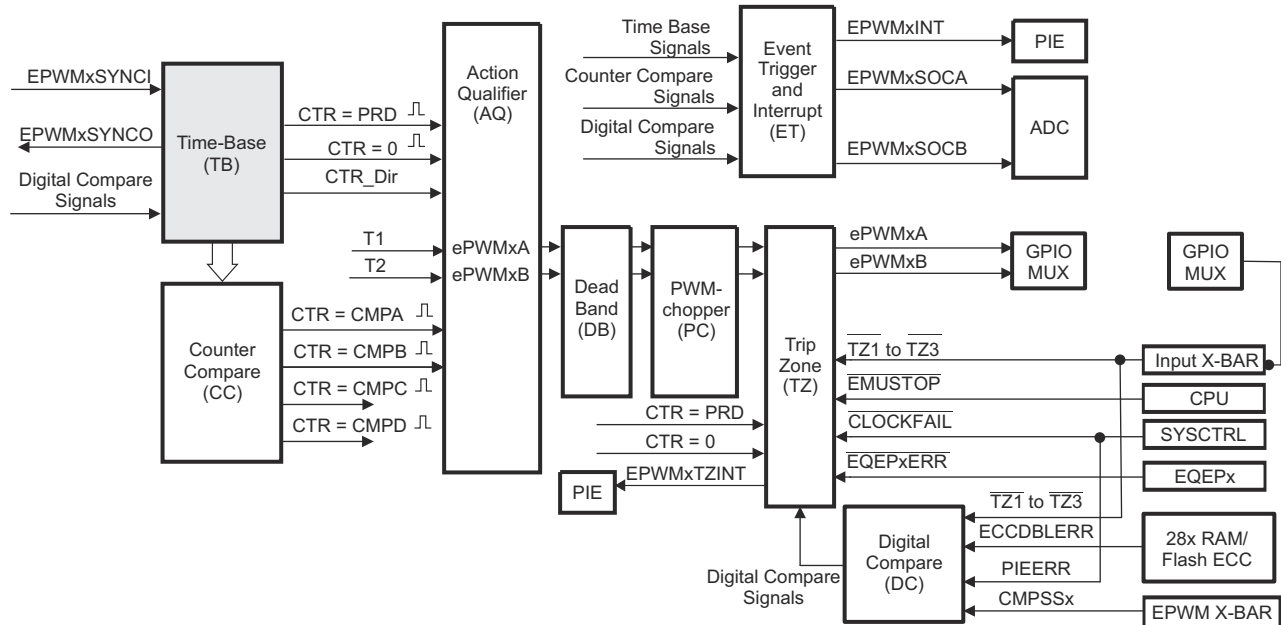

Figure 20-4. Time-Base Submodule

### 20.4.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

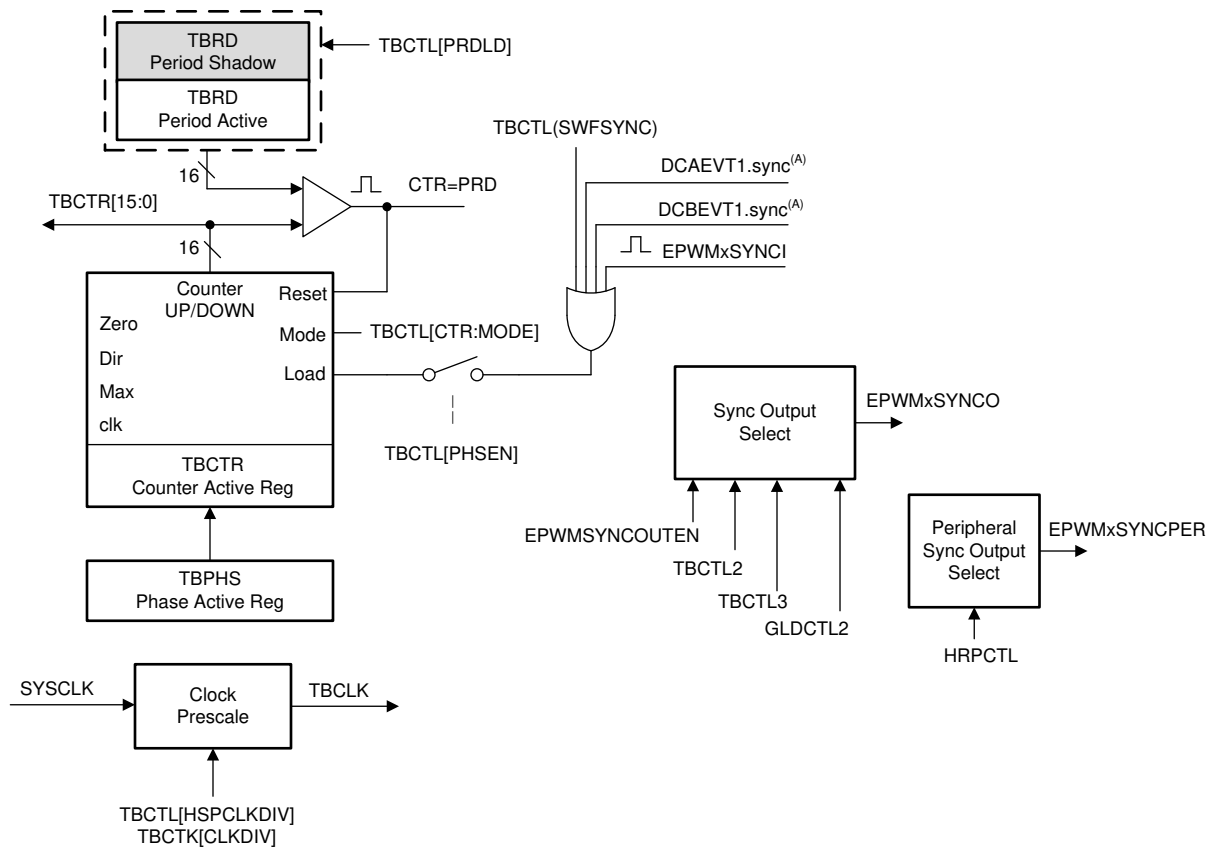

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

#### Note

If it is required by the application code to updated the TBCTR value through software, while the TBCTR is counting, it is important to note that the Time-Base module will need at least 1 TBCLK cycle for the Time-Base related events to be realized. Hence the TBCTR should either be written with TBCTR = PRD-1 instead of TBCTR = PRD (in case the counter is counting up) and should be written as TBCTR = 1 instead of TBCTR = 0(in case the counter is counting down) for the events to be realized.

### 20.4.2 Controlling and Monitoring the Time-Base Submodule

The block diagram in Figure 20-5 shows the critical signals and registers of the time-base submodule. Table 20-2 provides descriptions of the key signals associated with the time-base submodule.

A. These signals are generated by the digital compare (DC) submodule.

**Figure 20-5. Time-Base Submodule Signals and Registers**

**Table 20-2. Key Time-Base Signals**

| Signal       | Description  |
|--------------|--|
| EPWMxSYNCl   | Time-base synchronization input.<br><br>Input pulse used to synchronize the time-base counter with the counter of other ePWM modules. For more information on all of the signals available for synchronization, see EPWMSYNClNSEL. For information on the synchronization order of a particular device, see <a href="#">Section 20.4.3.3</a> . |
| EPWMxSYNCO   | Time-base synchronization output.<br><br>This output pulse is used to synchronize the counter of other ePWM modules. Using EPWMSYNCOUEN, TBCTL2, TBCTL3 and GLDCTL2, the source of the output pulse is selected.   |
| EPWMxSYNCPER | Time-base peripheral synchronization output.<br><br>This output signal is used to synchronize the CMPSS to the EPWM. It can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM.   |
| CTR = PRD    | Time-base counter equal to the specified period.<br><br>This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.  |
| CTR = Zero   | Time-base counter equal to zero<br><br>This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.  |
| CTR = CMPB   | Time-base counter equal to active counter-compare B register (TBCTR = CMPB).<br><br>This event is generated by the counter-compare submodule and used by the synchronization out logic   |
| CTR_dir      | Time-base counter direction.<br><br>Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.   |
| CTR_max      | Time-base counter equal max value. (TBCTR = 0xFFFF)<br><br>Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit   |
| TBCLK        | Time-base clock.<br><br>This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.   |

### 20.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 20-6 shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

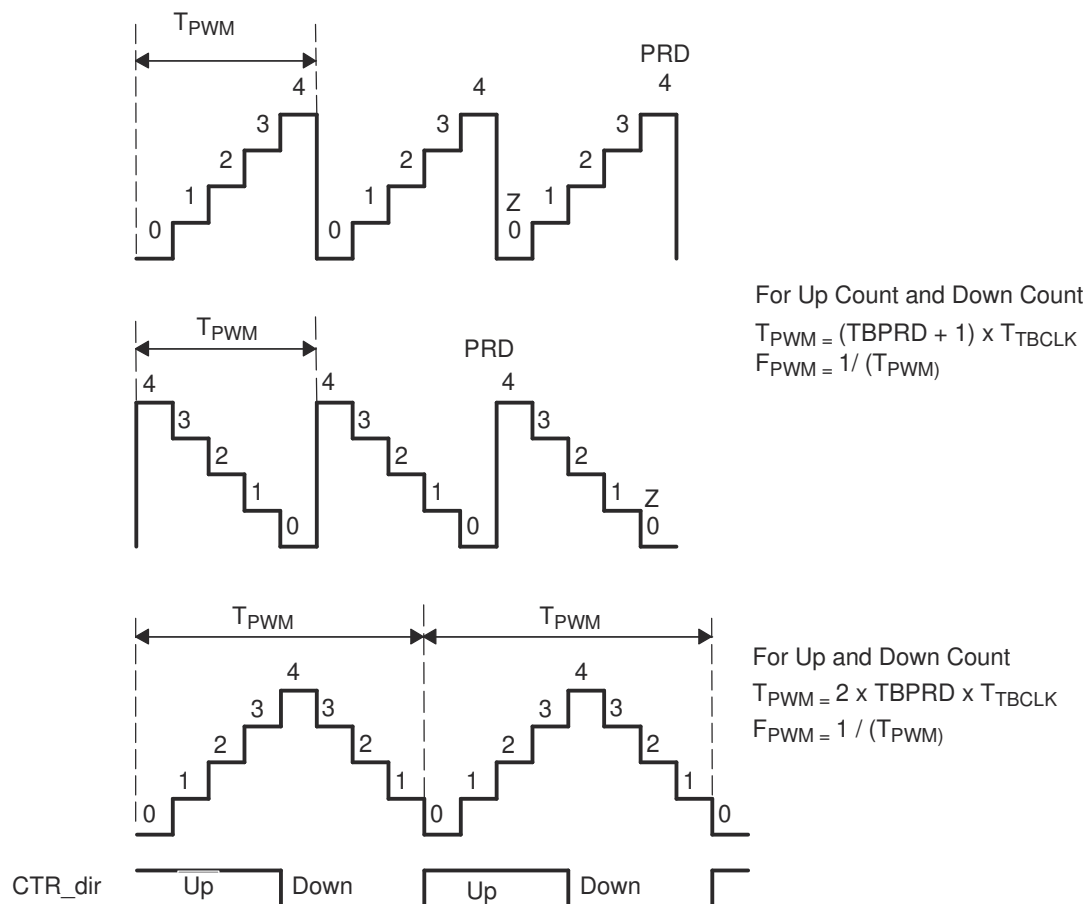

In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

**Figure 20-6. Time-Base Frequency and Period**

### 20.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDL] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in [Section 20.4.3.3](#).

The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in [Section 20.4.7](#).

- **Time-Base Period Immediate Load Mode:**

If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 20.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

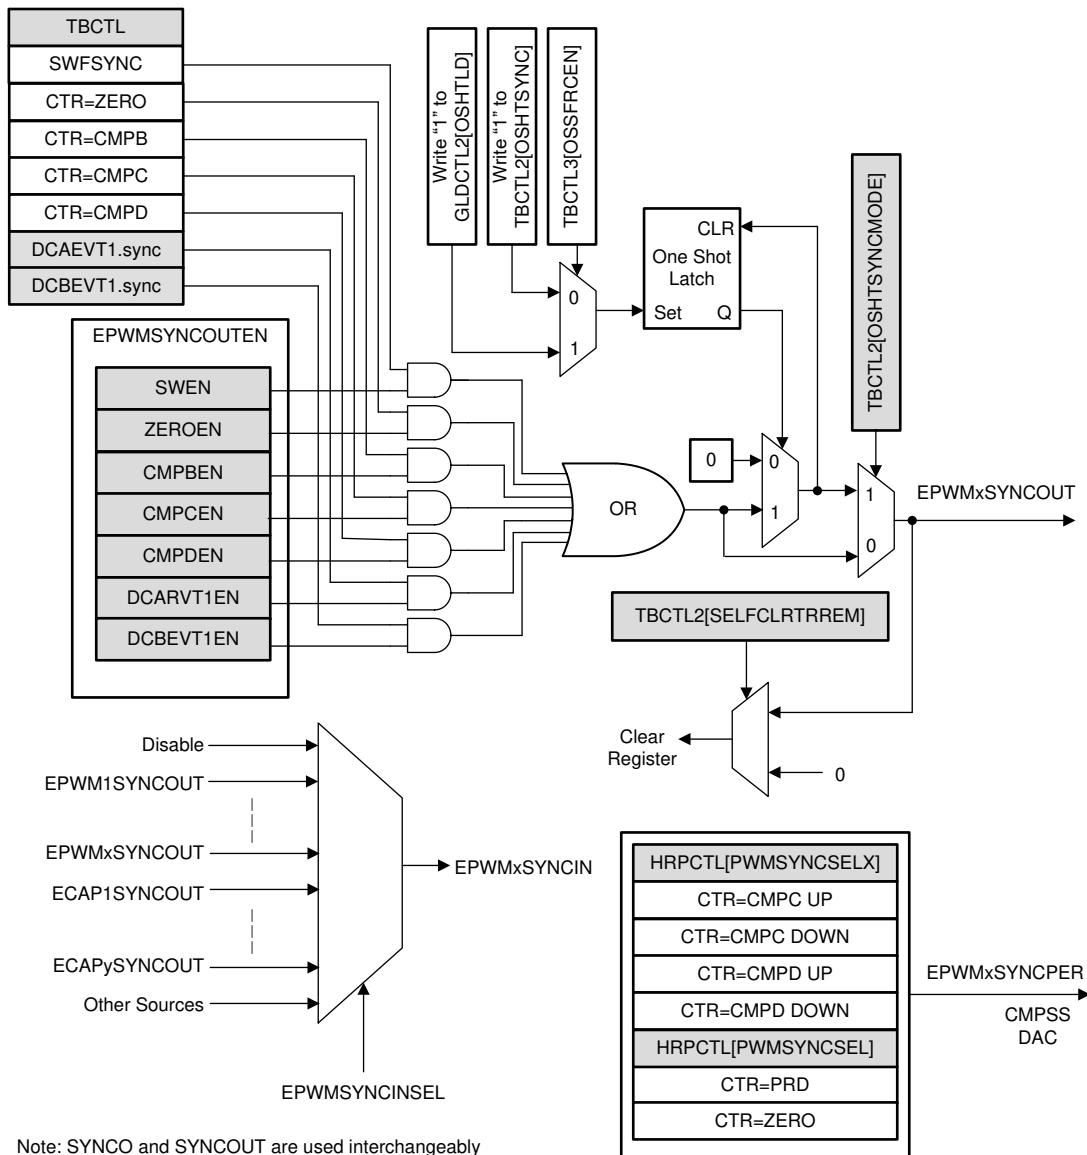

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC= 0
3. Configure ePWM modules
4. Set TBCLKSYNC= 1

### 20.4.3.3 Time-Base Counter Synchronization

The ePWM type 4 introduces a new synchronization scheme that allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCI), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 20-7, EXTSYN1 is sourced from INPUTXBAR5 and EXTSYN2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. Refer to Table 20-3 for a list of all sync inputs including INPUTXBAR5 and INPUTXBAR6. Figure 20-8 shows the sources that can be used for EXTSYNOUT.

**Figure 20-7. Time-Base Counter Synchronization Scheme**

**Figure 20-8. ePWM External SYNC Output**

**Note**

See the data manual for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:**

The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

- **Software Forced Synchronization Pulse:**

Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

- **Digital Compare Event Synchronization Pulse:**

DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

**Note**

If the EPWMxSYNCl signal is held HIGH, the sync will NOT continuously occur. The EPWMxSYNCl is rising edge activated.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PSHDIR bit is ignored in count-up or count-down modes. See [Figure 20-9](#) through [Figure 20-12](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse.

#### 20.4.3.4 ePWM SYNC Selection

[Table 20-3](#) specifies the sources for the ePWM SYNC input and output.

**Table 20-3. ePWM SYNC Selection**

| EPWMSYNCINSEL.SEL, ECAPSYNCINSEL.SEL | SYNC Source       |
|--------------------------------------|-------------------|
| 0x0                                  | Reserved          |
| 0x1                                  | EPWM1.SYNCOUT     |
| 0x2                                  | EPWM2.SYNCOUT     |
| 0x3                                  | EPWM3.SYNCOUT     |
| 0x4                                  | EPWM4.SYNCOUT     |
| 0x5                                  | EPWM5.SYNCOUT     |
| 0x6                                  | EPWM6.SYNCOUT     |
| 0x7                                  | EPWM7.SYNCOUT     |
| 0x8                                  | Reserved          |
| 0x9                                  | Reserved          |
| 0xA                                  | Reserved          |
| 0xB                                  | Reserved          |
| 0xC                                  | Reserved          |
| 0xD                                  | Reserved          |
| 0xE                                  | Reserved          |
| 0xF                                  | Reserved          |
| 0x10                                 | Reserved          |
| 0x11                                 | ECAP1.SYNCOUT     |

#### 20.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

#### 20.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

For a particular ePWM module # A, user code writes “B+1”, to the linked register bit-field in EPWMXLINK. “B” is the ePWM module # being linked to (that is, writes to the ePWM module “B” TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, or CMPC will simultaneously be written to corresponding register in ePWM module “A”). For instance if ePWM3 EPWMXLINK register is configured so that CMPA:CMPAHR are linked to ePWM1, then a write to CMPA:CMPAHR in ePWM 1 will simultaneously write the same value to CMPA:CMPAHR in ePWM3. If ePWM4 also has its CMPA:CMPAHR registers linked to ePWM1, then a write to ePWM 1 will write the same value to the CMPA:CMPAHR registers in both ePWM3 and ePWM4.

The register description for EPWMXLINK clearly explains the linked register bit-field values for corresponding ePWM. An example of using the EPWMXLINK is linking ePWM2 CMPA with CMPA of ePWM1. In this case, a write to CMPA of ePWM1 will also change the CMPA value for ePWM2.

### 20.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

**Figure 20-9. Time-Base Up-Count Mode Waveforms**

Figure 20-10. Time-Base Down-Count Mode Waveforms

Figure 20-11. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

Figure 20-12. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

### 20.4.7 Global Load

Figure 20-13 illustrates the signals and registers associated with the global load feature.

**Figure 20-13. Global Load: Signals and Registers**

#### Note

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = '1', shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = '1' and GLDCFG[REGx] = '0' global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

#### 20.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = '0' or GLDCFG[REGx] = '0').

### 20.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When `GLDCTL2[OSHTLD] = '1'` the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by `GLDCTL[GLDMODE]`.

Software force loading of contents from shadow register to active register is possible by using `GLDCTL2[GFRCLD]`. The `GLDCTL2` register can also be linked across multiple PWM modules by using `EPWMXLINK[GLDCTL2LINK]`. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

#### Note

One-shot load mode should **NOT** be used when high-resolution mode is enabled.

### 20.4.7.3 One-Shot Sync Mode

You can enable the one-shot sync mode to generate a `SYNCOUT` pulse by configuring `TBCLT2[OSHTSYNCMODE]` and setting the `TBCLT2[OSHTSYNC]` bit as shown in Figure 20-14.

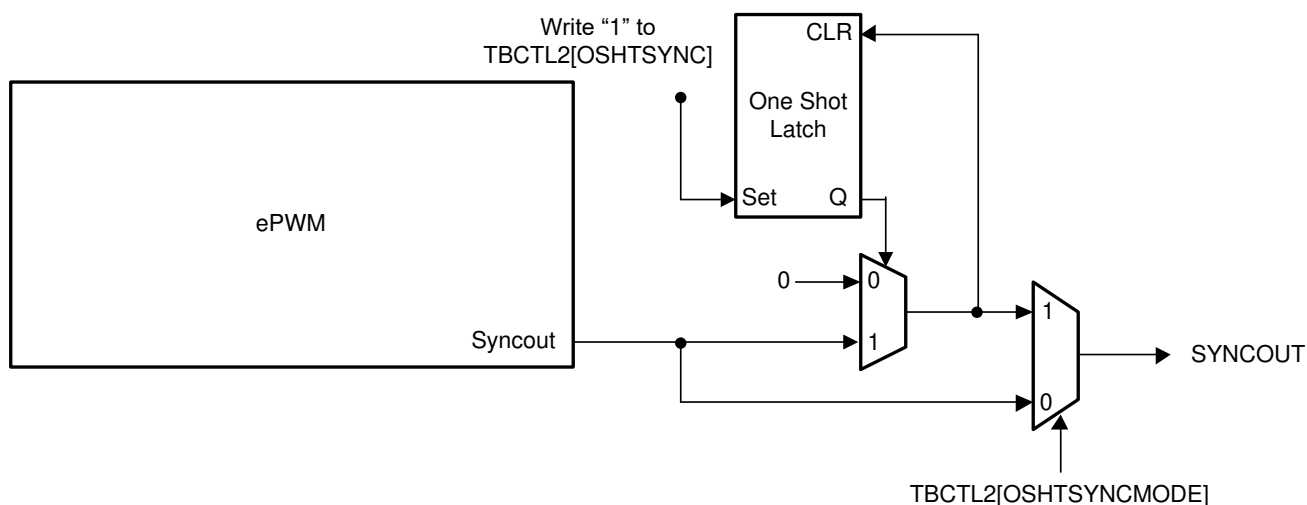

Figure 20-14. One-Shot Sync Mode

## 20.5 Counter-Compare (CC) Submodule

Figure 20-15 illustrates the counter-compare submodule within the ePWM.

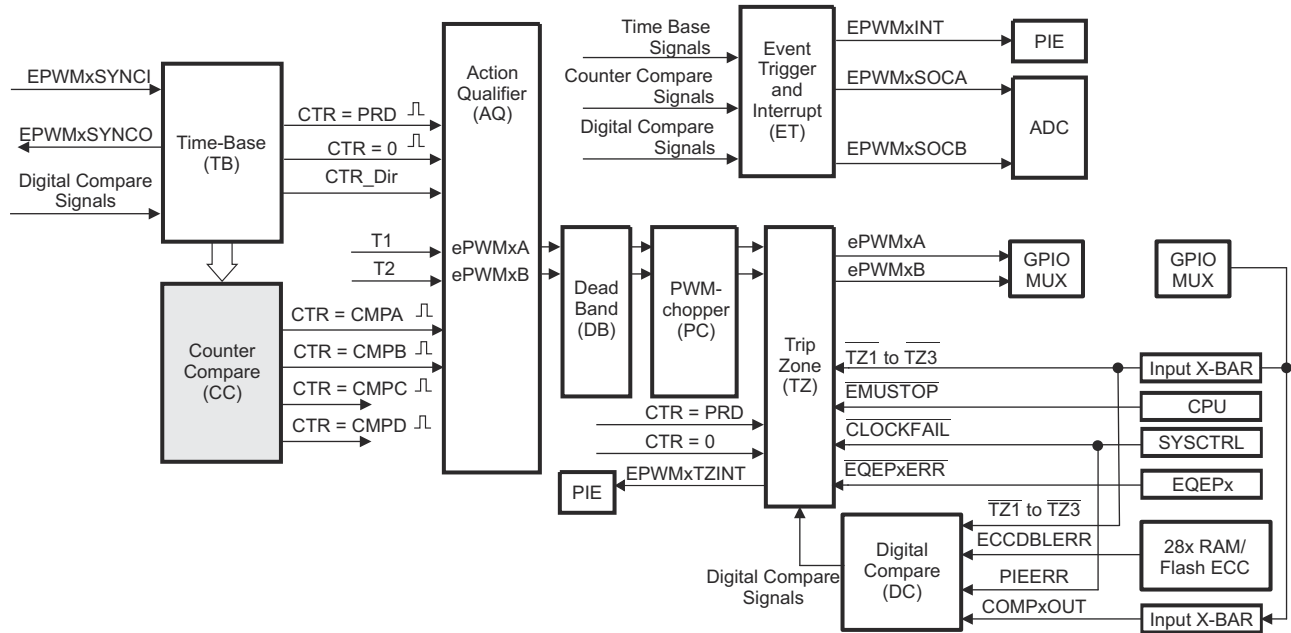

Figure 20-15. Counter-Compare Submodule

### 20.5.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 20.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 20-16.

A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 20-16. Detailed View of the Counter-Compare Submodule**

### 20.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events which can be used in the action-qualifier and/or event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only.

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode each event occurs twice per cycle if the compare value is between 0x00-TBPRD and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 20.6.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

#### Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

#### Immediate Mode:

If immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

## Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

### Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

### Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register will go directly to the active register.

### Global Load Support

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 20.4.7](#).

## 20.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 20-17](#) through [Figure 20-20](#) show when events are generated and how the EPWMxSYNCl signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 20-17. Counter-Compare Event Waveforms in Up-Count Mode**

**Figure 20-18. Counter-Compare Events in Down-Count Mode**

**Figure 20-19. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event**

**Figure 20-20. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event**

## 20.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 20-21 shows the action-qualifier (AQ) submodule in the ePWM system.

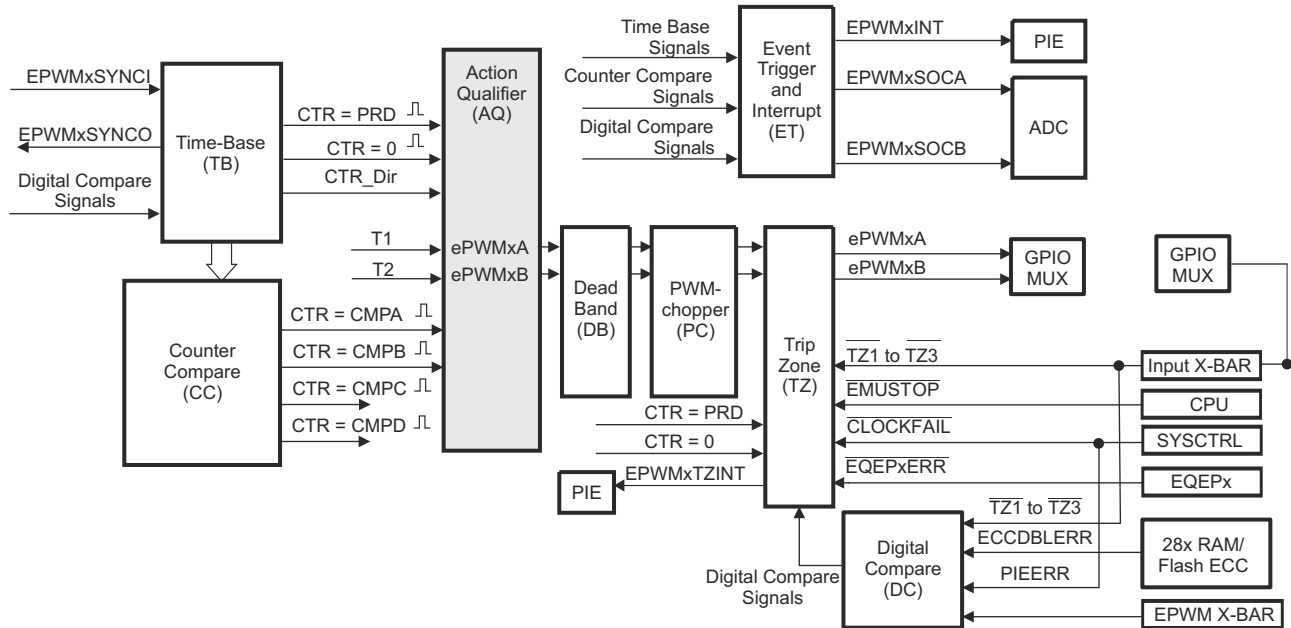

Figure 20-21. Action-Qualifier Submodule

### 20.6.1 Purpose of the Action-Qualifier Submodule

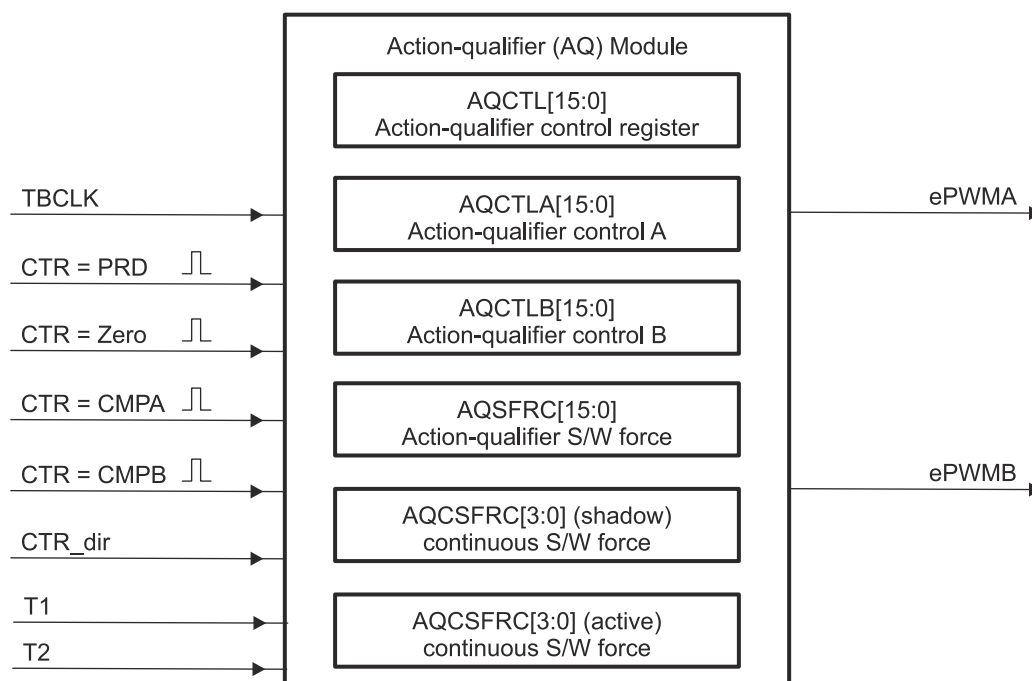

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

## 20.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in Figure 20-22 and monitored by way of the registers in Section 20.17.

**Figure 20-22. Action-Qualifier Submodule Inputs and Outputs**

For convenience, the possible input events are summarized again in Table 20-4.

**Table 20-4. Action-Qualifier Submodule Possible Input Events**

| Signal                | Description                                      | Registers Compared |
|-----------------------|--|--------------------|
| CTR = PRD             | Time-base counter equal to the period value      | TBCTR = TBPRD      |
| CTR = Zero            | Time-base counter equal to zero                  | TBCTR = 0x00       |
| CTR = CMPA            | Time-base counter equal to the counter-compare A | TBCTR = CMPA       |
| CTR = CMPB            | Time-base counter equal to the counter-compare B | TBCTR = CMPB       |
| T1 event              | Based on comparator, trip or syncin events       | None               |
| T2 event              | Based on comparator, trip or syncin events       | None               |
| Software forced event | Asynchronous event initiated by software         |                    |

The software forced action is a useful asynchronous event. This control is handled by the AQSFR and AQCSFR registers.

### Note

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**  
Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**  
Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**  
If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:**  
Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in [Section 20.10](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 20-23](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

| SW<br>force   | TB Counter equals   |   |   | Trigger Events  |   |   | Actions    |
|---|---|---|---|---|---|---|------------|
|   | Zero  | Comp<br>A   | Comp<br>B   | Period  | T1  | T2  |            |
|  |  |  |  |  |  |  | Do Nothing |
|  |  |  |  |  |  |  | Clear Lo   |
|  |  |  |  |  |  |  | Set Hi     |
|  |  |  |  |  |  |  | Toggle     |

**Figure 20-23. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event may or may not be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

### 20.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 20-5](#). A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

**Table 20-5. Action-Qualifier Event Priority for Up-Down-Count Mode**

| Priority Level | Event If TBCTR is Incrementing<br>TBCTR = Zero up to TBCTR = TBPRD | Event If TBCTR is Decrementing<br>TBCTR = TBPRD down to TBCTR = 1 |
|----------------|--|---|
| 1 (Highest)    | Software forced event  | Software forced event   |
| 2              | T1 on up-count (T1U)   | T1 on down-count (T1D)  |
| 3              | T2 on up-count (T2U)   | T2 on down-count (T2D)  |
| 4              | Counter equals CMPB on up-count (CBU)                              | Counter equals CMPB on down-count (CBD)                           |
| 5              | Counter equals CMPA on up-count (CAU)                              | Counter equals CMPA on down-count (CAD)                           |
| 6              | Counter equals zero  | Counter equals period (TBPRD)                                     |
| 7              | T1 on down-count (T1D)   | T1 on up-count (T1U)  |
| 8              | T2 on down-count (T2D)   | T2 on up-count (T2U)  |
| 9              | Counter equals CMPB on down-count (CBD)                            | Counter equals CMPB on up-count (CBU)                             |
| 10 (Lowest)    | Counter equals CMPA on down-count (CAD)                            | Counter equals CMPA on up-count (CAU)                             |

[Table 20-6](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and therefore, down-count events will never be taken.

**Table 20-6. Action-Qualifier Event Priority for Up-Count Mode**

| Priority Level | Event                                   |
|----------------|---|
| 1 (Highest)    | Software forced event                   |
| 2              | Counter equal to period (TBPRD)         |
| 3              | T1 on up-count (T1U)                    |
| 4              | T2 on up-count (T2U)                    |
| 5              | Counter equal to CMPB on up-count (CBU) |
| 6              | Counter equal to CMPA on up-count (CAU) |
| 7 (Lowest)     | Counter equal to Zero                   |

[Table 20-7](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 20-7. Action-Qualifier Event Priority for Down-Count Mode**

| Priority Level | Event                                     |
|----------------|---|
| 1 (Highest)    | Software forced event                     |
| 2              | Counter equal to Zero                     |
| 3              | T1 on down-count (T1D)                    |
| 4              | T2 on down-count (T2D)                    |
| 5              | Counter equal to CMPB on down-count (CBD) |
| 6              | Counter equal to CMPA on down-count (CAD) |
| 7 (Lowest)     | Counter equal to period (TBPRD)           |

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 20-8](#).

**Table 20-8. Behavior if CMPA/CMPB is Greater than the Period**

| Counter Mode       | Compare on Up-Count Event<br>CAD/CBD   | Compare on Down-Count Event<br>CAD/CBD   |
|--------------------|--|--|
| Up-Count Mode      | If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match (TBCTR=CMPA or CMPB).<br>If $CMPA/CMPB > TBPRD$ , then the event will not occur.  | Never occurs.  |
| Down-Count Mode    | Never occurs.  | If $CMPA/CMPB < TBPRD$ , the event will occur on a compare match (TBCTR=CMPA or CMPB).<br>If $CMPA/CMPB \geq TBPRD$ , the event will occur on a period match (TBCTR=TBPRD).                        |
| Up-Down-Count Mode | If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).<br>If $CMPA/CMPB \geq TBPRD$ , the event will occur on a period match (TBCTR = TBPRD). | If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).<br>If $CMPA/CMPB \geq TBPRD$ , the event occurs on a period match (TBCTR=TBPRD). |

#### 20.6.4 AQCTLA and AQCTLB Shadow Mode Operations

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is:

##### Shadow Mode

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE], AQCTL[LDAQBMODE], AQCTL[LDAQASYNC], and AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

##### Global Load Support

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2, and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 20.4.7](#).

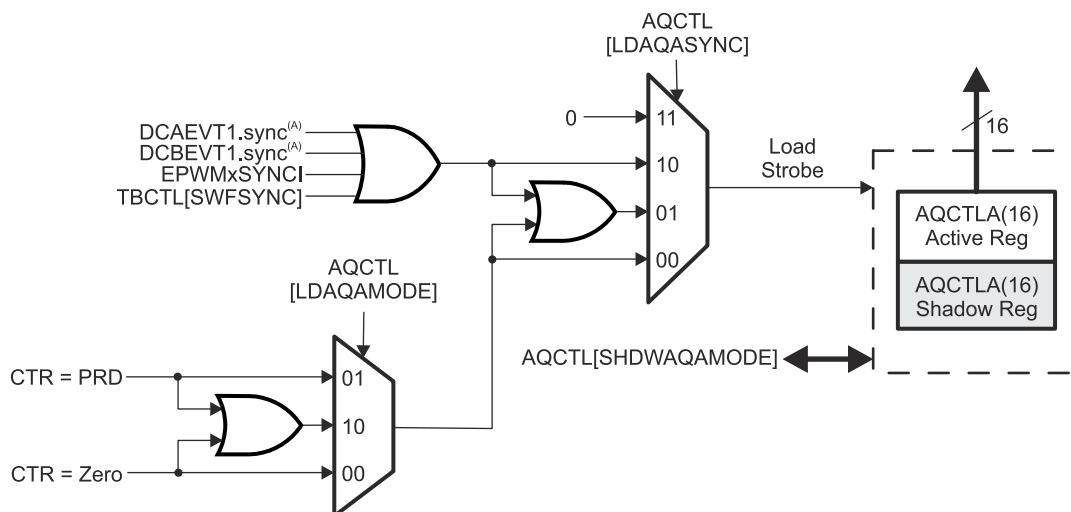

##### Immediate Load Mode

If immediate load mode is selected (that is, AQCTL[SHDWAQAMODE] = 0 or AQCTL[SHDWAQBMODE] = 0), then a read from or a write to the register will go directly to the active register. See [Figure 20-24](#) and [Figure 20-25](#).

**Note**

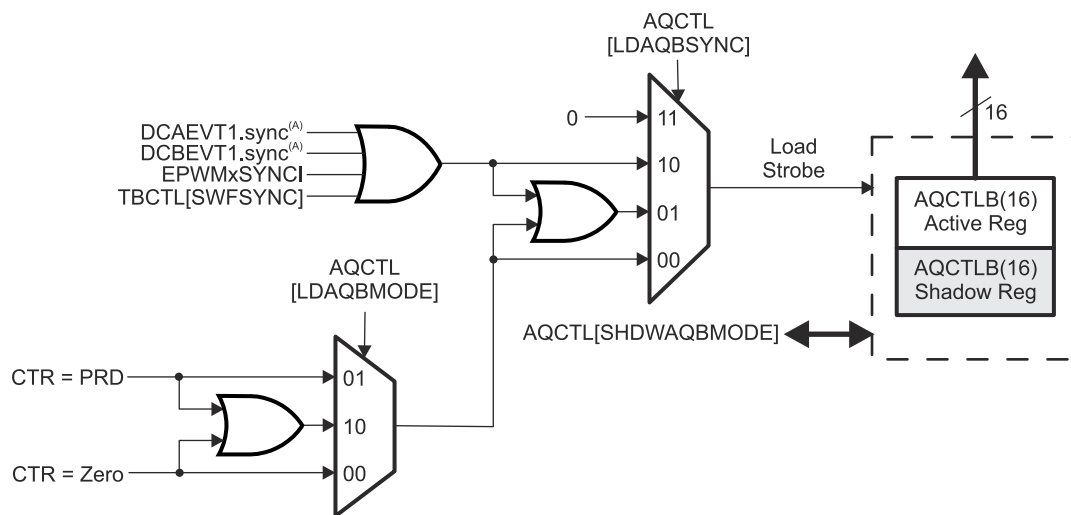

Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA and AQCTLB] on CMPA = 0 or CMPB = 0 boundary

If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA=0 and AQCTLA shadow to active load on TBCTR=0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention and it is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and T<sub>Z</sub> signals).

**Figure 20-24. AQCTL[SHDWAQAMODE]**

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and T<sub>Z</sub> signals).

**Figure 20-25. AQCTL[SHDWAQBMODE]**

## 20.6.5 Waveforms for Common Configurations

### Note

The waveforms in this document show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

#### Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

#### Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

#### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

#### When using up-count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met ( $CMPX < \text{Deadband}$ ) or ( $CMPX > \text{PRD} - \text{Deadband}$ ) the actions specified by the AQCTL register for CMPX will not take effect. To avoid this, the AQCTL settings will have to be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Ensure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

#### When using up-down-count mode to generate an asymmetric PWM with deadband enabled:

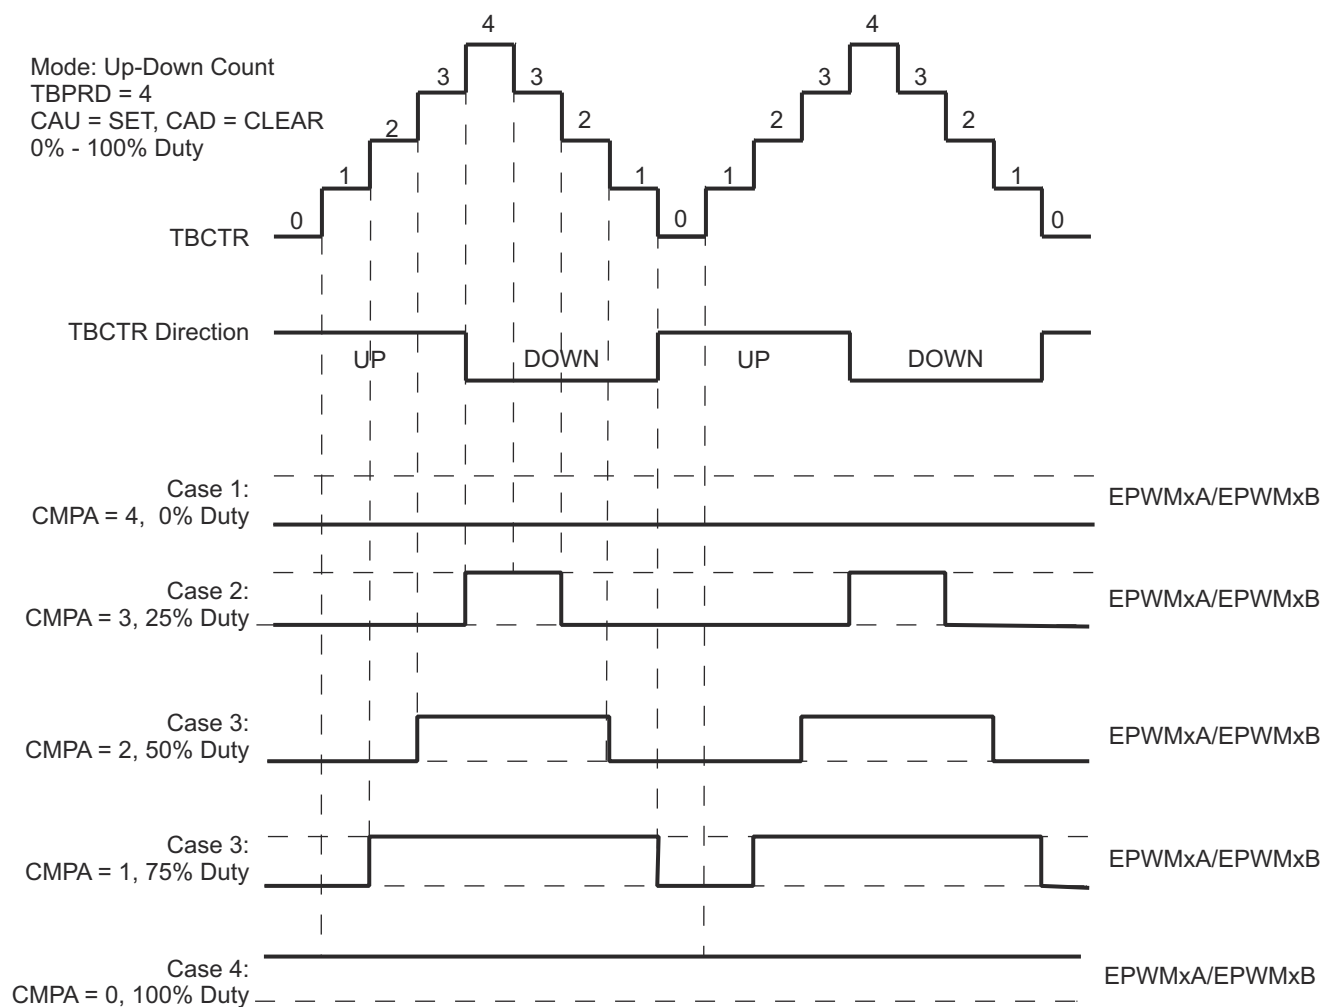

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met ( $CMPX < \text{Deadband}/2$ ) or ( $CMPX > \text{PRD} - (\text{Deadband})/2$ ) the actions specified by the AQCTL register for CMPX will not take effect. To avoid this, the AQCTL settings will have to be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Ensure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

See the [Using Enhanced Pulse Width Modulator \(ePWM\) Module for 0-100% Duty Cycle Control Application Report](#).

Figure 20-26 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode, 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When  $CMPA = 0$ , the PWM signal is high for the entire period giving a 100% duty waveform. When  $CMPA = TBPRD$ , the PWM signal is low achieving 0% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal

to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 20-26. Up-Down-Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 20-27](#) through [Figure 20-32](#) show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

- A.  $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- D. The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
- E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 20-27. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High**

- A.  $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 20-28. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low**

- A.  $PWM\ frequency = 1 / ((TBPRD + 1) \times T_{TBCLK})$
- B. Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
- C. High time duty proportional to (CMPB - CMPA)

**Figure 20-29. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA**

- A.  $PWM\ period = 2 \times TBPRD \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. Outputs EPWMxA and EPWMxB can drive independent power switches.

**Figure 20-30. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low**

- A.  $PWM\ period = 2 \times TBPRD \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.
- C. Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.
- D. Outputs EPWMx can drive upper/lower (complementary) power switches.
- E. Dead-band =  $CMPB - CMPA$  (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

**Figure 20-31. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary**

- A.  $\text{PWM period} = 2 \times \text{TBPRD} \times \text{TBCLK}$
- B. Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- C. Duty modulation for EPWMxA is set by CMPA and CMPB.
- D. Low time duty for EPWMxA is proportional to  $(\text{CMPA} + \text{CMPB})$ .
- E. To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).
- F. Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

**Figure 20-32. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low**

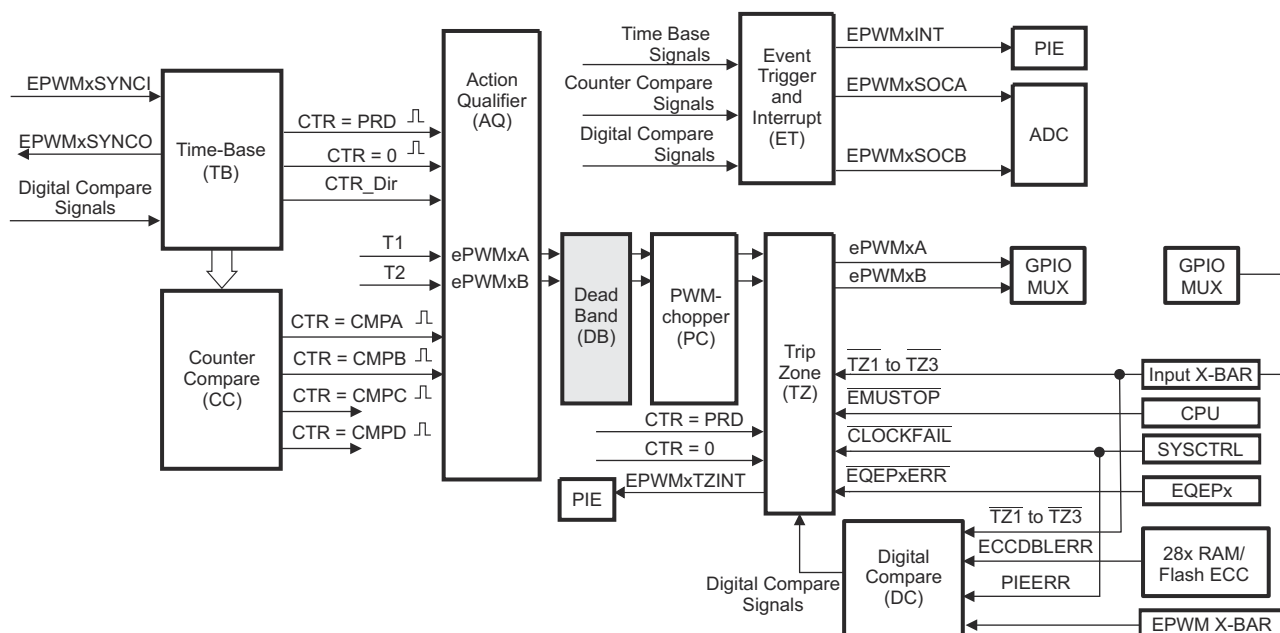

- A.  $PWM\ period = 2 \times TBPRD \times TTCLK$
- B. Independent T1 event actions when counter is counting up and when it is counting down are used to generate EPWMxA output.
- C. Independent T2 event actions when counter is counting up and when it is counting down are used to generate EPWMxB output.
- D. TZ1 is selected as the source for T1.
- E. TZ2 is selected as the source for T2.

**Figure 20-33. Up-Down-Count, PWM Waveform Generation Utilizing T1 and T2 Events**

## 20.7 Dead-Band Generator (DB) Submodule

Figure 20-34 illustrates the dead-band submodule within the ePWM module.

**Figure 20-34. Dead\_Band Submodule**

### 20.7.1 Purpose of the Dead-Band Submodule

The action-qualifier (AQ) module section discussed how it is possible to generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

## 20.7.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED could appear on one channel output and FED could appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in [Figure 20-35](#), RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

---

### Note

Phase shifting B-channel with respect to the A-channel using the dead-band submodule additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

---

- The dead-band counters have also been increased to 14 bits
- Dead-band and dead-band High-resolution registers are now shadowed
- High-resolution dead-band RED and FED have been enabled using the DBREDHR and DBFEDHR registers

---

### Note

The PWM chopper will not be enabled when high-resolution dead band is enabled.

High-resolution dead-band RED and FED requires Half-Cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB\_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. It is recommended to make sure the duty cycle value of the current waveform fed to the dead-band module is greater than the required phase shift amount.

The Type 4 action qualifier and dead-band outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

---

## Shadow Mode

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDDMODE] and DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

## Global Load Support

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR, and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in [Section 20.4.7](#).

---

### Note

When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED/DBFED value only affects the NEXT PWMx edge and not the current edge.

A Dead-band value of zero should not be used when the Global Shadow to Active Load is set to occur at CTR=ZERO. Similarly, a Dead-band value of PRD should not be used when the Global Shadow to Active Load is set to occur at CTR=PRD.

TBPRDHR should not be used with Global load. If high resolution period must be changed in the application, users must write to the individual period registers from an ePWM ISR (The ISR must be synchronous with the PWM switching period), where the Global Load One-Shot bit is also written to.

---

### 20.7.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in Figure 20-35.

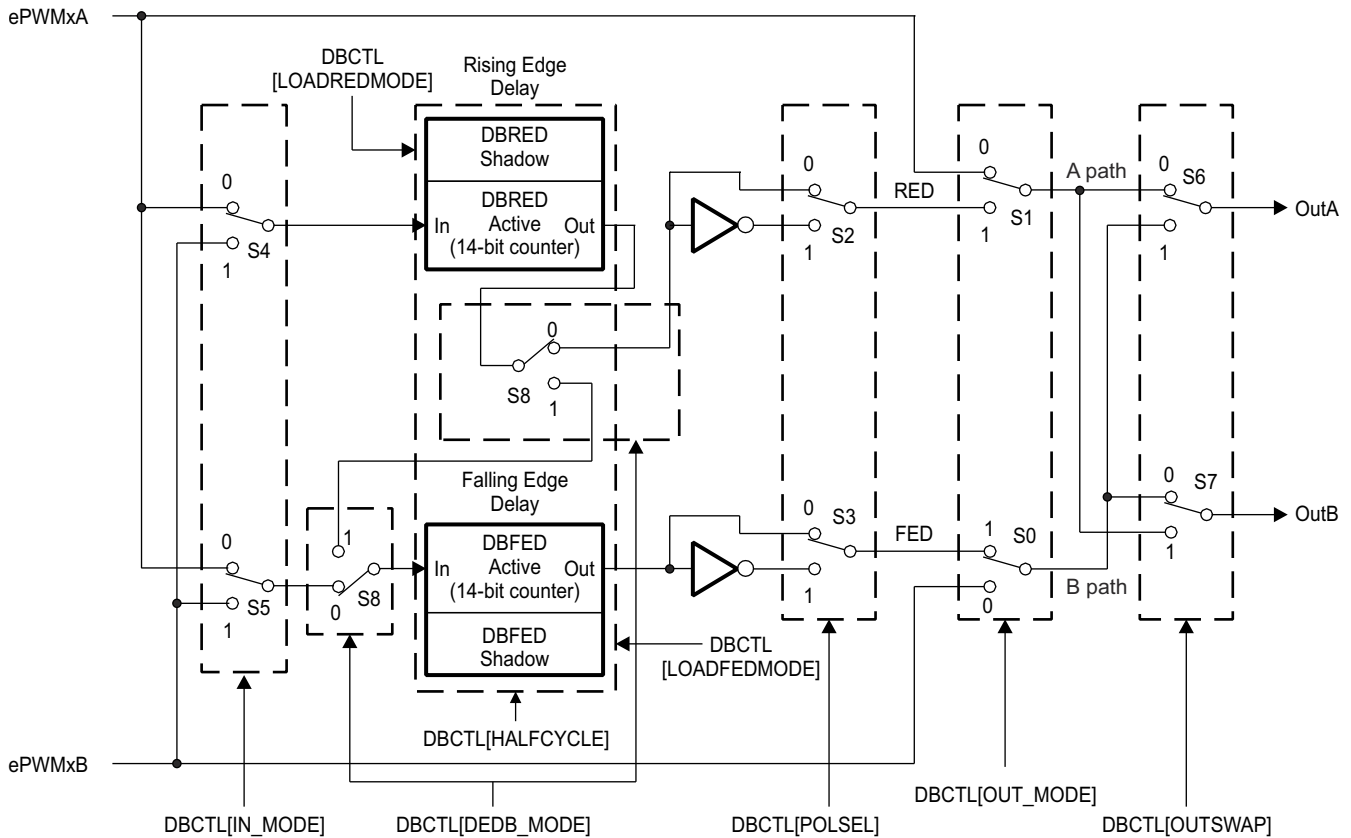

Figure 20-35. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. Table 20-9 documents some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 20-9 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**

Allows you to fully disable the dead-band submodule from the PWM signal path.

- **Mode 2-5: Classical Dead-Band Polarity Settings:**

These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 20-36. Note that to generate equivalent waveforms to Figure 20-36, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.

- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**

Finally the last two entries in Table 20-9 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Figure 20-36 shows waveforms for typical cases where  $0\% < \text{duty} < 100\%$ .

**Table 20-9. Classical Dead-Band Operating Modes**

| Mode | Mode Description                               | DBCTL[POLSEL] |        | DBCTL[OUT_MODE] |    |
|------|--|---------------|--------|-----------------|----|
|      |  | S3            | S2     | S1              | S0 |
| 1    | EPWMxA and EPWMxB Passed Through (No Delay)    | X             | X      | 0               | 0  |
| 2    | Active High Complementary (AHC)                | 1             | 0      | 1               | 1  |
| 3    | Active Low Complementary (ALC)                 | 0             | 1      | 1               | 1  |
| 4    | Active High (AH)                               | 0             | 0      | 1               | 1  |
| 5    | Active Low (AL)                                | 1             | 1      | 1               | 1  |
| 6    | EPWMxA Out = EPWMxA In (No Delay)              | 0 or 1        | 0 or 1 | 0               | 1  |
|      | EPWMxB Out = EPWMxA In with Falling Edge Delay |               |        |                 |    |
| 7    | EPWMxA Out = EPWMxA In with Rising Edge Delay  | 0 or 1        | 0 or 1 | 1               | 0  |
|      | EPWMxB Out = EPWMxB In with No Delay           |               |        |                 |    |

**Table 20-10. Additional Dead-Band Operating Modes**

| Mode Description   | DBCTL[DEDB-MODE] | DBCTL[OUTSWAP] |    |
|--|------------------|----------------|----|
|  | S8               | S6             | S7 |
| EPWMxA and EPWMxB signals are as defined by OUT-MODE bits.   | 0                | 0              | 0  |
| EPWMxA = A-path as defined by OUT-MODE bits.   | 0                | 0              | 1  |
| EPWMxB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A-signal path)  |                  |                |    |
| EPWMxA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B-signal path)   | 0                | 1              | 0  |
| EPWMxB = B-path as defined by OUT-MODE bits  |                  |                |    |
| EPWMxA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B-signal path)   | 0                | 1              | 1  |
| EPWMxB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A-signal path)  |                  |                |    |
| Rising edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only.                                      | 0                | X              | X  |
| Falling edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only.                                     |                  |                |    |
| Rising edge delay and falling edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only. <sup>(1)</sup> | 1                | X              | X  |

- (1) When this bit is set to 1, user should always either set OUT\_MODE bits such that Apath = InA **or** OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA will be invalid.

Figure 20-36. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$$FED = DBFED \times T_{TBCLK}$$

$$RED = DBRED \times T_{TBCLK}$$

Where  $T_{TBCLK}$  is the period of TBCLK, the prescaled version of EPWMCLK.

For convenience, delay values for various TBCLK options are shown in [Table 20-11](#). The ePWM input clock frequency that these delay values been computed by is 100 MHz.

**Table 20-11. Dead-Band Delay Values in  $\mu$ S as a Function of DBFED and DBRED**

| Dead-Band Value | Dead-Band Delay in $\mu$ S |                   |                    |                   |
|-----------------|----------------------------|-------------------|--------------------|-------------------|
|                 | DBFED, DBRED               | TBCLK = EPWMCLK/1 | TBCLK = EPWMCLK /2 | TBCLK = EPWMCLK/4 |
| 1               |                            | 0.01 $\mu$ S      | 0.02 $\mu$ S       | 0.04 $\mu$ S      |
| 5               |                            | 0.05 $\mu$ S      | 0.10 $\mu$ S       | 0.20 $\mu$ S      |
| 10              |                            | 0.10 $\mu$ S      | 0.20 $\mu$ S       | 0.40 $\mu$ S      |
| 100             |                            | 1.00 $\mu$ S      | 2.00 $\mu$ S       | 4.00 $\mu$ S      |
| 200             |                            | 2.00 $\mu$ S      | 4.00 $\mu$ S       | 8.00 $\mu$ S      |
| 400             |                            | 4.00 $\mu$ S      | 8.00 $\mu$ S       | 16.00 $\mu$ S     |
| 500             |                            | 5.00 $\mu$ S      | 10.00 $\mu$ S      | 20.00 $\mu$ S     |
| 600             |                            | 6.00 $\mu$ S      | 12.00 $\mu$ S      | 24.00 $\mu$ S     |
| 700             |                            | 7.00 $\mu$ S      | 14.00 $\mu$ S      | 28.00 $\mu$ S     |
| 800             |                            | 8.00 $\mu$ S      | 16.00 $\mu$ S      | 32.00 $\mu$ S     |
| 900             |                            | 9.00 $\mu$ S      | 18.00 $\mu$ S      | 36.00 $\mu$ S     |
| 1000            |                            | 10.00 $\mu$ S     | 20.00 $\mu$ S      | 40.00 $\mu$ S     |

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$FED = DBFED \times T_{TBCLK}/2$$

$$RED = DBRED \times T_{TBCLK}/2$$

## 20.8 PWM Chopper (PC) Submodule

Figure 20-37 illustrates the PWM chopper (PC) submodule within the ePWM module.

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

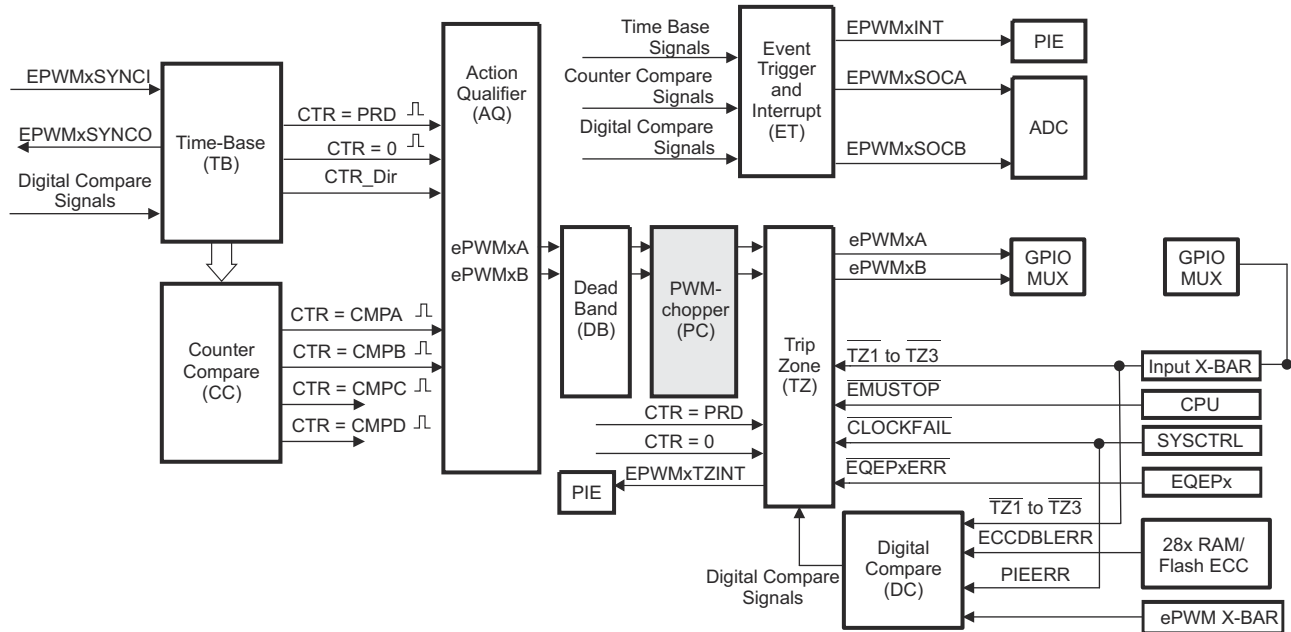

Figure 20-37. PWM Chopper Submodule

### 20.8.1 Purpose of the PWM Chopper Submodule

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

### 20.8.2 Operational Highlights for the PWM Chopper Submodule

Figure 20-38 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 20-38. PWM Chopper Submodule Operational Details

### 20.8.3 Waveforms

Figure 20-39 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 20-39. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only

### 20.8.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{EPWMCLK} \times 8 \times OSHTWTH$$

Where  $T_{EPWMCLK}$  is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 20-40 shows the first and subsequent sustaining pulses and Table 20-12 gives the possible pulse width values for a EPWMCLK = 80 MHz.

Figure 20-40. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

Table 20-12. Possible Pulse Width Values for EPWMCLK = 80 MHz

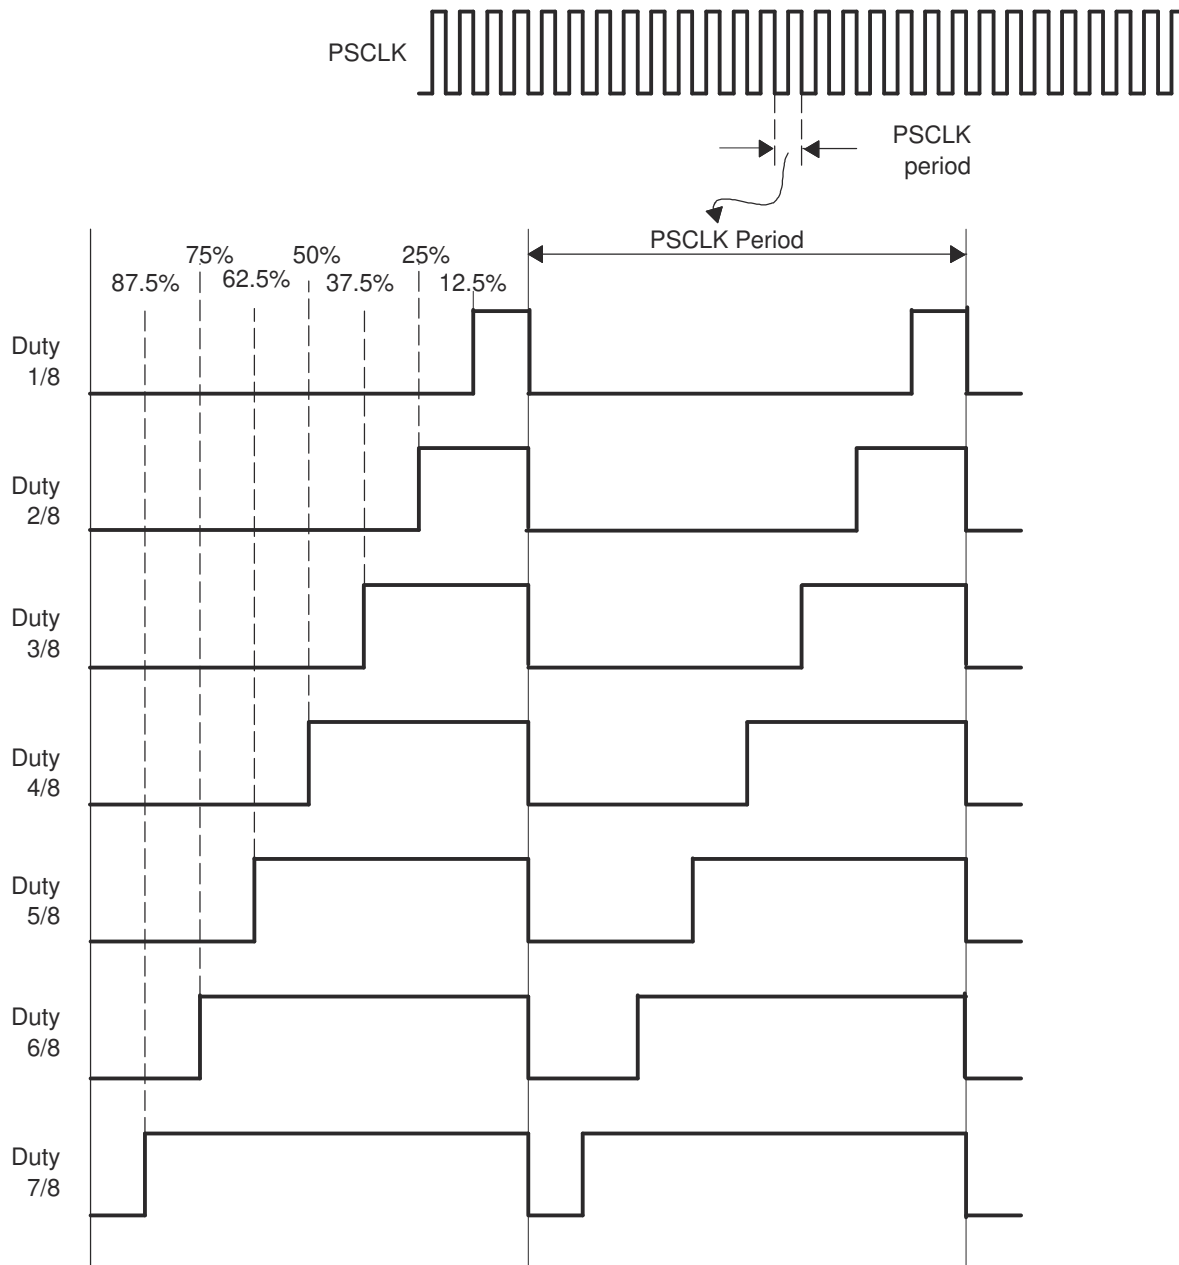

| OSHTWTHz (hex) | Pulse Width (nS) |
|----------------|------------------|
| 0              | 100              |
| 1              | 200              |
| 2              | 300              |
| 3              | 400              |
| 4              | 500              |
| 5              | 600              |
| 6              | 700              |
| 7              | 800              |
| 8              | 900              |
| 9              | 1000             |
| A              | 1100             |
| B              | 1200             |
| C              | 1300             |
| D              | 1400             |
| E              | 1500             |
| F              | 1600             |

### 20.8.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 20-41 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

**Figure 20-41. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

## 20.9 Trip-Zone (TZ) Submodule

Figure 20-42 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six  $\overline{TZ}$  signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).  $\overline{TZ1}$  to  $\overline{TZ3}$  are sourced from the GPIO mux.  $\overline{TZ4}$  is sourced from an inverted EQEPxERR signal on those devices with an EQEP module.  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

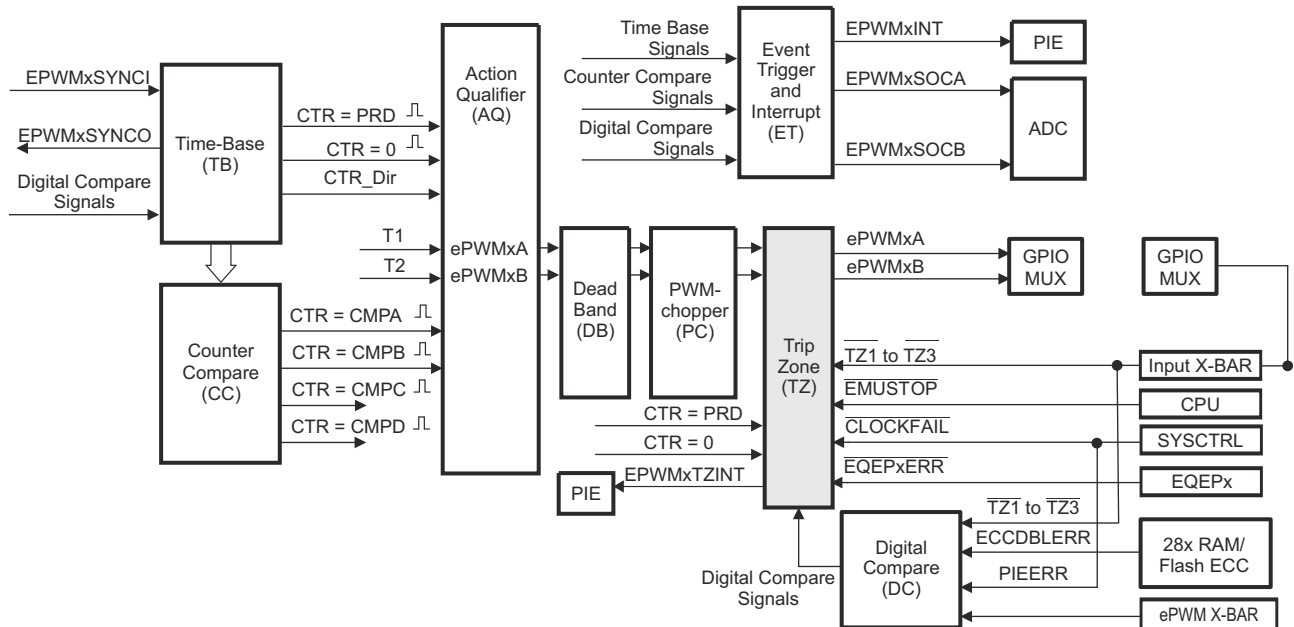

Figure 20-42. Trip-Zone Submodule

### 20.9.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZ6}$  can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or  $\overline{TZ1}$  to  $\overline{TZ3}$  signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

## 20.9.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals  $\overline{TZ1}$  to  $\overline{TZ6}$  (also collectively referred to as  $\overline{TZn}$ ) are active-low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of  $3 \cdot TBCLK$  low pulse width on  $\overline{TZn}$  inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on  $\overline{TZn}$  inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the *System Control and Interrupts* chapter.

Each  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input), respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB outputs. [Table 20-13](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] and TZCBCFLG flag bits will remain set until they are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and/or TZCBCFLG register bits are cleared, then these bits will again be immediately set.

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 20-13](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, TZOSTFLG register bit should be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

---

#### Note

Clear the TZFLG and TZOSTFLG flags after ensuring that the TRIPIN source of the OST has become inactive. Otherwise, if interrupts are enabled, depending on when the flags are cleared, an OST interrupt could occur and the OST flags are zero.

---

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRISEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see [Section 20.11](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 20-13](#) lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCB register. Actions specified in TZCTLDCA and TZCTLDCB registers take effect only when ETZE bit in TZCTL2 is set.

In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCB register bit fields. Some of the possible actions, shown in [Table 20-13](#), can be taken on a trip event.

**Table 20-13. Possible Actions On a Trip Event**

| TZCTL Register Bitfield Settings | EPWMxA and/or EPWMxB | Comment   |
|----------------------------------|----------------------|---|
| 0,0                              | High-Impedance       | Tripped   |
| 0,1                              | Force to High State  | Tripped   |
| 1,0                              | Force to Low State   | Tripped   |
| 1,1                              | No Change            | Do Nothing.<br>No change is made to the output. |

### Example 20-1. Trip-Zone Configurations

#### Scenario A:

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

#### Scenario B:

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

---

#### Note

When configuring the GPIOs and INPUT X-BAR/EPWM X-BAR options, be aware that a change in the X-BAR input selections may cause an unwanted event. Therefore, ideally, the user will set up the GPIO and X-BAR input configurations before enabling the ePWM Trip-Zone. If it is a requirement to change the GPIO/X-BAR configurations while the ePWM Trip-Zone is enabled, the user can turn off the TRIPs by clearing the TZSEL register and re-configuring the TRIP selection (TZSEL) after the INPUT XBAR selection is changed.

---

### 20.9.3 Generating Trip Event Interrupts

Figure 20-43 and Figure 20-44 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 20.11.

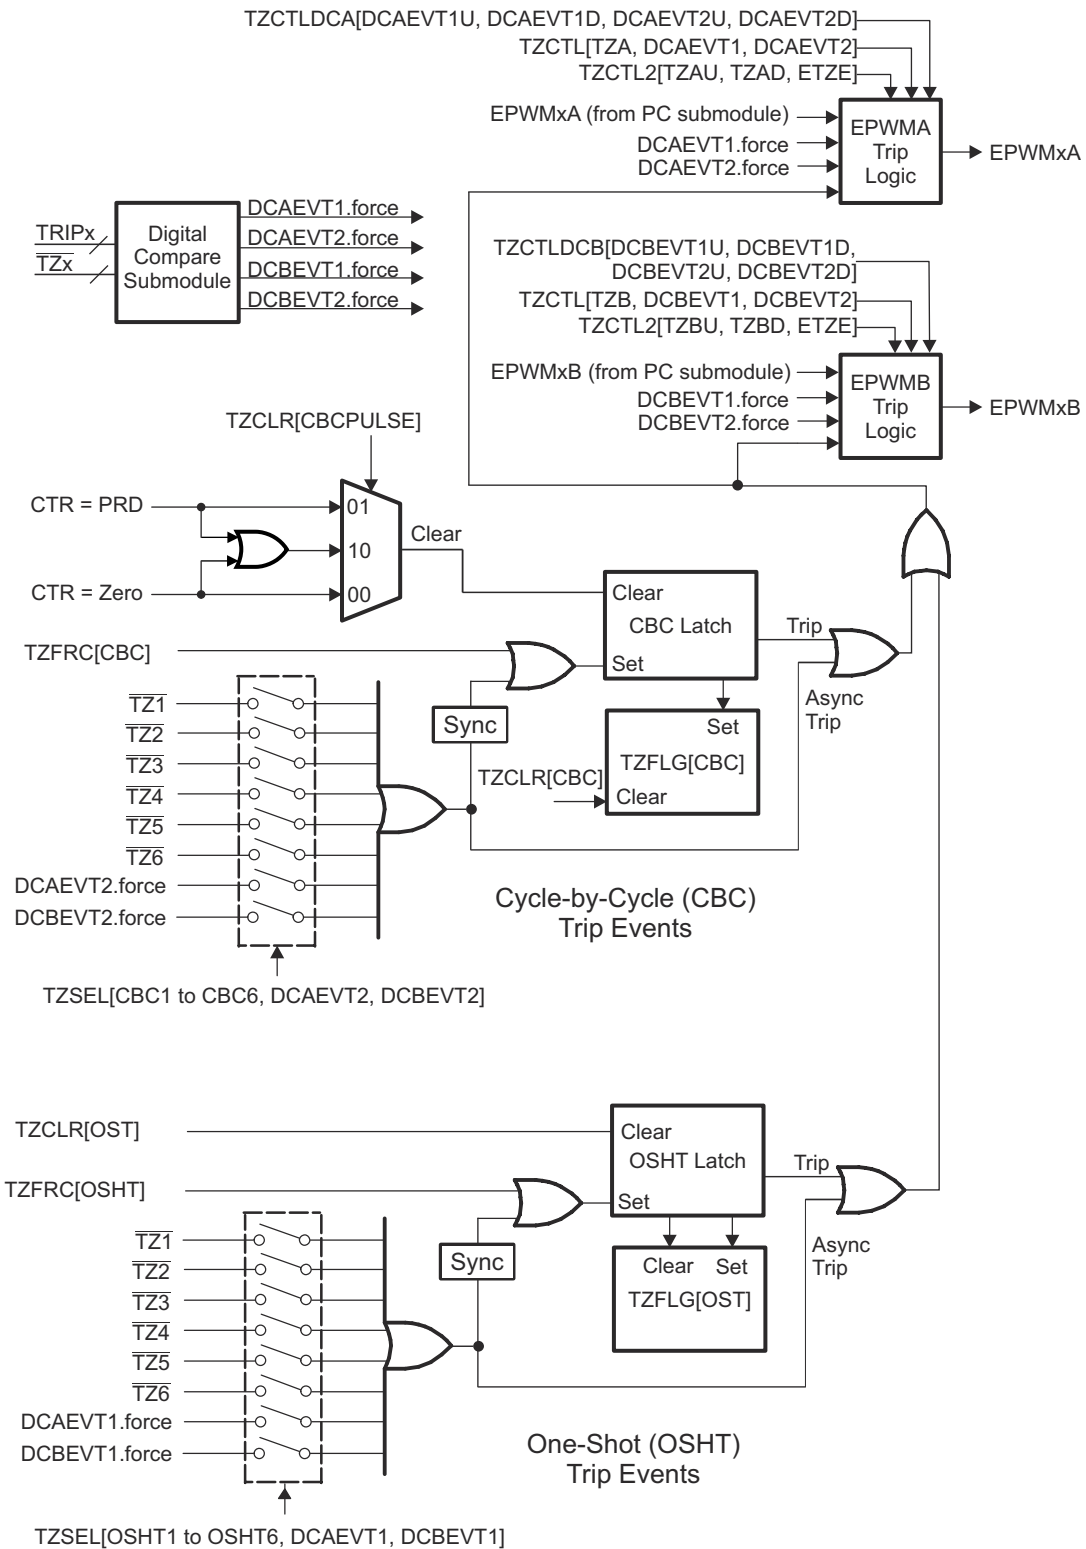

Figure 20-43. Trip-Zone Submodule Mode Control Logic

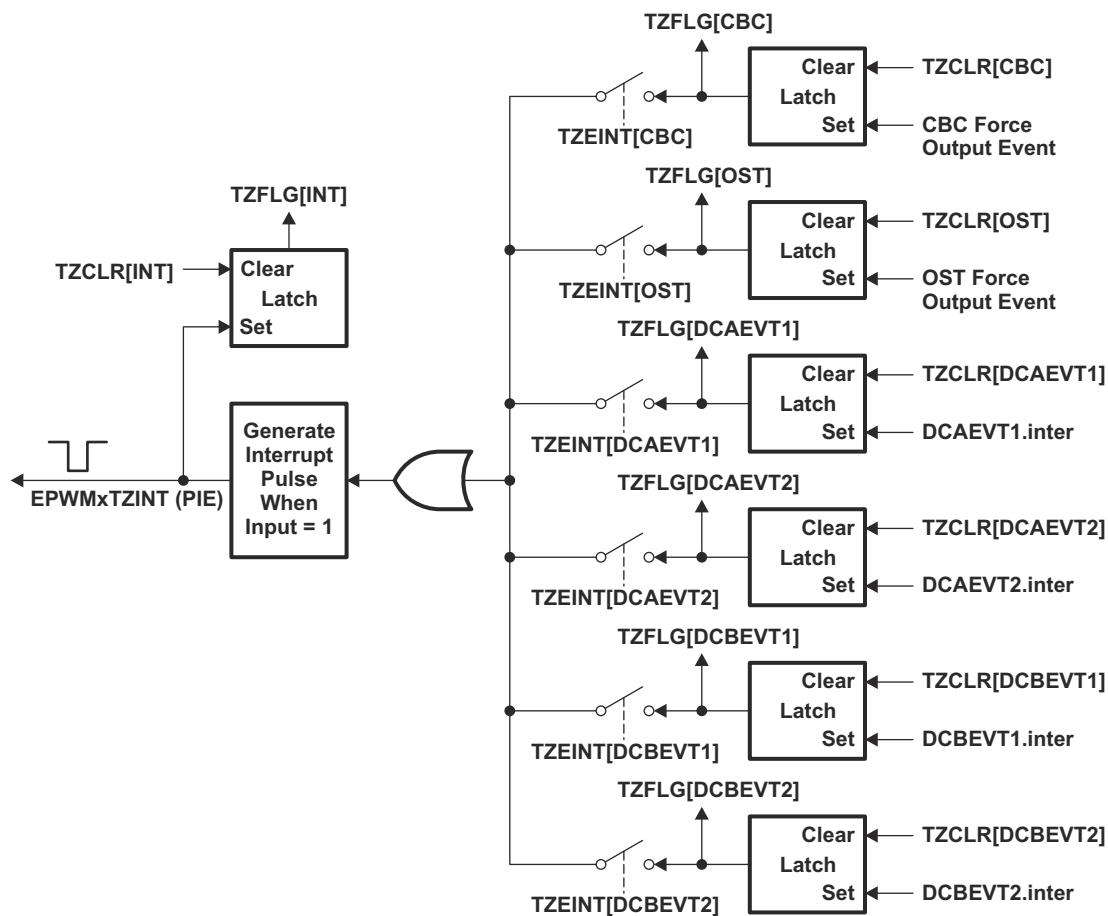

Figure 20-44. Trip-Zone Submodule Interrupt Logic

These individual flags for the CBC, OST and DCxEVTy can be used to detect the source of the EPWMxTZINT Interrupt. When multiple sources are used to generate the EPWMxTZINT interrupt, reading and clearing the flags will user to take different actions based on the specific event.

## 20.10 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs.

Figure 20-45 illustrates where the event-trigger submodule fits within the ePWM system.

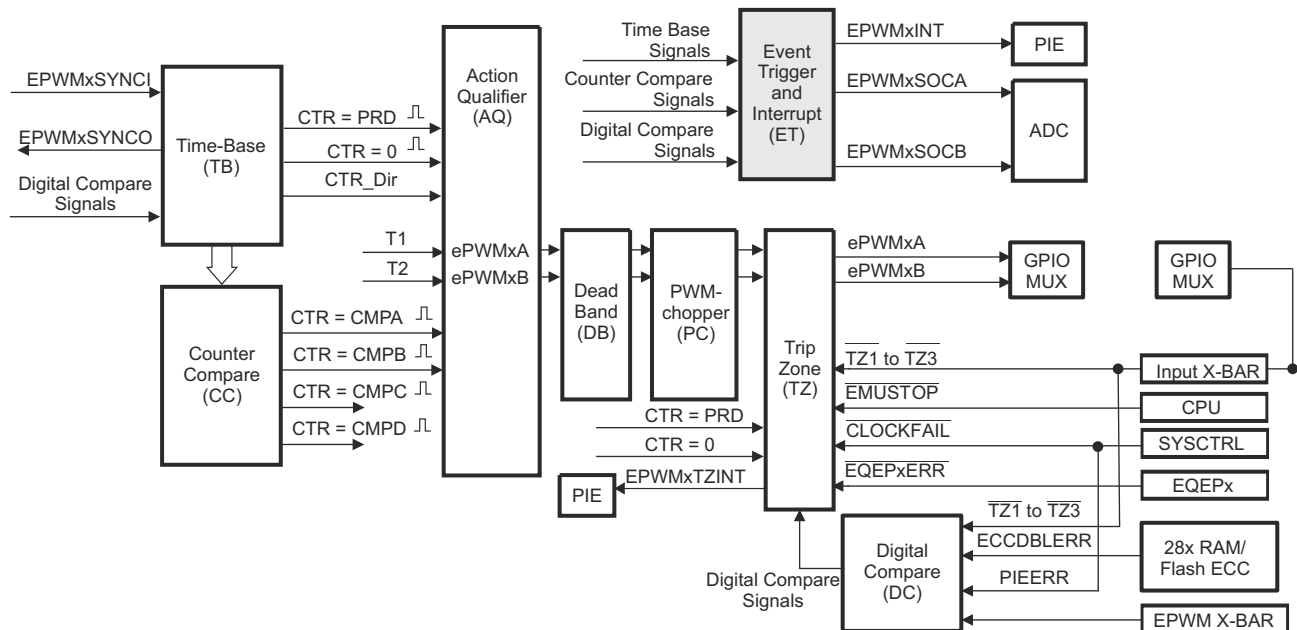

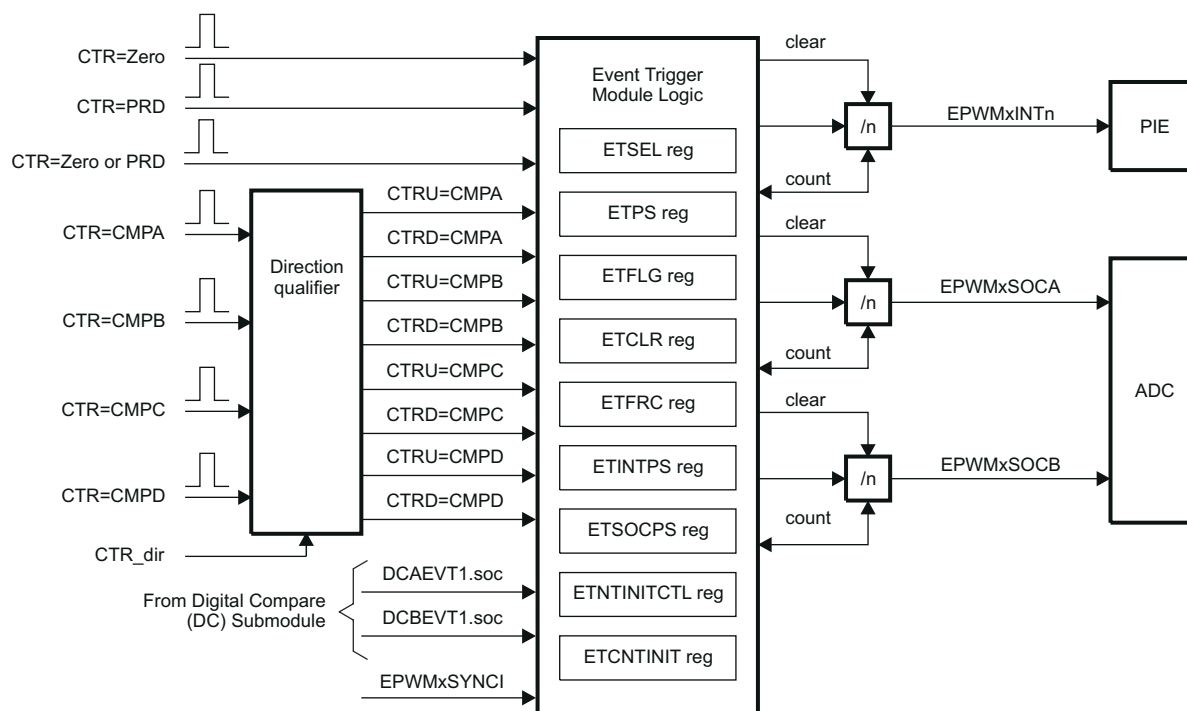

Figure 20-45. Event-Trigger Submodule

### 20.10.1 Operational Overview of the ePWM Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of Figure 20-46) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to every fifteenth event

**Figure 20-46. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- ETSEL - This selects which of the possible events will trigger an interrupt or start an ADC conversion.
- ETPS - This programs the event prescaling options mentioned above.
- ETFLG - These are flag bits indicating status of the selected and prescaled events.
- ETCLR - These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC - These bits allow software forcing of an event. Useful for debugging or software intervention.
- ETINTPS - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- ETSOCPS - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- ETNTINITCTL - These bits enable ETCNTINIT initialization via SYNC event OR via software force.
- ETCNTINIT - These bits allow you to initialize INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in [Figure 20-47](#), [Figure 20-48](#), and [Figure 20-49](#).

[Figure 20-47](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event.
- Generate an interrupt on every second event.
- Generate an interrupt on every third event.

On ePWM type 4, in order to enable event generation capability up to 15 events the following changes have been made. The selection made on ETPS[INTPSSEL] bit determines whether ETINTPS register, INTCNT2 and INTPRD2 bit fields determine frequency of events (interrupt once every 0-15 events).

The event that can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) and (ETSEL[INTSELCMP]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x00).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x00 || TBCTR = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is incrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is decrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is incrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter ETPS[INTCNT] or ETINTPS[INTCNT2] register bits based off of the selection made using ETPS[INTPSSEL]. That is, when the specified event occurs the ETPS[INTCNT] or ETINTPS[INTCNT2] bits are incremented until they reach the value specified by ETPS[INTPRD] or ETINTPS[INTPRD2] determined again by the selection made in ETPS[INTPSSEL]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the PIE.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behavior will occur [The below behavior is also applicable to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing '0' to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored. The same applies to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event if using the INTCNT and INTPRD. You can generate an interrupt on every event up to 15 events if using the INTCNT2 and INTPRD2.

The INTCNT2 value can be initialized with the value from ETCNTINIT[INTINIT] based on the selection made in ETCNTINITCTL[INTINITEN]. When ETCNTINITCTL[INTINITEN] is set, then it enables initialization of INTCNT2 counter with contents of ETCNTINIT[INTINIT] on a SYNC event or software force determined by ETCNTINITCTL[INTINITFRC].

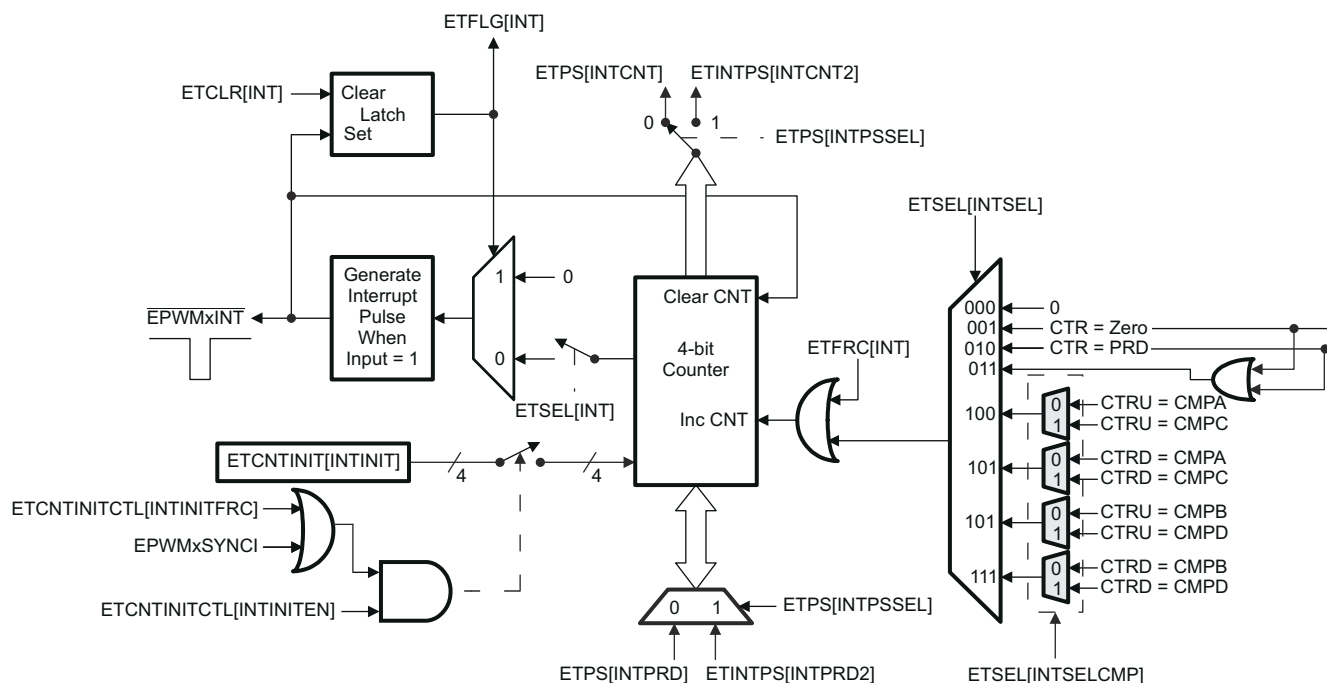

Figure 20-47. Event-Trigger Interrupt Generator

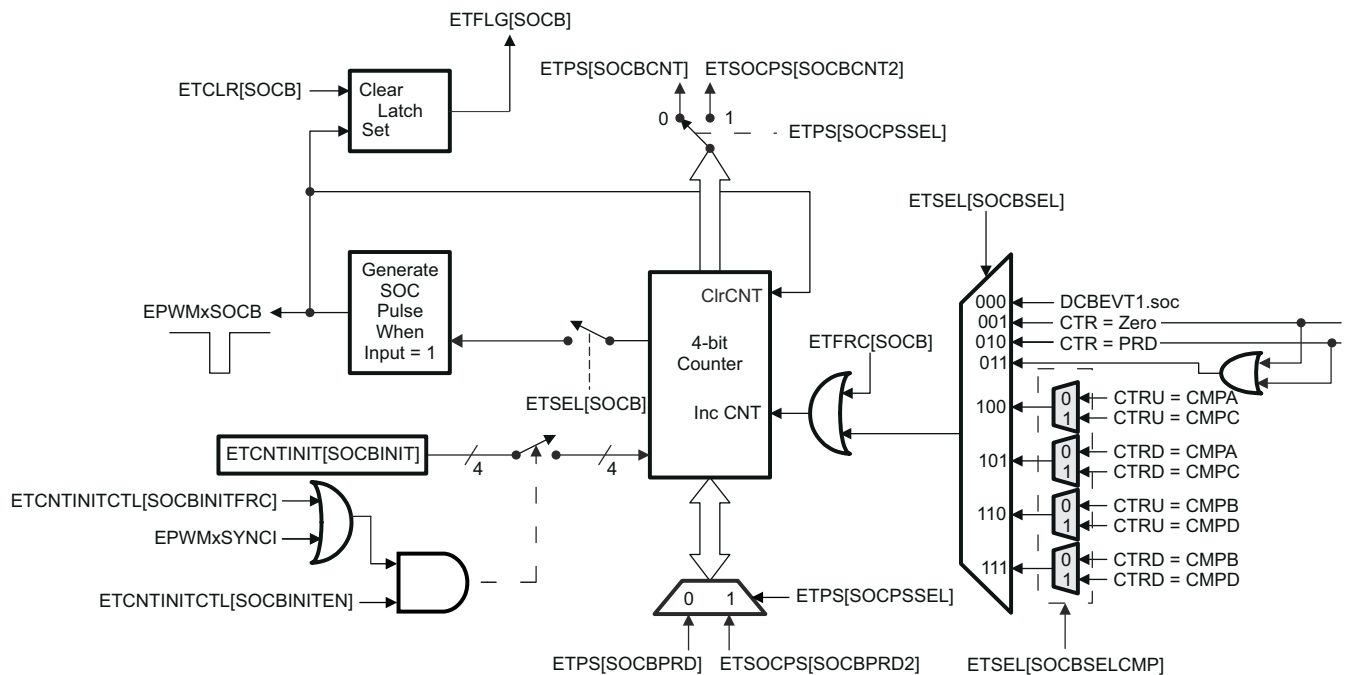

Figure 20-48 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The enhancements include SOCASELCMP and SOCBSELCMP bit fields defined in the ETSEL register enable CMPC and CMPD events respectively to cause a start of conversion. The ETPS[SOCPSSEL] bit field determines whether SOCACNT2 and SOCAPRD2 take control or not. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule. The SOCACNT2 initialization scheme is very similar to the interrupt generator with respective enable, value initialize and SYNC or software force options.

NOTE: The DCAEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 20.11.

Figure 20-48. Event-Trigger SOCA Pulse Generator

Figure 20-49 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

NOTE: The DCBEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 20.11.

Figure 20-49. Event-Trigger SOCB Pulse Generator

## 20.11 Digital Compare (DC) Submodule

Figure 20-50 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 20-51.

On this device, any of the GPIO pins can be flexibly mapped to be the trip-zone input and/or trip inputs to the trip-zone submodule and digital compare submodule. The Input X-BAR Input Select (INPUTxSELECT) register defines which GPIO pins gets assigned to be the trip-zone inputs / trip inputs.

The digital compare (DC) submodule compares signals external to the ePWM module (for instance, CMPSSx signals from the analog comparators) to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

### Note

The user is responsible for driving correct state on the selected pin before enabling clock and configuring the trip input for the respective ePWM peripheral to avoid spurious latch of TRIP signal.

Figure 20-50. Digital-Compare Submodule High-Level Block Diagram

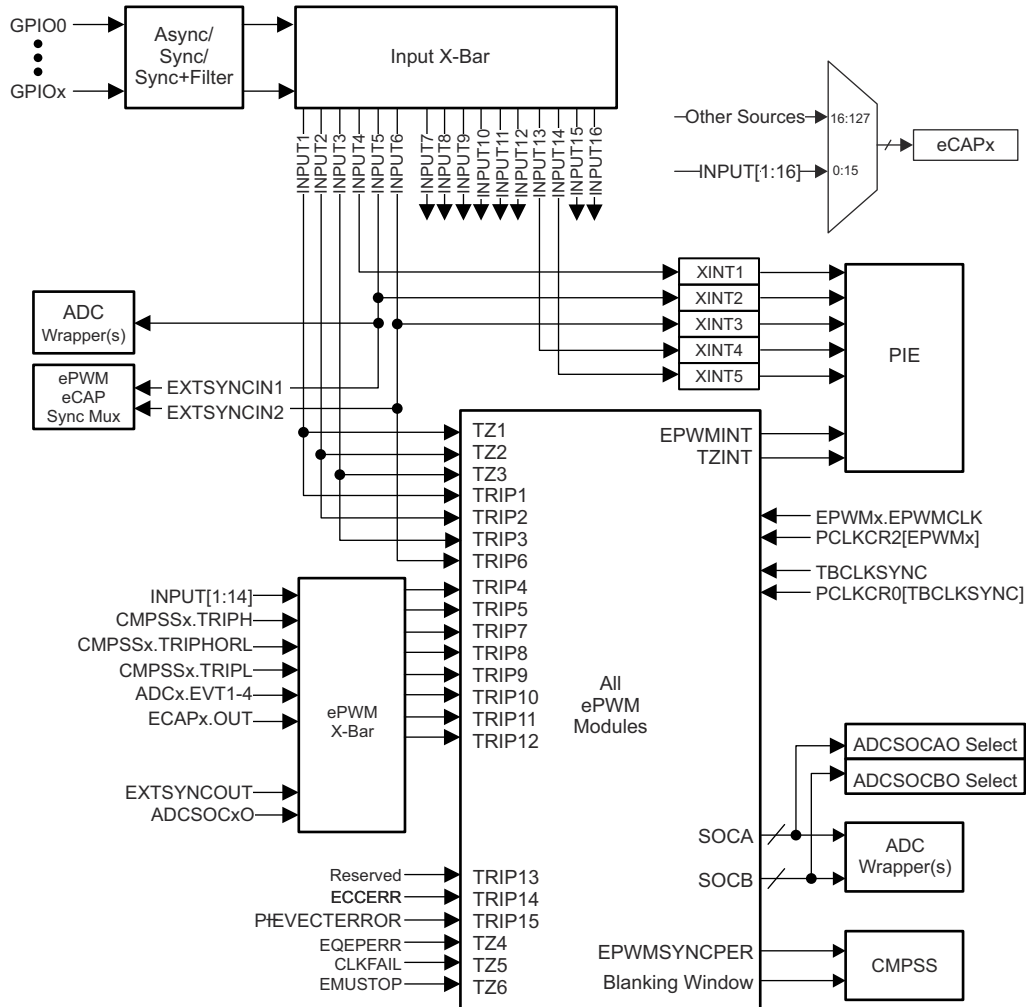

Figure 20-51. GPIO MUX-to-Trip Input Connectivity

### 20.11.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- Analog comparator (COMP) module outputs fed through the Input X-BAR logic externally using the GPIO peripheral, internal PIE, ECC error signals, TZ1, TZ2, and TZ3 inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

### 20.11.2 Enhanced Trip Action Using CMPSS

In order to allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

The user has a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

### 20.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps should be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification will be introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition will remain active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition will not be cleared until after the following PWM cycle has started. Thus, the new PWM cycle will detect a trip condition as soon as it begins.

To avoid this undesired trip condition, the user application should take steps to ensure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip will not be asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal via the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (via COMPSTSCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (via HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

### 20.11.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

#### 20.11.4.1 Digital Compare Events

As described in [Section 20.11.1](#), trip zone inputs ( $\overline{TZ1}$ ,  $\overline{TZ2}$ , and  $\overline{TZ3}$ ) and CMPSSx signals from the analog comparator (COMP) module can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

---

### Note

The  $\overline{TZn}$  signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. ePWM outputs are asynchronously tripped when either the  $\overline{TZn}$ , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of  $3 \cdot TBCLK$  sync pulse width is required. If pulse width is  $< 3 \cdot TBCLK$  sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

---

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Section 20.11.4.2](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

Output EPWMxA:

- TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
- TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
- TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

Output EPWMxB:

- TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
- TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
- TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)

- **interrupt signal:**

DCAEVT1/2.interrupt signals generate trip zone interrupts to the PIE. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

[Figure 20-52](#) and [Figure 20-53](#) show how the DCxEVT1, DCxEVT2, or DCEVTFLT signals are processed to generate the digital compare A and B event force, interrupt, soc and sync signals.

In some of the applications like Phase Shifted Full Bridge (PSFB) Converters, it is required that different actions are taken on a CBC trip event and an OST trip event. This can be achieved using the DCxEVT1LAT.

- This latch could be cleared on CNT=0, CTR=PRD, and CNT=0 OR CTR=PRD events based on the setting of DCxCTL.EVty.LATCLRSEL setting. This is similar to CBC latch clear mechanism.
- DCxEVty.force signal could be chosen to be either the latched version or the “un-latched” version based on DCxCTL.EVtyLATSEL value.

- The status of DCxEV<sub>Ty</sub>LAT signal can be accessed by reading DCxCTL.EV<sub>Ty</sub>LAT field.

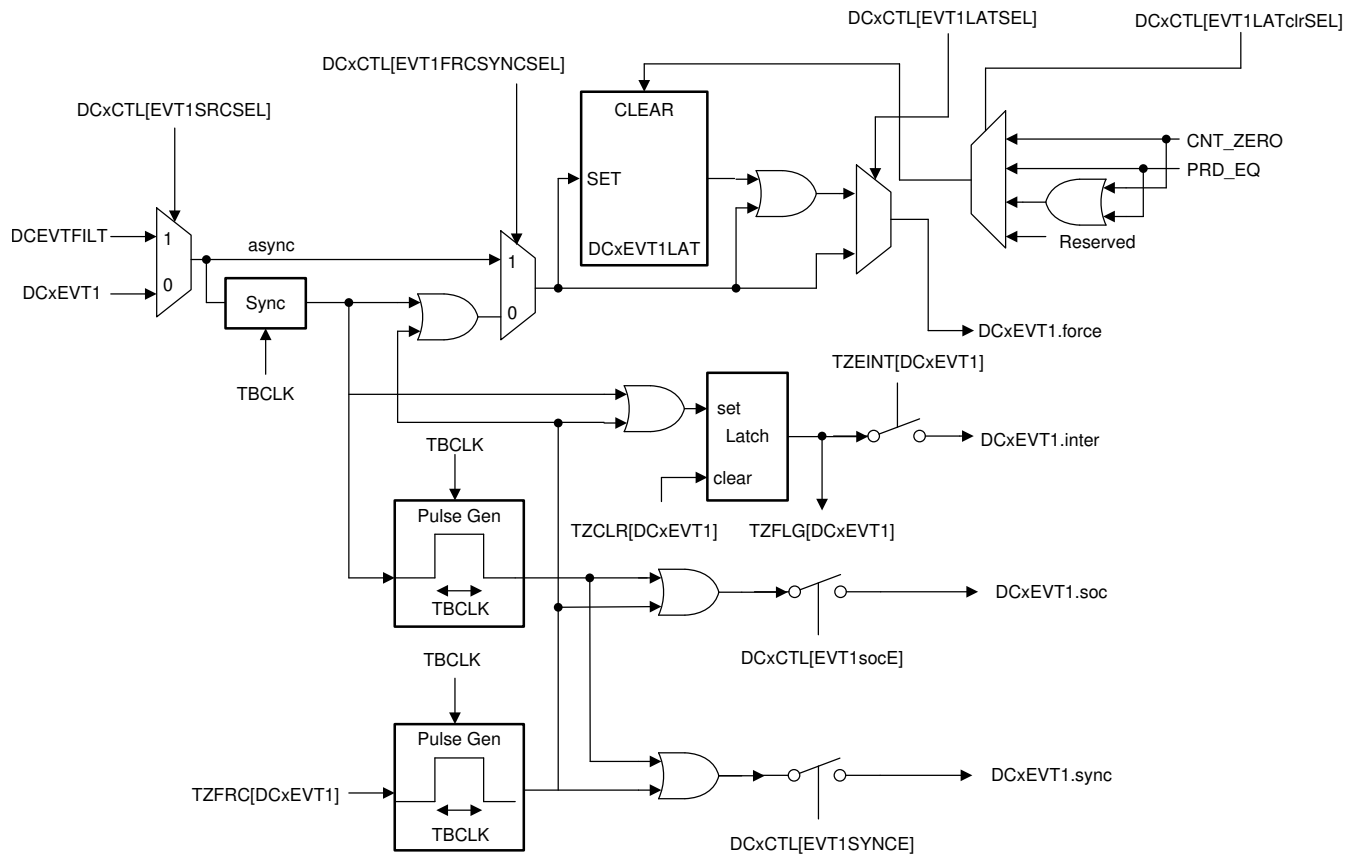

Figure 20-52. DCxEVT1 Event Triggering

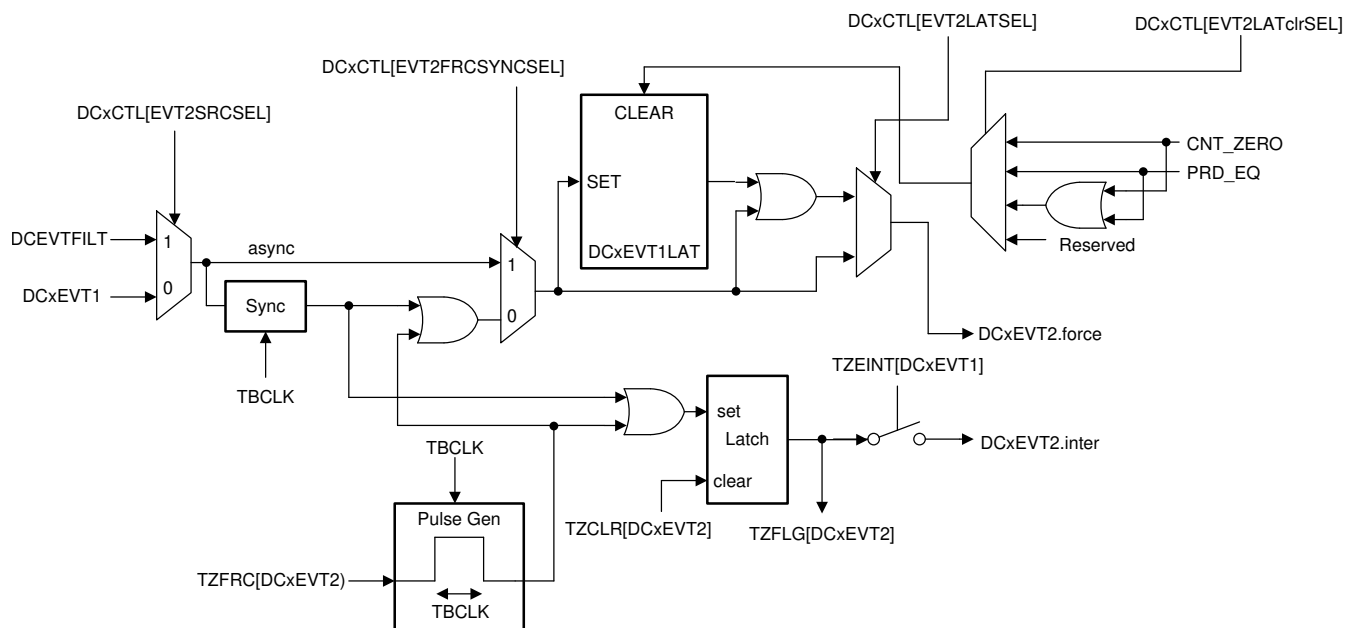

Figure 20-53. DCxEVT2 Event Triggering

### 20.11.4.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. Figure 20-54 shows the details of the event filtering logic.

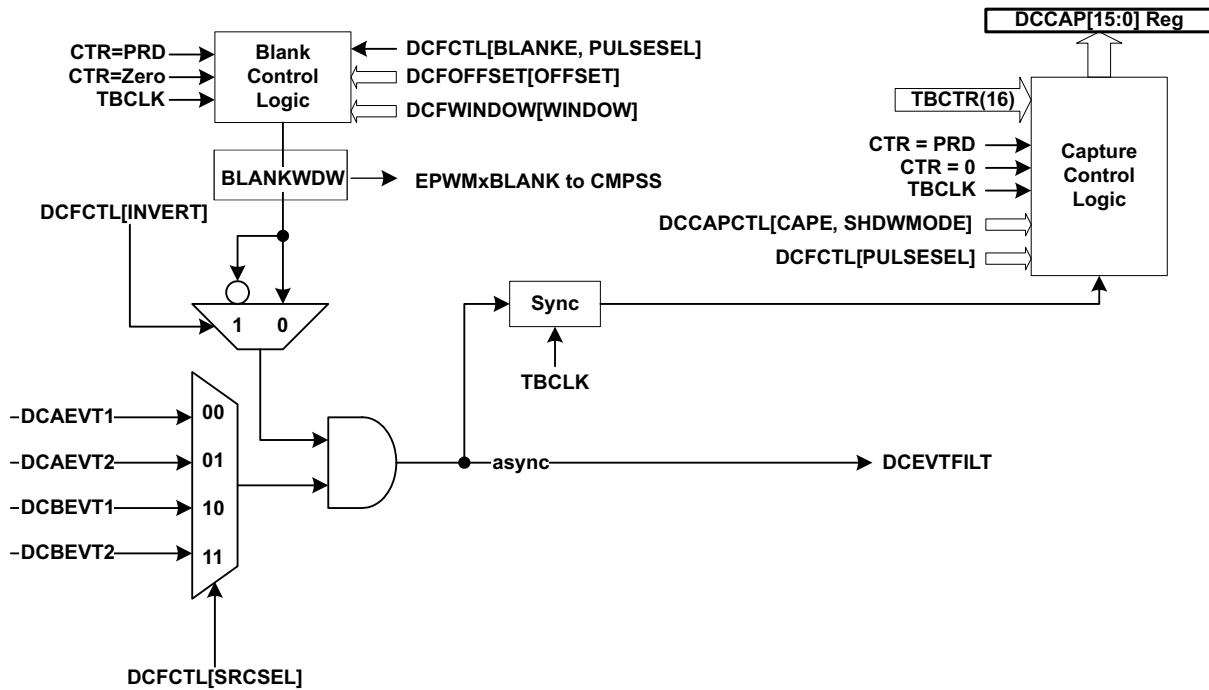

Figure 20-54. Event Filtering

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

#### Note

You must configure the ePWM blanking window appropriately so that the Trip Input stays valid for at least 3 ePWM cycles after the blanking window has expired.

### BLANKPULSEMIX Signals

The DCFCTL MUX (available for Blank Control Logic and Capture Control Logic) has new options which allows it to select the BLANKPULSEMIX signal respectively. The BLANKPULSEMIX signal is used if it is selected by DCFCTL[PULSESEL]

### 20.11.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in [Section 20.11.4.2](#). This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEV<sub>Ty</sub> signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEV<sub>Ty</sub> events as input to the valley switching block (DCFCTL[SRSEL]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture 'n' rising, falling or both edges through the edge selection logic (DCFCTL[EDGEMODE, EDGECOUNT]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[TRIGSEL]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[VCAPE]).
5. Select the start edge that will indicate the start of capture for oscillation period measurement (VCNTCFG[STARTEDGE]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[STOPEDGE]) that will indicate the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
  - The STOPEDGE value must always be greater than STARTEDGE value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEV<sub>Ty</sub> signal. The CNTVAL value may be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay may be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[VDELAYDIV])
8. Configure VCAPCTL[EDGEFILTDLYSEL] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[TRIGSEL]. In this implementation, the software trigger is used as the source for VCAPCTL[TRIGSEL]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the STARTEDGE. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the STARTEDGE.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in [Figure 20-55](#).

---

#### Note

A specific application example showcasing the usage of valley switching hardware and software is available on the controlSuite.

---

Figure 20-55. Valley Switching

### 20.12 ePWM Crossbar (X-BAR)

Figure 20-56 shows the architecture of the ePWM Crossbar (X-BAR). This module enables selection of various trigger sources into any of the eight dedicated ETWPM trips inputs, namely the TRIP4, TRIP5, TRIP7, TRIP8, TRIP9, TRIP10, TRIP11, and TRIP12.

**Note**

Refer to the *Crossbar (X-BAR)* chapter for more information on the X-BAR modules, including X-BAR flags.

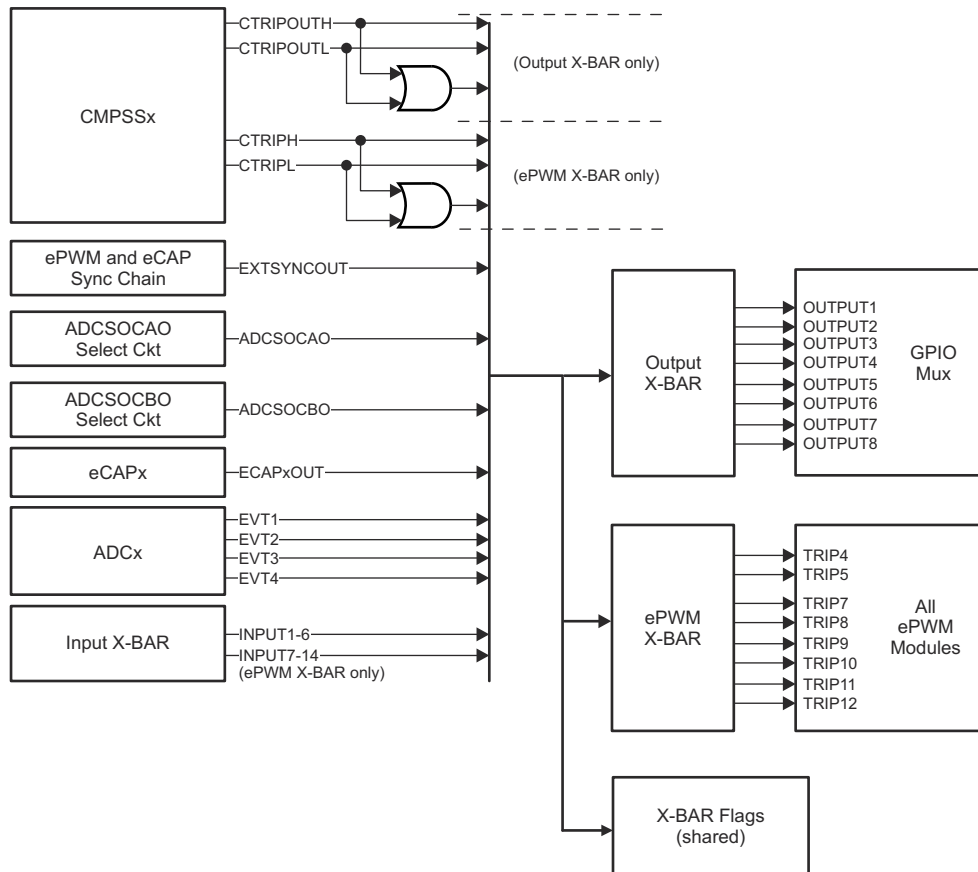

Figure 20-56. ePWM X-BAR

## 20.13 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### 20.13.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 20-57. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

Figure 20-57. Simplified ePWM Module

### 20.13.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

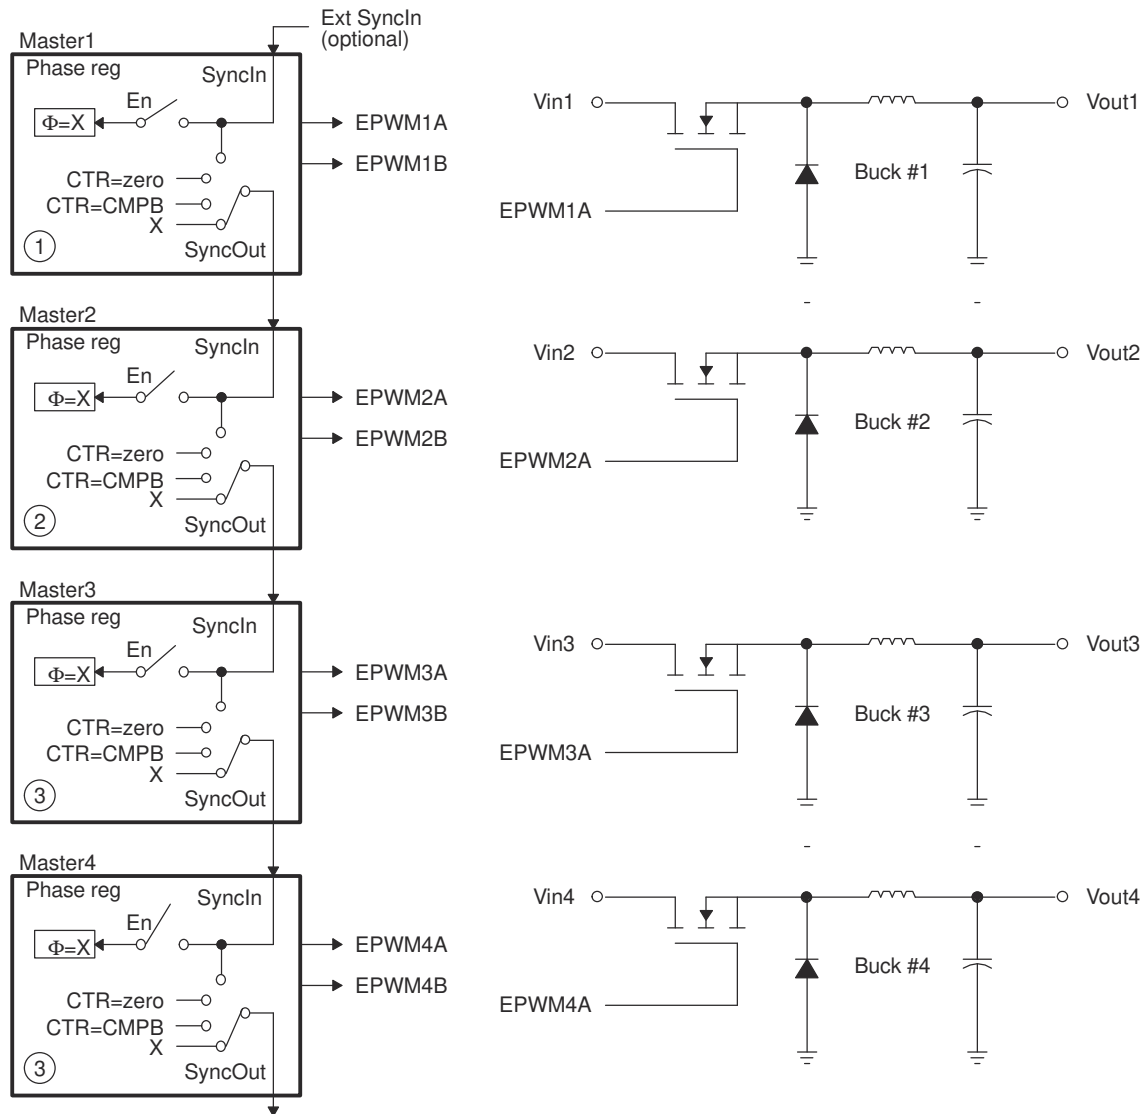

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it (that is, via the enable switch). Although various combinations are possible, the two most common—master module and slave module modes—are shown in [Figure 20-58](#).

**Figure 20-58. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

### 20.13.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 20-59 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 20-60 shows the waveforms generated by the setup shown in Figure 20-59; note that only three waveforms are shown, although there are four stages.

A.  $\phi = X$  indicates value in phase register is a "don't care"

**Figure 20-59. Control of Four Buck Stages. Here  $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$**

Figure 20-60. Buck Waveforms for Control of Four Buck Stages (Note: Only three bucks shown here)

### 20.13.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 20-61 shows such a configuration; Figure 20-62 shows the waveforms generated by the configuration.

A.  $\phi = X$  indicates value in phase register is a "don't care"

**Figure 20-61. Control of Four Buck Stages. (Note:  $F_{PWM2} = N \times F_{PWM1}$ )**

A. Starts ADC conversion.

**Figure 20-62. Buck Waveforms for Control of Four Buck Stages (Note:  $F_{PWM2} = F_{PWM1}$ )**

### 20.13.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 20-63 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 20-64 shows the waveforms generated by the configuration shown in Figure 20-63.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

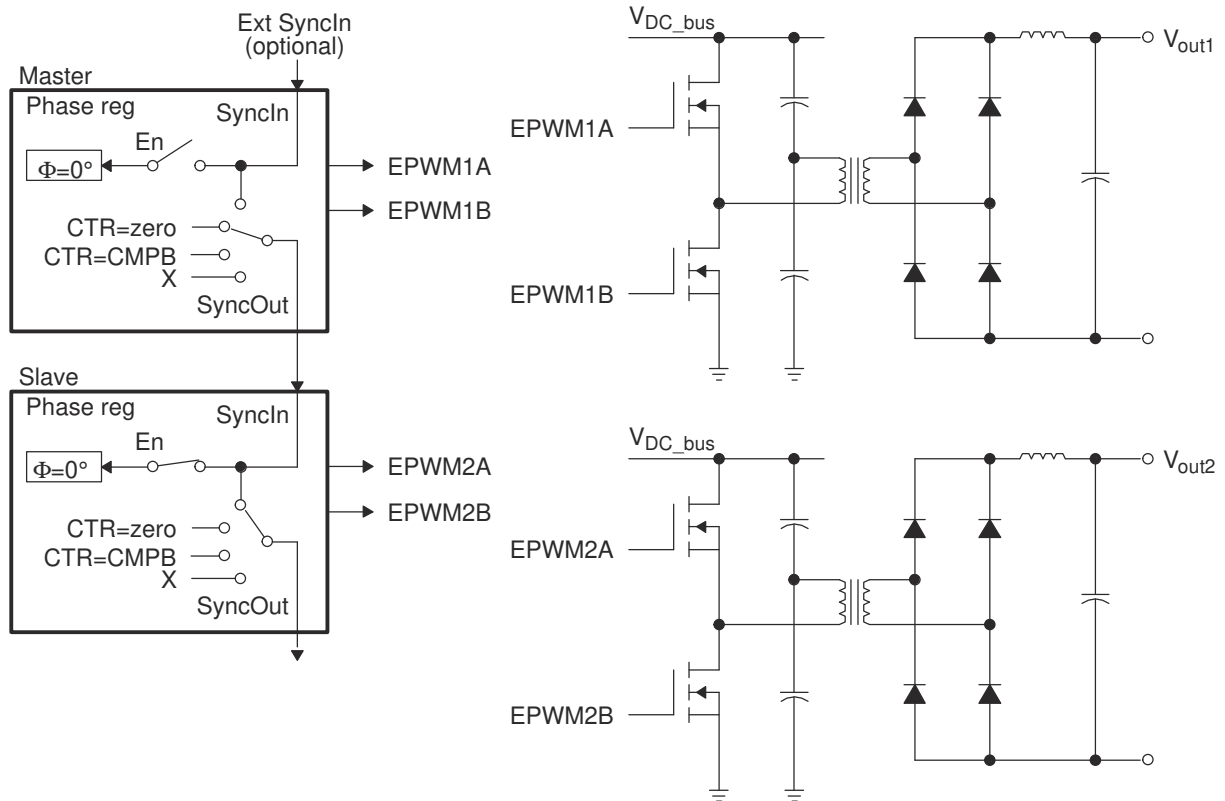

Figure 20-63. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ )

Figure 20-64. Half-H Bridge Waveforms for Control of Two Half-H Bridge Stages (Note: Here  $F_{PWM2} = F_{PWM1}$ )

### 20.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 20-65 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 20-65), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

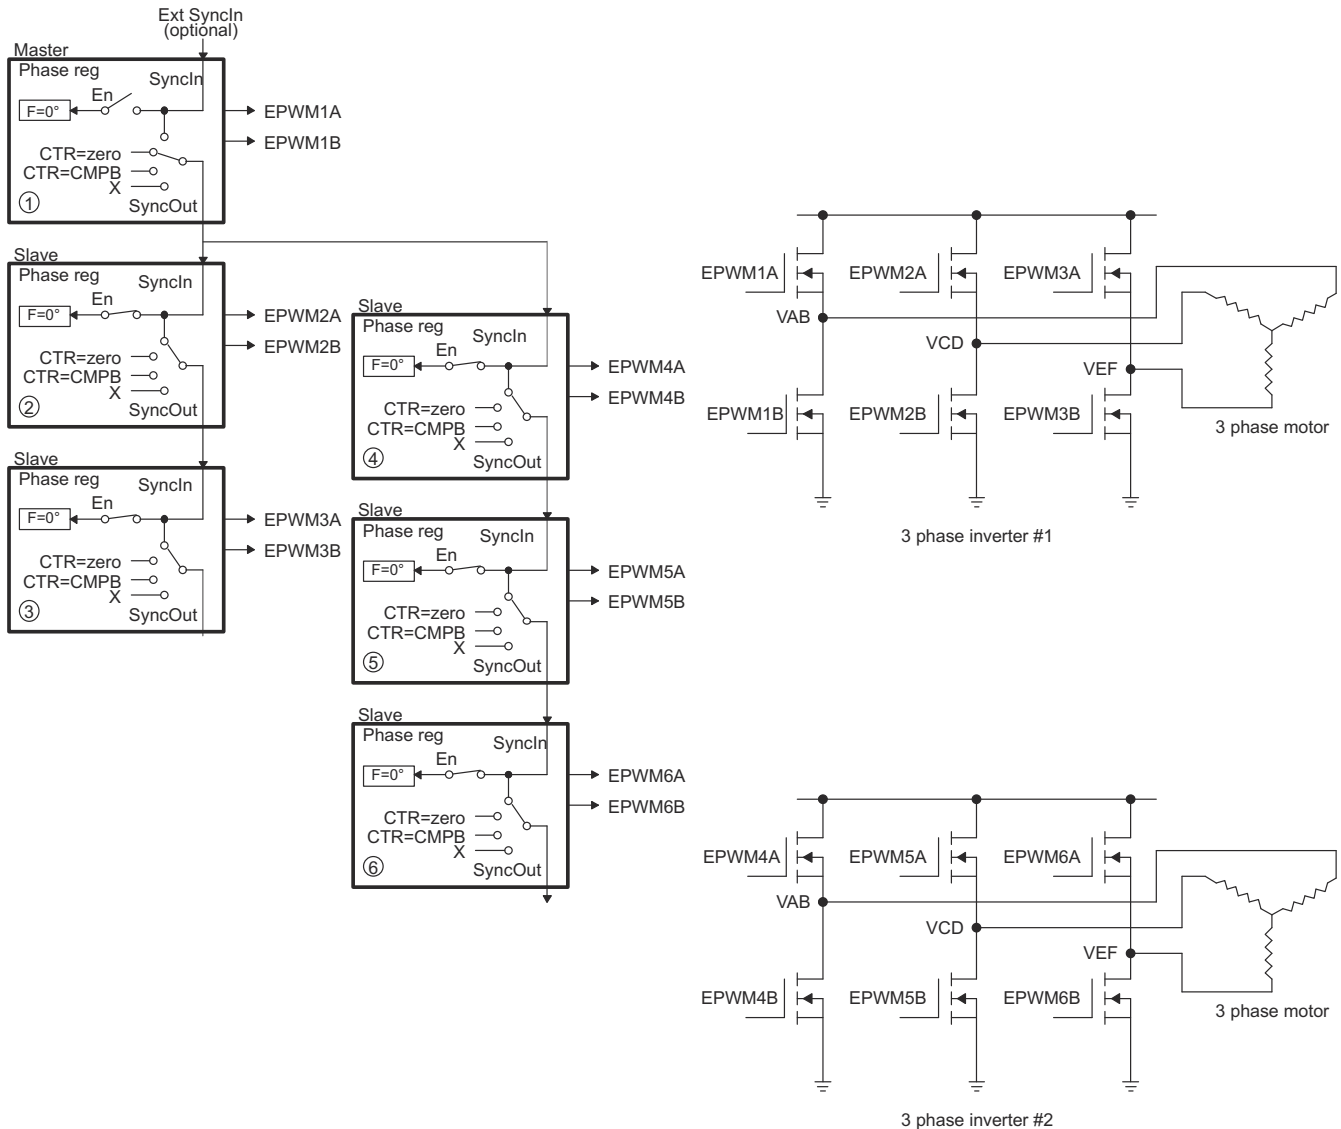

Figure 20-65. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

Figure 20-66. 3-Phase Inverter Waveforms for Control of Dual 3-Phase Inverter Stages (Only One Inverter Shown)

### 20.13.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, [Figure 20-67](#) shows a master and slave module with a phase relationship of 120° (that is, the slave leads the master).

**Figure 20-67. Configuring Two PWM Modules for Phase Control**

[Figure 20-68](#) shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is,  $200/600 \times 360^\circ = 120^\circ$ ). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120°.

**Figure 20-68. Timing Waveforms Associated With Phase Control Between Two Modules**

### 20.13.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in [Figure 20-69](#). This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be  $F = 120^\circ$ . This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master 1 module.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

$$\text{TBPHS}(N,M) = (\text{TBPRD}/N) \times (M-1) \quad (16)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N=3), TBPRD = 600,

TBPHS(3,2) = (600/3) x (2-1) = 200 (that is, Phase value for Slave module 2)

TBPHS(3,3) = 400 (that is, Phase value for Slave module 3)

[Figure 20-70](#) shows the waveforms for the configuration in [Figure 20-69](#).

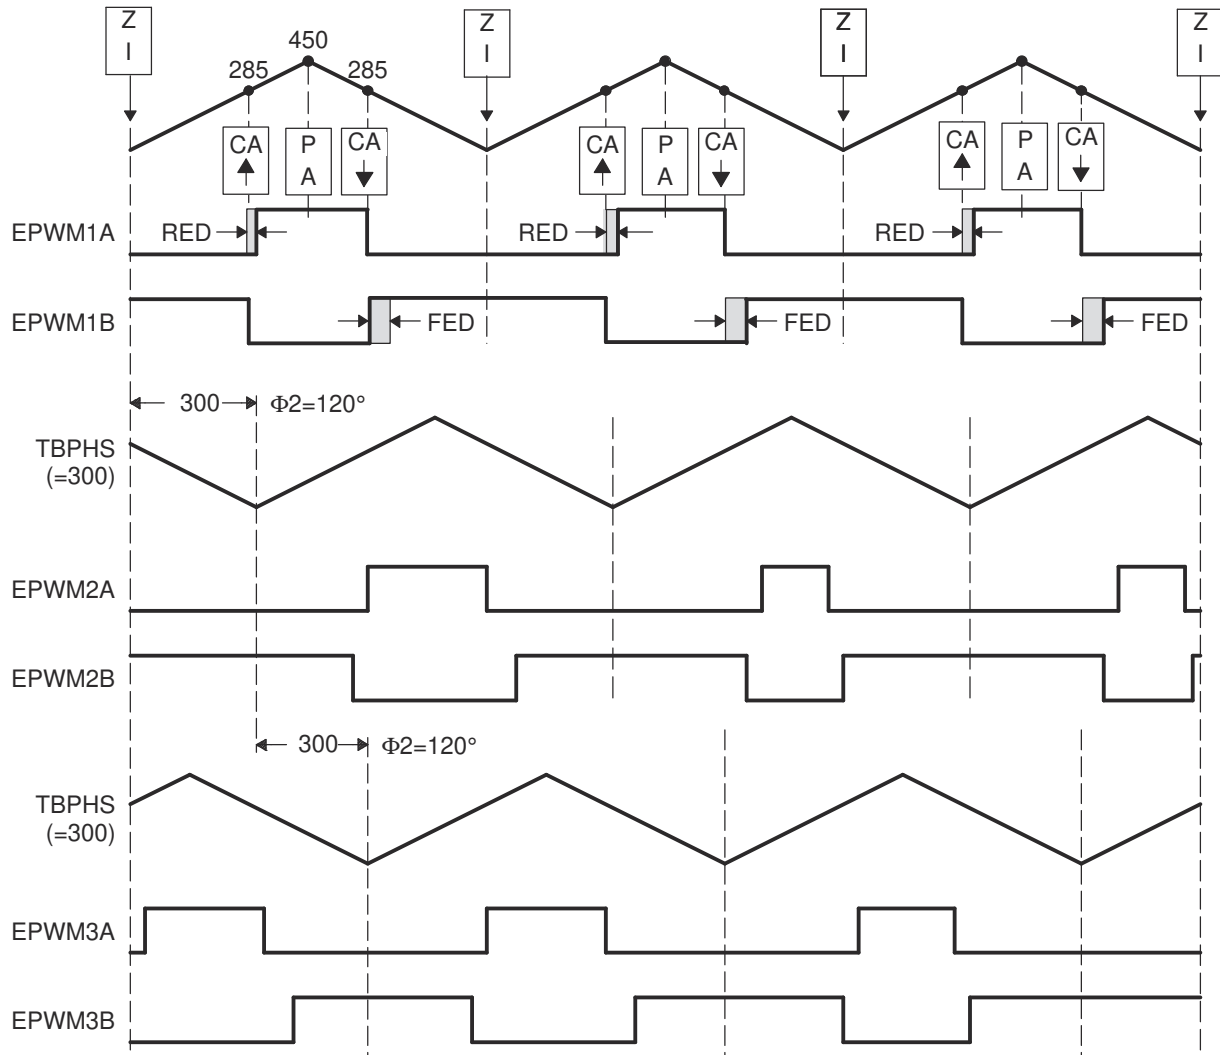

Figure 20-69. Control of a 3-Phase Interleaved DC/DC Converter

**Figure 20-70. 3-Phase Interleaved DC/DC Converter Waveforms for Control of a 3-Phase Interleaved DC/DC Converter**

### 20.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in [Figure 20-71](#) assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends itself to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge*. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. [Figure 20-72](#) shows a master/slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave's phase register (TBPHS). The master's phase register is not used and therefore can be initialized to zero.

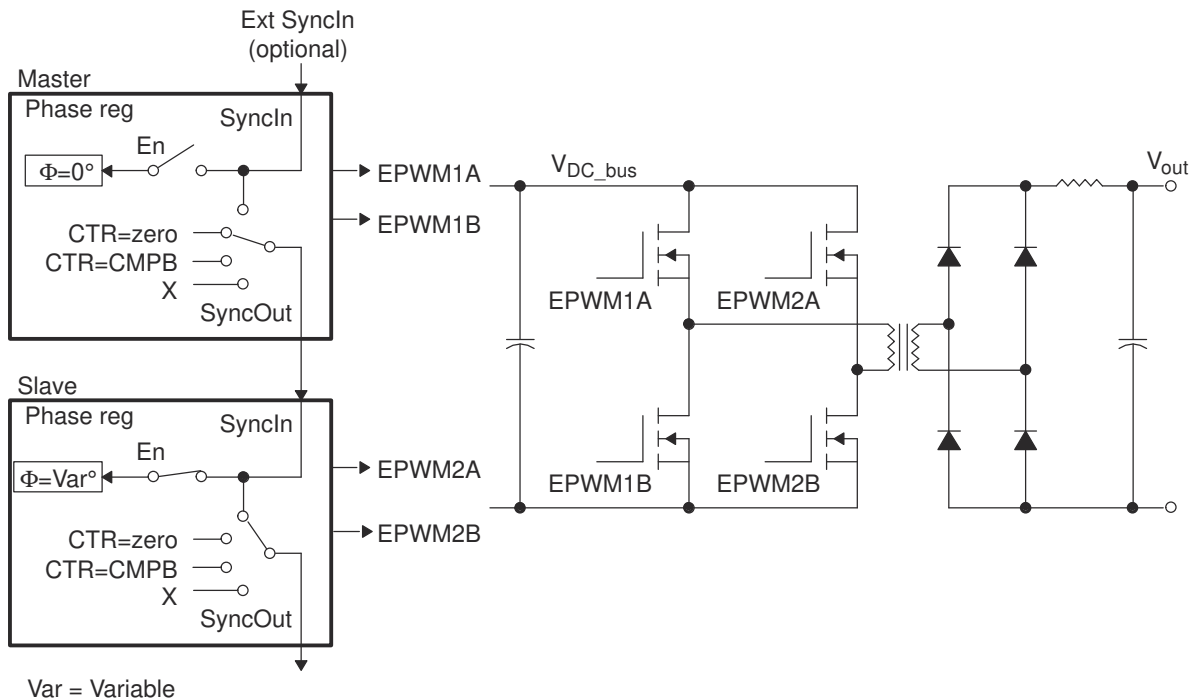

Figure 20-71. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ )

Figure 20-72. ZVS Full-H Bridge Waveforms

### 20.13.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 20-73 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 12-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference could be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 20-74 shows the waveforms generated by the configuration.

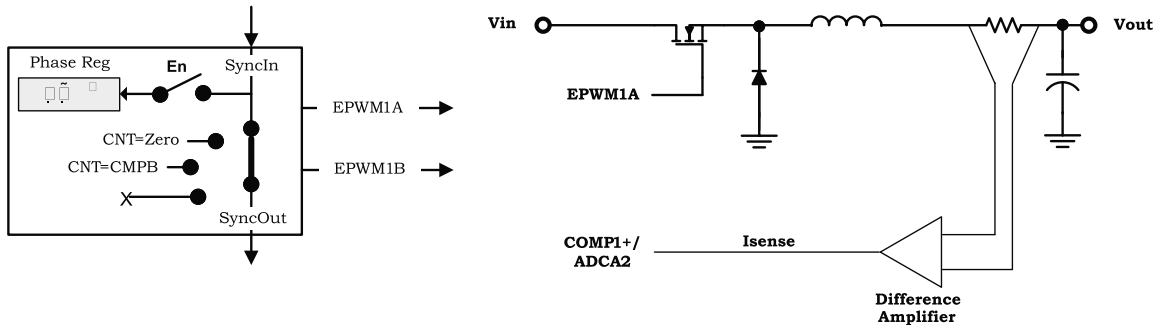

Figure 20-73. Peak Current Mode Control of a Buck Converter

Figure 20-74. Peak Current Mode Control Waveforms for Control of a Buck Converter

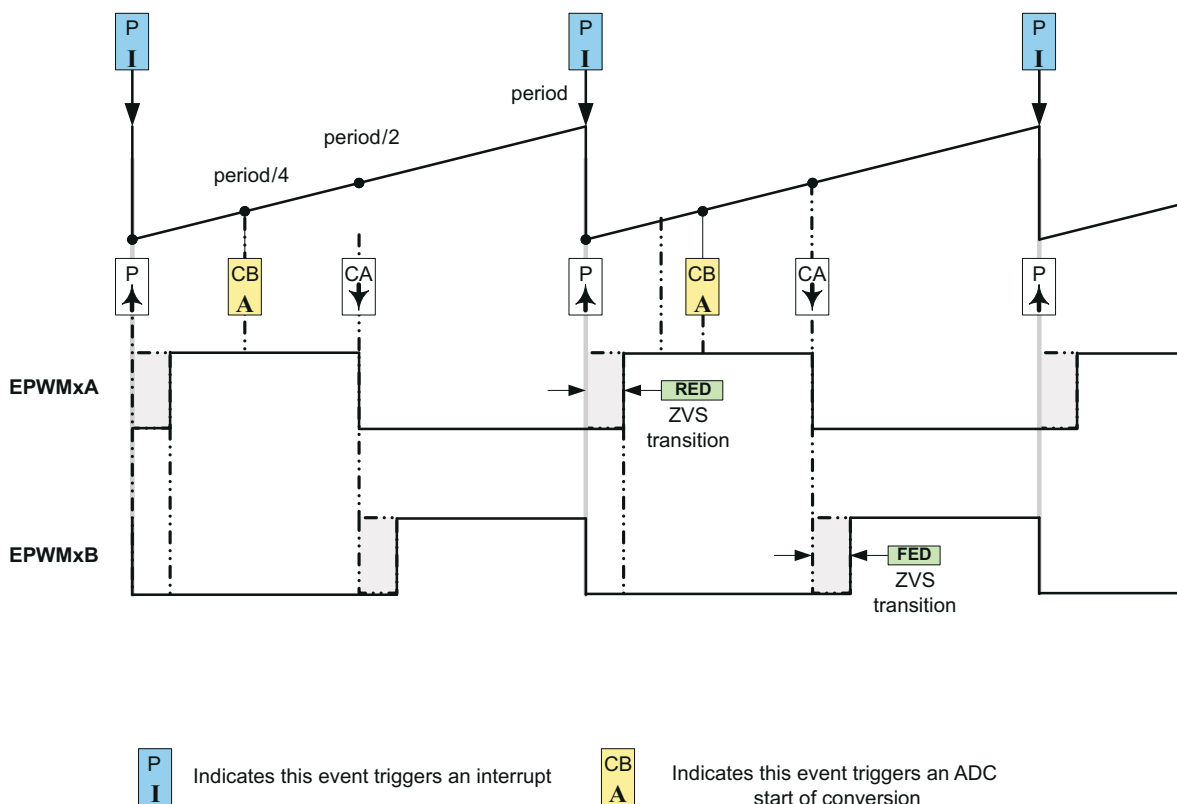

### 20.13.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example, single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multichannel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is frequency. Although the deadband is not controlled and kept constant as 300 ns (that is, 30 @100 MHz TBCLK), it is up to user to update it in real time to enhance the efficiency by adjusting enough time delay for soft switching.

NOTE:  $\Theta = X$  indicates value in phase register is 'don't care'

Figure 20-75. Control of Two Resonant Converter Stages

**P I** Indicates this event triggers an interrupt

**CB A** Indicates this event triggers an ADC start of conversion

Figure 20-76. H-Bridge LLC Resonant Converter PWM Waveforms

## 20.14 Register Lock Protection

The register lock protection mechanism is added to protect the critical ePWM registers from being corrupted by accidental writes in case of runaway code. The register EPWMLOCK contains the definition of Lock bits ([Table 20-14](#) shows the lock bits and the corresponding registers). This register also has a KEY field; writes to this register will succeed only if the KEY field is written with a value of 0xa5a5. Refer to the register descriptions for more details.

**Table 20-14. Lock Bits and Corresponding Registers**

| Bit Field | Definition                        | Registers Locked  |
|-----------|-----------------------------------|---|
| HRLOCK    | HRPWM Register Set Lock           | HRCNFG, HRPWR, HRMSTEP, HRPCTL  |
| GLLOCK    | Global Load Register Set Lock     | GLDCTL, GLDCFG  |
| TZCFGLOCK | TripZone Register Set Lock        | TZSEL, TZDCSEL, TZCTL, TZCTL2, TZCTLDCA, TZCTLDCB, TZEINT                                       |
| TZCLRLOCK | TripZone Clear Register Set Lock  | TZCLR, TZCBCCLR, TZOSTCLR, TZFRC  |
| DCLOCK    | Digital Compare Register Set Lock | DCTRIPSEL, DCACTL, DCBCTL, DCFCTL, DCCAPCTL, DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, DCBLTRIPSEL |

### Note

Due to the presence of the KEY field in the same register, only 32-bit writes will succeed if the KEY matches. The 16-bit writes to the upper or lower half of this register will be ignored.

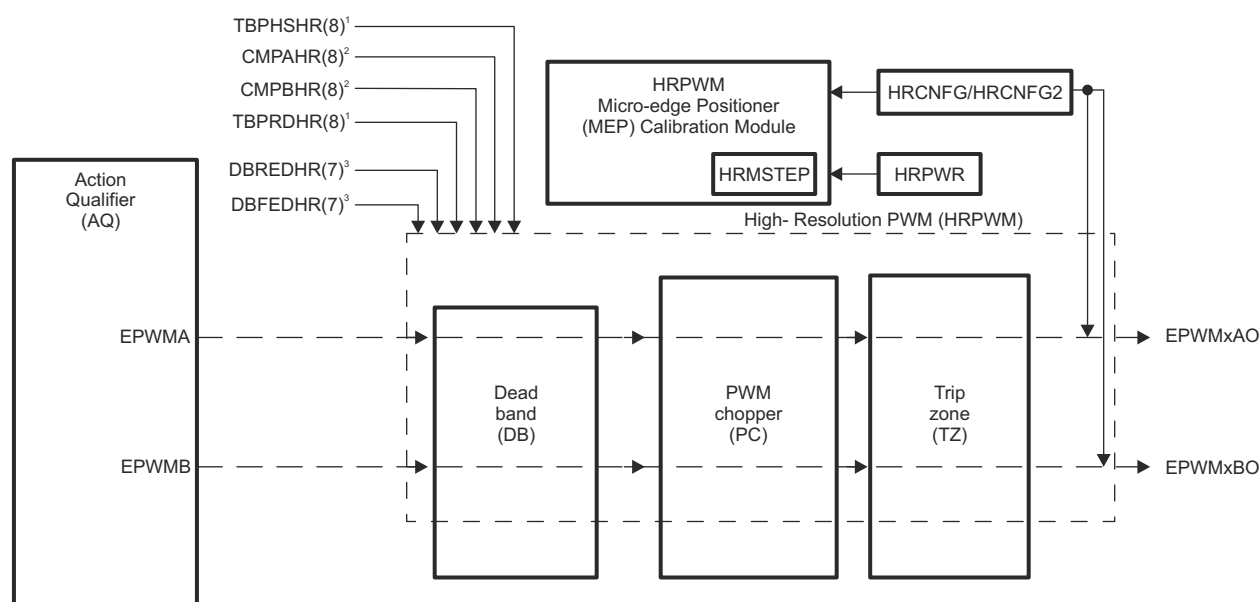

## 20.15 High-Resolution Pulse Width Modulator (HRPWM)

Figure 20-77 shows a block diagram of the HRPWM. This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~ 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A and B signal path of PWM, that is, on the EPWMxA and EPWMxB output
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running optimally
- Enables high resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output via inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module

### Note

See the device-specific datasheet to determine if your device has an ePWM module with high-resolution period support.

- A. From ePWM Time-base (TB) submodule  
 B. From ePWM counter-compare (CC) submodule  
 C. From ePWM Deadband (DB) submodule

**Figure 20-77. HRPWM Block Diagram**

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 20-78, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 20-78. Resolution Calculations for Conventionally Generated PWM**

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 20-15 shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180 ps. See the device-specific data sheet for typical and maximum performance specifications for the MEP.

**Table 20-15. Resolution for PWM and HRPWM**

| PWM Frequency (kHz) | Regular Resolution (PWM)<br>100 MHz EPWMCLK |      | High Resolution (HRPWM) |       |
|---------------------|---|------|-------------------------|-------|
|                     | Bits  | %    | Bits                    | %     |
| 20                  | 12.3  | 0.02 | 18.1                    | 0.000 |
| 50                  | 11  | 0.05 | 16.8                    | 0.001 |
| 100                 | 10  | 0.1  | 15.8                    | 0.002 |
| 150                 | 9.4   | 0.15 | 15.2                    | 0.003 |
| 200                 | 9   | 0.2  | 14.8                    | 0.004 |
| 250                 | 8.6   | 0.25 | 14.4                    | 0.005 |
| 500                 | 7.6   | 0.5  | 13.4                    | 0.009 |
| 1000                | 6.6   | 1    | 12.4                    | 0.018 |
| 1500                | 6.1   | 1.5  | 11.9                    | 0.027 |
| 2000                | 5.6   | 2    | 11.4                    | 0.036 |

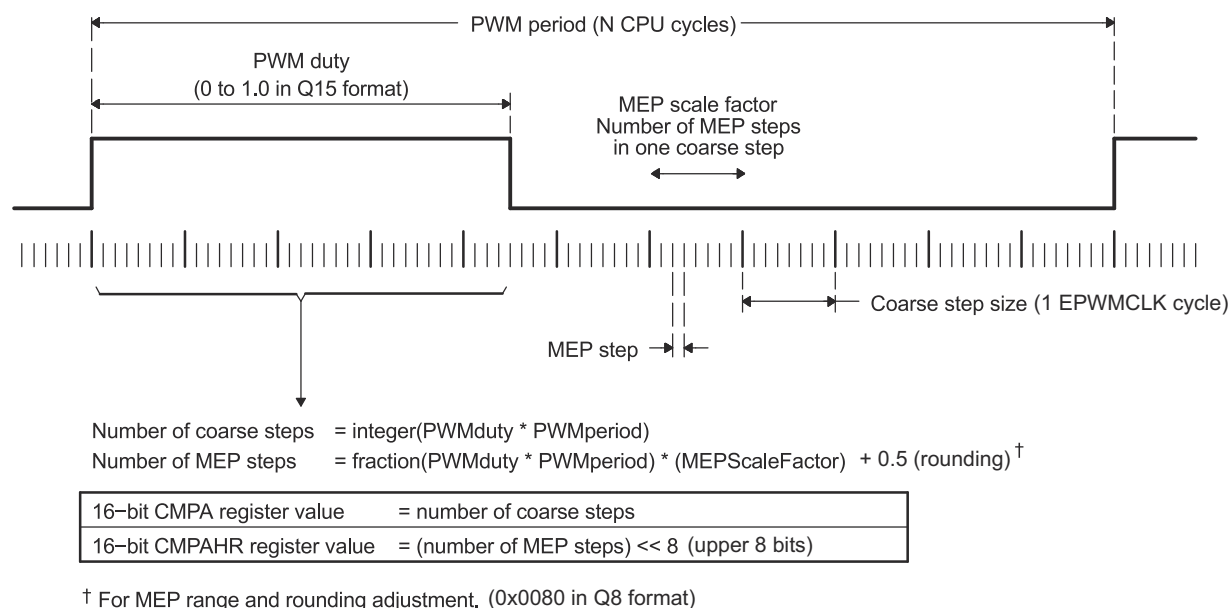

Although each application may differ, typical low frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

### 20.15.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. See the device-specific data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions. Details on software diagnostics and functions are in [Section 20.15.1.7](#).

[Figure 20-79](#) shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

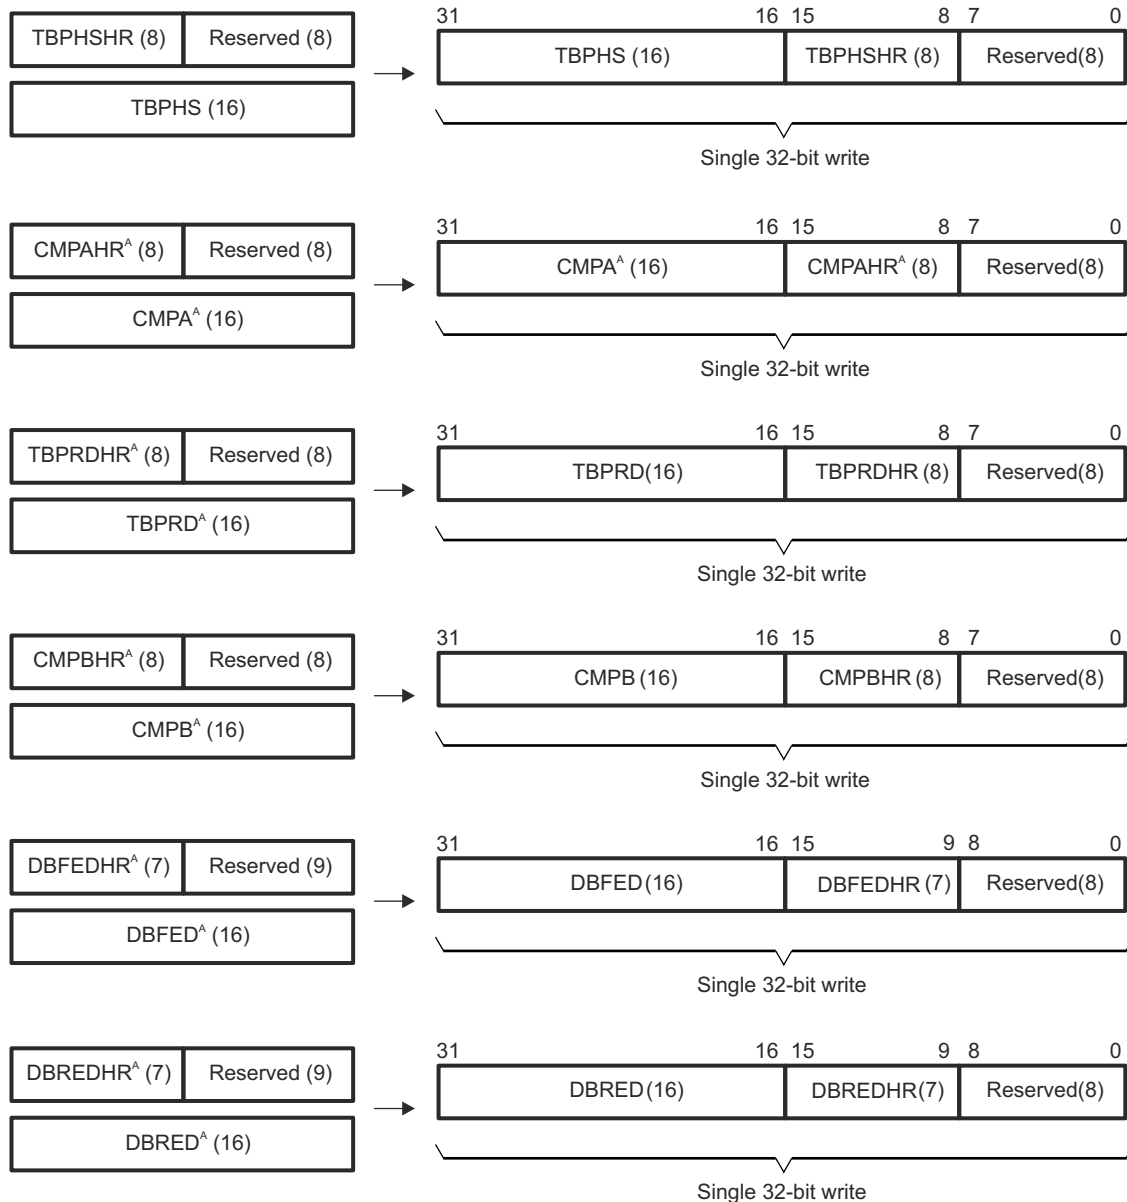

**Figure 20-79. Operating Logic Using MEP**

To generate an HRPWM waveform, configure the ePWM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in [Section 20.15.1.8](#).

#### 20.15.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM, and DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Deadband Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Deadband Generator Falling Edge Delay High Resolution Register

A. Dependant upon your device, these registers may be mirrored and can be written to at two different memory locations. Check the device-specific Technical Reference Manual's ePWM chapter for more details on how to read and write to these locations.

**Figure 20-80. HRPWM Extension Registers and Memory Configuration**

**Note**

HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during Dead Band half cycle clocking Operation. The number of MEP steps is half in size [bits 15:9] than duty and phase high resolution registers for the same reason

HRPWM capabilities are controlled using the Channel A and B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. Figure 20-81 shows how the HRPWM interfaces with the 8-bit extension registers.

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

**Figure 20-81. HRPWM System Interface**

### 20.15.1.2 HRPWM Source Clock

Each HRPWM module is clocked from the respective EPWMxCLK. HRCAL has a separate clock. For example, HRPWM1 is sourced from EPWM1CLK while HRPWM2 is clocked from the EPWM2CLK. Figure 20-82 shows the HRCAL and HRPWM modules are sourced from their respective ePWM clock source.

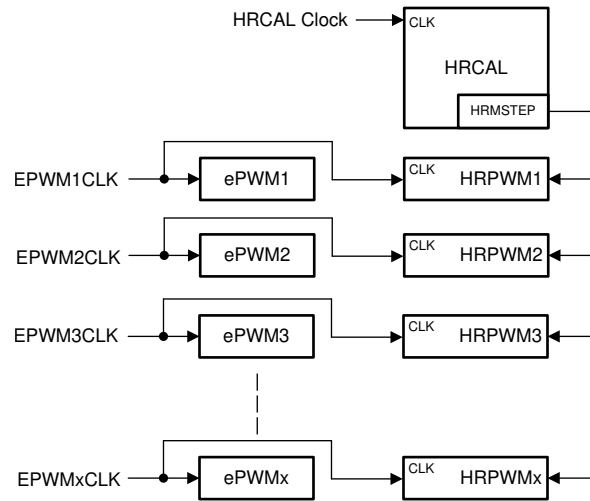

Figure 20-82. HRPWM and HRCAL Source Clock

### 20.15.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

- Edge Mode** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control).
- Control Mode** The MEP is programmed to be controlled either from the CMPAHR / CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR or CMPBHR register. BE control mode should be used with TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control) the duty cycle and phase can also be controlled via their respective high-resolution registers.
- Shadow Mode** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR and TBPRDHR registers and should be chosen to be the same as the regular load option for the CMPA, CMPB register. If TBPHSHR is used, then this option has no effect.
- High-Resolution B Signal Control** The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2 or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well.
- Swap ePWMxA and ePWMxB Outputs** This mode enables the swapping of the high resolution A and B outputs. The mode selection allows either A and B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A.
- Auto-conversion Mode** This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled,  $CMPAHR = \text{fraction}(PWMduty * PWMperiod) \ll 8$ . The scale factor optimization software will calculate the MEP scale factor in background code and automatically update the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module will then use the values in the HRMSTEP and CMPAHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and move the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and  $CMPAHR = (\text{fraction}(PWMduty * PWMperiod) * MEP \text{ Scale Factor} + 0.5) \ll 8$ . All calculations will need to be performed by user code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

### Note

If the HRPWM module is configured in UP-DOWN counter mode, the shadow mode for the HRPWM registers must be set to load on both ZERO AND PERIOD. New values from the user are loaded to the shadow registers only at CTR=ZERO, but the shadow mode of for the registers must be set to both ZERO AND PERIOD. The CTR=PRD event is used for specific internal logic inside the HRPWM module.

Auto-conversion Mode performs the calculation for CMPBHR , DBREDHR and DBFEDHR as well. The scale factor optimization software will calculate the MEP scale factor in background code and automatically update the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module will then use the values in the HRMSTEP and CMPBHR or DBREDHR / DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and move the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves same as CMPAHR.  $CMPBHR = (\text{fraction}(PWMduty * PWMperiod) * MEP \text{ Scale Factor} + 0.5) \ll 8$ .

#### 20.15.1.4 Configuring Hi-Res in Deadband Rising Edge and Falling Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity and deadband enabled in half cycle clocking mode, the high resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module's register space. This register provides the following configuration options:

**Edge Mode** The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED), or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.

**Control Mode** Selects the time event that loads the shadow value in active register for DBRED and DBFED in high resolution mode. You need to select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] and DBCTL[LOADFEDMODE] bits.

#### 20.15.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see device-specific data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 20-16](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 20-16. Relationship Between MEP Steps, PWM Frequency and Resolution**

| System (MHz) | MEP Steps Per EPWMCLK <sup>(1) (2) (3)</sup> | PWM Minimum (Hz) <sup>(4)</sup> | PWM Maximum (MHz) | Resolution at Maximum (Bits) <sup>(5)</sup> |
|--------------|--|---------------------------------|-------------------|---|
| 60.0         | 93   | 916                             | 3.00              | 10.9  |
| 70.0         | 79   | 1068                            | 3.50              | 10.6  |
| 80.0         | 69   | 1221                            | 4.00              | 10.4  |
| 90.0         | 62   | 1373                            | 4.50              | 10.3  |
| 100.0        | 56   | 1526                            | 5.00              | 10.1  |

(1) TBCLK = EPWMCLK.

(2) Table data based on a MEP time resolution of 180 ps (this is an example value. See the device-specific data sheet for MEP limits)

(3) MEP steps applied =  $T_{EPWMCLK}/180$  ps in this example.

(4) PWM minimum frequency is based on a maximum period value, (TBPRD = 65535). PWM mode is asymmetrical up-count.

(5) Resolution in bits is given for the maximum PWM frequency stated.

### 20.15.1.5.1 Edge Positioning

#### Note

The following example is presented using the [CMPA:CMPAHR] register combination. The theory of operation and equations is the same if you intend to use [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 20-83, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 20-17.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 20-17 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ps.

Figure 20-83. Required PWM Waveform for a Requested Duty = 40.5%

Table 20-17. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

| CMPA (count) <sup>(1) (2) (3)</sup> | Duty (%) | High Time (ns) | CMPA (count) | CMPAHR (count) | Duty (%) | High Time (ns) |
|-------------------------------------|----------|----------------|--------------|----------------|----------|----------------|
| 28                                  | 35.0     | 280            | 32           | 18             | 40.405   | 323.24         |
| 29                                  | 36.3     | 290            | 32           | 19             | 40.428   | 323.42         |
| 30                                  | 37.5     | 300            | 32           | 20             | 40.450   | 323.60         |
| 31                                  | 38.8     | 310            | 32           | 21             | 40.473   | 323.78         |
| 32                                  | 40.0     | 320            | 32           | 22             | 40.495   | 323.96         |
| 33                                  | 41.3     | 330            | 32           | 23             | 40.518   | 324.14         |
| 34                                  | 42.5     | 340            | 32           | 24             | 40.540   | 324.32         |
|                                     |          |                | 32           | 25             | 40.563   | 324.50         |
| Required                            | 40.5     | 324            | 32           | 26             | 40.585   | 324.68         |
| 32.40                               | 40.5     | 324            | 32           | 27             | 40.608   | 324.86         |

(1) Assumed MEP step size for the above example = 180 ps. See the device-specific data manual for typical and maximum MEP values.  
 (2) TBCLK = 100 MHz, 10 ns  
 (3) For a PWM Period register value of 80 counts, PWM Period = 80 x 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

### 20.15.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

#### Assumptions for this example:

|   |   |                          |
|---|---|--------------------------|
| TBCLK   | = | 10 ns (100 MHz)          |
| PWM frequency   | = | 1.25 MHz (1/800 ns)      |
| Required PWM duty cycle, <b>PWMDuty</b>   | = | 0.405 (40.5%)            |
| PWM period in terms of coarse steps, <b>PWMPeriod</b> (800 ns/10 ns)                            | = | 80                       |
| Number of MEP steps per coarse step at 180 ps (10 n/180 ps), <b>MEP_ScaleFactor</b>             | = | 55                       |
| Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value) | = | 0.5 (0080h in Q8 format) |

#### Step 1: Percentage Integer Duty value conversion for CMPA register

|                     |   |  |
|---------------------|---|--|
| CMPA register value | = | $\text{int}(\text{PWMDuty} * \text{PWMPeriod})$ ; int means integer part |
|                     | = | $\text{int}(0.405 * 80)$   |
|                     | = | $\text{int}(32.4)$   |
| CMPA register value | = | 32 (20h)   |

#### Step 2: Fractional value conversion for CMPAHR register

|        |   |   |
|--------|---|---|
| CMPAHR | = | $(\text{frac}(\text{PWMDuty} * \text{PWMPeriod}) * \text{MEP\_ScaleFactor} + 0.5) \ll 8$ ; frac means fractional part |
|        | = | $(\text{frac}(32.4) * 55 + 0.5) \ll 8$ ; Shifting is to move the value to the high byte of CMPAHR.                    |
|        | = | $(0.4 * 55 + 0.5) \ll 8$  |
|        | = | $(22 + 0.5) \ll 8$  |
|        | = | $22.5 * 256$ ; Shifting left by 8 is the same as multiplying by 256.  |
|        | = | 5760 (1680h)  |
| CMPAHR | = | 1680h CMPAHR value = 1600h (lower 8 bits will be ignored by hardware).  |

---

### Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value = frac (PWMDuty\*PWMperiod<<8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

The MEP scale factor (MEP\_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the C28x CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in [Section 20.15.1.8](#). The actual implementation takes advantage of the 32-bit CPU architecture of the C28x, and is somewhat different from the steps shown in [Section 20.15.1.5.2](#).

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

---

#### 20.15.1.5.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high resolution period (TBPRDHR) control is enabled via the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED and/or DBFED (the register corresponding to the edge with hi-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in [Figure 20-84](#) to [Figure 20-87](#). This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see [Table 20-18](#). When high-resolution period control is enabled (HRPCTL[HRPE]=1), the duty cycle must not fall within the restricted range. Otherwise, there may be undefined behavior on the ePWMxA output.

**Figure 20-84. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)**

**Table 20-18. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles**

| PWM Frequency <sup>(1)</sup><br>(kHz) | 3 Cycles<br>Minimum Duty | 3 Cycles<br>Maximum Duty <sup>(2)</sup> |
|---------------------------------------|--------------------------|---|
| 200                                   | 0.6%                     | 99.4%                                   |
| 400                                   | 1.2%                     | 98.8%                                   |
| 600                                   | 1.8%                     | 98.2%                                   |
| 800                                   | 2.4%                     | 97.6%                                   |
| 1000                                  | 3%                       | 97%                                     |
| 1200                                  | 3.6%                     | 96.4%                                   |
| 1400                                  | 4.2%                     | 95.8%                                   |
| 1600                                  | 4.8%                     | 95.2%                                   |

| 2000                                  | 6%                       | 94%                                     |

(1) EPWMCLK = TBCLK = 100 MHz

(2) This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in [Figure 20-85](#). In this configuration, the minimum duty cycle limitation is no longer an issue. However, there will be a maximum duty limitation with same percent numbers as given in [Table 20-18](#).

**CAUTION**

If the application has enabled high-resolution period control (HRPCTL[HRPE]=1), the duty cycle must not fall within the restricted range. Otherwise, there will be undefined behavior on the ePWM output.

Figure 20-85. High % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Figure 20-86. Up-Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1)

Figure 20-87. Up-Down Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1)

#### 20.15.1.5.4 High Resolution Period

High resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

---

#### Note

When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and vice versa, the non hi-res output will have +/- 1 TBCLK cycle jitter in up-count mode and +/- 2 TBCLK cycle jitter in up-down count mode.

---

The scaling procedure described for duty cycle in [Section 20.15.1.5.2](#) applies for high-resolution period as well:

#### Assumptions for this example:

|  |                               |
|--|-------------------------------|
| TBCLK  | = 10 ns (100 MHz)             |
| Required PWM frequency   | = 175 kHz (period of 571.428) |
| Number of MEP steps per coarse step at 180 ps (MEP_ScaleFactor)                              | = 55 (10 ns / 180 ps)         |
| Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value) | = 0.5 (0080h in Q8 format)    |

#### Problem:

In up-count mode:

If TBPRD = 571, then PWM frequency = 174.82 kHz (period =  $(571+1) * T_{TBCLK}$ ).

If TBPRD = 570, then PWM frequency = 175.13 kHz (period =  $(570+1) * T_{TBCLK}$ ).

In up-down count mode:

If TBPRD = 286, then PWM frequency = 174.82 kHz (period =  $(286*2) * T_{TBCLK}$ ).

If TBPRD = 285, then PWM frequency = 175.44 kHz (period =  $(285*2) * T_{TBCLK}$ ).

#### Solution:

With 55 MEP steps per coarse step at 180 ps each:

#### Step 1: Percentage Integer Period value conversion for TBPRD register

|                      |  |
|----------------------|--|
| Integer period value | = $571 * T_{TBCLK}$<br>= $\text{int}(571.428) * T_{TBCLK}$<br>= $\text{int}(\text{PWMperiod}) * T_{TBCLK}$ |
|----------------------|--|

In up-count mode:

|       |   |
|-------|---|
| TBPRD | = 570 (TBPRD = period value - 1)<br>= 023Ah |
|-------|---|

In up-down count mode:

|       |   |
|-------|---|
| TBPRD | = 285 (TBPRD = period value / 2)<br>= 011Dh |
|-------|---|

#### Step 2: Fractional value conversion for TBPRDHR register

|  |   |
|--|---|
| TBPRDHR register value                   | = $(\text{frac}(\text{PWMperiod}) * \text{MEP\_ScaleFactor} + 0.5)$                                 |
| If auto-conversion enabled and HRMSTEP = |   |
| MEP_ScaleFactor value (55):              | = $\text{frac}(\text{PWMperiod}) \ll 8$ (Shifting is to move the value to the high byte of TBPRDHR) |
| TBPRDHR register value                   | = $\text{frac}(571.428) \ll 8$<br>= $0.428 * 256$<br>= 6D00h  |

The autoconversion will then automatically perform the calculation such that TBPRDHR MEP delay is scaled by hardware to:

$$=((\text{TBPRDHR}(15:0) \gg 8) \times \text{HRMSTEP} + 80\text{h}) \ll 8$$

$$= (006\text{Dh} \times 55 + 80\text{h}) \gg 8$$

$$=(17\text{EBh}) \gg 8$$

Period MEP delay

$$=0017\text{h MEP Steps}$$

#### 20.15.1.5.4.1 High-Resolution Period Configuration

To use High Resolution Period, the ePWMx module must be initialized in the exact order presented.

The steps below use CMPA with shadow registers and the corresponding HRCNFG bits for hi-resolution operation on EPWMxA. For hi-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
  - ePWMx may only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
  - TBPRD and CC registers must be configured for shadow loads.
  - CMPCTL[LOADAMODE]
    - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
    - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR=0 or CTR=PRD)
5. Configure the HRCNFG register such that:
  - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
  - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
  - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired via the SFO() function described in [Section 20.15.2](#).
11. To control high-resolution period, write to the TBPRDHR(M) registers.

#### Note

When high-resolution period mode is enabled, an EPWMxSYNC pulse will introduce +/- 1 - 2 cycle jitter to the PWM (+/- 1 cycle in up-count mode and +/- 2 cycle in up-down count mode). For this reason, EPWMxSYNCO source should not be set to CTR = 0 or CTR = CMPB. Otherwise, the jitter will occur on every PWM cycle with the synchronization pulse.

When EPWMxSYNCl is EPWMxSYNCO source, a software synchronization pulse should be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter will appear on the PWM output at the time of the sync pulse.

### 20.15.1.6 Deadband High Resolution Operation

---

#### Note

In up-count mode, the deadband module is **NOT** available when any high resolution mode is enabled.

---

#### Assumptions for this example:

|  |                            |
|--|----------------------------|
| System clock   | = 10 ns (100 MHz)          |
| Deadband Enabled in half cycle mode, TBCLK = EPWMCLK |                            |
| Required PWM frequency                               | 1.33 MHz (1 / 750 ns)      |
| Required PWM duty cycle                              | 0.5 (50%)                  |
| Required Dead band Rising Edge Delay                 | 5% over duty               |
| Required Dead band Rising Edge Delay in ns           | (0.05 * 375 ns) = 18.75 ns |

---

#### Note

Just like the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use high resolution deadband.

---

#### Deadband Delay Values as a Function of DBFED and DBRED:

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$FED = DBFED * TBCLK / 2$$

$$RED = DBRED * TBCLK / 2$$

#### DBRED and DBFED Calculated Values:

Required Dead band Rising Edge Delay in ns = 18.75 ns

$$DBRED = RED / (TBCLK / 2)$$

$$DBRED = 18.75 \text{ ns} / 5 \text{ ns}$$

$$DBRED \text{ Required} = 3.75 \text{ ns}$$

With 55 MEP steps per coarse step at 180 ps each:

#### Step 1: Integer Dead band value conversion for DBREDM register

|                     |                           |
|---------------------|---------------------------|
| Integer DBRED value | = int (RED / (TBCLK / 2)) |
|                     | = int (3.75)              |
| DBRED               | = 3                       |

## Step 2: Fractional value conversion for Dead band high resolution register DBREDHR

|                        |  |
|------------------------|--|
| DBREDHR register value | $= (\text{frac}(\text{DBRED Required}) * \text{MEP\_ScaleFactor} + 0.5) \ll 8$ (Shifting is to move the value to the high byte of DBREDHR) |
|                        | $= (\text{frac}(3.75) * 55 + 0.5) \ll 8$   |
|                        | $= (0.75 * 55 + 0.5) \ll 8$  |
|                        | $= (41.75) * 256$ Shifting left by 8 is the same as multiplying by 256.  |
| DBREDHR value          | = 29C0h MEP Steps  |
|                        | Hardware will ignore lower 9 bits in the above calculated DBREDHR value  |

### Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED =  $\text{frac}(\text{required DB value}) \ll 8$ . The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

### 20.15.1.7 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150 ps (see device-specific data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature should use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO\_TI\_Build\_V8.lib software can be found in [Section 20.15.2](#).

### 20.15.1.8 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used.

[Example 20-2](#) assumes MEP step size of 150 ps and does not use the SFO library.

#### Example 20-2. #Defines for HRPWM Header Files

```
// HRPWM (High Resolution PWM) //
=====
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1 // Rising Edge position
#define HR_FEP 0x2 // Falling Edge position
#define HR_BEP 0x3 // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1 // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1 // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B 0x0 // Normal ePWMxB output
#define HR_INVERT_B 0x1 // ePWMxB is inverted ePWMxA output
```

### 20.15.1.8.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:

- PWM frequency = 1 MHz (that is, TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150 ps)

Figure 20-88 and Figure 20-89 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 20-88. Simple Buck Controlled Converter Using a Single PWM**

**Figure 20-89. PWM Waveform Generated for Simple Buck Controlled Converter**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

Example 20-3 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150 ps and does not use the SFO library.

Example 20-4 shows an assembly example of run-time code for the HRPWM buck converter.

### Example 20-3. HRPWM Buck Converter Initialization Code

```

void HrBuckDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDLT = TB_IMMEDIATE;           // set Immediate load
EPwm1Regs.TBPRD = 100;                             // Period set for 1000 kHz PWM
hrbuck_period = 200;                                // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;            // EPWM1 is the Master

EPwm1Regs.EPWSYNCOUTEN.all = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;      // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;        // optional
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;                // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;              // optional
// Now configure the HRPWM resources
EALLOW;                                           // Note these registers are protected
                                                    // and act only on ChA
EPwm1Regs.HRCNFG.all = 0x0;                       // clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;           // Control Falling Edge Position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;          // CMPAHR controls the MEP
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;      // Shadow load on CTR=Zero
EDIS;
MEP_ScaleFactor = 66*256;                          // Start with typical Scale Factor
                                                    // value for 100 MHz
                                                    // Note: Use SFO functions to update
                                                    // MEP_ScaleFactor dynamically
}

```

### Example 20-4. HRPWM Buck Converter Run-Time Code

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRBUCK_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, # HRBUCK_In
    MOVL XAR2,@_HRBUCK_In           ; Pointer to Input Q15 Duty (XAR2)
    MOVL XAR3,#CMPAHR1             ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM)
    MOV T,*XAR2 ; T <= Duty
    MPYU ACC,T,@_hrbuck_period     ; Q15 to Q0 scaling based on Period
    MOV T,@_MEP_ScaleFactor        ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL                   ; P <= T * AL, Optimizer scaling
    MOVH @AL,P                     ; AL <= P, move result back to ACC
    ADD ACC, #0x080                ; MEP range and rounding adjustment
    MOVL *XAR3,ACC                 ; CMPA: CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH               ; Store ACCH to regular CMPB

```

### 20.15.1.8.2 Implementing a DAC Function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400 kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150 ps)

Figure 20-90 and Figure 20-91 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 20-90. Simple Reconstruction Filter for a PWM-based DAC**

**Figure 20-91. PWM Waveform Generated for the PWM DAC Function**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP\_SP and does not use the SFO library.

Example 20-5 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

Example 20-6 shows an assembly example of run-time code that can execute in a high-speed ISR loop.

### Example 20-5. PWM DAC Function Initialization Code

```

void HrPwmDacDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;           // Set Immediate load
EPwm1Regs.TBPRD = 250;                             // Period set for 400 kHz PWM
hrDAC_period = 250;                                 // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;           // EPWM1 is the Master

EPwm1Regs.EPWSYNCOUEN.all = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;    // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;      // optional

EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;               // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;            // optional
// Now configure the HRPWM resources
EALLOW;                                           // Note these registers are protected
                                                    // and act only on ChA.
EPwm1Regs.HRCNFG.all = 0x0;                       // Clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;          // Control falling edge position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;          // CMPAHR controls the MEP.
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;      // Shadow load on CTR=Zero.
EDIS;
MEP_ScaleFactor = 66*256;                         // Start with typical Scale Factor
                                                    // value for 100 MHz.
                                                    // Use SFO functions to update MEP_ScaleFactor
                                                    // dynamically.
}

```

### Example 20-6. PWM DAC Function Run-Time Code

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, # HRDAC_In
    MOVL XAR2,@_HRDAC_In           ; Pointer to input Q15 duty (XAR2)
    MOVL XAR3,#CMPAHR1            ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM
    MOV T,*XAR2                   ; T <= duty
    MPY ACC,T,@_hrDAC_period       ; Q15 to Q0 scaling based on period
    ADD ACC,@_hrDAC_period<<15    ; Offset for bipolar operation
    MOV T,@_MEP_ScaleFactor        ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL                  ; P <= T * AL, optimizer scaling
    MOVH @AL,P                    ; AL <= P, move result back to ACC
    ADD ACC,#0x080                ; MEP range and rounding adjustment
    MOVL *XAR3,ACC                ; CMPA: CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH              ; Store ACCH to regular CMPB

```

## 20.15.2 SFO Library Software - SFO\_TI\_Build\_V8.lib

Table 20-19 lists several features of the SFO\_TI\_Build\_V8.lib library.

**Table 20-19. SFO Library Features**

|   | SFO_TI_Build_V8.lib | Unit                  |
|---|---------------------|-----------------------|
| Completion-checking?  | Yes                 | Function return value |
| Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts | 130,000             | EPWMCLK cycles        |

### 20.15.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100 MHz and assuming the MEP step size is 150 ps, the typical scale factor value at 100 MHz = 66 MEP steps per TBCLK unit (10 ns)

The function returns a MEP scale factor value:

MEP\_ScaleFactor = Number of MEP steps per EPWMCLK.

#### Constraints when using this function:

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50 MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50 MHz, with device process variation, the MEP step size may decrease under cold temperature and high core voltage conditions to such a point, that 255 MEP steps will not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module

#### Usage:

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated, or a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP\_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register will maintain the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3-EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see [Section 20.15.1.5.3](#)).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting CMPAHR =  $\text{fraction}(\text{PWMduty} * \text{PWMperiod}) \ll 8$  or CMPBHR =  $\text{fraction}(\text{PWMduty} * \text{PWMperiod}) \ll 8$  or TBPRDHR =  $\text{fraction}(\text{PWMperiod})$  while running SFO() in the background. The MEP Calibration Module will then use the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software will need to perform the necessary calculations manually so that:
  - $\text{CMPAHR} = (\text{fraction}(\text{PWMduty} * \text{PWMperiod}) * \text{MEP Scale Factor}) \ll 8 + 0x080$ .
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

The following snippet shows how to use the HRPWM DUTY using driverlib functions.

```
float32_t dutyFine = 85.62;
float32_t count = (dutyFine * (float32_t)(EPWM_TIMER_TBPRD << 8))/100;
uint32_t compCount = (count);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_A, compCount);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_B, compCount);
```

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore it is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution may have to be performed more frequently to match the application. Note, there is no high limit restriction on the SFO function repetition rate, hence it can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic will not be active for the first three EPWMCLK cycles of the PWM period (and the last three EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE=0]) and the CMPA/CMPB register value is less than three cycles, then its CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE=1]), the CMPA register value must not fall below three or above TBPRD-3. This would avoid any unexpected transitions on the PWM signal.

### 20.15.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP\_ScaleFactor. For example, see [Table 20-20](#).

**Table 20-20. Factor Values**

| Software Function call | Functional Description                           | Updated Variables                     |
|------------------------|--|---------------------------------------|
| SFO()                  | Returns MEP scale factor in the HRMSTEP register | MEP_ScaleFactor and HRMSTEP register. |

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

#### Step 1. Add "Include" Files

The SFO\_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)\_Device.h and (Device)\_Epwm\_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

#### Example 20-7. A Sample of How to Add "Include" Files

```
#include "F28x7x_Device.h" // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h" // init defines
#include "SFO_V8.h" // SFO lib functions (needed for HRPWM)
```

## Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

### Example 20-8. Declaring an Element

```
int MEP_ScaleFactor = 0;    //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

## Step 3. MEP\_ScaleFactor Initialization

The SFO() function does not require a starting scale factor value in MEP\_ScaleFactor. Prior to using the MEP\_ScaleFactor variable in application code, SFO() should be called to drive the MEP calibration module to calculate an MEP\_ScaleFactor value.

As part of the one-time initialization code prior to using MEP\_ScaleFactor, include the following:

### Example 20-9. Initializing With a Scale Factor Value

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

## Step 4. Application Code

While the application is running, fluctuations in both device temperature and supply voltage may be expected. To be sure that optimal Scale Factors are used for each ePWM module, the SFO function should be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

---

### Note

See the HRPWM\_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

---

### Example 20-10. SFO Function Calls

```
main ()
{
  int status;
  // User code
  // ePWM1, 2, 3, 4 are running in HRPWM mode
  // The status variable returns 1 once a new MEP_ScaleFactor has been
  // calculated by the MEP Calibration Module running SFO
  // diagnostics.
  status = SFO();
  if(status==2) {ESTOP0;} // The function returns a 2 if MEP_ScaleFactor is greater
  // than the maximum 255 allowed (error condition)
}
```

## 20.16 Software

### 20.16.1 EPWM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/epwm

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 20.16.1.1 ePWM Chopper

FILE: epwm\_ex10\_chopper.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 with Chopper disabled (Reference)
- ePWM2 with chopper enabled at 1/8 duty cycle
- ePWM3 with chopper enabled at 6/8 duty cycle
- ePWM4 with chopper enabled at 1/2 duty cycle with One-Shot Pulse enabled

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

#### Watch Variables

- None.

#### 20.16.1.2 EPWM Configure Signal

FILE: epwm\_ex11\_configure\_signal.c

This example configures ePWM1, ePWM2, ePWM3 to produce signal of desired frequency and duty. It also configures phase between the configured modules.

Signal of 10kHz with duty of 0.5 is configured on ePWMxA & ePWMxB with ePWMxB inverted. Also, phase of 120 degree is configured between ePWM1 to ePWM3 signals.

During the test, monitor ePWM1, ePWM2, and/or ePWM3 outputs on an oscilloscope.

- ePWM1A is on GPIO0
- ePWM1B is on GPIO1
- ePWM2A is on GPIO2
- ePWM2B is on GPIO3
- ePWM3A is on GPIO4
- ePWM3B is on GPIO5

#### 20.16.1.3 Realization of Monoshot Mode

FILE: epwm\_ex12\_monoshot\_mode.c

This example showcases how to generate a monoshot PWM output based on an external trigger, that is, generating just a single pulse output on receipt of an external trigger. And the next pulse will be generated only when the next trigger comes. The example utilizes external synchronization and T1 action qualifier event features to achieve the desired output.

ePWM1 is used to generate the monoshot output and ePWM2 is used as an external trigger for that. No external connections are required as ePWM2A is fed as the trigger using Input X-BAR automatically.

ePWM1 is configured to generate a single pulse of 0.5  $\mu$ s when received an external trigger. This is achieved by enabling the phase synchronization feature and configuring EPWMxSYNCl as EXTSYNClN1. And this EPWMxSYNCl is also configured as T1 event of action qualifier to set output HIGH while "CTR = PRD" action is used to set output LOW.

ePWM2 is configured to generate a 100 kHz signal with a duty of 1% (to simulate a rising edge trigger) which is routed to EXTSYNClN1 using Input XBAR.

Observe GPIO0 (EPWM1A : Monoshot Output) and GPIO2(EPWM2 : External Trigger) on oscilloscope.

*NOTE* : In the following example, the ePWM timer is still running in a continuous mode rather than a one-shot mode thus for more reliable implementation, refer to CLB based one shot PWM implementation demonstrated in "clb\_ex17\_one\_shot\_pwm" example

#### **20.16.1.4 EPWM Action Qualifier (epwm\_up\_aq)**

FILE: epwm\_ex13\_up\_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce an waveform with independent modulation on EPWMxA and EPWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up count mode for this example.

View the EPWM1A/B(GPIO0 & GPIO1), EPWM2A/B(GPIO2 & GPIO3) and EPWM3A/B(GPIO4 & GPIO5) waveforms via an oscilloscope.

#### **20.16.1.5 ePWM Trip Zone**

FILE: epwm\_ex1\_trip\_zone.c

This example configures ePWM1 and ePWM2 as follows

- ePWM1 has TZ1 as one shot trip source
- ePWM2 has TZ1 as cycle by cycle trip source

Initially tie TZ1 high. During the test, monitor ePWM1 or ePWM2 outputs on a scope. Pull TZ1 low to see the effect.

#### *External Connections*

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2
- TZ1 is on GPIO12

This example also makes use of the Input X-BAR. GPIO12 (the external trigger) is routed to the input X-BAR, from which it is routed to TZ1.

The TZ-Event is defined such that ePWM1A will undergo a One-Shot Trip and ePWM2A will undergo a Cycle-By-Cycle Trip.

#### **20.16.1.6 ePWM Up Down Count Action Qualifier**

FILE: epwm\_ex2\_updown\_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce a waveform with independent modulation on ePWMxA and ePWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up/down count mode for this example.

View the ePWM1A/B(GPIO0 & GPIO1), ePWM2A/B(GPIO2 & GPIO3) and ePWM3A/B(GPIO4 & GPIO5) waveforms on oscilloscope.

#### **20.16.1.7 ePWM Synchronization**

FILE: epwm\_ex3\_synchronization.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 without phase shift as master
- ePWM2 with phase shift of 300 TBCLKs
- ePWM3 with phase shift of 600 TBCLKs
- ePWM4 with phase shift of 900 TBCLKs

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

#### *Watch Variables*

- None.

### **20.16.1.8 ePWM Digital Compare**

FILE: epwm\_ex4\_digital\_compare.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TZ1, pull this pin low to trip the ePWM

#### *Watch Variables*

- None.

### **20.16.1.9 ePWM Digital Compare Event Filter Blanking Window**

FILE: epwm\_ex5\_digital\_compare\_event\_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCBEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the blanking window to ignore the DCBEVT1 for the duration of DC Blanking window

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1, pull this pin low to trip the ePWM

#### *Watch Variables*

- None.

### 20.16.1.10 ePWM Valley Switching

FILE: epwm\_ex6\_valley\_switching.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the valley switching module to delay the
- DCFILT signal by a software defined DELAY value.

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

#### Watch Variables

- None.

### 20.16.1.11 ePWM Digital Compare Edge Filter

FILE: epwm\_ex7\_edge\_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCBEVT2 forcing the ePWM output LOW as a CBC source
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCBEVT2
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- The DCBEVT2 is the source for DCFILT
- The DCFILT will count edges of the DCBEVT2 and generate a signal to trip the ePWM on the 4th edge of DCBEVT2

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

#### Watch Variables

- None.

### 20.16.1.12 ePWM Deadband

FILE: epwm\_ex8\_deadband.c

This example configures ePWM1 through ePWM6 as follows

- ePWM1 with Deadband disabled (Reference)
- ePWM2 with Deadband Active High
- ePWM3 with Deadband Active Low
- ePWM4 with Deadband Active High Complimentary
- ePWM5 with Deadband Active Low Complimentary
- ePWM6 with Deadband Output Swap (switch A and B outputs)

#### External Connections

- GPIO0 EPWM1A

- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B
- GPIO8 EPWM5A
- GPIO9 EPWM5B
- GPIO10 EPWM6A
- GPIO11 EPWM6B

#### Watch Variables

- None.

### 20.16.1.13 ePWM DMA

FILE: epwm\_ex9\_dma.c

This example configures ePWM1 and DMA as follows:

- ePWM1 is set up to generate PWM waveforms
- DMA5 is set up to update the CMPAHR, CMPA, CMPBHR and CMPB every period with the next value in the configuration array. This allows the user to create a DMA enabled fifo for all the CMPx and CMPxHR registers to generate unconventional PWM waveforms.
- DMA6 is set up to update the TBPHSHR, TBPHS, TBPRDHR and TBPRD every period with the next value in the configuration array.
- Other registers such as AQCTL can be controlled through the DMA as well by following the same procedure. (Not used in this example)

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B

#### Watch Variables

- None.

### 20.16.2 HRPWM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:

C2000Ware\_VERSION#/driverlib/f28003x/examples/hrpwm

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 20.16.2.1 HRPWM Duty Control with SFO

FILE: hrpwm\_ex1\_duty\_sfo.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

### External Connections

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### 20.16.2.2 HRPWM Slider

FILE: hrpwm\_ex2\_slider.c

This example modifies the MEP control registers to show edge displacement due to HRPWM. Control blocks of the respective ePWM module channel A and B will have fine edge movement due to HRPWM logic.

Monitor ePWM1 A/B pins on an oscilloscope.

#### 20.16.2.3 HRPWM Period Control

FILE: hrpwm\_ex3\_prd\_updown\_sfo.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

### External Connections

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### 20.16.2.4 HRPWM Duty Control with UPDOWN Mode

FILE: hrpwm\_ex4\_duty\_updown\_sfo.c

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

### External Connections

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

### 20.16.2.5 HRPWM Slider Test

FILE: hrpwm\_ex5\_slider\_qformat.c

This example modifies the MEP control registers to show edge displacement due to HRPWM. Control blocks of the respective ePWM module channel A and B will have fine edge movement due to HRPWM logic. Load the hrpwm\_slider.gel file. Select the HRPWM\_eval from the GEL menu. A FineDuty slider graphics will show up in CCS. Load the program and run. Use the Slider to and observe the EPWM edge displacement for each slider step change. This explains the MEP control on the EPwmxA channels.

Monitor ePWM1 and ePWM2 A/B pins on an oscilloscope.

### 20.16.2.6 HRPWM Duty Up Count

FILE: hrpwm\_ex6\_duty\_sfo\_qformat.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

To run this example:

1. Run this example at maximum SYSCLKOUT
2. Activate Real time mode
3. Run the code

#### External Connections

- Monitor ePWM1/2 A/B pins on an oscilloscope.

#### Watch Variables

- status - Example run status
- updateFine - Set to 1 use HRPWM capabilities and observe in fine MEP steps(default) Set to 0 to disable HRPWM capabilities and observe in coarse SYSCLKOUT cycle steps

### 20.16.2.7 HRPWM Period Up-Down Count

FILE: hrpwm\_ex7\_prd\_updown\_sfo\_qformat.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

To run this example:

1. Run this example at maximum SYSCLKOUT
2. Activate Real time mode
3. Run the code

#### *External Connections*

- Monitor ePWM1/2 A/B pins on an oscilloscope.

#### *Watch Variables*

- updateFine - Set to 1 use HRPWM capabilities and observe in fine MEP steps(default) Set to 0 to disable HRPWM capabilities and observe in coarse SYSCLKOUT cycle steps

## 20.17 ePWM Registers

This section describes the Enhanced Pulse Width Modulator registers.

### 20.17.1 EPWM Base Address Table

**Table 20-21. EPWM Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| EPwm1Regs      | EPWM_REGS | EPWM1_BASE     | 0x0000_4000  | YES  | YES | YES | YES | YES                |
| EPwm2Regs      | EPWM_REGS | EPWM2_BASE     | 0x0000_4100  | YES  | YES | YES | YES | YES                |

## 20.17.2 EPWM\_REGS Registers

Table 20-22 lists the memory-mapped registers for the EPWM\_REGS registers. All register offset addresses not listed in Table 20-22 should be considered as reserved locations and the register contents should not be modified.

**Table 20-22. EPWM\_REGS Registers**

| Offset | Acronym       | Register Name   | Write Protection | Section            |
|--------|---------------|---|------------------|--------------------|
| 0h     | TBCTL         | Time Base Control Register  |                  | <a href="#">Go</a> |
| 1h     | TBCTL2        | Time Base Control Register 2  |                  | <a href="#">Go</a> |
| 3h     | EPWMSYNCINSEL | EPWMxSYNCIN Source Select Register                                    |                  | <a href="#">Go</a> |
| 4h     | TBCTR         | Time Base Counter Register  |                  | <a href="#">Go</a> |
| 5h     | TBSTS         | Time Base Status Register   |                  | <a href="#">Go</a> |
| 6h     | EPWMSYNCOUTEN | EPWMxSYNCOUT Source Enable Register                                   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. [Table 20-23](#) shows the codes that are used for access types in this section.

**Table 20-23. EPWM\_REGS Access Type Codes**

| Access Type              | Code  | Description  |
|--------------------------|-------|--|
| Read Type                |       |  |
| R                        | R     | Read   |
| R-0                      | R-0   | Read Returns 0s  |
| Write Type               |       |  |
| W                        | W     | Write  |
| W1C                      | W1C   | Write 1 to clear   |
| W1S                      | W1S   | Write 1 to set   |
| WOnce                    | WOnce | Write Write once   |
| Reset or Default Value   |       |  |
| -n                       |       | Value after reset or the default value   |
| Register Array Variables |       |  |
| i,j,k,l,m,n              |       | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |       | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 20.17.2.1 TBCTL Register (Offset = 0h) [Reset = 83h]

TBCTL is shown in [Figure 20-89](#) and described in [Table 20-24](#).

Return to the [Summary Table](#).

Time Base Control Register

| Bit   | Field     | Type | Reset | Description  |
|-------|-----------|------|-------|--|
| 15-14 | FREE_SOFT | R/W  | 0h    | Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events<br>00: Stop after the next time-base counter increment or decrement<br>01: Stop when counter completes a whole cycle:<br>- Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD)<br>- Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00)<br>- Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00)<br>1x: Free run<br>Reset type: SYSRSn  |
| 13    | PHSDIR    | R/W  | 0h    | Phase Direction Bit<br>This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.<br>In the up-count and down-count modes this bit is ignored.<br>0: Count down after the synchronization event.<br>1: Count up after the synchronization event.<br>Reset type: SYSRSn |
| 12-10 | CLKDIV    | R/W  | 0h    | Time Base Clock Pre-Scale Bits<br>These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV):<br>000: /1 (default on reset)<br>001: /2<br>010: /4<br>011: /8<br>100: /16<br>101: /32<br>110: /64<br>111: /128<br>Reset type: SYSRSn   |

**Table 20-24. TBCTL Register Field Descriptions (continued)**

| Bit | Field     | Type    | Reset | Description   |
|-----|-----------|---------|-------|---|
| 9-7 | HSPCLKDIV | R/W     | 1h    | High Speed Time Base Clock Pre-Scale Bits<br>These bits determine part of the time-base clock prescale value.<br>$TBCLK = EPWMCLK / (HSPCLKDIV \times CLKDIV)$ . This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral.<br>000: /1<br>001: /2 (default on reset)<br>010: /4<br>011: /6<br>100: /8<br>101: /10<br>110: /12<br>111: /14<br>Reset type: SYSRSn   |
| 6   | SWFSYNC   | R-0/W1S | 0h    | Software Forced Sync Pulse<br>0: Writing a 0 has no effect and reads always return a 0.<br>1: Writing a 1 forces a one-time synchronization pulse to be generated.<br>SWFSYNC can be enabled to affect EPWMxSYNCO by setting the EPWMSYNCOUTEN.SWEN bit.<br>Reset type: SYSRSn  |
| 5-4 | RESERVED  | R       | 0h    | Reserved  |
| 3   | PRDL      | R/W     | 0h    | Active Period Reg Load from Shadow Select<br>0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit.<br>A write/read to the TBPRD register accesses the shadow register.<br>1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register.<br>Reset type: SYSRSn   |
| 2   | PHSEN     | R/W     | 0h    | Counter Reg Load from Phase Reg Enable<br>0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS).<br>1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCl input signal occurs or a software-forced sync signal, see bit 6.<br>Reset type: SYSRSn   |
| 1-0 | CTRM      | R/W     | 3h    | Counter Mode<br>The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows:<br>00: Up-count mode<br>01: Down-count mode<br>10: Up-down count mode<br>11: Freeze counter operation (default on reset)<br>Reset type: SYSRSn |

### 20.17.2.2 TBCTL2 Register (Offset = 1h) [Reset = 0h]

TBCTL2 is shown in [Figure 20-90](#) and described in [Table 20-25](#).

Return to the [Summary Table](#).

**Table 20-33. DBCTL Register Field Descriptions**

| Bit   | Field         | Type | Reset | Description   |
|-------|---------------|------|-------|---|
| 15    | HALFCYCLE     | R/W  | 0h    | Half Cycle Clocking Enable Bit<br>0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate.<br>1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2.<br>Reset type: SYSRSn   |
| 14    | DEDB_MODE     | R/W  | 0h    | Dead Band Dual-Edge B Mode Control (S8 switch)<br>0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only.<br>1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath otherwise, OutA will be invalid.<br>Reset type: SYSRSn  |
| 13-12 | OUTSWAP       | R/W  | 0h    | Dead Band Output Swap Control<br>Bit 13 controls the S6 switch and bit 12 controls the S7 switch.<br>00: OutA and OutB signals are as defined by OUT-MODE bits.<br>01: OutA = A-path as defined by OUT-MODE bits.<br>OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path).<br>10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path).<br>OutB = B-path as defined by OUT-MODE bits.<br>11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path).<br>OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path).<br>Reset type: SYSRSn |
| 11    | SHDWDBFEDMODE | R/W  | 0h    | FED Dead-Band Load Mode<br>0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate "FED dead-band action."<br>1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy).<br>Reset type: SYSRSn   |

**Table 20-33. DBCTL Register Field Descriptions (continued)**

| Bit | Field         | Type | Reset | Description  |
|-----|---------------|------|-------|--|
| 10  | SHDWDBREDMODE | R/W  | 0h    | RED Dead-Band Load Mode<br>0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate "RED dead-band action."<br>1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy).<br>Reset type: SYSRSn  |
| 9-8 | LOADFEDMODE   | R/W  | 0h    | Active DBFED Load from Shadow Select Mode<br>00: Load on Counter = 0 (CNT_eq)<br>01: Load on Counter = Period (PRD_eq)<br>10: Load on either Counter = 0, or Counter = Period<br>11: Freeze (no loads possible)<br>Note: has no effect in Immediate mode.<br>Reset type: SYSRSn  |
| 7-6 | LOADREDMODE   | R/W  | 0h    | Active DBRED Load from Shadow Select Mode<br>00: Load on Counter = 0 (CNT_eq)<br>01: Load on Counter = Period (PRD_eq)<br>10: Load on either Counter = 0, or Counter = Period<br>11: Freeze (no loads possible)<br>Note: has no effect in Immediate mode.<br>Reset type: SYSRSn  |
| 5-4 | IN_MODE       | R/W  | 0h    | Dead-Band Input Mode Control<br>Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays.<br>00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.<br>01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal.<br>EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal.<br>10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal.<br>EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal.<br>11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.<br>Reset type: SYSRSn |
| 3-2 | POLSEL        | R/W  | 0h    | Polarity Select Control<br>Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes.<br>00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default).<br>01: Active low complementary (ALC) mode. EPWMxA is inverted.<br>10: Active high complementary (AHC). EPWMxB is inverted.<br>11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.<br>Reset type: SYSRSn  |

**Table 20-33. DBCTL Register Field Descriptions (continued)**

| Bit | Field    | Type | Reset | Description   |
|-----|----------|------|-------|---|
| 1-0 | OUT_MODE | R/W  | 0h    | Dead-Band Output Mode Control<br>Bit 1 controls the S1 switch and bit 0 controls the S0 switch.<br>00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect.<br>01: Apath = InA (delay is by-passed for A signal path)<br>Bpath = FED (Falling Edge Delay in B signal path)<br>10: Apath = RED (Rising Edge Delay in A signal path)<br>Bpath = InB (delay is by-passed for B signal path)<br>11: DBM is fully enabled (i.e. both RED and FED active)<br>Reset type: SYSRSn |

| 2    | TBPHSHRLOADE | R/W  | 0h    | TBPHSHR Load Enable<br>This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution.<br>0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event:<br>1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PHSEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature. This bit and the TBCTL[PHSEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled.<br>Reset type: SYSRSn |
| 1    | PWMSYNCSEL   | R/W  | 0h    | PWMSYNC Source Select Bit: This bit selects the source for the EPWMSYNCPER signal that goes to the CMPSS and GPDAC:<br>0 CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD)<br>1 CTR = zero: Time-base counter equal to zero (TBCTR = 0x00)<br>Reset type: SYSRSn   |

**Table 20-44. HRPCTL Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description   |
|-----|-------|------|-------|---|
| 0   | HRPE  | R/W  | 0h    | High Resolution Period Enable Bit<br>0: High resolution period feature disabled. In this mode the ePWM behaves as a Type 0 ePWM.<br>1: High resolution period enabled. In this mode the HRPWM module can control high-resolution of both the duty and frequency. When high-resolution period is enabled, TBCTL[CTRMODE] = 0,1 (down-count mode) is not supported.<br>Reset type: SYSRSn |

### 20.17.2.22 TRREM Register (Offset = 2Eh) [Reset = 0h]

TRREM is shown in [Figure 20-110](#) and described in [Table 20-45](#).

Return to the [Summary Table](#).

HRPWM High Resolution Remainder Register

This register is only accessible on EPWM modules with HRPWM capabilities.

**Figure 20-110. TRREM Register**

| TBPHS  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | TBPHSHR |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | R/W-0h  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 20-59. TBPHS Register Field Descriptions**

| Bit   | Field   | Type | Reset | Description   |
|-------|---------|------|-------|---|
| 31-16 | TBPHS   | R/W  | 0h    | Phase Offset Register<br>These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal.<br>- If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase.<br>- If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization.<br>Reset type: SYSRSn |
| 15-0  | TBPHSHR | R/W  | 0h    | Phase Offset (High Resolution) Register.<br>TBPHSHR must not be used. Instead TRREM (HRPWM remainder register) must be used to mimic the functionality of TBPHSHR.<br>The lower 8 bits in this register are ignored - writes are ignored and reads return zero<br>Reset type: SYSRSn  |

### 20.17.2.37 TBPRDHR Register (Offset = 62h) [Reset = 0h]

TBPRDHR is shown in [Figure 20-125](#) and described in [Table 20-60](#).

Return to the [Summary Table](#).

Time Base Period High Resolution Register

**Figure 20-125. TBPRDHR Register**

|         |    |    |    |    |    |   |   |
|---------|----|----|----|----|----|---|---|
| 15      | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| TBPRDHR |    |    |    |    |    |   |   |
| R/W-0h  |    |    |    |    |    |   |   |
| 7       | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| TBPRDHR |    |    |    |    |    |   |   |
| R/W-0h  |    |    |    |    |    |   |   |

**Table 20-60. TBPRDHR Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description   |
|------|---------|------|-------|---|
| 15-0 | TBPRDHR | R/W  | 0h    | Period High Resolution Bits<br>The upper 8-bits contain the high-resolution portion of the period value. The TBPRDHR register is not affected by the TBCTL[PRDL] bit. Reads from this register always reflect the shadow register. Likewise writes are also to the shadow register. The TBPRDHR register is only used when the high resolution period feature is enabled. This register is only available with ePWM modules which support high-resolution period control.<br>The lower 8 bits in this register are ignored - writes are ignored and reads return zero<br>Reset type: SYSRSn |

### 20.17.2.38 TBPRD Register (Offset = 63h) [Reset = 0h]

TBPRD is shown in [Figure 20-126](#) and described in [Table 20-61](#).

Return to the [Summary Table](#).

Time Base Period Register

**Figure 20-126. TBPRD Register**

|        |    |    |    |    |    |   |   |
|--------|----|----|----|----|----|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| TBPRD  |    |    |    |    |    |   |   |

| 7      | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| TBPRD  |    |    |    |    |    |   |   |
| R/W-0h |    |    |    |    |    |   |   |

**Table 20-61. TBPRD Register Field Descriptions**

| Bit  | Field | Type | Reset | Description   |
|------|-------|------|-------|---|
| 15-0 | TBPRD | R/W  | 0h    | Time Base Period Register<br>These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed.<br>- If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero.<br>- If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.<br>- The active and shadow registers share the same memory map address.<br>Reset type: SYSRSn |

### 20.17.2.39 CMPA Register (Offset = 6Ah) [Reset = 0h]

CMPA is shown in [Figure 20-127](#) and described in [Table 20-62](#).

Return to the [Summary Table](#).

Counter Compare A Register

**Figure 20-127. CMPA Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CMPA   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | CMPAHR |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | R/W-0h |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 20-62. CMPA Register Field Descriptions**

| Bit   | Field  | Type | Reset | Description  |
|-------|--------|------|-------|--|
| 31-16 | CMPA   | R/W  | 0h    | <p>Compare A Register</p> <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>- Do nothing</li> <li>the event is ignored.</li> <li>- Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>- Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>- Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>- If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.</li> <li>- Before a write, the CMPCTL[SHDWFULL] bit can be read to determine if the shadow register is currently full.</li> <li>- If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>- In either mode, the active and shadow registers share the same memory map address.</li> </ul> <p>Reset type: SYSRSn</p> |
| 15-0  | CMPAHR | R/W  | 0h    | <p>Compare A HRPWM Extension Register</p> <p>The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register.</p> <p>The lower 8 bits in this register are ignored</p> <p>Reset type: SYSRSn</p>   |

### 20.17.2.40 CMPB Register (Offset = 6Ch) [Reset = 0h]

CMPB is shown in [Figure 20-128](#) and described in [Table 20-63](#).

Return to the [Summary Table](#).

Compare B Register

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 15-0 | CMPD  | R/W  | 0h    | <p>Compare D Register</p> <p>The value in the active CMPD register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare D" event.</p> <p>Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWDMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>- If CMPCTL2[SHDWDMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL2[LOADDMODE] bit field determines which event will load the active register from the shadow register:</li> <li>- If CMPCTL2[SHDWDMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register that is, the register actively controlling the hardware.</li> <li>- In either mode, the active and shadow registers share the same memory map address.</li> </ul> <p>Reset type: SYSRSn</p> |

### 20.17.2.43 GLDCTL2 Register (Offset = 74h) [Reset = 0h]

GLDCTL2 is shown in [Figure 20-131](#) and described in [Table 20-66](#).

Return to the [Summary Table](#).

Global PWM Load Control Register 2

**Figure 20-131. GLDCTL2 Register**

|          |    |    |    |    |    |            |            |
|----------|----|----|----|----|----|------------|------------|

**Table 20-75. TZFLG Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 15-7 | RESERVED | R    | 0h    | Reserved   |
| 6    | DCBEVT2  | R    | 0h    | Latched Status Flag for Digital Compare Output B Event 2<br>0: Indicates no trip event has occurred on DCBEVT2<br>1: Indicates a trip event has occurred for the event defined for DCBEVT2<br>Reset type: SYSRSn   |
| 5    | DCBEVT1  | R    | 0h    | Latched Status Flag for Digital Compare Output B Event 1<br>0: Indicates no trip event has occurred on DCBEVT1<br>1: Indicates a trip event has occurred for the event defined for DCBEVT1<br>Reset type: SYSRSn   |
| 4    | DCAEVT2  | R    | 0h    | Latched Status Flag for Digital Compare Output A Event 2<br>0: Indicates no trip event has occurred on DCAEVT2<br>1: Indicates a trip event has occurred for the event defined for DCAEVT2<br>Reset type: SYSRSn   |
| 3    | DCAEVT1  | R    | 0h    | Latched Status Flag for Digital Compare Output A Event 1<br>0: Indicates no trip event has occurred on DCAEVT1<br>1: Indicates a trip event has occurred for the event defined for DCAEVT1<br>Reset type: SYSRSn   |
| 2    | OST      | R    | 0h    | Latched Status Flag for A One-Shot Trip Event<br>0: No one-shot trip event has occurred.<br>1: Indicates a trip event has occurred on a pin selected as a one-shot trip source.<br>This bit is cleared by writing the appropriate value to the TZCLR register.<br>Reset type: SYSRSn   |
| 1    | CBC      | R    | 0h    | Latched Status Flag for Cycle-By-Cycle Trip Event<br>0: No cycle-by-cycle trip event has occurred.<br>1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared.<br>This bit is cleared by writing the appropriate value to the TZCLR register.<br>Reset type: SYSRSn |

**Table 20-75. TZFLG Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description  |
|-----|-------|------|-------|--|
| 0   | INT   | R    | 0h    | Latched Trip Interrupt Status Flag<br>0: Indicates no interrupt has been generated.<br>1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition.<br>No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register.<br>Reset type: SYSRSn |

### 20.17.2.53 TZCBCFLG Register (Offset = 94h) [Reset = 0h]

TZCBCFLG is shown in [Figure 20-141](#) and described in [Table 20-76](#).

Return to the [Summary Table](#).

This chapter describes the enhanced capture (eCAP) module, which is used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 2 eCAP. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an eCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 21.1 Introduction

### 21.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

The capture functionality of the Type 1 eCAP is enhanced from the Type 0 eCAP with the following added features:

- Event filter reset bit
  - Writing a 1 to ECCTL2[CTRFILTRESET] will clear the event filter, the modulo counter, and any pending interrupts flags. Resetting the bit is useful for initialization and debug.
- Modulo counter status bits
  - The modulo counter (ECCTL2 [MODCNRSTS]) indicates which capture register will be loaded next. In the Type 0 eCAP, it was not possible to know current state of modulo counter.
- DMA trigger source
  - eCAPxDMA was added as a DMA trigger. CEVT[1-4] can be configured as the source for eCAPxDMA.
- Input multiplexer
  - ECCTL0 [INPUTSEL] selects one of 128 input signals, which are detailed in [Section 21.3](#).
- EALLOW protection
  - EALLOW protection was added to critical registers. To maintain software compatibility with Type-0, configure DEV\_CFG\_REGS.ECAPTYPE to make these registers unprotected.

The capture functionality of the Type 2 eCAP is enhanced from the Type 1 eCAP with the following added features:

- Added ECAPxSYNCINSEL register
  - ECAPxSYNCINSEL register is added for each eCAP to select an external SYNCIN. Every eCAP can have a separate SYNCIN signal.

## 21.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Capture inputs can be connected using the Input X-BAR
- 128:1 input multiplexer
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Modulo counter status register (MODCNRSTS) to indicate sequencer state
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Ability to reset event filter, modulo counter, and interrupt flags
- Interrupt capabilities on any of the four capture events
- Separate DMA trigger
- EALLOW protection to control registers

## 21.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPXQSELn register bits. Using synchronized inputs can help with noise immunity but will affect the eCAP's accuracy by  $\pm 2$  cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

New to the Type 1 eCAP module, a 128:1 input multiplexer must also be configured (see [Figure 21-3](#)). This multiplexer can select a variety of inputs detailed in [Table 21-1](#) by configuring ECCTL0.INPUTSEL.

| GPIOTRIP-XBAR[16:1]     | 15:0         |

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

---

#### Note

ECAPxIN has to be at least 2\*SYSCLK cycles wide to be properly captured by the ECAP module. Otherwise the input pulse might get missed from sampling by the SYSCLK.

---

### 21.4 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 21-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 21-2 further describes the output of the eCAP in APWM mode based on the CMP and PRD values.

- A. A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

**Figure 21-1. Capture and APWM Modes of Operation**

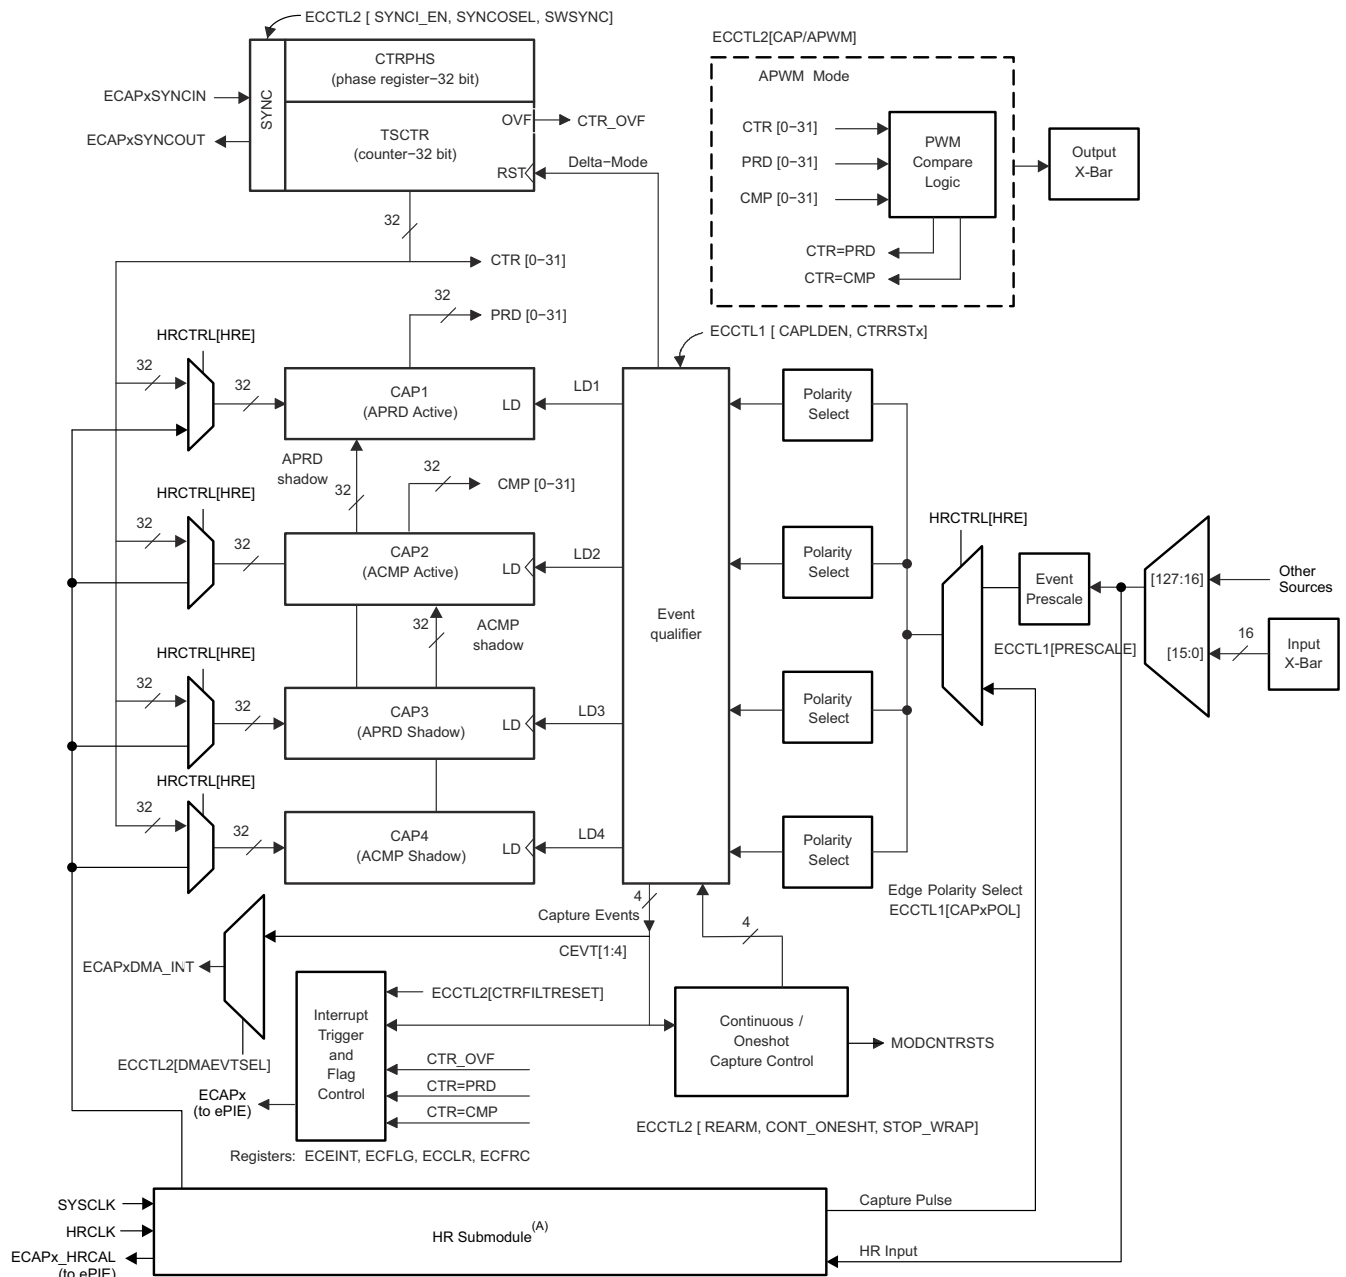

Figure 21-2. Counter Compare and PRD Effects on the eCAP Output in APWM Mode

### 21.5 Capture Mode Description

Figure 21-3 shows the various components that implement the capture function.

Copyright © 2018, Texas Instruments Incorporated

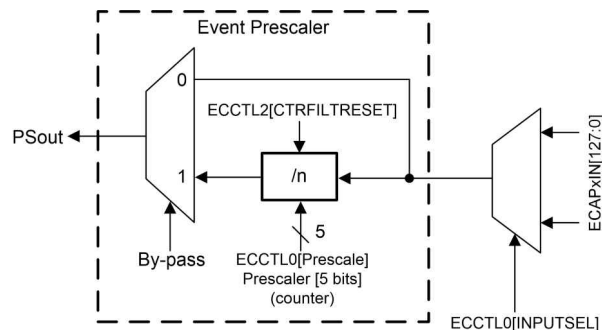

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 21-3. eCAP Block Diagram

### 21.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 21-4 shows a functional diagram and Figure 21-5 shows the operation of the prescale function. The event prescaler can be reset by setting the ECCTL2.CTRFILTRESET register bit.

- A. When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.
- B. The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

Figure 21-4. Event Prescale Control

Figure 21-5. Prescale Function Waveforms

### 21.5.2 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

### 21.5.3 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

- The Mod4 (2-bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP\_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, it will still keep resetting the TSCCTR counter on capture event (CEVTx) after the STOP\_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

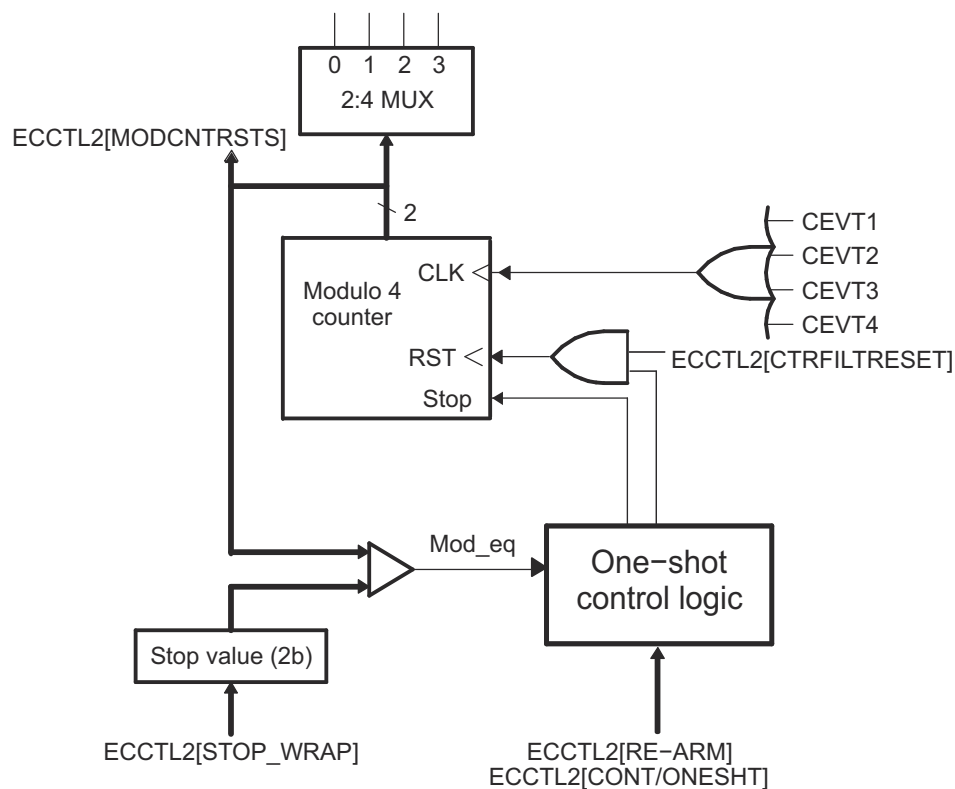

Figure 21-6. Details of the Continuous/One-shot Block

### 21.5.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

**Figure 21-7. Details of the Counter and Synchronization Block**

### 21.5.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACOMP) for CAP1 and CAP2 during APWM operation.

### 21.5.6 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from eCAP, X-Bar or EPWM. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 21-7. The SYNC signal is defined by the selection of ECAPxSYNCINSEL[SEL] as shown in Figure 21-8.

Figure 21-8. eCAP Synchronization Scheme

Figure 21-9. eCAP Synchronization Scheme

#### 21.5.6.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP2.

- Configure ECAP[1..2].ECAPxSYNCINSEL.SEL = 0x0 to disable external SYNCIN coming to eCAP1.
- Configure ECAP[1..2].ECCTL2.SWSYNC = 0x1, to force Software Synchronization of the TSCTR counter.

To use SWSYNC with other eCAP modules, ensure that the previous eCAP chain is not generating a SYNCOUT signal which will interfere with the software synchronization.

### 21.5.7 Interrupt Control

Operation and features of the eCAP interrupt control include (see [Figure 21-10](#)):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE and CLA.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. All interrupt flags will be cleared upon an event filter reset by writing a "1" to ECCTL2[CLRFLTRESET]. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

---

#### Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

---

Figure 21-10. Interrupts in eCAP Module

### 21.5.8 DMA Interrupt

On Type 0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type 1 eCAP, a separate DMA Trigger (ECAP\_DMA\_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events (CEVT1, CEVT2, CEVT3 and CEVT4) can be selected as the trigger source for ECAP\_DMA\_INT using ECCTL2 [DMAEVTSEL].

### 21.5.9 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal,  $CTR[31:0] = PRD[31:0]$ .

### 21.5.10 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a  $CTR = PRD$  trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

**Figure 21-11. PWM Waveform Details Of APWM Mode Operation**

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

**Figure 21-12. Time-Base Frequency and Period Calculation**

## 21.6 Application of the eCAP Module

The following sections will provide applications examples to show how to operate the eCAP module.

### 21.6.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 21-13 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), it wraps around to 00000000 (not shown in Figure 21-13), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the 4th event), hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

**Figure 21-13. Capture Sequence for Absolute Time-stamp and Rising Edge Detect**

### 21.6.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 21-14, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is:  $\text{Period1} = t_3 - t_1$ ,  $\text{Period2} = t_5 - t_3$ , ...and so on.  $\text{Duty Cycle1 (on-time \%)} = (t_2 - t_1) / \text{Period1} \times 100\%$ , and so on.  $\text{Duty Cycle1 (off-time \%)} = (t_3 - t_2) / \text{Period1} \times 100\%$ , and so on.

Figure 21-14. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect

### 21.6.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

Figure 21-15 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (Max value), before the next event, it wraps around to 00000000 and continues, a CANTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is,  $Period1 = T_1$ ,  $Period2 = T_2$ , and so on. As shown in Figure 21-15, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

**Figure 21-15. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect**

**21.6.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger**

In Figure 21-16, the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information, that is:  $Period1 = T_1 + T_2$ ,  $Period2 = T_3 + T_4$ , and so on.  $Duty Cycle1 (on-time \%) = T_1 / Period1 \times 100\%$ ,  $Duty Cycle1 (off-time \%) = T_2 / Period1 \times 100\%$ , and so on.

During initialization, you must write to the active registers for both period and compare. This action will automatically copy the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

**Figure 21-16. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect**

## 21.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

### 21.7.1 Example 1 - Simple PWM Generation (Independent Channel/s)

**Figure 21-17. PWM Waveform Details of APWM Mode Operation**

## 21.8 Software

### 21.8.1 ECAP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/ecap

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 21.8.1.1 eCAP APWM Example

FILE: `ecap_ex1_apwm.c`

This program sets up the eCAP module in APWM mode. The PWM waveform will come out on GPIO5. The frequency of PWM is configured to vary between 5Hz and 10Hz using the shadow registers to load the next period/compare values.

#### 21.8.1.2 eCAP Capture PWM Example

FILE: `ecap_ex2_capture_pwm.c`

This example configures ePWM3A for:

- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1 is configured to capture the time between rising and falling edge of the ePWM3A output.

#### *External Connections*

- eCAP1 is on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

#### *Watch Variables*

- `ecap1PassCount` - Successful captures.
- `ecap1IntCount` - Interrupt counts.

#### 21.8.1.3 eCAP APWM Phase-shift Example

FILE: `ecap_ex3_apwm_phase_shift.c`

This program sets up the eCAP1 and eCAP2 modules in APWM mode to generate the two phase-shifted PWM outputs of same duty and frequency value. The frequency, duty and phase values can be programmed of choice by updating the defined macros. By default 10 KHz frequency, 50% duty and 30% phase shift values are used. eCAP2 output leads the eCAP1 output by 30%. GPIO5 and GPIO6 are used as eCAP1/2 outputs and can be probed using analyzer/CRO to observe the waveforms.

### 21.8.1.4 eCAP Software Sync Example

FILE: `ecap_ex4_sw_sync.c`

This example configures ePWM3A for:

- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1, eCAP2, and eCAP3 are configured to capture the time between rising and falling edge of the ePWM3A output.

- eCAP1, eCAP2, eCAP3 are on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

#### Watch Variables

- `ecapPassCount` - Successful captures.
- `ecap3IntCount` - Interrupt counts.

## 21.9 eCAP Registers

This section describes the Enhanced Capture Registers.

### 21.9.1 ECAP Base Address Table

**Table 21-2. ECAP Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| ECap1Regs      | ECAP_REGS | ECAP1_BASE     | 0x0000_5200  | YES  | YES | YES | YES | YES                |
| ECap2Regs      | ECAP_REGS | ECAP2_BASE     | 0x0000_5240  | YES  | YES | YES | YES | YES                |
| ECap3Regs      | ECAP_REGS | ECAP3_BASE     | 0x0000_5280  | YES  | YES | YES | YES | YES                |

## 21.9.2 ECAP\_REGS Registers

Table 21-3 lists the memory-mapped registers for the ECAP\_REGS registers. All register offset addresses not listed in Table 21-3 should be considered as reserved locations and the register contents should not be modified.

**Table 21-3. ECAP\_REGS Registers**

| Offset | Acronym       | Register Name                       | Write Protection | Section            |
|--------|---------------|-------------------------------------|------------------|--------------------|
| 0h     | TSCTR         | Time-Stamp Counter                  |                  | <a href="#">Go</a> |
| 2h     | CTRPHS        | Counter Phase Offset Value Register |                  | <a href="#">Go</a> |
| 4h     | CAP1          | Capture 1 Register                  |                  | <a href="#">Go</a> |
| 6h     | CAP2          | Capture 2 Register                  |                  | <a href="#">Go</a> |
| 8h     | CAP3          | Capture 3 Register                  |                  | <a href="#">Go</a> |
| Ah     | CAP4          | Capture 4 Register                  |                  | <a href="#">Go</a> |
| 12h    | ECCTL0        | Capture Control Register 0          | EALLOW           | <a href="#">Go</a> |
| 14h    | ECCTL1        | Capture Control Register 1          | EALLOW           | <a href="#">Go</a> |
| 15h    | ECCTL2        | Capture Control Register 2          | EALLOW           | <a href="#">Go</a> |
| 16h    | ECEINT        | Capture Interrupt Enable Register   | EALLOW           | <a href="#">Go</a> |
| 17h    | ECFLG         | Capture Interrupt Flag Register     |                  | <a href="#">Go</a> |
| 18h    | ECCLR         | Capture Interrupt Clear Register    |                  | <a href="#">Go</a> |
| 19h    | ECFRC         | Capture Interrupt Force Register    | EALLOW           | <a href="#">Go</a> |
| 1Eh    | ECAPSYNCINSEL | SYNC source select register         | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 21-4 shows the codes that are used for access types in this section.

**Table 21-4. ECAP\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |

**Table 21-4. ECAP\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description   |
|-------------|------|---|
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 21.9.2.1 TSCTR Register (Offset = 0h) [Reset = 0h]

TSCTR is shown in [Figure 21-18](#) and described in [Table 21-5](#).

Return to the [Summary Table](#).

Time-Stamp Counter

**Figure 21-18. TSCTR Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| 11    | CTRFILTRESET | R-0/W1C | 0h    | Reset Bit<br>0h (R) = No effect<br>1h (W) = Resets event filter, counter, modulo counter and CEVT[1,2,3,4] and CNTOVF, HRERROR flags<br>Note: This provides an ability start capture module from known state in case spurious inputs are captured while ECAP is configured.<br>Reset type: CPU1.SYSRSn   |
| 10    | APWMPOL      | R/W     | 0h    | APWM output polarity select. This is applicable only in APWM operating mode.<br>Reset type: SYSRSn<br>0h (R/W) = Output is active high (Compare value defines high time)<br>1h (R/W) = Output is active low (Compare value defines low time)   |
| 9     | CAP_APWM     | R/W     | 0h    | CAP/APWM operating mode select<br>Reset type: SYSRSn<br>0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration:<br>- Inhibits TSCTR resets via CTR = PRD event<br>- Inhibits shadow loads on CAP1 and 2 registers<br>- Permits user to enable CAP1-4 register load<br>- CAPx/APWMx pin operates as a capture input<br>1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration:<br>- Resets TSCTR on CTR = PRD event (period boundary)<br>- Permits shadow loading on CAP1 and 2 registers<br>- Disables loading of time-stamps into CAP1-4 registers<br>- CAPx/APWMx pin operates as a APWM output |

**Table 21-13. ECCTL2 Register Field Descriptions (continued)**

| Bit | Field       | Type    | Reset | Description   |
|-----|-------------|---------|-------|---|
| 8   | SWSYNC      | R-0/W1S | 0h    | Software-forced Counter (TSCTR) Synchronizer. This provides the user a method to generate a synchronization pulse through software. In APWM mode, the synchronization pulse can also be sourced from the CTR = PRD event.<br>Reset type: SYSRSn<br>0h (R/W) = Writing a zero has no effect. Reading always returns a zero<br>1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero.<br>Note: Selection CTR = PRD is meaningful only in APWM mode however, you can choose it in CAP mode if you find doing so useful.  |
| 7-6 | SYNCO_SEL   | R/W     | 0h    | Sync-Out Select<br>Reset type: SYSRSn<br>0h (R/W) = sync out signal is SWSYNC<br>1h (R/W) = Select CTR = PRD event to be the sync-out signal<br>2h (R/W) = Disable sync out signal<br>3h (R/W) = Disable sync out signal  |
| 5   | SYNCI_EN    | R/W     | 0h    | Counter (TSCTR) Sync-In select mode<br>Reset type: SYSRSn<br>0h (R/W) = Disable sync-in option<br>1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.  |
| 4   | TSCTRSTOP   | R/W     | 0h    | Time Stamp (TSCTR) Counter Stop (freeze) Control<br>Reset type: SYSRSn<br>0h (R/W) = TSCTR stopped<br>1h (R/W) = TSCTR free-running   |
| 3   | REARM       | R-0/W1S | 0h    | Re-Arming Control. Note: The re-arm function is valid in one shot or continuous mode<br>Reset type: SYSRSn<br>0h (R/W) = Has no effect (reading always returns a 0)<br>1h (R/W) = Arms the one-shot sequence as follows:<br>1) Resets the Mod4 counter to zero<br>2) Unfreezes the Mod4 counter<br>3) Enables capture register loads  |
| 2-1 | STOP_WRAP   | R/W     | 3h    | Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped.<br>Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again.<br>Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur:<br>- Mod4 counter is stopped (frozen)<br>- Capture register loads are inhibited<br>In one-shot mode, further interrupt events are blocked until re-armed.<br>Reset type: SYSRSn<br>0h (R/W) = Stop after Capture Event 1 in one-shot mode<br>Wrap after Capture Event 1 in continuous mode.<br>1h (R/W) = Stop after Capture Event 2 in one-shot mode<br>Wrap after Capture Event 2 in continuous mode.<br>2h (R/W) = Stop after Capture Event 3 in one-shot mode<br>Wrap after Capture Event 3 in continuous mode.<br>3h (R/W) = Stop after Capture Event 4 in one-shot mode<br>Wrap after Capture Event 4 in continuous mode. |
| 0   | CONT_ONESHT | R/W     | 0h    | Continuous or one-shot mode control (applicable only in capture mode)<br>Reset type: SYSRSn<br>0h (R/W) = Operate in continuous mode<br>1h (R/W) = Operate in one-Shot mode   |

### 21.9.2.10 ECEINT Register (Offset = 16h) [Reset = 0h]

ECEINT is shown in [Figure 21-27](#) and described in [Table 21-14](#).

Return to the [Summary Table](#).

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is as follows:

- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

**Figure 21-27. ECEINT Register**

This page intentionally left blank.

This chapter describes the operation of the high resolution capture (HRCAP) module. The HRCAP submodule described here is part of the Type1 eCAP. HRCAP measures the width of external pulses to a higher degree of accuracy than the eCAP module. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an HRCAP module of the same type, to determine the differences between types, and for a list of device-specific differences within a type. A detailed description of all referenced functions can be found in the C2000Ware documentation.

## 22.1 Introduction

Uses for the HRCAP module include:

- Capacitive touch applications
- High-resolution period and duty cycle measurements of pulse train cycles
- Instantaneous speed measurements
- Instantaneous frequency measurements
- Voltage measurements across an isolation boundary
- Distance/sonar measurement and scanning
- Measuring flow

### 22.1.1 HRCAP Related Collateral

#### Foundational Materials

- [C2000 Academy - Control Peripherals](#)

#### Getting Started Materials

- [Leveraging High Resolution Capture \(HRCAP\) for Single Wire Data Transfer Application Report](#)

### 22.1.2 Features

The HRCAP module includes the following features:

- Pulse-width capture in either non-high-resolution or high-resolution modes
- Absolute mode pulse-width capture
- Continuous or one-shot capture
- Interrupt on either falling or rising edge
- Continuous mode capture of pulse widths in 4-deep buffer
- Hardware calibration logic for precision high-resolution capture

All of the previous resources are available on any pin using the Input X-BAR.

### 22.1.3 Description

Improvements from the Type 0 HRCAP are:

- Simplified calibration scheme:
  - HRCAP is always functional; never offline to perform calibration
  - Calibration is always running in the background; drastically reduced software overhead to calibrate
- Reduced software overhead to compute fractional bits
- Fractional and integer portions are packed into 32 bits
- All eCAP hardware is accessible when using the HRCAP enhancements. See [Section 22.3](#) for practical considerations.
- Usage of the HRCAP is now unified with the eCAP

The HRCAP enhancement has been added to eCAP 3 to allow signals to be captured asynchronously to SYSCLK. Each HRCAP submodule includes one capture channel in addition to a hardware calibration block. All eCAP hardware is accessible when using the HRCAP enhancements; however, using the Event Filter or the Input Qualifier is not valid, as these are synchronous to SYSCLK.

Each HRCAP-capable channel has the following independent key resources:

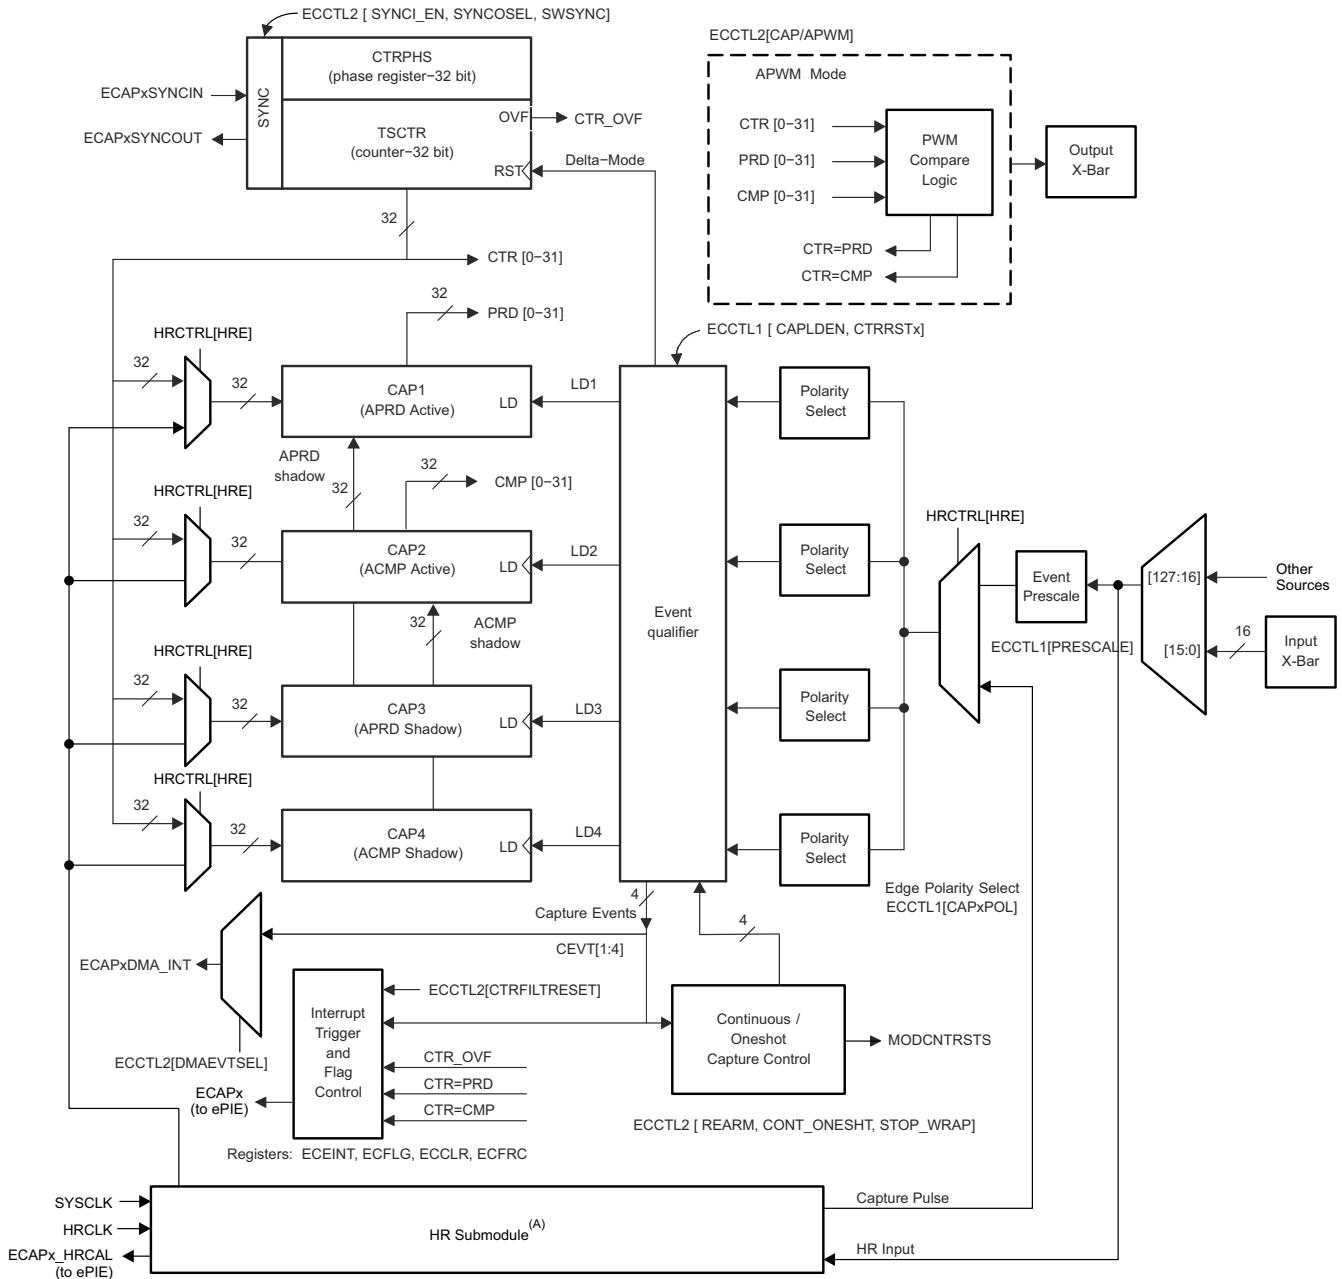

- All hardware of the respective eCAP
- High-resolution calibration logic
- Dedicated calibration interrupt

## 22.2 Operational Details

[Figure 22-1](#) shows the various components that implement the high-resolution capture functionality of the eCAP module. Note that existing eCAP resources are reused, which requires that the eCAP module is set up before

using the HRCAP enhancements. For simplicity, absolute timestamp measurements are recommended. See Section 22.3 for more details.

All HRCAP measurements are relative-time measures, in terms of minimum step size. Calibration hardware as well as software functions, have been provided to convert relative-time measurements to time-converted measurements in terms of seconds. The calibration hardware and software is only required if time-converted measurements are required.

Copyright © 2018, Texas Instruments Incorporated

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 22-1. HRCAP Operations Block Diagram

### 22.2.1 HRCAP Clocking

Unlike previous Type-0 HRCAP modules, the Type-1 eCAP, with HRCAP functionality, does not require a second PLL. However, the module still requires both SYSCLK and a second asynchronous clock source called HRCLK. The HRCLK is sensitive to changes in both temperature and voltage. For this reason, when using time-converted measurements, it is required to make periodic continuous calibrations.

### 22.2.2 HRCAP Initialization Sequence

Following are the HRCAP initialization sequence steps. When using the HRCAP to take relative-time measurements, only steps 1-5 are required. When using the HRCAP to take time-converted measurements, all steps are required.

1. Enable HRCLK using `HRCAP_enableHighResolutionClock()`
2. Delay 1  $\mu$ S
3. Enable HR mode using `HRCAP_enableHighResolution()`
4. Delay 1  $\mu$ S
5. Configure the eCAP module as desired, including interrupts
6. Set calibration period using `HRCAP_setCalibrationPeriod()`
7. Enable continuous calibration using `HRCAP_setCalibrationMode()`
8. Enable interrupts using `HRCAP_enableCalibrationInterrupt()`
9. Start calibration using `HRCAP_startCalibration()`

### 22.2.3 HRCAP Interrupts

The HRCAP enhancements leverage the existing eCAP interrupts (see *Interrupt Control* in the ECAP chapter) in addition to HRCALINT, which is used exclusively by the hardware calibration block. HRCALINT can be triggered by the following conditions:

1. SYSCLKCTR = HRCALIBPERIOD
2. SYSCLKCTR or HRCLKCTR experience an overflow condition

Figure 22-2 shows this logic.

**Figure 22-2. HRCAP Calibration**

## 22.2.4 HRCAP Calibration

---

### Note

For HRCAP calibration to work, the system needs to operate at SYSCLK frequency > 100 MHz.

---

The following section applies only to time-converted measurements; calibration for relative-time measurements is not required. All values captured by the HRCAP submodule are in number of HRCLK cycles. The HRCLK speed varies widely with temperature and voltage, thus a scale factor is required to convert the capture value to the SYSCLK domain. For the same reason, it is required to periodically recalculate the scale factor. The HRCAP submodule has a calibration block to reduce software overhead when calculating a scale factor between HRCLK and SYSCLK.

The calibration block contains the following key resources:

- **HRSYSCLKCNT:** A 32-bit counter connected to SYSCLK. The counter will start counting when CALIBSTART is set.
- **HRCLKCNT:** A 32-bit counter connected to HRCLK. The counter will start counting when CALIBSTART is set.
- **HRCALIBPERIOD:** Calibration period, calibration is stopped when HRSYSCLKCNT is equal to the value in this register.
- **HRSYSCLKCAP:** On a calibration period match, the value of HRSYSCLKCNT is captured into HRSYSCLKCAP.
- **HRCLKCAP:** On a calibration period match, the value of HRCLKCNT is captured into HRCLKCAP.
- **HRCALINT:** An interrupt that occurs on a calibration period match, or when one of the counter registers experiences an overflow condition.

The calibration logic consists of two free-running counters; one clocked by HRCLK(HRCLKCTR) and the other clocked by SYSCLK(HRSYSCLKCTR). When HRSYSCLKCTR is equal to HRCALIBPERIOD, the calibration block will capture and reset both counter values, then trigger an interrupt, indicating a new scale factor is ready to be calculated. The scale factor can be found by dividing HRSYSCLKCAP by HRCLKCAP (see [Equation 17](#)). A DriverLib function, HRCAP\_getScaleFactor, has been provided to determine the scale factor. This function should be called inside of the calibration interrupt service routine. If one of the counters experiences overflow, the CALPRDCHKSTS flag will be set. The full details of the calibration block are described in [Figure 22-2](#).

$$ScaleFactor = \frac{HRSYSCLKCAP}{HRCLKCAP} \quad (17)$$

---

### Note

- Even with calibration, noise on the 1.2V VDD supply will negatively affect the standard deviation of the HRCAP submodule. Care should be taken to ensure that the 1.2V supply is clean, and that noisy internal events such as enabling and disabling clock trees have been minimized while using the HRCAP submodule.
  - When HRCLK > SYSCLK, calibration stops immaturely, in order to mitigate improper calibration, SYSCLK must be set to at least 100 MHz.
-

### 22.2.4.1 Applying the Scale Factor

A DriverLib function has been provided to apply the scale factor to a capture value, `HRCAP_getEventTimeStampNanoseconds()`. [Equation 2](#) shows how to convert a raw count to seconds without using the DriverLib function.

$$Measurement(ns) = \frac{RawCount \times scaleFactor}{128} * SysClkPrd(ns) \quad (18)$$

**Table 22-1. Scale Factor**

| Parameter                  | Explanation  |
|----------------------------|--|
| RawCount                   | Capture value as read from ECAP_REGS_CAP1-4                    |
| ScaleFactor <sup>(1)</sup> | The Scale factor as calculated from <a href="#">Equation 2</a> |
| 128                        | Constant determined by the hardware of the HRCAP submodule     |
| SysClkPrd(nS)              | Period of the system clock                                     |
| Measurement(nS)            | Signal converted to nS   |

(1) The scale factor is not automatically applied to captured values. You are required to apply the scale factor to all captured values as shown in [Equation 2](#).

## 22.3 Known Exceptions

In HRCAP mode:

- Enabling and disabling core clocks negatively affects the standard deviation of the HRCAP submodule. Do not enable or disable core clocks while taking measurements.
- TSCTR is not writable; however, it can be reset using ECCTL2[CTRFILTRESET]
- Input synchronization is not applicable when using the HRCAP enhancements, because the HRCAP submodule is asynchronous to SYSCLK.
- The Event Filter functionality is not applicable for HRCAP, which defeats the purpose of HRCAP as the Event Filter's output is synchronous to SYSCLK.
- The best practice is to use absolute time mode for high resolution mode. If time difference mode is used, it may lead to inaccurate results if the fractional value is not taken into consideration for capture events that have reset the time base counter.
  - Actual Capture Value = (Capture Value) – (fractional value of reference event that reset the counter)
- For high-frequency input signals, the CPU may not be able cope with the speed of the captures. In such a case, One-Shot mode is recommended. This mode allows the device to capture up to four edges before waiting to be serviced when the CPU is ready. This is applicable for the eCAP as well; however in that case the event filter can be used to reduce the rate of captures.

## 22.4 Software

### 22.4.1 HRCAP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/hrcap

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 22.4.1.1 HRCAP Capture and Calibration Example

FILE: hrcap\_ex1\_capture.c

This example configures ECAP3 to use HRCAP functionality to capture time between edges on input GPIO2.

##### *External Connections*

The user must provide a signal to GPIO2. XCLKOUT has been configured to GPIO16 and can be externally jumped to serve this purpose.

##### *Watch Variables*

- onTime1, onTime2
- offTime1, offTime2
- period1, period2

## 22.5 HRCAP Registers

This section describes the High-Resolution Capture Registers.

### 22.5.1 HRCAP Base Address Table

**Table 22-2. HRCAP Base Address Table**

| Bit Field Name |            | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|------------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure  |                |              |      |     |     |     |                    |
| HRCap3Regs     | HRCAP_REGS | HRCAP3_BASE    | 0x0000_52A0  | YES  | YES | YES | YES | YES                |

## 22.5.2 HRCAP\_REGS Registers

Table 22-3 lists the memory-mapped registers for the HRCAP\_REGS registers. All register offset addresses not listed in Table 22-3 should be considered as reserved locations and the register contents should not be modified.

**Table 22-3. HRCAP\_REGS Registers**

| Offset | Acronym     | Register Name                                  | Write Protection | Section            |
|--------|-------------|--|------------------|--------------------|
| 0h     | HRCTL       | High-Res Control Register                      | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 22-4 shows the codes that are used for access types in this section.

**Table 22-4. HRCAP\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 22.5.2.1 HRCTL Register (Offset = 0h) [Reset = 0h]

HRCTL is shown in [Figure 22-3](#) and described in [Table 22-5](#).

Return to the [Summary Table](#).

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type 2 eQEP. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

## 23.1 Introduction

An incremental encoder disk is patterned with a track of slots along its periphery, as shown in [Figure 23-1](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

**Figure 23-1. Optical Encoder Disk**

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and conversely, as shown in [Figure 23-2](#).

**Figure 23-2. QEP Encoder Output Signal for Forward/Reverse Movement**

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 kHz, so

by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 23-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 23-3. Index Pulse Example**

Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \tag{19}$$

$$v(k) \approx \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \tag{20}$$

where:

- $v(k)$  = Velocity at time instant  $k$
- $x(k)$  = Position at time instant  $k$
- $x(k-1)$  = Position at time instant  $k-1$
- $T$  = Fixed unit time or inverse of velocity calculation rate
- $\Delta X$  = Incremental position movement in unit time
- $t(k)$  = Time instant " $k$ "
- $t(k-1)$  = Time instant " $k-1$ "
- $X$  = Fixed unit position
- $\Delta T$  = Incremental time elapsed for unit position movement

Equation 19 is the conventional approach to velocity estimation and it requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on [Equation 19](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 20](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 20](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does [Equation 19](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 20](#) at low speed and have the DSP software switch over to [Equation 19](#) when the motor speed rises above some specified threshold.

## 23.3 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured via the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode should not be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 23.4 Description

This section provides the eQEP inputs, memory map, and functional description.

### 23.4.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYSCLK prior to entering the module. The application code should enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- **QEPA/XCLK and QEPB/XDIR**

These two pins can be used in quadrature-clock mode or direction-count mode.

- Quadrature-clock Mode

The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase.

This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and conversely. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

- Direction-count Mode

In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- **QEPI: Index or Zero Marker**

The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- **QEPS: Strobe Input**

This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

Input signals to the eQEP (QEPA, QEPB, QEPI and QEPS) can come from multiple sources; that is, device pin, CMPSSx, or PWMXBARx. One typical used case is if SinCos transducers are used in the motor control system to estimate the position of motor shaft and Index signal is coming from traditional rotary encoder, source of the eQEP signals (QEPA, QEPB and QEPI) can be configured as output of CMPSSx which decodes the Sin, Cos and Index signals. [Figure 23-4](#) illustrates the use case.

Selection of the source of Input signals (QEPA, QEPB, and QEPI) is user-configurable through the QEPSRCSEL register as shown in [Table 23-1](#).

**Note**

Configuration of QEPSRCSEL register to select the source of QEPA, QEPB, and QEPI signals can lead to unexpected transition on these signals, which can cause an undesirable outcome if eQEP is already running. You need to make sure that the eQEP is disabled before configuring the QEPSRCSEL register for input signals.

### 23.4.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 23-5):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)
- Quadrature Mode Adapter (QMA)

### 23.5 Quadrature Decoder Unit (QDU)

Figure 23-6 shows a functional block diagram of the QDU.

Figure 23-6. Functional Block Diagram of Decoder Unit

#### 23.5.1 Position Counter Input Modes

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode

- DOWN-count mode

### 23.5.1.1 Quadrature Count Mode

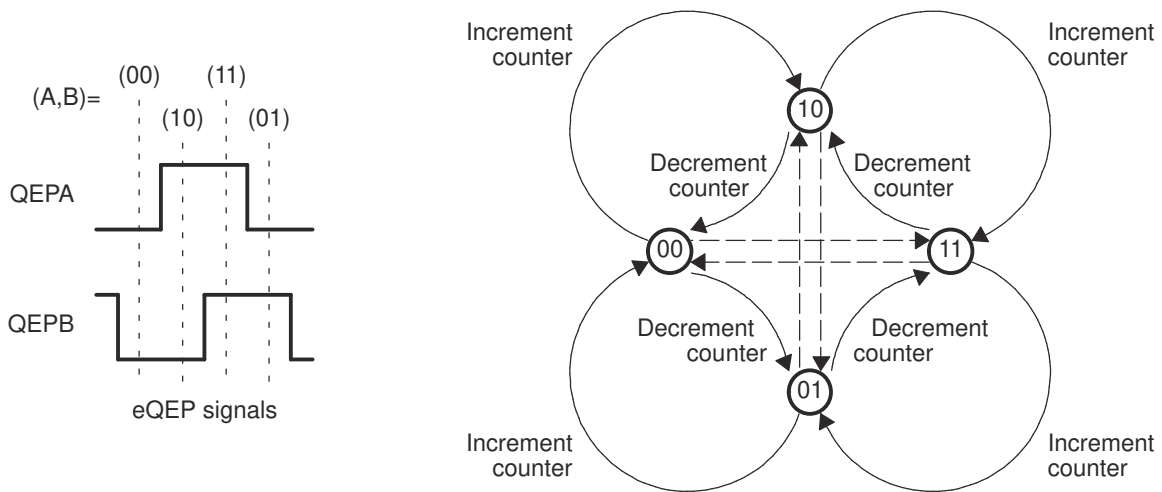

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

#### Direction Decoding

The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. Table 23-3 and Figure 23-7 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 23-8 shows the direction decoding and clock generation from the eQEP input signals.

**Table 23-3. Quadrature Decoder Truth Table**

| Previous Edge | Present Edge | QDIR   | QPOSCNT                |
|---------------|--------------|--------|------------------------|
| QA↑           | QB↑          | UP     | Increment              |
|               | QB↓          | DOWN   | Decrement              |
|               | QA↓          | TOGGLE | Increment or Decrement |
| QA↓           | QB↓          | UP     | Increment              |
|               | QB↑          | DOWN   | Decrement              |
|               | QA↑          | TOGGLE | Increment or Decrement |
| QB↑           | QA↑          | DOWN   | Decrement              |
|               | QA↓          | UP     | Increment              |
|               | QB↓          | TOGGLE | Increment or Decrement |
| QB↓           | QA↓          | DOWN   | Decrement              |
|               | QA↑          | UP     | Increment              |
|               | QB↑          | TOGGLE | Increment or Decrement |

**Figure 23-7. Quadrature Decoder State Machine**

**Figure 23-8. Quadrature-clock and Direction Decoding**

**Phase Error Flag** In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOSCNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 23-7](#) are invalid transitions that generate a phase error.

**Count Multiplication** The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 23-8](#).

**Reverse Count** In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder, thereby reversing the counting direction.

### 23.5.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for the position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

### 23.5.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by a factor of 2x. In up-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

### 23.5.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

### 23.5.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit will invert the index input.

### 23.5.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

## 23.6 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

### 23.6.1 Position Counter Operating Modes

Position-counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after "0". The Interrupt flag is set to indicate overflow/underflow in QFLG register.

### 23.6.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM]=00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOS MAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in [Figure 23-9](#).

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to '00' or '11' when pcr=0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOS LAT register on every index marker.

**Figure 23-9. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or 0xF9F)**

#### Note

In case of a boundary condition where the time period between the Index Event and the previous QCLK edge is less than SYSCLK period, then QPOSCNT gets reset to zero or QPOS MAX in the same SYSCLK cycle and does not wait for the next QCLK edge to occur.

### 23.6.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 23-10 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

Figure 23-10. Position Counter Underflow/Overflow (QPOSMAX = 4)

### 23.6.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 23.6.1.2.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

### 23.6.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, QPOSCNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

### 23.6.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

#### 23.6.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

#### Latch on Rising Edge (QEPCTL[IEL]=01)

The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

#### Latch on Falling Edge (QEPCTL[IEL] = 10)

The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

#### Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)

The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

Figure 23-11 shows the position counter latch using an index event marker.

Figure 23-11. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)

### 23.6.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction, and on the falling edge of the strobe input for reverse direction as shown in Figure 23-12.

The strobe event latch interrupt flag (QLFG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

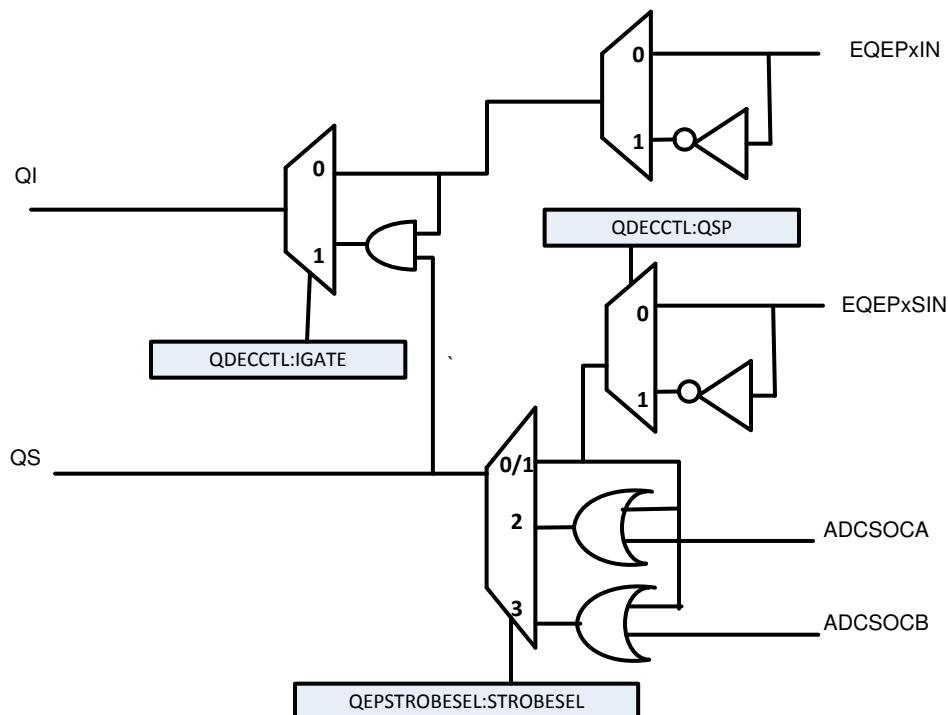

Figure 23-12. Strobe Event Latch (QEPCTL[SEL] = 1)

There is an added feature on Type 2.0 eQEP where position-counter value can also be latched on ADCSOCA and ADCSOCB events by configuring the register QEPSTROBESEL.STROBESEL as shown in figure [Figure 23-13](#)

**Figure 23-13. Latching Position Counter on ADCSOCA/ADCSOCB event**

### 23.6.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

#### **Index Event Initialization (IEI)**

The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization will be on the falling edge of the index input.

#### **Strobe Event Initialization (SEI)**

If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

#### **Software Initialization (SWI)**

The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to it again, the position counter will be re-initialized.

### 23.6.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 23-14 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 23-14. eQEP Position-compare Unit

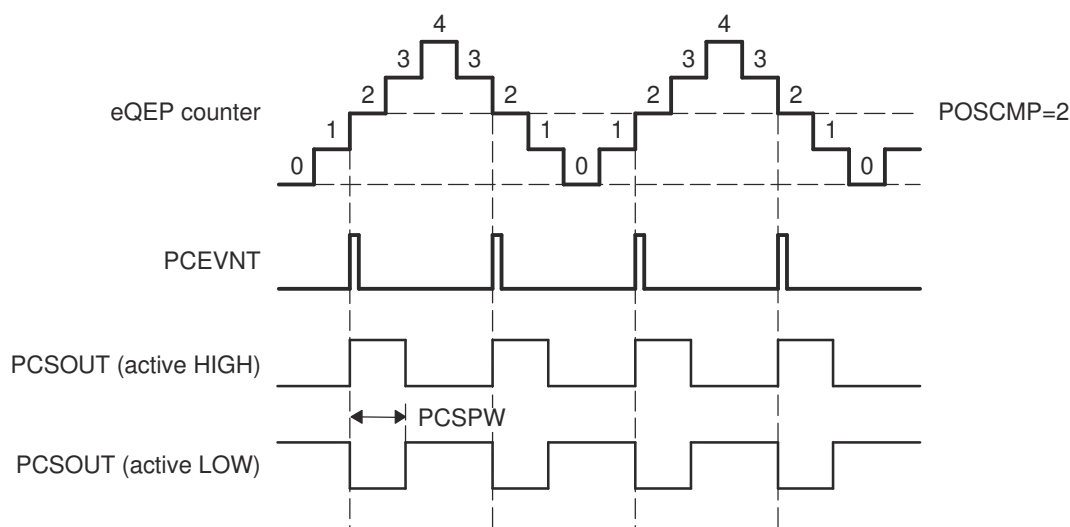

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

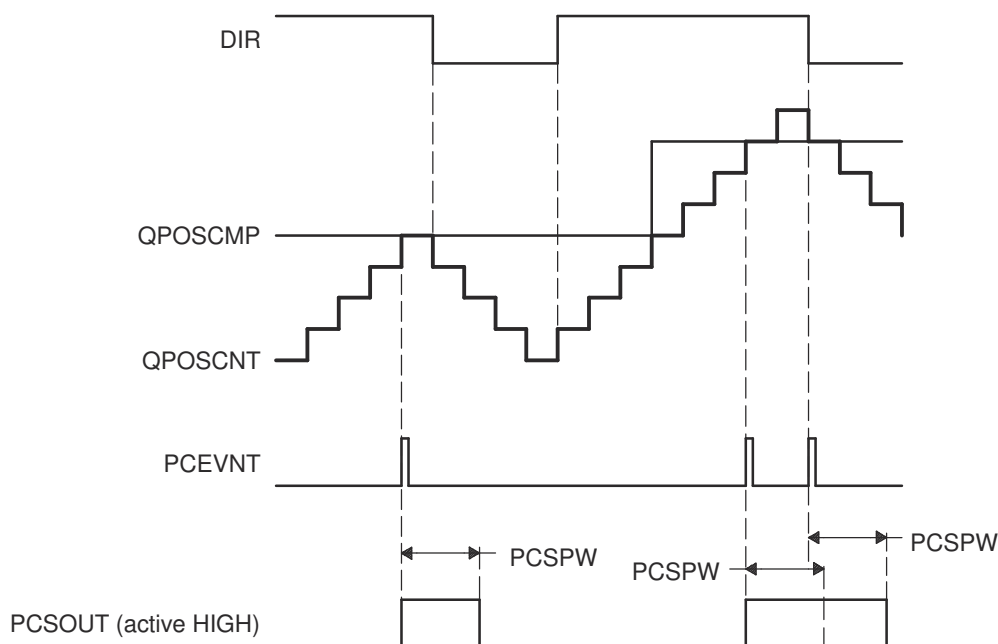

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 23-15).

See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

**Figure 23-15. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 23-16](#).

**Figure 23-16. eQEP Position-compare Sync Output Pulse Stretcher**

## 23.7 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 23-17](#). This feature is typically used for low-speed measurement using the following formula:

$$v(k) = \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (21)$$

where:

- $X$  = Unit position is defined by integer multiple of quadrature edges (see [Figure 23-18](#))
- $\Delta T$  = Elapsed time between unit position events
- $v(k)$  = Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

If the QEP capture timer overflows between unit position events, then it sets the QEP capture overflow flag (QEPSTS[COEF]) in the status register and the QCPRDLAT register is set to 0xFFFF. If direction change occurs between the unit position events, then the error flag is set in the status register (QEPSTS[CDEF]) and the QCPRDLAT register is set to 0xFFFF.

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 23-19](#) shows the capture unit operation along with the position counter.

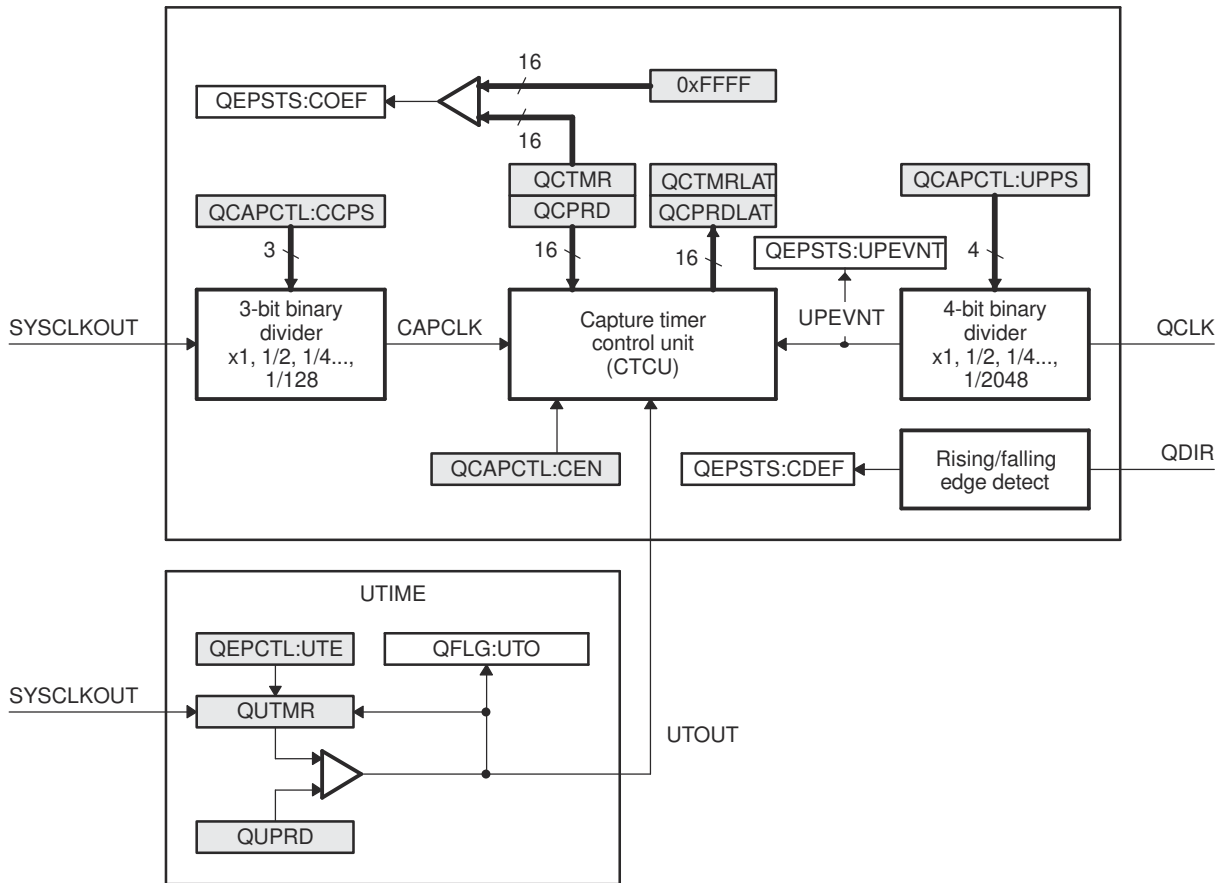

Figure 23-17. eQEP Edge Capture Unit

**Note**

The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CCPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

**Figure 23-18. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)**

**Figure 23-19. eQEP Edge Capture Unit - Timing Details**

Velocity calculation equation:

$$v(k) = \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \quad (22)$$

where:

- $v(k)$  = Velocity at time instant  $k$
- $x(k)$  = Position at time instant  $k$
- $x(k-1)$  = Position at time instant  $k-1$
- $T$  = Fixed unit time or inverse of velocity calculation rate
- $\Delta X$  = Incremental position movement in unit time
- $X$  = Fixed unit position
- $\Delta T$  = Incremental time elapsed for unit position movement
- $t(k)$  = Time instant " $k$ "
- $t(k-1)$  = Time instant " $k-1$ "

Unit time ( $T$ ) and unit period ( $X$ ) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QOSLAT and QCPRDLAT registers.

| Parameter  | Relevant Register to Configure or Read the Information                  |
|------------|---|
| $T$        | Unit Period Register (QUPRD)  |
| $\Delta X$ | Incremental Position = QOSLAT( $k$ ) - QOSLAT( $k-1$ )                  |
| $X$        | Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits |
| $\Delta T$ | Capture Period Latch (QCPRDLAT)   |

### 23.8 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer (Figure 23-20) that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match ( $QWDPRD = QWDTMR$ ), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

Figure 23-20. eQEP Watchdog Timer

### 23.9 eQEP Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations, see Figure 23-21. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), it resets the unit timer (QUTMR) and also generates the unit time out interrupt flag (QFLG[UTO]). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 23.7.

Figure 23-21. eQEP Unit Timer Base

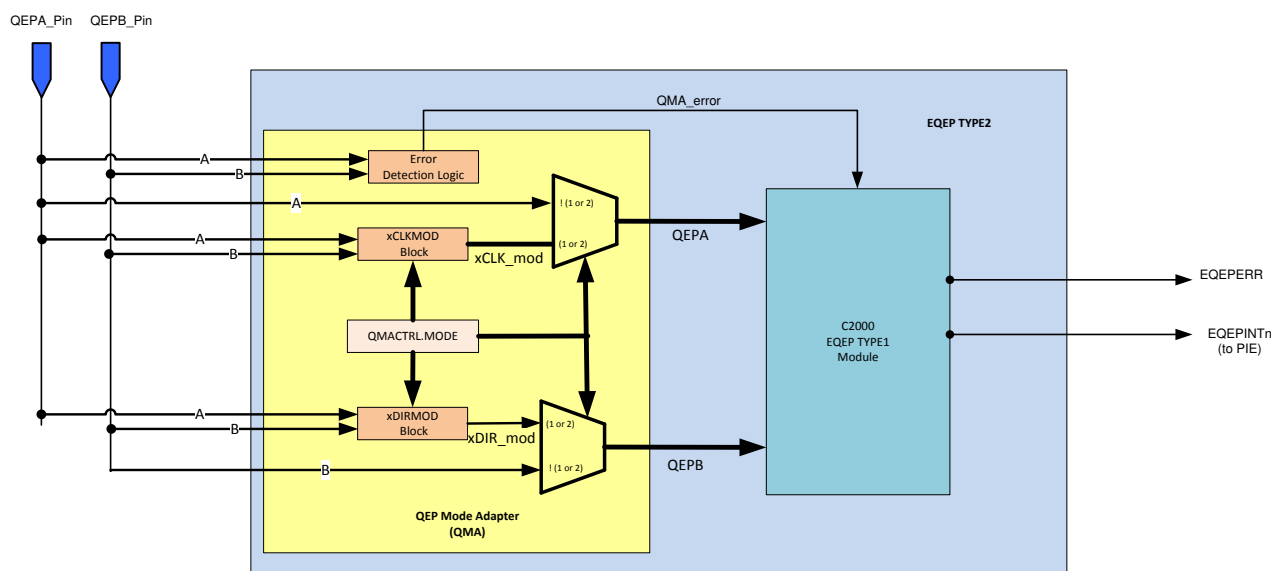

## 23.10 QMA Module

The QEP Mode Adapter (QMA) is designed to extend the C2000™ eQEP module capabilities to support the additional modes described. [Figure 23-22](#) depicts how the QMA module is integrated into the eQEP module.

At reset, by default QMA logic is bypassed and the EQEPA and EQEPB inputs from the pins go directly into the eQEP module. When QMA module is enabled by configuring the QMACTRL[MODE] register, the EQEPA and EQEPB input are processed by this module and modified version of EQEPA and EQEPB signals are sent to the eQEP module. The QMA module requires the eQEP module to be configured in the Direction-Count mode and generates a clock signal on EQEPA input and direction signal on EQEPB input as needed for the proper operation of the intended mode.

- The xCLKMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the clock signal on the EQEPA input to the eQEP module.
- The xDIRMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the direction signal on the EQEPB input to the eQEP module.

The QMA module has error detection logic to detect illegal transitions on EQEPA and EQEPB input signals. The QMA module's error and interrupt are integrated inside the eQEP module as described in [Section 23.11](#). In addition, the QMACTRL register configuration can be locked using the QMALOCK register. Refer to the register description for more details.

**Figure 23-22. QMA Module Block Diagram**

### 23.10.1 Modes of Operation

The QMA module can be operated in the following modes by configuring the QMACTRL register:

- QMA Mode-1 (QMACTRL[MODE]=1)
- QMA Mode-2 (QMACTRL[MODE]=2)

#### 23.10.1.1 QMA Mode-1 (QMACTRL[MODE]=1)

This mode is used when the default state of EQEPA and EQEPB inputs is high. In this mode, outputs of QMA correspond to the following as shown in [Figure 23-23](#):

- EQEPA Output of QMA is the AND of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is the direction signal generated by QMA based on EQEPA and EQEPB inputs

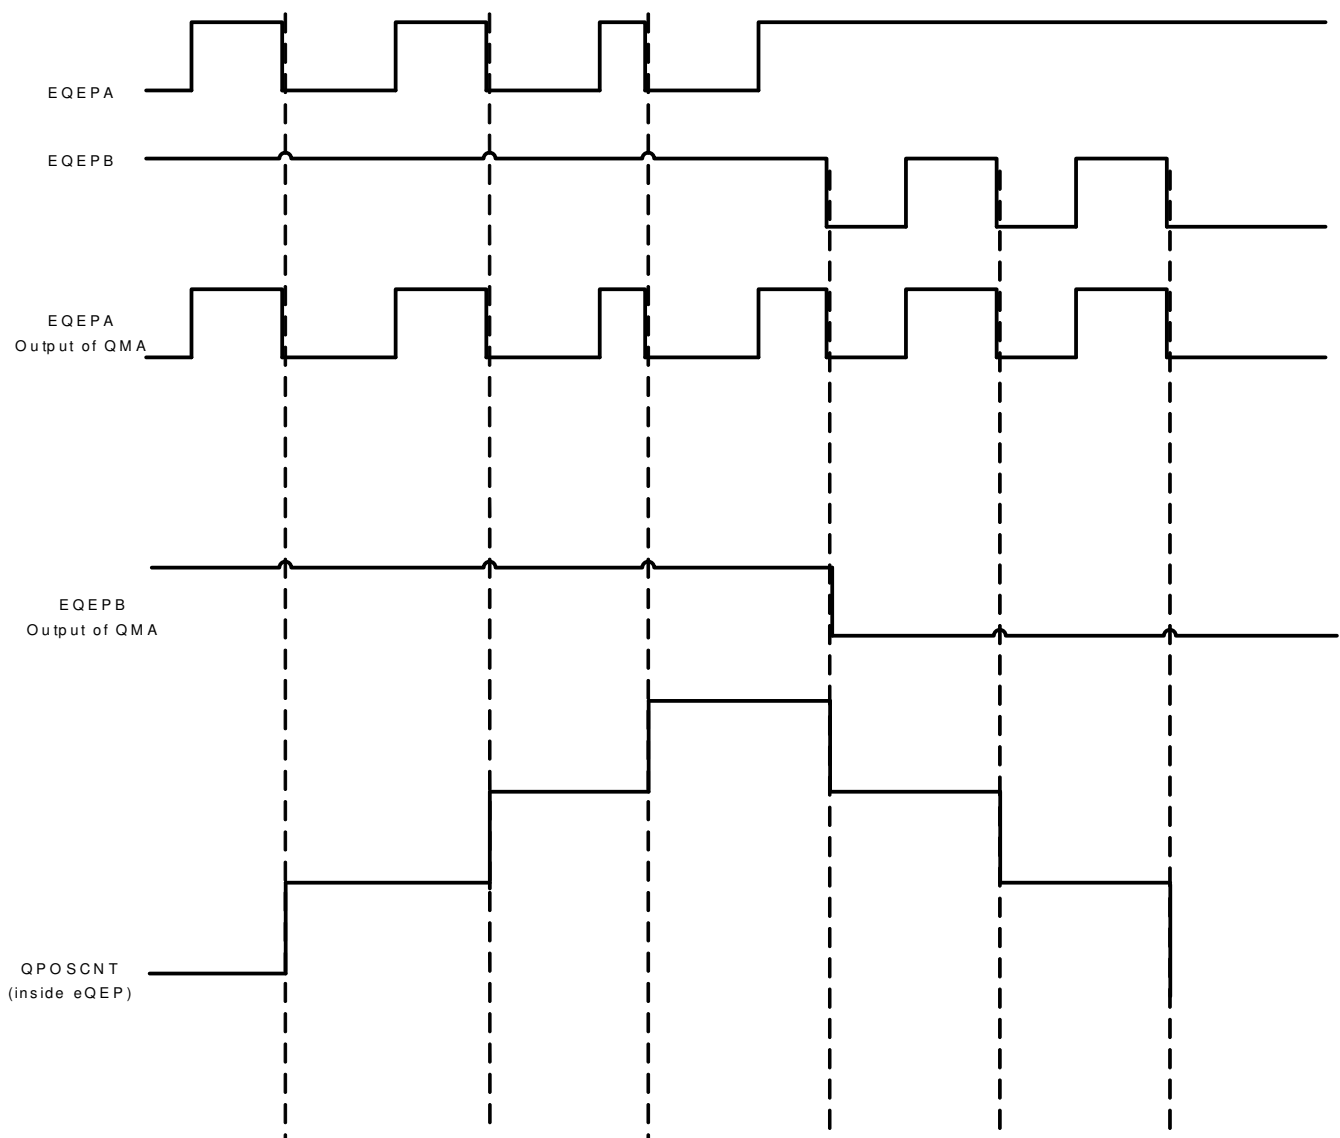

Figure 23-23. QMA Mode-1

### 23.10.1.2 QMA Mode-2 (QMACTRL[MODE]=2)

This mode is used when the default state of EQEPA and EQEPB inputs is low. In this mode, outputs of QMA correspond to the following as shown in Figure 23-24:

- EQEPA Output of QMA is the OR of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is the direction signal generated by QMA based on EQEPA and EQEPB inputs

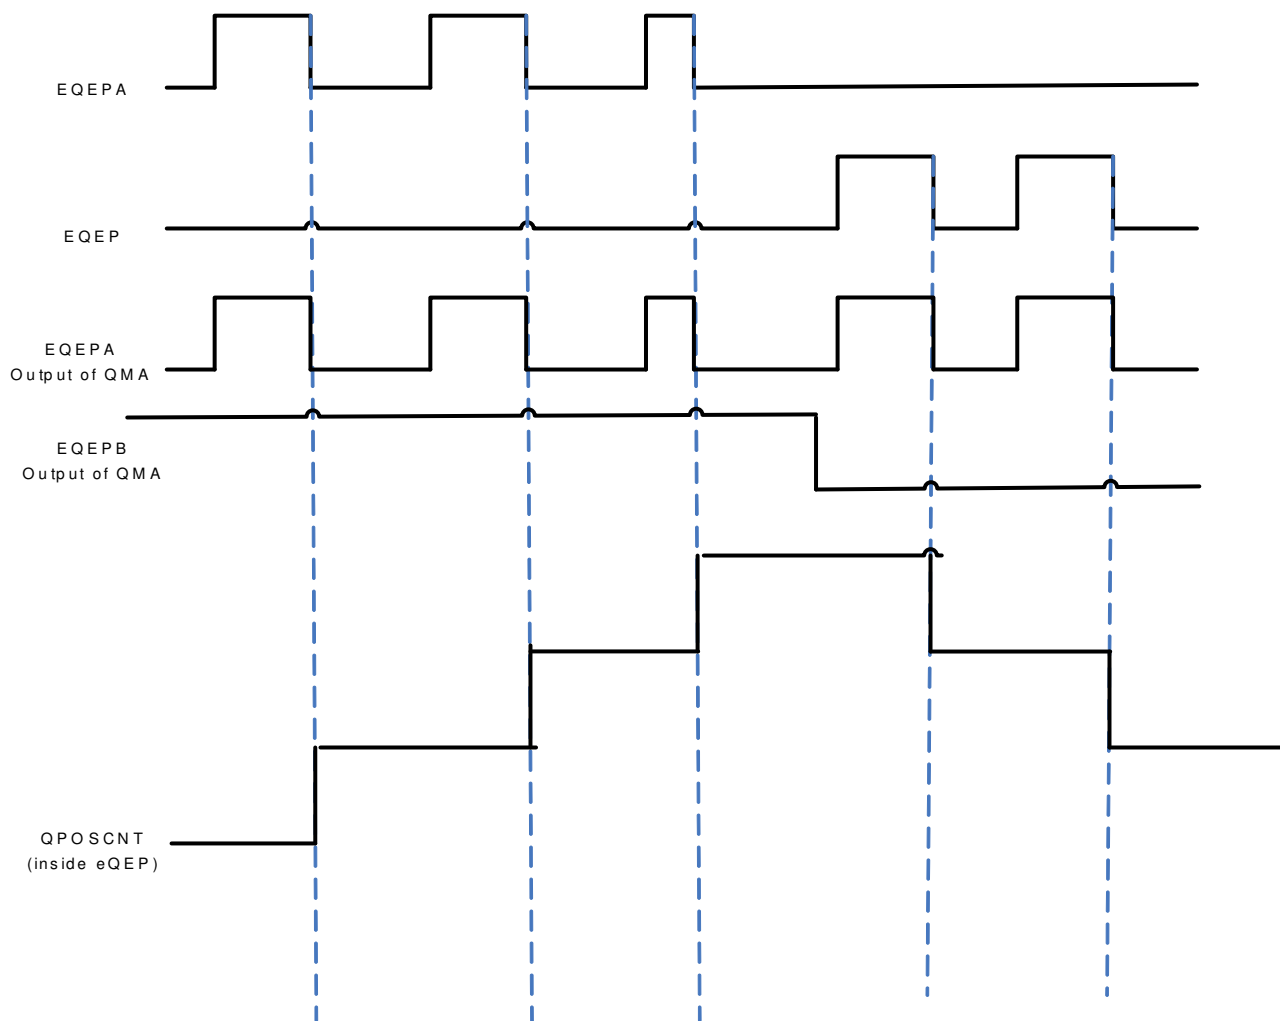

Figure 23-24. QMA Mode-2

### 23.10.2 Interrupt and Error Generation

The error detection logic detects illegal transitions on EQEPA and EQEPB signals and generates an error signal. This error signal can be used to generate eQEP interrupt and error output. Refer to Section 23.11 for details.

### 23.11 eQEP Interrupt Structure

Figure 23-25 shows how the interrupt mechanism works in the eQEP module.

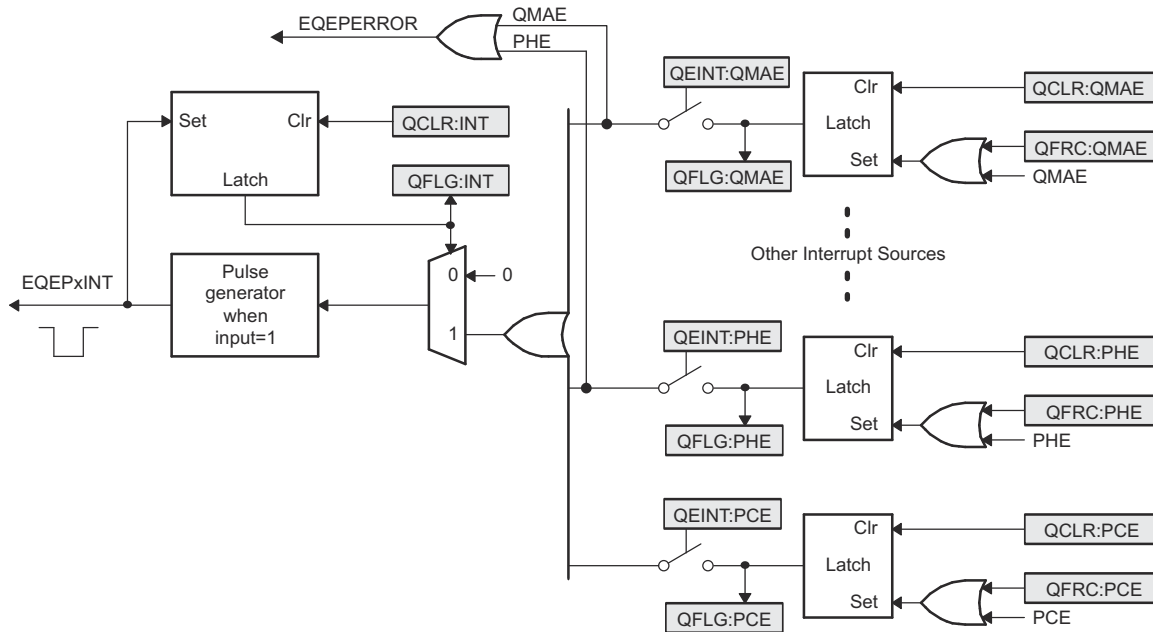

Figure 23-25. eQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT).

An interrupt pulse is generated to PIE when:

1. Interrupt is enabled for eQEP event inside QEINT register
2. Interrupt flag for eQEP event inside QFLG register is set, and
3. Global interrupt status flag bit QFLG[INT] had been cleared for previously generated interrupt event. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, by way of the interrupt clear register (QCLR), before any other interrupt pulses are generated. If either flags inside the QFLG register are not cleared, further interrupt events will not generate an interrupt to PIE. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

## 23.12 Software

### 23.12.1 EQEP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/eqep

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 23.12.1.1 Frequency Measurement Using eQEP

FILE: eqep\_ex1\_freq\_cal.c

This example will calculate the frequency of an input signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. It will interrupt once every period and call the frequency calculation function. This example uses the IQMath library to simplify high-precision calculations.

In addition to the main example file, the following files must be included in this project:

- *eqep\_ex1\_calculation.c* - contains frequency calculation function
- *eqep\_ex1\_calculation.h* - includes initialization values for frequency structure

The configuration for this example is as follows

- Maximum frequency is configured to 10 kHz (baseFreq)
- Minimum frequency is assumed at 50 Hz for capture pre-scalar selection

*SPEED\_FR*: High Frequency Measurement is obtained by counting the external input pulses for 10 ms (unit timer set to 100 Hz).  $\text{SPEED\_FR} = \frac{\text{Count} \Delta t}{10 \text{ ms}}$

*SPEED\_PR*: Low Frequency Measurement is obtained by measuring time period of input edges. Time measurement is averaged over 64 edges for better results and the capture unit performs the time measurement using pre-scaled SYSCLK.

Note that the pre-scalar for capture unit clock is selected such that the capture timer does not overflow at the required minimum frequency. This example runs indefinitely until the user stops it.

For more information about the frequency calculation see the comments at the beginning of eqep\_ex1\_calculation.c and the XLS file provided with the project, eqep\_ex1\_calculation.xls.

#### External Connections

- Connect GPIO25/eQEP1A to GPIO0/ePWM1A

#### Watch Variables

- *freq.freqHzFR* - Frequency measurement using position counter/unit time out
- *freq.freqHzPR* - Frequency measurement using capture unit

#### 23.12.1.2 Position and Speed Measurement Using eQEP

FILE: eqep\_ex2\_pos\_speed.c

This example provides position and speed measurement using the capture unit and speed measurement using unit time out of the eQEP module. ePWM1 and a GPIO are configured to generate simulated eQEP signals. The ePWM module will interrupt once every period and call the position/speed calculation function. This example uses the IQMath library to simplify high-precision calculations.

In addition to the main example file, the following files must be included in this project:

- *eqep\_ex2\_calculation.c* - contains position/speed calculation function
- *eqep\_ex2\_calculation.h* - includes initialization values for position/speed structure

The configuration for this example is as follows

- Maximum speed is configured to 6000 rpm (baseRPM)
- Minimum speed is assumed at 10 rpm for capture pre-scalar selection
- Pole pair is configured to 2 (polePairs)
- Encoder resolution is configured to 4000 counts/revolution (mechScaler)

- Which means:  $4000 / 4 = 1000$  line/revolution quadrature encoder (simulated by ePWM1)
- ePWM1 (simulating QEP encoder signals) is configured for a 5 kHz frequency or 300 rpm ( $= 4 * 5000 \text{ counts/sec} * 60 \text{ sec/min} / 4000 \text{ counts/rev}$ )

**SPEEDRPM\_FR**: High Speed Measurement is obtained by counting the QEP input pulses for 10 ms (unit timer set to 100 Hz).

$$\text{SPEEDRPM\_FR} = (\text{Position Delta} / 10 \text{ ms}) * 60 \text{ rpm}$$

**SPEEDRPM\_PR**: Low Speed Measurement is obtained by measuring time period of QEP edges. Time measurement is averaged over 64 edges for better results and the capture unit performs the time measurement using pre-scaled SYSCLK.

Note that the pre-scaler for capture unit clock is selected such that the capture timer does not overflow at the required minimum frequency. This example runs indefinitely until the user stops it.

For more information about the position/speed calculation see the comments at the beginning of eqep\_ex2\_calculation.c and the XLS file provided with the project, eqep\_ex2\_calculation.xls.

#### External Connections

- Connect GPIO25/eQEP1A to GPIO0/ePWM1A (simulates eQEP Phase A signal)
- Connect GPIO29/eQEP1B to GPIO1/ePWM1B (simulates eQEP Phase B signal)
- Connect GPIO23/eQEP1I to GPIO2 (simulates eQEP Index Signal)

#### Watch Variables

- *posSpeed.speedRPMFR* - Speed meas. in rpm using QEP position counter
- *posSpeed.speedRPMPR* - Speed meas. in rpm using capture unit
- *posSpeed.thetaMech* - Motor mechanical angle (Q15)
- *posSpeed.thetaElec* - Motor electrical angle (Q15)

### 23.12.1.3 ePWM Frequency Measurement Using eQEP with X-BAR Connection

FILE: eqep\_ex3\_epwm\_xbar.c

This example will calculate the frequency of an PWM signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. This ePWM signal is connected to input of eQEP using Input CrossBar and EPWM XBAR. ePWM module will interrupt once every period and call the frequency calculation function. This example uses the IQMath library to simplify high-precision calculations.

In addition to the main example file, the following files must be included in this project:

- *eqep\_ex1\_calculation.c* - contains frequency calculation function
- *eqep\_ex1\_calculation.h* - includes initialization values for frequency structure

The configuration for this example is as follows

- Maximum frequency is configured to 10 kHz (baseFreq)
- Minimum frequency is assumed at 50 Hz for capture pre-scalar selection
- GPIO0 is connected to output of INPUT\_XBAR1
- INPUT\_XBAR1 is connected to output of PWMXBAR at TRIP4
- eQEPA source is configured as PWMXBAR.1 output (TRIP4)

**SPEED\_FR**: High Frequency Measurement is obtained by counting the external input pulses for 10 ms (unit timer set to 100 Hz).  $\lfloor \text{SPEED\_FR} = \frac{\text{Count} \Delta}{10 \text{ ms}} \rfloor$

**SPEED\_PR**: Low Frequency Measurement is obtained by measuring time period of input edges. Time measurement is averaged over 64 edges for better results and the capture unit performs the time measurement using pre-scaled SYSCLK.

Note that the pre-scaler for capture unit clock is selected such that the capture timer does not overflow at the required minimum frequency. This example runs indefinitely until the user stops it.

For more information about the frequency calculation see the comments at the beginning of eqep\_ex1\_calculation.c and the XLS file provided with the project, eqep\_ex1\_calculation.xls.

#### Watch Variables

- *freq.freqHzFR* - Frequency measurement using position counter/unit time out
- *freq.freqHzPR* - Frequency measurement using capture unit

#### 23.12.1.4 Frequency Measurement Using eQEP with Unit Timeout Interrupt

FILE: eqep\_ex4\_freq\_cal\_interrupt.c

This example will calculate the frequency of an input signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. EQEP unit timeout is set which will generate an interrupt every *UNIT\_PERIOD* microseconds and frequency calculation occurs continuously

The configuration for this example is as follows

- PWM frequency is specified as 5000 Hz
- *UNIT\_PERIOD* is specified as 10000  $\mu$ s
- Minimum frequency is  $(1/(2*10\text{ms}))$ , that is 50 Hz
- Highest frequency can be  $(2^{32})/((2*10\text{ ms}))$
- Resolution of frequency measurement is 50 Hz

*freq* : Frequency Measurement is obtained by counting the external input pulses for *UNIT\_PERIOD* (unit timer set to 10 ms).

#### External Connections

- Connect GPIO25/eQEP1A to GPIO0/ePWM1A

#### Watch Variables

- *freq* - Frequency measurement using position counter/unit time out
- *pass* - If measured frequency matches with PWM frequency then *pass* = 1, else 0

#### 23.12.1.5 Motor Speed and Direction Measurement Using eQEP with Unit Timeout Interrupt

FILE: eqep\_ex5\_speed\_dir\_motor.c

This example can be used to sense the speed and direction of motor using eQEP in quadrature encoder mode. ePWM1A is configured to simulate motor encoder signals with frequency of 5 kHz on both A and B pins with 90 degree phase shift (so as to run this example without motor). EQEP unit timeout is set which will generate an interrupt every *UNIT\_PERIOD* microseconds and speed calculation occurs continuously based on the direction of motor

The configuration for this example is as follows

- PWM frequency is specified as 5000 Hz
- *UNIT\_PERIOD* is specified as 10000  $\mu$ s
- Simulated quadrature signal frequency is 20000 Hz ( $4 * 5000$ )
- Encoder holes assumed as 1000
- Thus Simulated motor speed is 300 rpm ( $5000 * (60 / 1000)$ )

*freq* : Simulated quadrature signal frequency measured by counting the external input pulses for *UNIT\_PERIOD* (unit timer set to 10 ms).

*speed* : Measure motor speed in rpm

*dir* : Indicates clockwise (1) or anticlockwise (-1)

#### External Connections (if motor encoder signals are simulated by ePWM)

- Connect GPIO25/eQEP1A to GPIO0/ePWM1A
- Connect GPIO29/eQEP1B to GPIO1/ePWM1B with motor
- Comment in "MOTOR" includes
- Connect GPIO25/eQEP1A to encoder A output
- Connect GPIO29/eQEP1B to encoder B output

### Watch Variables

- *freq* : Simulated motor frequency measurement is obtained by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms).
- *speed* : Measure motor speed in rpm
- *dir* : Indicates clockwise (1) or anticlockwise (-1)
- *pass* : If measured quadrature frequency matches with input quadrature frequency (4 \* PWM frequency) then pass = 1, else fail = 1 (\*\* only when "MOTOR" is commented out)

## 23.13 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

### 23.13.1 EQEP Base Address Table

**Table 23-4. EQEP Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| EQep1Regs      | EQEP_REGS | EQEP1_BASE     | 0x0000_5100  | YES  | YES | YES | YES | YES                |

Complex bit access types are encoded to fit into small table cells. Table 23-6 shows the codes that are used for access types in this section.

**Table 23-6. EQEP\_REGS Access Type Codes**

| Access Type            | Code    | Description        |
|------------------------|---------|--------------------|
| Read Type              |         |                    |
| R                      | R       | Read               |
| R-0                    | R<br>-0 | Read<br>Returns 0s |
| Write Type             |         |                    |
| W                      | W       | Write              |
| W1S                    | W<br>1S | Write<br>1 to set  |
| Reset or Default Value |         |                    |

**Table 23-6. EQEP\_REGS Access Type Codes  
(continued)**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 23.13.2.1 QPOSCNT Register (Offset = 0h) [Reset = 0h]

QPOSCNT is shown in [Figure 23-25](#) and described in [Table 23-7](#).

Return to the [Summary Table](#).

Position Counter

**Figure 23-25. QPOSCNT Register**

|         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSCNT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-7. QPOSCNT Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description   |
|------|---------|------|-------|---|
| 31-0 | QPOSCNT | R/W  | 0h    | Position Counter<br>This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point. This Register acts as a Read ONLY register while counter is counting up/down.<br>Note: It is recommended to only write to the position counter register (QPOSCNT) during initialization, i.e. when the eQEP position counter is disabled (QPEN bit of QEPCTL is zero). Once the position counter is enabled (QPEN bit is one), writing to the eQEP position counter register (QPOSCNT) may cause unexpected results.<br>Reset type: SYSRSn |

### 23.13.2.2 QPOSINIT Register (Offset = 2h) [Reset = 0h]

QPOSINIT is shown in [Figure 23-26](#) and described in [Table 23-8](#).

Return to the [Summary Table](#).

Position Counter Init

**Figure 23-26. QPOSINIT Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSINIT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-8. QPOSINIT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 31-0 | QPOSINIT | R/W  | 0h    | Position Counter Init<br>This register contains the position value that is used to initialize the position counter based on external strobe or index event. The position counter can be initialized through software. Writes to this register should always be full 32-bit writes.<br>Reset type: SYSRSn |

### 23.13.2.3 QPOSMAX Register (Offset = 4h) [Reset = 0h]

QPOSMAX is shown in [Figure 23-27](#) and described in [Table 23-9](#).

Return to the [Summary Table](#).

Maximum Position Count

**Figure 23-27. QPOSMAX Register**

|         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSMAX |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-9. QPOSMAX Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description   |
|------|---------|------|-------|---|
| 31-0 | QPOSMAX | R/W  | 0h    | Maximum Position Count<br>This register contains the maximum position counter value. Writes to this register should always be full 32-bit writes.<br>Reset type: SYSRSn |

### 23.13.2.4 QPOSCMP Register (Offset = 6h) [Reset = 0h]

QPOSCMP is shown in [Figure 23-28](#) and described in [Table 23-10](#).

Return to the [Summary Table](#).

Position Compare

**Figure 23-28. QPOSCMP Register**

|         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSCMP |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-10. QPOSCMP Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description  |
|------|---------|------|-------|--|
| 31-0 | QPOSCMP | R/W  | 0h    | Position Compare<br>The position-compare value in this register is compared with the position counter (QPOSCNT) to generate sync output and/or interrupt on compare match.<br>Reset type: SYSRSn |

### 23.13.2.5 QPOSILAT Register (Offset = 8h) [Reset = 0h]

QPOSILAT is shown in [Figure 23-29](#) and described in [Table 23-11](#).

Return to the [Summary Table](#).

Index Position Latch

**Figure 23-29. QPOSILAT Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSILAT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-11. QPOSILAT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 31-0 | QPOSILAT | R    | 0h    | Index Position Latch<br>The position-counter value is latched into this register on an index event as defined by the QEPCTL[IEL] bits.<br>Reset type: SYSRSn |

### 23.13.2.6 QPOSSLAT Register (Offset = Ah) [Reset = 0h]

QPOSSLAT is shown in [Figure 23-30](#) and described in [Table 23-12](#).

Return to the [Summary Table](#).

Strobe Position Latch

**Figure 23-30. QPOSSLAT Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSSLAT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-12. QPOSSLAT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description   |
|------|----------|------|-------|---|
| 31-0 | QPOSSLAT | R    | 0h    | Strobe Position Latch<br>The position-counter value is latched into this register on a strobe event as defined by the QEPCTL[SEL] bits.<br>Reset type: SYSRSn |

### 23.13.2.7 QPOSLAT Register (Offset = Ch) [Reset = 0h]

QPOSLAT is shown in [Figure 23-31](#) and described in [Table 23-13](#).

Return to the [Summary Table](#).

Position Latch

**Figure 23-31. QPOSLAT Register**

|         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QPOSLAT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-13. QPOSLAT Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description  |
|------|---------|------|-------|--|
| 31-0 | QPOSLAT | R    | 0h    | Position Latch<br>The position-counter value is latched into this register on a unit time out event.<br>Reset type: SYSRSn |

### 23.13.2.8 QUTMR Register (Offset = Eh) [Reset = 0h]

QUTMR is shown in [Figure 23-32](#) and described in [Table 23-14](#).

Return to the [Summary Table](#).

QEP Unit Timer

**Figure 23-32. QUTMR Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QUTMR  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-14. QUTMR Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 31-0 | QUTMR | R/W  | 0h    | QEP Unit Timer<br>This register acts as time base for unit time event generation. When this timer value matches the unit time period value a unit time event is generated.<br>Reset type: SYSRSn |

### 23.13.2.9 QUPRD Register (Offset = 10h) [Reset = 0h]

QUPRD is shown in [Figure 23-33](#) and described in [Table 23-15](#).

Return to the [Summary Table](#).

QEP Unit Period

**Figure 23-33. QUPRD Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| QUPRD  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 23-15. QUPRD Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 31-0 | QUPRD | R/W  | 0h    | QEP Unit Period<br>This register contains the period count for the unit timer to generate periodic unit time events. These events latch the eQEP position information at periodic intervals and optionally generate an interrupt. Writes to this register should always be full 32-bit writes.<br>Reset type: SYSRSn |

### 23.13.2.10 QWDTMR Register (Offset = 12h) [Reset = 0h]

QWDTMR is shown in [Figure 23-34](#) and described in [Table 23-16](#).

Return to the [Summary Table](#).

QEP Watchdog Timer

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion via devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the master or slave operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

## 24.1 Introduction

### 24.1.1 Features

The SPI module features include:

- SPISOMI: SPI slave-output/master-input pin
- SPISIMO: SPI slave-input/master-output pin
- $\overline{\text{SPISTE}}$ : SPI slave transmit-enable pin
- SPICLK: SPI serial-clock pin

---

#### Note

All four pins can be used as GPIO if the SPI module is not used.

---

- Two operational modes: Master and Slave
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device-specific data manual for more details.
- Data word length: one to sixteen data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- 16-level transmit/receive FIFO
- DMA support
- High-speed mode
- Delayed transmit control
- 3-wire SPI mode
- $\overline{\text{SPISTE}}$  inversion for digital audio interface receive mode on devices with two SPI modules

### 24.1.2 Block Diagram

Figure 24-1 shows the SPI CPU interfaces.

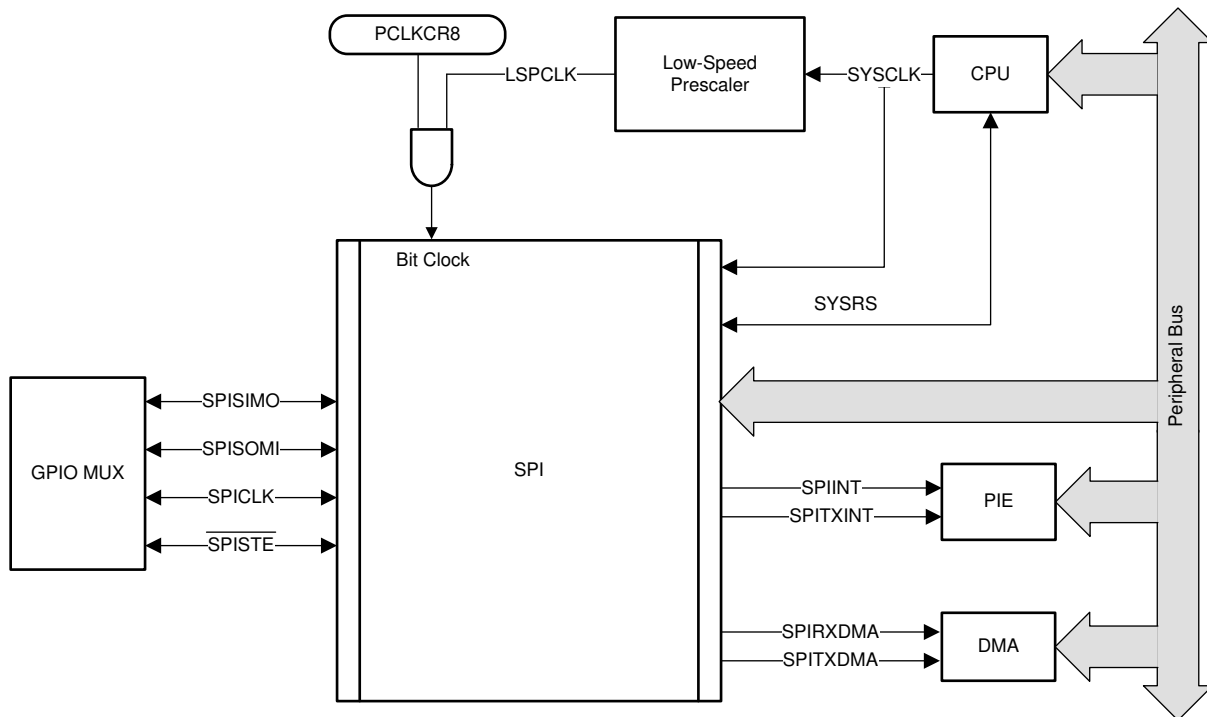

Figure 24-1. SPI CPU Interface

## 24.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

### 24.2.1 SPI Module Signals

Table 24-1 classifies and provides a summary of the SPI module signals.

Table 24-1. SPI Module Signal Summary

| Signal Name                | Description  |
|----------------------------|--|
| <b>External Signals</b>    |  |
| SPICLK                     | SPI clock  |
| SPISIMO                    | SPI slave in, master out   |
| SPISOMI                    | SPI slave out, master in   |
| $\overline{\text{SPISTE}}$ | SPI slave transmit enable  |
| <b>Control</b>             |  |
| SPI Clock Rate             | LSPCLK   |
| <b>Interrupt Signals</b>   |  |
| SPIINT/SPIRXINT            | Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT)<br>Receive interrupt in FIFO mode |
| SPITXINT                   | Transmit interrupt in FIFO mode  |
| <b>DMA Triggers</b>        |  |
| SPITXDMA                   | Transmit request to DMA  |
| SPIRXDMA                   | Receive request to DMA   |

## Special Considerations

The  $\overline{\text{SPISTE}}$  signal provides the ability to gate any spurious clock and data pulses when the SPI is in slave mode. A HIGH logic signal on  $\overline{\text{SPISTE}}$  will not allow the slave to receive data. This prevents the SPI slave from losing synchronization with the master. It is this reason that TI does not recommend that the  $\overline{\text{SPISTE}}$  always be tied to the active state.

If the SPI slave does ever lose synchronization with the master, toggling SPISWRESET resets the internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI interprets the next clock transition as the first bit of a new transmission. The register bit fields that are reset by SPISWRESET are found in [Section 24.6](#).

## Configuring a GPIO to Emulate $\overline{\text{SPISTE}}$

In many systems, a SPI master may be connected to multiple SPI slaves using multiple instances of  $\overline{\text{SPISTE}}$ . Though this SPI module does not natively support multiple  $\overline{\text{SPISTE}}$  signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the master. Rather than using the GPIO Mux to select  $\overline{\text{SPISTE}}$ , the application would configure pins to be GPIO outputs, one GPIO per SPI slave. Before transmitting any data, the application would drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select would be driven to the inactive state. This process can be repeated for many slaves which share the SPICLK, SPISIMO, and SPISOMI lines.

### 24.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

#### 24.2.2.1 GPIOs Required for High-Speed Mode

The high-speed mode of the SPI is available on all GPIO mux options. To enable the high-speed enhancements, set SPICCR.HS\_MODE to 1. Ensure that the capacitive loading on the pin does not exceed the value stated in the device Data Manual.

When not operating in high-speed mode, or if the capacitive loading on the pins exceed the value stated in the device Data Manual, SPICCR.HS\_MODE should be set to 0.

### 24.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module.

The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

#### SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT\_FLAG), or there is overrun in the receiver (OVERRUN\_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT\_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT\_FLAG will generate an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN\_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN\_FLAG will generate an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN\_FLAG was previously cleared.

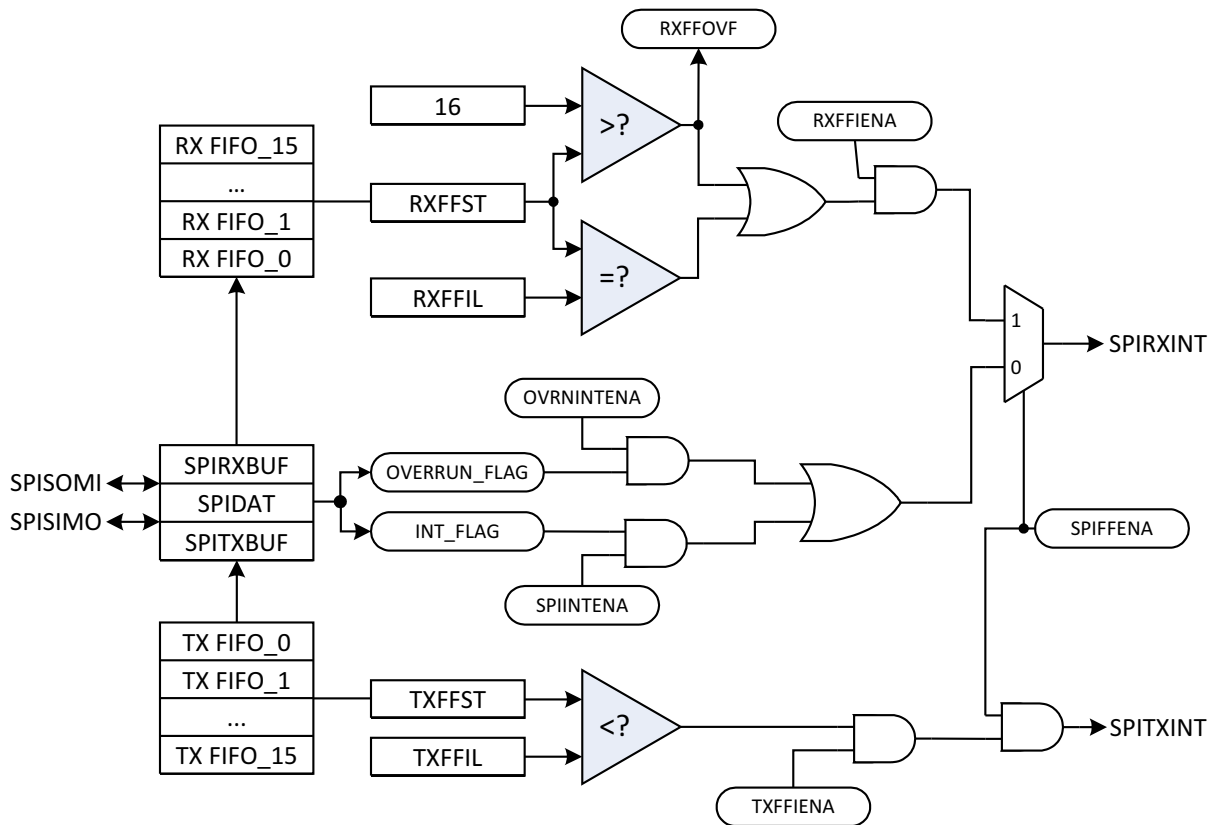

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) will be set. SPIRXINT will be triggered in the PIE block if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

**SPITXINT**

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) will be set. SPITXINT will be triggered in the PIE block if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 24-2 and Table 24-2 show how these control bits influence the SPI interrupt generation.

**Figure 24-2. SPI Interrupt Flags and Enable Logic Generation**

**Table 24-2. SPI Interrupt Flag Modes**

| FIFO Options     | SPI Interrupt Source | Interrupt Flags | Interrupt Enables | FIFO Enable (SPIFFENA) | Interrupt Line <sup>(1)</sup> |
|------------------|----------------------|-----------------|-------------------|------------------------|-------------------------------|
| SPI without FIFO | Receive overrun      | RXOVRN          | OVRNINTENA        | 0                      | SPIRXINT                      |
|                  | Data receive         | SPIINT          | SPIINTENA         | 0                      | SPIRXINT                      |
|                  | Transmit empty       | SPIINT          | SPIINTENA         | 0                      | SPIRXINT                      |
| SPI FIFO mode    | FIFO receive         | RXFFIL          | RXFFIENA          | 1                      | SPIRXINT                      |
|                  | Transmit empty       | TXFFIL          | TXFFIENA          | 1                      | SPITXINT                      |

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in C28x devices.

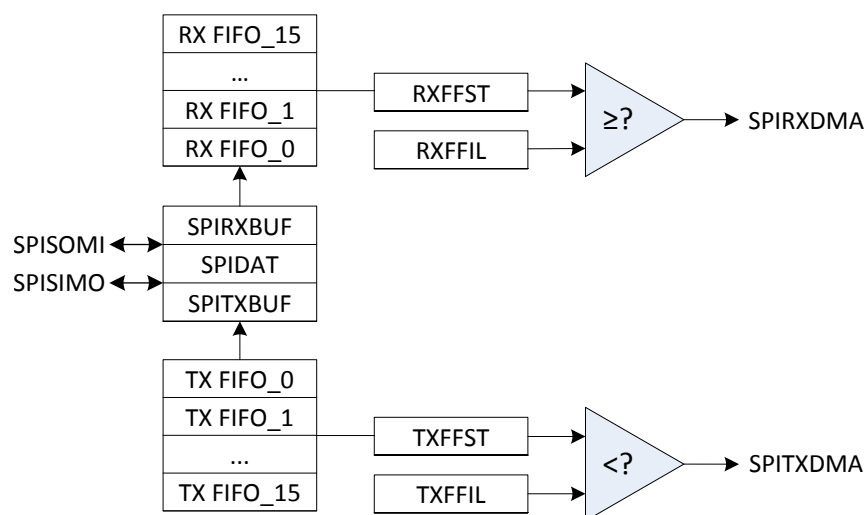

### 24.2.4 DMA Support

Both the CPU and DMA have access to the SPI data registers via the internal peripheral bus. This access is limited to 16-bit register read/writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled in order for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers, refer to [Section 24.3.8](#).

[Figure 24-3](#) is a block diagram showing the DMA trigger generation from the SPI module.

**Figure 24-3. SPI DMA Trigger Diagram**

## 24.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

### 24.3.1 Introduction to Operation

Figure 24-4 shows typical connections of the SPI for communications between two controllers: a master and a slave.

The master transfers data by sending the SPICLK signal. For both the slave and the master, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK\_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Master sends data; slave sends dummy data.
- Master sends data; slave sends data.
- Master sends dummy data; slave sends data.

The master can initiate data transfer at any time because it controls the SPICLK signal. The software, however, determines how the master detects when the slave is ready to broadcast data.

The SPI can operate in master or slave mode. The MASTER\_SLAVE bit selects the operating mode and the source of the SPICLK signal.

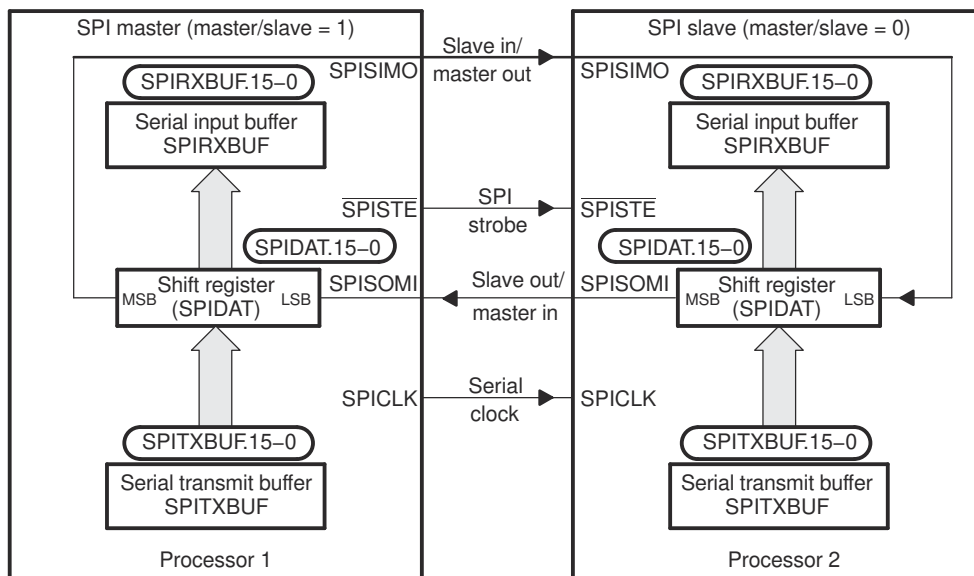

Figure 24-4. SPI Master/Slave Connection

### 24.3.2 Master Mode

In master mode (MASTER\_SLAVE = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPISIMO pin and latched from the SPISOMI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPISIMO pin, MSB (most significant bit) first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB (least significant bit)

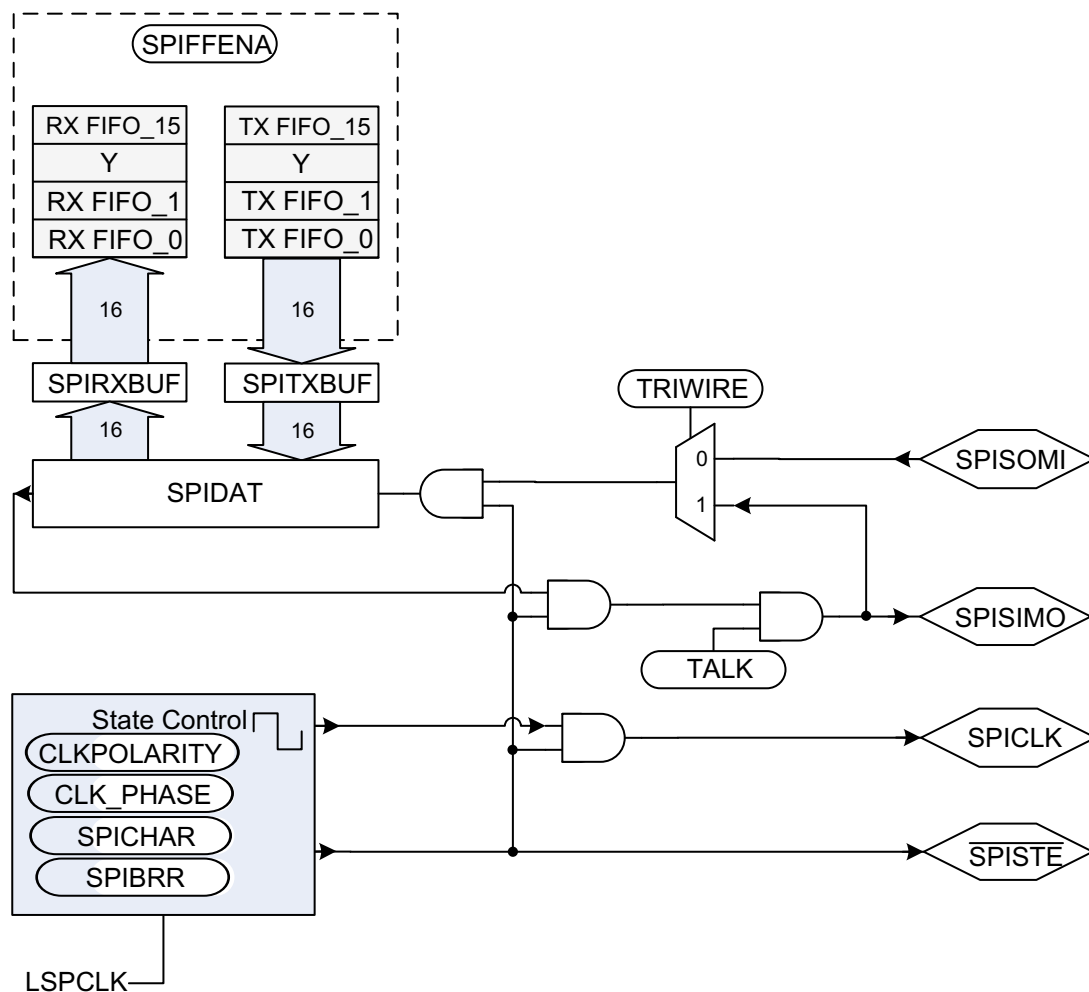

of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT\_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the Transmit Buffer Full Flag (BUFFULL\_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the  $\overline{\text{SPISTE}}$  pin serves as a chip-enable pin for a slave SPI device. This pin is driven low by the master before transmitting data to the slave and is taken high after the transmission is complete.

Figure 24-5 is a block diagram of the SPI in master mode. It shows the basic control blocks available in SPI master mode.

**Figure 24-5. SPI Module Master Configuration**

### 24.3.3 Slave Mode

In slave mode ( $\text{MASTER\_SLAVE} = 0$ ), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock. The SPICLK input frequency should be no greater than the LSPCLK frequency divided by 4.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network master. Data written to the SPITXBUF register will be transferred to the SPIDAT register when all bits of the character to be transmitted have been shifted out of SPIDAT. If no character is currently being transmitted when SPITXBUF is written to, the data will be transferred immediately to SPIDAT. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts the data on the SPISIMO pin into SPIDAT. If data is to be transmitted by the slave simultaneously, and SPITXBUF has not been previously loaded, the data must be written to SPITXBUF or SPIDAT before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPISOMI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPISOMI is forced into the high-impedance state. This ensures that the SPI is still able to receive incoming data correctly. This TALK bit allows many slave devices to be tied together on the network, but only one slave at a time is allowed to drive the SPISOMI line.

The SPIS $\overline{T}$ E pin operates as the slave-select pin. An active-low signal on the SPIS $\overline{T}$ E pin allows the slave SPI to transfer data to the serial data line; an inactive-high signal causes the slave SPI serial shift register to stop and its serial output pin to be put into the high-impedance state. This allows many slave devices to be tied together on the network, although only one slave device is selected at a time.

Figure 24-6 is a block diagram of the SPI in slave mode. It shows the basic control blocks available in SPI slave mode.

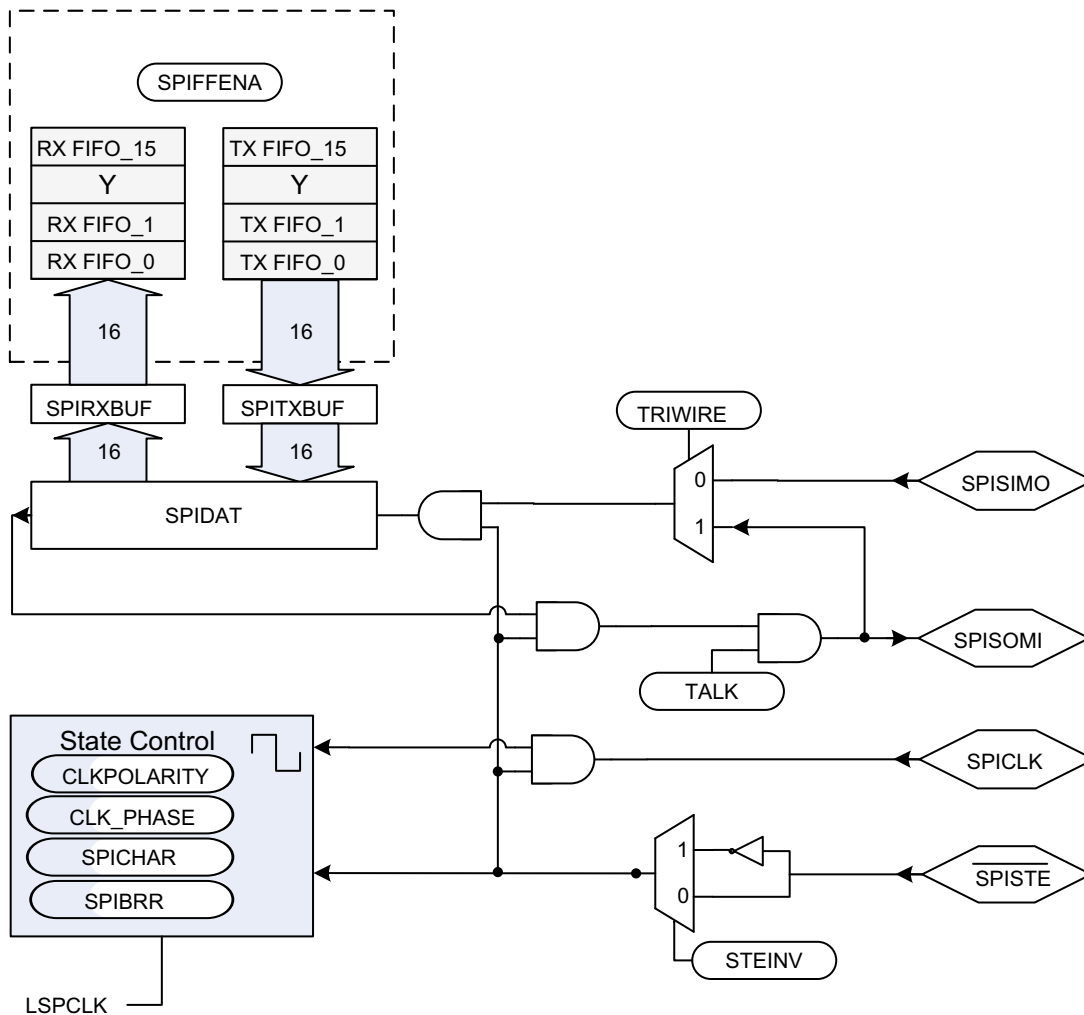

Figure 24-6. SPI Module Slave Configuration

### 24.3.4 Data Format

The four-bit SPICHR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmission(s) that have been shifted to the left (shown in [Example 24-1](#)).

#### Example 24-1. Transmission of Bit from SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in bits SPICHR)
2. The current value of SPIDAT = 737Bh

| SPIDAT (before transmission)  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                  |          |
|-------------------------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|------------------|----------|
|                               | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1                |          |
| SPIDAT (after transmission)   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                  |          |
| (TXed) 0 ←                    | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1 | x <sup>(1)</sup> | ← (RXed) |
| SPIRXBUF (after transmission) |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                  |          |
|                               | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1 | x <sup>(1)</sup> |          |

(1) x = 1 if SPISOMI data is high; x = 0 if SPISOMI data is low; master mode is assumed.

### 24.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in slave or master mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the slave mode, the SPI clock is received on the SPICLK pin from the external source, and can be no greater than the LSPCLK frequency divided by 4.
- In the master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin, and can be no greater than the LSPCLK frequency divided by 4.

---

#### Note

The baud rate should be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device Data Manual for the maximum GPIO toggle frequency

---

[Example 24-2](#) shows how to determine the SPI baud rates.

#### Example 24-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)} \quad (23)$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4} \quad (24)$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the master SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (which is device-specific) and the baud rate at which you will be operating.

[Example 24-3](#) shows how to calculate the baud rate of the SPI module in standard SPI mode (HS\_MODE=0).

#### Example 24-3. Baud Rate Calculation in Non-High Speed Mode (HS\_MODE=0)

$$\begin{aligned} \text{SPI Baud Rate} &= \frac{\text{LSPCLK}}{\text{SPIBRR} + 1} \quad \text{LSPCLK} = 50 \text{ MHz} \\ &= \frac{50 \times 10^6}{3 + 1} \\ &= 12.5 \text{ Mbps} \end{aligned} \quad (25)$$

### 24.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK\_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK\_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are as follows:

- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in [Table 24-3](#). Examples of these four clocking schemes relative to transmitted and received data are shown in [Figure 24-7](#).

**Table 24-3. SPI Clocking Scheme Selection Guide**

| SPICLK Scheme              | CLKPOLARITY | CLK_PHASE <sup>(1)</sup> |
|----------------------------|-------------|--------------------------|
| Rising edge without delay  | 0           | 0                        |
| Rising edge with delay     | 0           | 1                        |
| Falling edge without delay | 1           | 0                        |
| Falling edge with delay    | 1           | 1                        |

(1) The description of CLK\_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.

**Note:** Previous data bit

**Figure 24-7. SPICLK Signal Options**

SPICLK symmetry is retained only when the result of  $(SPIBRR+1)$  is an even value. When  $(SPIBRR + 1)$  is an odd value and  $SPIBRR$  is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when  $CLKPOLARITY$  bit is clear (0). When  $CLKPOLARITY$  bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in [Figure 24-8](#).

**Figure 24-8. SPI: SPICLK-LSPCLK Characteristic When  $(BRR + 1)$  is Odd,  $BRR > 3$ , and  $CLKPOLARITY = 1$**

### 24.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode will work with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of its operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT will be active.
5. **Interrupts.** FIFO mode has two interrupts one for the transmit FIFO, SPITXINT and one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI will be disabled and this interrupt will service as SPI receive FIFO interrupt. For more information, refer to [Section 24.2.3](#).
6. **Buffers.** Transmit and receive buffers are each supplemented with a 16 word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer will be loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7–0) FFTXDLY7–FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) will reset the FIFO pointers to zero when these bits are set to 1. The FIFOs will resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits will be 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

### 24.3.8 SPI DMA Transfers

#### 24.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA\_BURST\_SIZE) should be no greater than 16 – TXFFIL in order to prevent the DMA from writing to an already full FIFO. This will lead to data loss and is not recommended.

For complete data transmission, follow these steps:

1. Calculate the total number of words to be transmitted. [NUM\_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the number of DMA transfers. [DMA\_TRANSFER\_SIZE]
4. Calculate the size of the DMA Burst. [DMA\_BURST\_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM\_WORDS: 128

TXFFIL: 8

DMA\_TRANSFER\_SIZE:  $(\text{NUM\_WORDS} / \text{TXFFIL}) - 1 = (128/8) - 1 = 15$  (16 transfers)

DMA\_BURST\_SIZE:  $(16 - \text{TXFFIL}) - 1 = (16 - 8) - 1 = 7$  (8 words per burst)

---

#### Note

Avoid setting TXFFIL to 0h or 10h to ensure proper DMA configuration.

---

#### 24.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST\_SIZE) should be no greater than RXFFIL in order to prevent the DMA from reading from an empty FIFO. To ensure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size should equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, follow these steps:

1. Calculate the number of words to be received. [NUM\_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA\_TRANSFER\_SIZE]
4. Calculate the size of the DMA Burst. [DMA\_BURST\_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM\_WORDS = 200

RXFFIL: 4

DMA\_TRANSFER\_SIZE:  $(\text{NUM\_WORDS} / \text{RXFFIL}) - 1 = (200/4) - 1 = 49$  (50 transfers)

DMA\_BURST\_SIZE = RXFFIL-1 = 3 (4 words per burst)

---

#### Note

Avoid setting RXFFIL to 0h to ensure proper DMA configuration.

---

### 24.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer the device Data Manual.

In order to achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single master to single slave configuration is supported.
- Loading on the pins must not exceed the value stated in the device Data Manual.

When configuring the GPIOs to support High-Speed mode, refer to [Section 24.2.2.1](#) for more information.

### 24.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In master mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPISIMOX becomes the bi-directional SPIMOMIx (SPI master out, master in) pin, and SPISOMIx is no longer used by the SPI. In slave mode, if the TRIWIRE bit is set, SPISOMIx becomes the bi-directional SPISISOX (SPI slave in, slave out) pin, and SPISIMOX is no longer used by the SPI.

[Table 24-4](#) indicates the pin function differences between 3-wire and 4-wire SPI mode for a master and slave SPI.

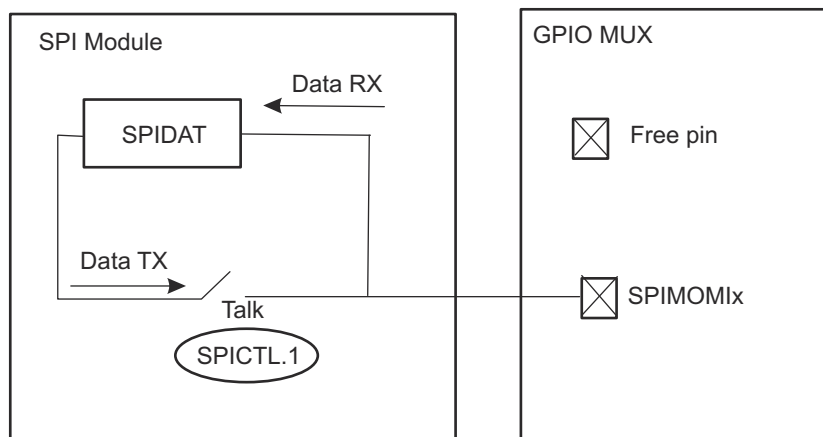

**Table 24-4. 4-wire vs. 3-wire SPI Pin Functions**

| 4-wire SPI | 3-wire SPI (Master) | 3-wire SPI (Slave) |
|------------|---------------------|--------------------|
| SPICLKx    | SPICLKx             | SPICLKx            |
| SPISTEx    | SPISTEx             | SPISTEx            |
| SPISIMOX   | SPIMOMIx            | Free               |
| SPISOMIx   | Free                | SPISISOX           |

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received by itself. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In master mode, in order to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPIMOMI pin) before reading from the data register.

[Figure 24-9](#) and [Figure 24-10](#) illustrate 3-wire master and slave mode.

**Figure 24-9. SPI 3-wire Master Mode**

**Figure 24-10. SPI 3-wire Slave Mode**

Table 24-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

**Table 24-5. 3-Wire SPI Pin Configuration**

| Pin Mode           | SPIPRI[TRIWIRE] | SPICTL[TALK] | SPISIMO             | SPISOMI             |
|--------------------|-----------------|--------------|---------------------|---------------------|
| <b>Master Mode</b> |                 |              |                     |                     |
| 4-wire             | 0               | X            | TX                  | RX                  |
| 3-pin mode         | 1               | 0            | RX                  | Disconnect from SPI |
|                    |                 | 1            | TX/RX               |                     |
| <b>Slave Mode</b>  |                 |              |                     |                     |
| 4-wire             | 0               | X            | RX                  | TX                  |
| 3-pin mode         | 1               | 0            | Disconnect from SPI | RX                  |
|                    |                 | 1            |                     | TX/RX               |

## 24.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

### 24.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a slave module (MASTER\_SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

### 24.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration may be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
  - Select either master or slave mode (MASTER\_SLAVE).
  - Choose SPICLK polarity and phase (CLKPOLARITY and CLK\_PHASE).
  - Set the desired baud rate (SPIBRR).
  - Enable high speed mode if desired (HS\_MODE).
  - Set the SPI character length (SPICHR).
  - Clear the SPI Flags (OVERRUN\_FLAG, INT\_FLAG).
  - Enable  $\overline{\text{SPISTE}}$  inversion (STEINV) if needed.
  - Enable 3-wire mode (TRIWIRE) if needed.
  - If using FIFO enhancements:
    - Enable the FIFO enhancements (SPIFFENA).
    - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
    - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
    - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
  - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
  - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

---

#### Note

Do not change the SPI configuration when communication is in progress.

---

### 24.4.3 Configuring the SPI for High-Speed Mode

In order to achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100 MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO\_CTRL\_REGS.

During the SPI configuration procedure:

Set HS\_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3.  $SPICLK = LSPCLK / (SPIBRR + 1) = 25\text{-MHz}$

```
SpiaRegs.SPIBRR = 0x3;
```

There are no other differences in the configuration from normal SPI operation. Sending and receiving data, DMA operation, and interrupts will operate without change.

### 24.4.4 Data Transfer Example

The timing diagram shown in Figure 24-11 illustrates an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 24-8) shares similar characterizations with Figure 24-11 except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 24-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.

- A. Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.
- B. Master sets the slave  $\overline{\text{SPISTE}}$  signal low (active).
- C. Master writes 058h to SPIDAT, which starts the transmission procedure.
- D. First byte is finished and sets the interrupt flags.
- E. Slave reads 0Bh from its SPIRXBUF (right-justified).
- F. Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.
- G. Master writes 06Ch to SPIDAT, which starts the transmission procedure.
- H. Master reads 01Ah from the SPIRXBUF (right-justified).
- I. Second byte is finished and sets the interrupt flags.
- J. Master reads 89h and the slave reads 8Dh from their respective SPIRXBUF. After the user's software masks off the unused bits, the master receives 09h and the slave receives 0Dh.
- K. Master clears the slave  $\overline{\text{SPISTE}}$  signal high (inactive).

Figure 24-11. Five Bits per Character

### 24.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire master and slave mode. The following examples demonstrate these considerations.

In 3-wire master mode, SPICLKx, SPISTEx, and SPISIMOX pins must be configured as SPI pins (SPISOMIx pin can be configured as non-SPI pin). When the master transmits, it receives the data it transmits (because SPISIMOX and SPISOMIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

#### Example 24-4. 3-Wire Master Mode Transmit

```

Uint16 data;
Uint16 dummy;
    SpiaRegs.SPICTL.bit.TALK = 1;           // Enable Transmit path
    SpiaRegs.SPITXBUF = data; // Master transmits data
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    dummy = SpiaRegs.SPIRXBUF;             // Clears junk data from itself
                                           // bc it rx'd same data tx'd

```

To receive data in 3-wire master mode, the master must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data in order to initiate the transfer from the slave. Because the TALK bit is 0, unlike in transmit mode, the master dummy data does not appear on the SPISIMOX pin, and the master does not receive its own dummy data. Instead, the data from the slave is received by the master.

#### Example 24-5. 3-Wire Master Mode Receive

```

Uint16 rdata;
Uint16 dummy;
    SpiaRegs.SPICTL.bit.TALK = 0;           // Disable Transmit path
    SpiaRegs.SPITXBUF = dummy;             // Send dummy to start tx
    // NOTE: because TALK = 0, data does not tx onto SPISIMOX pin
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
    rdata = SpiaRegs.SPIRXBUF;             // Master reads data

```

In 3-wire slave mode, SPICLKx, SPISTEx, and SPISOMIx pins must be configured as SPI pins (SPISIMOX pin can be configured as non-SPI pin). Like in master mode, when transmitting, the slave receives the data it transmits and must clear this junk data from its receive buffer.

#### Example 24-6. 3-Wire Slave Mode Transmit

```

Uint16 data;
Uint16 dummy;
    SpiaRegs.SPICTL.bit.TALK = 1;           // Enable Transmit path
    SpiaRegs.SPITXBUF = data;             // Slave transmits data
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
    dummy = SpiaRegs.SPIRXBUF;             // Clears junk data from itself

```

As in 3-wire master mode, the TALK bit must be cleared to 0. Otherwise, the slave receives data normally.

**Example 24-7. 3-Wire Slave Mode Receive**

```

Uint16 rdata;
SpiaRegs.SPICTL.bit.TALK = 0;           // Disable Transmit path
while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
rdata = SpiaRegs.SPIRXBUF;              // Slave reads data
    
```

**24.4.6 SPI STEINV Bit in Digital Audio Transfers**

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in slave mode. The SPI module that receives a normal active-low  $\overline{\text{SPISTE}}$  signal stores right-channel data, and the SPI module that receives an inverted active-high  $\overline{\text{SPISTE}}$  signal stores left-channel data from the master. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in [Figure 24-12](#).

**Note**

This configuration is only applicable to slave mode (MASTER\_SLAVE = 0). When the SPI is configured as master (MASTER\_SLAVE = 1), the STEINV bit will have no effect on the  $\overline{\text{SPISTE}}$  pin.

**Figure 24-12. SPI Digital Audio Receiver Configuration Using Two SPIs**

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See your device-specific data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK\_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in [Figure 24-13](#).

**Figure 24-13. Standard Right-Justified Digital Audio Data Format**

## 24.5 Software

### 24.5.1 SPI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/spi

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 24.5.1.1 SPI Digital Loopback

FILE: spi\_ex1\_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configured through the sysconfig file.

The sent data looks like this:

```
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000
```

This pattern is repeated forever.

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data

#### 24.5.1.2 SPI Digital Loopback with FIFO Interrupts

FILE: spi\_ex2\_loopback\_fifo\_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
```

....

```
FFFE FFFF
FFFF 0000
```

etc..

This pattern is repeated forever.

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

### 24.5.1.3 SPI Digital External Loopback without FIFO Interrupts

FILE: spi\_ex3\_external\_loopback.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a slave and SPI B is configured as master. This example demonstrates full duplex communication where both master and slave transmits and receives data simultaneously.

#### External Connections

- GPIO40 and GPIO8 - SPISIMO
- GPIO41 and GPIO10 - SPISOMI
- GPIO22 and GPIO9 - SPICLK
- GPIO23 and GPIO11 - SPISTE

#### Watch Variables

- *TxData\_SPIA* - Data send from SPIA (slave)
- *TxData\_SPIB* - Data send from SPIB (master)
- *RxData\_SPIA* - Data received by SPIA (slave)
- *RxData\_SPIB* - Data received by SPIB (master)

### 24.5.1.4 SPI Digital External Loopback with FIFO Interrupts

FILE: spi\_ex4\_external\_loopback\_fifo\_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and their interrupts are used. SPIA is configured as a slave and receives data from SPI B which is configured as a master.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
```

....

```
FFFF FFFF
FFFF 0000
```

etc..

This pattern is repeated forever.

#### External Connections

- GPIO40 and GPIO8 - SPISIMO
- GPIO41 and GPIO10 - SPISOMI
- GPIO22 and GPIO9 - SPICLK
- GPIO23 and GPIO11 - SPISTE

#### Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

### 24.5.1.5 SPI Digital Loopback with DMA

FILE: spi\_ex5\_loopback\_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable `sData` into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable `rData`.

When all data has been placed into `rData`, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

#### *External Connections*

- None

#### *Watch Variables*

- `sData` - Data to send
- `rData` - Received data

### 24.5.1.6 SPI EEPROM

FILE: spi\_ex6\_eeprom.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256.

#### External Connections

- Connect external SPI EEPROM
- Connect GPIO08 (SIMO) to external EEPROM SI pin
- Connect GPIO10 (SOMI) to external EEPROM SO pin
- Connect GPIO09 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

#### Watch Variables

- writeBuffer - Data that is written to external EEPROM
- readBuffer - Data that is read back from EEPROM
- error - Error count

### 24.5.1.7 SPI DMA EEPROM

FILE: spi\_ex7\_eeprom\_dma.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI using DMA and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256.

#### External Connections

- Connect external SPI EEPROM
- Connect GPIO08 (SIMO) to external EEPROM SI pin
- Connect GPIO10 (SOMI) to external EEPROM SO pin
- Connect GPIO09 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

#### Watch Variables

- writeBuffer - Data that is written to external EEPROM
- SPI\_DMA\_Handle.RXdata - Data that is read back from EEPROM when number of received bytes is less than 4
- SPI\_DMA\_Handle.pSPIRXDMA->pbuffer - Start address of received data from EEPROM
- error - Error count

## 24.6 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

### 24.6.1 SPI Base Address Table

**Table 24-6. SPI Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| SpiaRegs       | SPI_REGS  | SPIA_BASE      | 0x0000_6100  | YES  | YES | YES | YES | YES                |
| SpibRegs       | SPI_REGS  | SPIB_BASE      | 0x0000_6110  | YES  | YES | YES | YES | YES                |

## 24.6.2 SPI\_REGS Registers

Table 24-7 lists the memory-mapped registers for the SPI\_REGS registers. All register offset addresses not listed in Table 24-7 should be considered as reserved locations and the register contents should not be modified.

**Table 24-7. SPI\_REGS Registers**

| Offset | Acronym  | Register Name                      | Write Protection | Section            |
|--------|----------|------------------------------------|------------------|--------------------|
| 0h     | SPICCR   | SPI Configuration Control Register |                  | <a href="#">Go</a> |
| 1h     | SPICTL   | SPI Operation Control Register     |                  | <a href="#">Go</a> |
| 2h     | SPISTS   | SPI Status Register                |                  | <a href="#">Go</a> |
| 4h     | SPIBRR   | SPI Baud Rate Register             |                  | <a href="#">Go</a> |
| 6h     | SPIRXEMU | SPI Emulation Buffer Register      |                  | <a href="#">Go</a> |
| 7h     | SPIRXBUF | SPI Serial Input Buffer Register   |                  | <a href="#">Go</a> |
| 8h     | SPITXBUF | SPI Serial Output Buffer Register  |                  | <a href="#">Go</a> |
| 9h     | SPIDAT   | SPI Serial Data Register           |                  | <a href="#">Go</a> |
| Ah     | SPIFFTX  | SPI FIFO Transmit Register         |                  | <a href="#">Go</a> |
| Bh     | SPIFFRX  | SPI FIFO Receive Register          |                  | <a href="#">Go</a> |
| Ch     | SPIFFCT  | SPI FIFO Control Register          |                  | <a href="#">Go</a> |
| Fh     | SPIPRI   | SPI Priority Control Register      |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 24-8 shows the codes that are used for access types in this section.

**Table 24-8. SPI\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| RC                       | R<br>C  | Read<br>to Clear   |
| Write Type               |         |  |

| 7                | 6        | 5                | 4        | 3  | 2  | 1 | 0 |
| OVERRUN_FL<br>AG | INT_FLAG | BUFFULL_FL<br>AG | RESERVED |    |    |   |   |
| W1C-0h           | RC-0h    | R-0h             | R-0h     |    |    |   |   |

**Table 24-11. SPISTS Register Field Descriptions**

| Bit  | Field        | Type | Reset | Description   |
|------|--------------|------|-------|---|
| 15-8 | RESERVED     | R    | 0h    | Reserved  |
| 7    | OVERRUN_FLAG | W1C  | 0h    | <p><b>SPI Receiver Overrun Flag</b></p> <p>This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways:</p> <ul style="list-style-type: none"> <li>- Writing a 1 to this bit</li> <li>- Writing a 0 to SPI SW RESET (SPICCR.7)</li> <li>- Resetting the system</li> </ul> <p>If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = A receive overrun condition has not occurred.</p> <p>1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application).</p> <p>Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.</p> |

**Table 24-11. SPISTS Register Field Descriptions (continued)**

| Bit | Field        | Type | Reset | Description   |
|-----|--------------|------|-------|---|
| 6   | INT_FLAG     | RC   | 0h    | <p>SPI Interrupt Flag</p> <p>SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways:</p> <ul style="list-style-type: none"> <li>- Reading SPIRXBUF</li> <li>- Writing a 0 to SPI SW RESET (SPICCR.7)</li> <li>- Resetting the system</li> </ul> <p>Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No full words have been received or transmitted.</p> <p>1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.</p> |
| 5   | BUFFULL_FLAG | R    | 0h    | <p>SPI Transmit Buffer Full Flag</p> <p>This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmit buffer is not full.</p> <p>1h (R/W) = Transmit buffer is full.</p>   |
| 4-0 | RESERVED     | R    | 0h    | Reserved  |

#### 24.6.2.4 SPIBRR Register (Offset = 4h) [Reset = 0h]

SPIBRR is shown in [Figure 24-17](#) and described in [Table 24-12](#).

Return to the [Summary Table](#).

SPIBRR contains the bits used for baud-rate selection.

**Figure 24-17. SPIBRR Register**

|          |              |    |    |    |    |   |   |

| RESERVED | SPI_BIT_RATE |    |    |    |    |   |   |
| R-0h     | R/W-0h       |    |    |    |    |   |   |

**Table 24-12. SPIBRR Register Field Descriptions**

| Bit  | Field        | Type | Reset | Description  |
|------|--------------|------|-------|--|
| 15-7 | RESERVED     | R    | 0h    | Reserved   |
| 6-0  | SPI_BIT_RATE | R/W  | 0h    | <p>SPI Baud Rate Control</p> <p>These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 master. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.)</p> <p>If the SPI is a network slave, the module receives a clock on the SPICLK pin from the network master. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the master should not exceed the slave SPI's LSPCLK signal divided by 4.</p> <p>In master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula:</p> <p>For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1)</p> <p>For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4</p> <p>Reset type: SYSRSn</p> <p>3h (R/W) = SPI Baud Rate = LSPCLK/4</p> <p>4h (R/W) = SPI Baud Rate = LSPCLK/5</p> <p>7Eh (R/W) = SPI Baud Rate = LSPCLK/127</p> <p>7Fh (R/W) = SPI Baud Rate = LSPCLK/128</p> |

### 24.6.2.5 SPIRXEMU Register (Offset = 6h) [Reset = 0h]

SPIRXEMU is shown in [Figure 24-18](#) and described in [Table 24-13](#).

Return to the [Summary Table](#).

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

**Figure 24-18. SPIRXEMU Register**

|       |    |    |    |    |    |   |   |
|-------|----|----|----|----|----|---|---|
| 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| ERXBn |    |    |    |    |    |   |   |

| 7     | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| ERXBn |    |    |    |    |    |   |   |
| R-0h  |    |    |    |    |    |   |   |

**Table 24-13. SPIRXEMU Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 15-0 | ERXBn | R    | 0h    | <p>Emulation Buffer Received Data</p> <p>SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set.</p> <p>This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately.</p> <p>It is recommended that you view SPIRXEMU in the normal emulator run mode.</p> <p>Reset type: SYSRSn</p> |

### 24.6.2.6 SPIRXBUF Register (Offset = 7h) [Reset = 0h]

SPIRXBUF is shown in [Figure 24-19](#) and described in [Table 24-14](#).

Return to the [Summary Table](#).

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

**Figure 24-19. SPIRXBUF Register**

|      |    |    |    |    |    |   |   |
|------|----|----|----|----|----|---|---|
| 15   | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| RXBn |    |    |    |    |    |   |   |

| RXBn |    |    |    |    |    |   |   |
| R-0h |    |    |    |    |    |   |   |

**Table 24-14. SPIRXBUF Register Field Descriptions**

| Bit  | Field | Type | Reset | Description   |
|------|-------|------|-------|---|
| 15-0 | RXBn  | R    | 0h    | Received Data<br>Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register.<br>Reset type: SYSRSn |

### 24.6.2.7 SPITXBUF Register (Offset = 8h) [Reset = 0h]

SPITXBUF is shown in [Figure 24-20](#) and described in [Table 24-15](#).

Return to the [Summary Table](#).

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set. In master mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

**Figure 24-20. SPITXBUF Register**

**Table 24-15. SPITXBUF Register Field Descriptions**

| Bit  | Field | Type | Reset | Description   |
|------|-------|------|-------|---|
| 15-0 | TXBn  | R/W  | 0h    | Transmit Data Buffer<br>This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified.<br>Reset type: SYSRSn |

### 24.6.2.8 SPIDAT Register (Offset = 9h) [Reset = 0h]

SPIDAT is shown in [Figure 24-21](#) and described in [Table 24-16](#).

Return to the [Summary Table](#).

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

**Figure 24-21. SPIDAT Register**

|        |    |    |    |    |    |   |   |
|--------|----|----|----|----|----|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| SDATn  |    |    |    |    |    |   |   |
| R/W-0h |    |    |    |    |    |   |   |

| SDATn  |    |    |    |    |    |   |   |
| R/W-0h |    |    |    |    |    |   |   |

**Table 24-16. SPIDAT Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 15-0 | SDATn | R/W  | 0h    | Serial Data Shift Register<br>- It provides data to be output on the serial output pin if the TALK bit (SPICTL.1) is set.<br>- When the SPI is operating as a master, a data transfer is initiated. When initiating a transfer, check the CLOCK POLARITY bit (SPICCR.6) described in Section 10.2.1.1 and the CLOCK PHASE bit (SPICTL.3) described in Section 10.2.1.2, for the requirements. In master mode, writing dummy data to SPIDAT initiates a receiver sequence. Since the data is not hardware-justified for characters shorter than sixteen bits, transmit data must be written in left-justified form, and received data read in right-justified form.<br>Reset type: SYSRSn |

### 24.6.2.9 SPIFFTX Register (Offset = Ah) [Reset = A000h]

SPIFFTX is shown in [Figure 24-22](#) and described in [Table 24-17](#).

Return to the [Summary Table](#).

SPIFFTX contains both control and status bits related to the output FIFO buffer. This includes FIFO reset control, FIFO interrupt level control, FIFO level status, as well as FIFO interrupt enable and clear bits.

**Figure 24-22. SPIFFTX Register**

### 24.6.2.10 SPIFFRX Register (Offset = Bh) [Reset = 201Fh]

SPIFFRX is shown in [Figure 24-23](#) and described in [Table 24-18](#).

Return to the [Summary Table](#).

SPIFFRX contains both control and status bits related to the input FIFO buffer. This includes FIFO reset control, FIFO interrupt level control, FIFO level status, as well as FIFO interrupt enable and clear bits.

**Figure 24-23. SPIFFRX Register**

**Table 24-18. SPIFFRX Register Field Descriptions (continued)**

| Bit | Field  | Type | Reset | Description  |
|-----|--------|------|-------|--|
| 4-0 | RXFFIL | R/W  | 1Fh   | <p>Receive FIFO Interrupt Level Bits</p> <p>Receive FIFO generates an interrupt when the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The default value of these bits after reset is 11111. This avoids frequent interrupts after reset, as the receive FIFO will be empty most of the time.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = A RX FIFO interrupt request is generated when there is 0 or more words in the RX buffer.</p> <p>1h (R/W) = A RX FIFO interrupt request is generated when there are 1 or more words in the RX buffer.</p> <p>2h (R/W) = A RX FIFO interrupt request is generated when there are 2 or more words in the RX buffer.</p> <p>10h (R/W) = A RX FIFO interrupt request is generated when there are 16 words in the RX buffer.</p> <p>1Fh (R/W) = Reserved.</p> |

### 24.6.2.11 SPIFFCT Register (Offset = Ch) [Reset = 0h]

SPIFFCT is shown in [Figure 24-24](#) and described in [Table 24-19](#).

Return to the [Summary Table](#).

SPIFFCT controls the FIFO transmit delay bits.

**Figure 24-24. SPIFFCT Register**

|          |    |    |    |    |    |   |   |

| 15-8 | RESERVED | R    | 0h    | Reserved  |
| 7-0  | TXDLY    | R/W  | 0h    | <p><b>FIFO Transmit Delay Bits</b></p> <p>These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word.</p> <p>1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word.</p> <p>2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word.</p> <p>FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.</p> |

### 24.6.2.12 SPIPRI Register (Offset = Fh) [Reset = 0h]

SPIPRI is shown in [Figure 24-25](#) and described in [Table 24-20](#).

Return to the [Summary Table](#).

SPIPRI controls auxillary functions for the SPI including emulation control, SPISTE inversion, and 3-wire control.

**Figure 24-25. SPIPRI Register**

|          |  |          |  |        |  |        |  |          |  |    |  |        |  |          |  |

**Table 24-20. SPIPRI Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 15-7 | RESERVED | R    | 0h    | Reserved   |
| 6    | RESERVED | R/W  | 0h    | Reserved   |
| 5    | SOFT     | R/W  | 0h    | <p>Emulation Soft Run</p> <p>This bit only has an effect when the FREE bit is 0.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point.</p> <p>1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used.</p> <p>Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty.</p> <p>In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.</p> |
| 4    | FREE     | R/W  | 0h    | <p>Emulation Free Run</p> <p>These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Emulation mode is selected by the SOFT bit</p> <p>1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.</p>  |
| 3-2  | RESERVED | R    | 0h    | Reserved   |
| 1    | STEINV   | R/W  | 0h    | <p>SPISTEn Inversion Bit</p> <p>On devices with 2 SPI modules, inverting the SPISTE signal on one of the modules allows the device to receive left and right- channel digital audio data.</p> <p>This bit is only applicable to slave mode. Writing to this bit while configured as master (MASTER_SLAVE = 1) has no effect</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SPISTEn is active low (normal)</p> <p>1h (R/W) = SPISTE is active high (inverted)</p>  |

**Table 24-20. SPIPRI Register Field Descriptions (continued)**

| Bit | Field   | Type | Reset | Description  |
|-----|---------|------|-------|--|
| 0   | TRIWIRE | R/W  | 0h    | SPI 3-wire Mode Enable<br>Reset type: SYSRSn<br>0h (R/W) = Normal 4-wire SPI mode.<br>1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In master mode, the SPISIMO pin becomes the SPIMOMI (master receive and transmit) pin and SPISOMI is free for non-SPI use. In slave mode, the SPISOMI pin becomes the SPISISO (slave receive and transmit) pin and SPISIMO is free for non-SPI use. |

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a 16-level deep FIFO for reducing servicing overhead, and each has its own separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

## 25.1 Introduction

The SCI interfaces are shown in [Figure 25-1](#).

**Figure 25-1. SCI CPU Interface**

### 25.1.1 SCI Related Collateral

#### Foundational Materials

- [C2000 Academy - Communications](#)
- [One Minute RS-485 Introduction \(Video\)](#)
- [RS-232, RS-422, RS-485: What Are the Differences? \(Video\)](#)

#### Getting Started Materials

- [\[FAQ\] My C2000 SCI is not Transmitting and/or Receiving data correctly, how do I fix this?](#)

### 25.1.2 Features

Features of the SCI module include:

- Two external pins:
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin

Both pins can be used as GPIO if not used for SCI.

- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)

- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- 16-level transmit/receive FIFO

### 25.1.3 Block Diagram

Figure 25-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in Section 25.15.

## 25.2 Architecture

The major elements used in full-duplex operation are shown in Figure 25-2 and include:

- A transmitter (TX) and its major registers (upper half of Figure 25-2)
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and its major registers (lower half of Figure 25-2)
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

## 25.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in [Table 25-1](#).

**Table 25-1. SCI Module Signal Summary**

| Signal Name              | Description                                |
|--------------------------|--|
| <b>External signals</b>  |  |
| SCIRXD                   | SCI Asynchronous Serial Port receive data  |
| SCITXD                   | SCI Asynchronous Serial Port transmit data |
| <b>Control</b>           |  |
| Baud clock               | LSPCLK Prescaled clock                     |
| <b>Interrupt signals</b> |  |
| TXINT                    | Transmit interrupt                         |
| RXINT                    | Receive Interrupt                          |

## 25.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

Figure 25-2. Serial Communications Interface (SCI) Module Block Diagram

## 25.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see [Section 25.8](#)) and the address-bit multiprocessor mode (see [Section 25.9](#)). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see [Section 25.10](#)) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

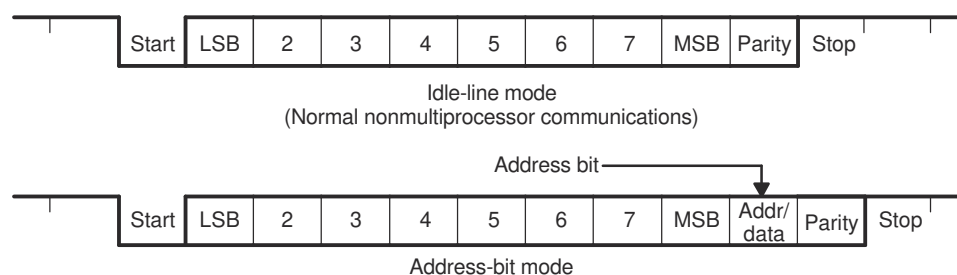

- One start bit
- One to eight data bits
- An even/odd parity bit or no parity bit
- One or two stop bits

## 25.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in [Figure 25-3](#), consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with its formatting information is called a frame and is shown in [Figure 25-3](#).

**Figure 25-3. Typical SCI Data Frame Formats**

To program the data format, use the SCICCR register. The bits used to program the data format are shown in [Table 25-2](#).

**Table 25-2. Programming the Data Format Using SCICCR**

| Bit(s) | Bit Name           | Designation | Functions   |
|--------|--------------------|-------------|---|
| 2-0    | SCICHAR            | SCICCR.2:0  | Select the character (data) length (one to eight bits).   |
| 5      | PARITYENA (ENABLE) | SCICCR.5    | Enables the parity function if set to 1, or disables the parity function if cleared to 0.                 |
| 6      | PARITY (EVEN/ODD)  | SCICCR.6    | If parity is enabled, selects odd parity if cleared to 0; even parity if set to 1.                        |
| 7      | STOPBITS           | SCICCR.7    | Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1. |

## 25.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there should be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

### Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

### Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that they are interrupted only when the address byte is detected. When a processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, it does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

### 25.7.1 Recognizing the Address Byte

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode ([Section 25.8](#)) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than ten bytes of data. The idle-line mode should be used for typical non-multiprocessor SCI communication.
- The address-bit mode ([Section 25.9](#)) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, it does not have to wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

### 25.7.2 Controlling the SCI TX and RX Features

The multiprocessor mode is software selectable via the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

### 25.7.3 Receipt Sequence

In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt). It reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against its device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

## 25.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit=0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 25-4 (ADDR/IDLE MODE bit is bit 3 of SCICCR).

**Figure 25-4. Idle-Line Multiprocessor Communication Format**

### 25.8.1 Idle-Line Mode Steps

The steps followed by the idle-line mode:

1. SCI wakes up after receipt of the block-start signal.
2. The processor recognizes the next SCI interrupt.
3. The interrupt service routine compares the received address (sent by a remote transmitter) to its own.
4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.
5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute its main program without being interrupted by the SCI port until the next detection of a block start.

### 25.8.2 Block Start Signal

There are two ways to send a block-start signal:

- **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
- **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

### 25.8.3 Wake-UP Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in [Figure 25-5](#).

**Figure 25-5. Double-Buffered WUT and TXSHF**

#### 25.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don't care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.

3. Write a new address value to SCITXBUF.

A don't-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don't-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE, if necessary) can be written to again because TXSHF and WUT are both double-buffered.

### 25.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does it request a receive interrupt until an address frame is detected.

## 25.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit=1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 25-6).

### 25.9.1 Sending an Address

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

When this address value is transferred to the TXSHF register and shifted out, its address bit is sent as a 1. This flags the other processors on the serial link to read the address.

2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.)
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

#### Note

As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

**Figure 25-6. Address-Bit Multiprocessor Communication Format**

## 25.10 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 25-7). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 25-7. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 25-7 illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes itself to frames, the external transmitting and receiving devices do not have to use a synchronized serial clock. The clock can be generated locally.

Figure 25-7. SCI Asynchronous Communications Format

### 25.10.1 Receiver Signals in Communication Modes

Figure 25-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

Figure 25-8. SCI RX Signals in Communication Modes

Notes:

1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

## 25.10.2 Transmitter Signals in Communication Modes

Figure 25-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

**Figure 25-9. SCI TX Signals in Communications Mode**

### Notes:

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and it requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

## 25.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag that is a logical-OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits that are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the Peripheral Interrupts section of the *System Control and Interrupts* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for 9.625 bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

---

### Note

Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

---

## 25.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock (LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. [Table 25-3](#) shows the baud-select values for common SCI bit rates. LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100 MHz, then the maximum baud rate is 6.25 Mbps.

**Table 25-3. Asynchronous Baud Register Values for Common SCI Bit Rates**

| Ideal Baud | LSPCLK Clock Frequency, 100 MHz |             |         |
|------------|---------------------------------|-------------|---------|
|            | BRR                             | Actual Baud | % Error |
| 2400       | 5207 (1457h)                    | 2400        | 0       |
| 4800       | 2603 (A2Bh)                     | 4800        | 0       |
| 9600       | 1301 (515h)                     | 9601        | 0.01    |
| 19200      | 650 (28Ah)                      | 19201       | 0.01    |
| 38400      | 324 (144h)                      | 38462       | 0.16    |

## 25.13 SCI Enhanced Features

The C28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

### 25.13.1 SCI FIFO Description

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. **Reset.** At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. **Standard SCI.** The standard SCI modes will work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. **FIFO enable.** FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of its operation.
4. **Active registers.** All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. **Interrupts.** FIFO mode has two interrupts; one for transmit FIFO, TXINT and one for receive FIFO, RXINT. RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI will be disabled and this interrupt will service as SCI transmit FIFO interrupt.
6. **Buffers.** Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8 bits wide and receive FIFO registers are 10 bits wide. The one-word transmit buffer (SCITXBUF) of the standard SCI functions as a transition buffer before the transmit FIFO and shift register. SCITXBUF is loaded into either the FIFO (when FIFO is enabled) or TXSHF (when FIFO is disabled). When FIFO is enabled, SCITXBUF loads into the FIFO only after the last bit of the shift register is shifted out, so SCITXBUF should not be treated as an additional level of buffer. With the FIFO enabled, TXSHF is directly loaded from the FIFO (not TXBUF) after an optional delay value (SCIFFCT). When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. **Delayed transfer.** The rate at which words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7–0) FFTXDLY7–FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.
8. **FIFO status bits.** Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12–8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to 1.
9. **Programmable interrupt levels.** Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12–8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4–0). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits will be 0x1111 for receive FIFO and 0x0000 for transmit FIFO, respectively.

Figure 25-10 and Table 25-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

Figure 25-10. SCI FIFO Interrupt Flags and Enable Logic

Table 25-4. SCI Interrupt Flags

| FIFO Options <sup>(1)</sup> | SCI Interrupt Source            | Interrupt Flags      | Interrupt Enables | FIFO Enable<br>SCIFFENA | Interrupt Line |
|-----------------------------|---------------------------------|----------------------|-------------------|-------------------------|----------------|
| SCI without FIFO            | Receive error                   | RXERR <sup>(2)</sup> | RXERRINTENA       | 0                       | RXINT          |
|                             | Receive break                   | BRKDT                | RX/BKINTENA       | 0                       | RXINT          |
|                             | Data receive                    | RXRDY                | RX/BKINTENA       | 0                       | RXINT          |
|                             | Transmit empty                  | TXRDY                | TXINTENA          | 0                       | TXINT          |
| SCI with FIFO               | Receive error and receive break | RXERR                | RXERRINTENA       | 1                       | RXINT          |
|                             | FIFO receive                    | RXFFIL               | RXFFIENA          | 1                       | RXINT          |
|                             | Transmit empty                  | TXFFIL               | TXFFIENA          | 1                       | TXINT          |
| Auto-baud                   | Auto-baud detected              | ABD                  | Don't care        | x                       | TXINT          |

(1) FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.

(2) RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag.

### 25.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

### 25.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit should be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt will occur (TXINT). After the interrupt service CDC bit has to be cleared by software. If CDC remains set even after interrupt service, there should be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (Bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500 Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud-detect hardware will detect the incoming baud rate and set the ABD bit.
4. The auto-detect hardware will update the baud rate register with the equivalent baud value hex. The logic will also generate an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt will occur (TXINT). After the interrupt service CDC bit must be cleared by software.

---

#### Note

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications may work well, this slew rate may limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and C28x SCI boot loader using a lower baud rate.
  - The host may then handshake with the loaded C28x application to set the SCI baud rate register to the desired higher baud rate.
-

## 25.14 Software

### 25.14.1 SCI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/sci

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 25.14.1.1 Tune Baud Rate via UART Example

FILE: baud\_tune\_via\_uart.c

This example demonstrates the process of tuning the UART/SCI baud rate of a C2000 device based on the UART input from another device. As UART does not have a clock signal, reliable communication requires baud rates to be reasonably matched. This example addresses cases where a clock mismatch between devices is greater than is acceptable for communications, requiring baud compensation between boards. As reliable communication only requires matching the EFFECTIVE baud rate, it does not matter which of the two boards executes the tuning (the board with the less-accurate clock source does not need to be the one to tune; as long as one of the two devices tunes to the other, then proper communication can be established).

To tune the baud rate of this device, SCI data (of the desired baud rate) must be sent to this device. The input SCI baud rate must be within the +/- MARGINPERCENT of the TARGETBAUD chosen below. These two variables are defined below, and should be chosen based on the application requirements. Higher MARGINPERCENT will allow more data to be considered "correct" in noisy conditions, and may decrease accuracy. The TARGETBAUD is what was expected to be the baud rate, but due to clock differences, needs to be tuned for better communication robustness with the other device.

NOTE: Lower baud rates have more granularity in register options, and therefore tuning is more affective at these speeds.

*External Connections for Control Card*

- SCIA\_RX/eCAP1 is on GPIO9, connect to incoming SCI communications
- SCIA\_TX is on GPIO8, for observation externally

*Watch Variables*

- *avgBaud* - Baud rate that was detected and set after tuning

#### 25.14.1.2 SCI FIFO Digital Loop Back

FILE: sci\_ex1\_loopback.c

This program uses the internal loop back test mode of the peripheral. Other than boot mode pin configuration, no other hardware configuration is required. The pinmux and SCI modules are configured through the sysconfig file.

This test uses the loopback test mode of the SCI module to send characters starting with 0x00 through 0xFF. The test will send a character and then check the receive buffer for a correct match.

*Watch Variables*

- *loopCount* - Number of characters sent
- *errorCount* - Number of errors detected
- *sendChar* - Character sent
- *receivedChar* - Character received

### 25.14.1.3 SCI Digital Loop Back with Interrupts

FILE: sci\_ex2\_loopback\_interrupts.c

This test uses the internal loop back test mode of the peripheral. Other than boot mode pin configuration, no other hardware configuration is required. Both interrupts and the SCI FIFOs are used.

A stream of data is sent and then compared to the received stream. The SCI-A sent data looks like this:

```
00 01
01 02
02 03
....
FE FF
FF 00
etc.
```

The pattern is repeated forever.

#### Watch Variables

- *sDataA* - Data being sent
- *rDataA* - Data received
- *rDataPointA* - Keep track of where we are in the data stream. This is used to check the incoming data

### 25.14.1.4 SCI Echoback

FILE: sci\_ex3\_echoback.c

This test receives and echo-backs data through the SCI-A port.

A terminal such as 'putty' can be used to view the data from the SCI and to send information to the SCI. Characters received by the SCI port are sent back to the host.

*Running the Application* Open a COM port with the following settings using a terminal:

- Find correct COM port
- Bits per second = 9600
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out a greeting and then ask you to enter a character which it will echo back to the terminal.

#### Watch Variables

- *loopCounter* - the number of characters sent

#### External Connections

Connect the USB cable from Control card J1:A to PC

## 25.15 SCI Registers

The section describes the Serial Communication Interface module registers.

### 25.15.1 SCI Base Address Table

**Table 25-5. SCI Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| SciaRegs       | SCI_REGS  | SCIA_BASE      | 0x0000_7200  | YES  | -   | YES | -   | YES                |
| ScibRegs       | SCI_REGS  | SCIB_BASE      | 0x0000_7210  | YES  | -   | YES | -   | YES                |

## 25.15.2 SCI\_REGS Registers

Table 25-6 lists the memory-mapped registers for the SCI\_REGS registers. All register offset addresses not listed in Table 25-6 should be considered as reserved locations and the register contents should not be modified.

**Table 25-6. SCI\_REGS Registers**

| Offset | Acronym  | Register Name                     | Write Protection | Section            |
|--------|----------|-----------------------------------|------------------|--------------------|
| 0h     | SCICCR   | Communications control register   |                  | <a href="#">Go</a> |
| 1h     | SCICTL1  | Control register 1                |                  | <a href="#">Go</a> |
| 2h     | SCIHBAUD | Baud rate (high) register         |                  | <a href="#">Go</a> |
| 3h     | SCILBAUD | Baud rate (low) register          |                  | <a href="#">Go</a> |
| 4h     | SCICTL2  | Control register 2                |                  | <a href="#">Go</a> |
| 5h     | SCIRXST  | Receive status register           |                  | <a href="#">Go</a> |
| 6h     | SCIRXEMU | Receive emulation buffer register |                  | <a href="#">Go</a> |
| 7h     | SCIRXBUF | Receive data buffer               |                  | <a href="#">Go</a> |
| 9h     | SCITXBUF | Transmit data buffer              |                  | <a href="#">Go</a> |
| Ah     | SCIFFTX  | FIFO transmit register            |                  | <a href="#">Go</a> |
| Bh     | SCIFFRX  | FIFO receive register             |                  | <a href="#">Go</a> |
| Ch     | SCIFFCT  | FIFO control register             |                  | <a href="#">Go</a> |
| Fh     | SCIPRI   | SCI priority control              |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 25-7 shows the codes that are used for access types in this section.

**Table 25-7. SCI\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 25.15.2.1 SCICCR Register (Offset = 0h) [Reset = 0h]

SCICCR is shown in [Figure 25-11](#) and described in [Table 25-8](#).

Return to the [Summary Table](#).

SCICCR defines the character format, protocol, and communications mode used by the SCI.

**Figure 25-11. SCICCR Register**

|          |        |           |           |               |         |   |   |
|----------|--------|-----------|-----------|---------------|---------|---|---|
| 15       | 14     | 13        | 12        | 11            | 10      | 9 | 8 |
| RESERVED |        |           |           |               |         |   |   |
| R-0h     |        |           |           |               |         |   |   |
| 7        | 6      | 5         | 4         | 3             | 2       | 1 | 0 |
| STOPBITS | PARITY | PARITYENA | LOOPBKENA | ADDRIDLE_MODE | SCICHAR |   |   |
| R/W-0h   | R/W-0h | R/W-0h    | R/W-0h    | R/W-0h        | R/W-0h  |   |   |

**Table 25-8. SCICCR Register Field Descriptions**

| Bit  | Field         | Type | Reset | Description   |
|------|---------------|------|-------|---|
| 15-8 | RESERVED      | R    | 0h    | Reserved  |
| 7    | STOPBITS      | R/W  | 0h    | SCI number of stop bits.<br>This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit.<br>Reset type: SYSRSn<br>0h (R/W) = One stop bit<br>1h (R/W) = Two stop bits   |
| 6    | PARITY        | R/W  | 0h    | SCI parity odd/even selection.<br>If the PARITY ENABLE bit (SCICCR, bit 5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters).<br>Reset type: SYSRSn<br>0h (R/W) = Odd parity<br>1h (R/W) = Even parity  |
| 5    | PARITYENA     | R/W  | 0h    | SCI parity enable.<br>This bit enables or disables the parity function. If the SCI is in the addressbit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation.<br>Reset type: SYSRSn<br>0h (R/W) = Parity disabled<br>no parity bit is generated during transmission or is expected during reception<br>1h (R/W) = Parity is enabled   |
| 4    | LOOPBKENA     | R/W  | 0h    | Loop Back test mode enable.<br>This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin.<br>Reset type: SYSRSn<br>0h (R/W) = Loop Back test mode disabled<br>1h (R/W) = Loop Back test mode enabled  |
| 3    | ADDRIDLE_MODE | R/W  | 0h    | SCI multiprocessor mode control bit.<br>This bit selects one of the multiprocessor protocols. Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1, bit 2 and SCICTL1, bit 3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications.<br>Reset type: SYSRSn<br>0h (R/W) = Idle-line mode protocol selected<br>1h (R/W) = Address-bit mode protocol selected |

**Table 25-8. SCICCR Register Field Descriptions (continued)**

| Bit | Field    | Type | Reset | Description   |
|-----|----------|------|-------|---|
| 2-0 | SCICCHAR | R/W  | 0h    | Character-length control bits 2-0.<br>These bits select the SCI character length from one to eight bits.<br>Characters of less than eight bits are right-justified in SCIRXBUF<br>and SCIRXEMU and are padded with leading zeros in SCIRXBUF.<br>SCITXBUF doesn't need to be padded with leading zeros.<br>Reset type: SYSRSn<br>0h (R/W) = SCICCHAR_LENGTH_1<br>1h (R/W) = SCICCHAR_LENGTH_2<br>2h (R/W) = SCICCHAR_LENGTH_3<br>3h (R/W) = SCICCHAR_LENGTH_4<br>4h (R/W) = SCICCHAR_LENGTH_5<br>5h (R/W) = SCICCHAR_LENGTH_6<br>6h (R/W) = SCICCHAR_LENGTH_7<br>7h (R/W) = SCICCHAR_LENGTH_8 |

### 25.15.2.2 SCICTL1 Register (Offset = 1h) [Reset = 0h]

SCICTL1 is shown in [Figure 25-12](#) and described in [Table 25-9](#).

Return to the [Summary Table](#).

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

**Figure 25-12. SCICTL1 Register**

|          |             |         |          |        |        |        |        |

**Table 25-9. SCICTL1 Register Field Descriptions (continued)**

| Bit | Field  | Type | Reset | Description  |
|-----|--------|------|-------|--|
| 3   | TXWAKE | R/W  | 0h    | <p>SCI transmitter wake-up method select.</p> <p>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3)</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1</p> <p>1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5)</p> <p>it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.</p>                        |
| 2   | SLEEP  | R/W  | 0h    | <p>SCI sleep.</p> <p>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode.</p> <p>The receiver still operates when the SLEEP bit is set however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Sleep mode disabled</p> <p>1h (R/W) = Sleep mode enabled</p>  |
| 1   | TXENA  | R/W  | 0h    | <p>SCI transmitter enable.</p> <p>Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmitter disabled</p> <p>1h (R/W) = Transmitter enabled</p>   |
| 0   | RXENA  | R/W  | 0h    | <p>SCI receiver enable.</p> <p>Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers).</p> <p>Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, the receiver shift register can continue to assemble characters. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers</p> <p>1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF</p> |

### 25.15.2.3 SCIHBAUD Register (Offset = 2h) [Reset = 0h]

SCIHBAUD is shown in [Figure 25-13](#) and described in [Table 25-10](#).

Return to the [Summary Table](#).

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

|------|----------|------|-------|--|
| 15-8 | RESERVED | R    | 0h    | Reserved   |
| 7    | RXERROR  | R    | 0h    | SCI receiver error flag.<br>The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE).<br>A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly<br>it is cleared by an active SW RESET or by a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No error flags set<br>1h (R/W) = Error flag(s) set  |
| 6    | RXRDY    | R    | 0h    | SCI receiver-ready flag.<br>When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, or by a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No new character in SCIRXBUF<br>1h (R/W) = Character ready to be read from SCIRXBUF   |
| 5    | BRKDT    | R    | 0h    | SCI break-detect flag.<br>The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCI_RXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded. A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1. BRKDT is cleared by an active SW RESET or by a system reset. It is not cleared by receipt of a character after the break is detected. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit or by a system reset.<br>Reset type: SYSRSn<br>0h (R/W) = No break condition<br>1h (R/W) = Break condition occurred |

**Table 25-13. SCIRXST Register Field Descriptions (continued)**

| Bit | Field    | Type | Reset | Description   |
|-----|----------|------|-------|---|
| 4   | FE       | R    | 0h    | <p>SCI framing-error flag.</p> <p>The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit or by a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No framing error detected<br/>1h (R/W) = Framing error detected</p>  |
| 3   | OE       | R    | 0h    | <p>SCI overrun-error flag.</p> <p>The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU or DMAC. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET or by a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No overrun error detected<br/>1h (R/W) = Overrun error detected</p>   |
| 2   | PE       | R    | 0h    | <p>SCI parity-error flag.</p> <p>This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET or a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No parity error or parity is disabled<br/>1h (R/W) = Parity error is detected</p>  |
| 1   | RXWAKE   | R    | 0h    | <p>Receiver wake-up-detect flag</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No detection of a receiver wake-up condition<br/>1h (R/W) = A value of 1 in this bit indicates detection of a receiver wake-up condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following:</p> <ul style="list-style-type: none"> <li>- The transfer of the first byte after the address byte to SCIRXBUF (only in non-FIFO mode)</li> <li>- The reading of SCIRXBUF</li> <li>- An active SW RESET</li> <li>- A system reset</li> </ul> |
| 0   | RESERVED | R    | 0h    | Reserved  |

### 25.15.2.7 SCIRXEMU Register (Offset = 6h) [Reset = 0h]

SCIRXEMU is shown in [Figure 25-17](#) and described in [Table 25-14](#).

Return to the [Summary Table](#).

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented

it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

**Figure 25-17. SCIRXEMU Register**

### 25.15.2.8 SCIRXBUF Register (Offset = 7h) [Reset = 0h]

SCIRXBUF is shown in [Figure 25-18](#) and described in [Table 25-15](#).

Return to the [Summary Table](#).

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RXBKINTENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

**Figure 25-18. SCIRXBUF Register**

### 25.15.2.9 SCITXBUF Register (Offset = 9h) [Reset = 0h]

SCITXBUF is shown in [Figure 25-19](#) and described in [Table 25-16](#).

Return to the [Summary Table](#).

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

**Figure 25-19. SCITXBUF Register**

### 25.15.2.10 SCIFFTX Register (Offset = Ah) [Reset = A000h]

SCIFFTX is shown in [Figure 25-20](#) and described in [Table 25-17](#).

Return to the [Summary Table](#).

SCIFFTX controls the transmit FIFO interrupt, FIFO enhancements, and reset for the SCI transmit and receive channels.

**Figure 25-20. SCIFFTX Register**

This interrupt is triggered whenever the transmit FIFO status (TXFFST) bits match (equal to or less than) the interrupt trigger level bits TXFFIL (bits 4-0).  |
| 4-0 | TXFFIL   | R/W  | 0h    | TXFFIL4-0 Transmit FIFO interrupt level bits.<br>The transmit FIFO generates an interrupt whenever the FIFO status bits (TXFFST4-0) are less than or equal to the FIFO level bits (TXFFIL4-0). The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the TX FIFO. The default value of these bits after reset is 00000b. Users should set TXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of SCI bus bandwidth.<br>Reset type: SYSRSn |

### 25.15.2.11 SCIFFRX Register (Offset = Bh) [Reset = 201Fh]

SCIFFRX is shown in [Figure 25-21](#) and described in [Table 25-18](#).

Return to the [Summary Table](#).

SCIFFRX controls the receive FIFO interrupt, receive FIFO reset, and status of the receive FIFO overflow.

**Figure 25-21. SCIFFRX Register**

|         |            |             |         |    |    |   |   |  |

The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the RX FIFO. The default value of these bits after reset is 11111b. Users should set RXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of received SCI data.<br>Reset type: SYSRSn |

### 25.15.2.12 SCIFFCT Register (Offset = Ch) [Reset = 0h]

SCIFFCT is shown in [Figure 25-22](#) and described in [Table 25-19](#).

Return to the [Summary Table](#).

SCIFFCT contains the status of auto-baud detect, clears the auto-baud flag, and calibrate for A-detect bit.

**Figure 25-22. SCIFFCT Register**

|         |        |        |          |    |    |   |   |

| FFTXDLY |        |        |          |    |    |   |   |
| R/W-0h  |        |        |          |    |    |   |   |

**Table 25-19. SCIFFCT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 15   | ABD      | R    | 0h    | Auto-baud detect (ABD) bit<br>Reset type: SYSRSn<br>0h (R/W) = Auto-baud detection is not complete. "A", "a" character has not been received successfully.<br>1h (R/W) = Auto-baud hardware has detected "A" or "a" character on the SCI receive register. Auto-detect is complete.  |
| 14   | ABDCLR   | W    | 0h    | ABD-clear bit<br>Reset type: SYSRSn<br>0h (R/W) = Write 0 has no effect on ABD flag bit. Bit reads back a zero.<br>1h (R/W) = Write 1 to clear ABD flag in bit 15.   |
| 13   | CDC      | R/W  | 0h    | CDC calibrate A-detect bit<br>Reset type: SYSRSn<br>0h (R/W) = Disables auto-baud alignment<br>1h (R/W) = Enables auto-baud alignment  |
| 12-8 | RESERVED | R    | 0h    | Reserved   |
| 7-0  | FFTXDLY  | R/W  | 0h    | FIFO transfer delay. These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in the number of SCI serial baud clock cycles. The 8 bit register could define a minimum delay of 0 baud clock cycles and a maximum of 256 baud clock cycles<br>In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In FIFO mode, TXBUF should not be treated as one additional level of buffer. The delayed transmit feature will help to create an auto-flow scheme without RTS/CTS controls as in standard UARTS.<br>When SCI is configured for one stop-bit, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to.<br>When SCI is configured for two stop-bits, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to minus 1.<br>Reset type: SYSRSn |

### 25.15.2.13 SCIPRI Register (Offset = Fh) [Reset = 0h]

SCIPRI is shown in [Figure 25-23](#) and described in [Table 25-20](#).

Return to the [Summary Table](#).

SCIPRI determines what happens when an emulation suspend event occurs.

**Figure 25-23. SCIPRI Register**

|          |    |    |          |    |    |          |   |
|----------|----|----|----------|----|----|----------|---|

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

---

### Note

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this document. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMR.

## 26.1 Introduction

The I2C module supports any slave or master I2C-compatible device. [Figure 26-1](#) shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

**Figure 26-1. Multiple I2C Modules Connected**

### 26.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers
  - Support for multiple slave-transmitters and master-receivers
  - Combined master transmit/receive and receive/transmit mode
  - Data transfer rate from 10 kbps up to 400 kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as slave
  - I2Cx\_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable/disable capability
- Free data format mode

### 26.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

### 26.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the master or the slave when performing data transfers. A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave. The I2C module supports the multi-master mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in [Figure 26-2](#). These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins both are bidirectional. They each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- Standard Mode: Send exactly *n* data values, where *n* is a value you program in an I2C module register. See the I2CCNT register in [Section 26.7](#) for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in [Section 26.7](#) for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

[Figure 26-2](#) shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

Figure 26-2. I2C Module Conceptual Block Diagram

### 26.1.5 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C master clock on the SCL pin. Figure 26-3 shows the clock generation diagram for I2C module.

Figure 26-3. Clocking Diagram for the I2C Module

#### Note

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7-12 MHz.

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)} \quad (26)$$

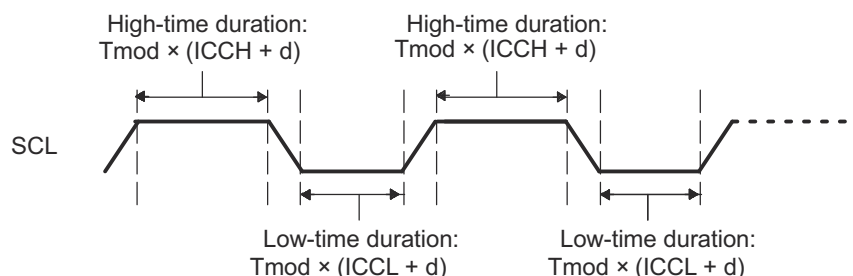

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 26-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 26.1.6 for the master clock frequency equation.

### 26.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 26.1.5, when the I2C module is a master, the I2C module clock is divided down further to use as the master clock on the SCL pin. As shown in Figure 26-4, the shape of the master clock depends on two divide-down values:

- ICCL in I2CCLKL. For each master clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCLKH. For each master clock cycle, ICCH determines the amount of time the signal is high.

**Figure 26-4. The Roles of the Clock Divide-Down Values (ICCL and ICCH)**

#### 26.1.6.1 Formula for the Master Clock Period

The master clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Master Clock period (Tmst)} = \frac{[(\text{ICCH} + d) + (\text{ICCL} + d)]}{\text{I2C Module Clock (Fmod)}} \quad (27)$$

where d depends on the divide-down value IPSC, as shown in Table 26-1. IPSC is described in the I2CPSC register.

**Table 26-1. Dependency of Delay d on the Divide-Down Value IPSC**

| IPSC           | d |
|----------------|---|
| 0              | 7 |
| 1              | 6 |
| Greater than 1 | 5 |

## 26.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 26.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

### 26.3.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of  $V_{DD}$ . For details, see the data manual for your particular device.

### 26.3.2 Data Validity

The data on SDA must be stable during the high period of the clock (see [Figure 26-5](#)). The high or low state of the data line, SDA, should change only when the clock signal on SCL is low.

**Figure 26-5. Bit Transfer on the I2C bus**

### 26.3.3 Operating Modes

The I2C module has four basic operating modes to support data transfers as a master and as a slave. See [Table 26-2](#) for the names and descriptions of the modes.

If the I2C module is a master, it begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. To receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, it begins as a slave-receiver and typically sends acknowledgment when it recognizes its slave address from a master. If the master will be sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

**Table 26-2. Operating Modes of the I2C Module**

| Operating Mode          | Description   |
|-------------------------|---|
| Slave-receiver mode     | The I2C module is a slave and receives data from a master.<br><br>All slaves begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See <a href="#">Section 26.3.7</a> for more details.  |
| Slave-transmitter mode  | The I2C module is a slave and transmits data to a master.<br><br>This mode can be entered only from the slave-receiver mode; the I2C module must first receive a command from the master. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its slave-transmitter mode if the slave address byte is the same as its own address (in I2COAR) and the master has transmitted R/ $\bar{W}$ = 1. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See <a href="#">Section 26.3.7</a> for more details. |
| Master-receiver mode    | The I2C module is a master and receives data from a slave.<br><br>This mode can be entered only from the master-transmitter mode; the I2C module must first transmit a command to the slave. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its master-receiver mode after transmitting the slave address byte and R/ $\bar{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.  |
| Master-transmitter mode | The I2C module is a master and transmits control information and data to a slave.<br><br>All masters begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.  |

To summarize, SCL will be held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Slave-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Slave-transmitter mode.

I2C slave nodes have to accept and provide data when the I2C master node requests it.

- To release SCL in slave-receiver mode, read data from I2CDRR.
- To release SCL in slave-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

**Table 26-3. Master-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR**

| RM | STT | STP | Bus Activity <sup>(1)</sup> | Description  |
|----|-----|-----|-----------------------------|--|
| 0  | 0   | 0   | None                        | No activity  |
| 0  | 0   | 1   | P                           | STOP condition   |
| 0  | 1   | 0   | S-A-D..(n)..D.              | START condition, slave address, n data bytes (n = value in I2CCNT)   |
| 0  | 1   | 1   | S-A-D..(n)..D-P             | START condition, slave address, n data bytes, STOP condition (n = value in I2CCNT)   |
| 1  | 0   | 0   | None                        | No activity  |
| 1  | 0   | 1   | P                           | STOP condition   |
| 1  | 1   | 0   | S-A-D-D-D.                  | Repeat mode transfer: START condition, slave address, continuous data transfers until STOP condition or next START condition |
| 1  | 1   | 1   | None                        | Reserved bit combination (No activity)   |

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

Figure 26-6. I2C Slave TX / RX Flowchart

Figure 26-7. I2C Master TX / RX Flowchart

### 26.3.4 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a master on the I2C bus. As shown in [Figure 26-8](#):

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

**Figure 26-8. I2C Module START and STOP Conditions**

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and its bits (including MST, STT, and STP), see [Section 26.7](#).

The I2C peripheral cannot detect a START or STOP condition while it is in reset (IRS = 0). The BB bit will remain in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1) the BB bit will not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, users can ensure that at least one START or STOP condition will have occurred on the I2C bus and been captured by the BB bit. After this period, the BB bit will correctly reflect the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers ensures that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

### 26.3.5 Non-repeat Mode vs Repeat Mode

#### Non-repeat mode:

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted (or) received
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit doesn't get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

---

#### Note

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C statemachine expects to transmit (or) receive 65536 bytes and not 0 bytes.

---

#### Repeat mode:

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents don't determine the number of bytes to be transmitted (or) received.
- Number of bytes to be transmitted (or) received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte

---

#### Note

Once you start I2C transaction in non-repeat mode (or) repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

---

### 26.3.6 Serial Data Formats

Figure 26-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 26-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 26-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 26-10 through Figure 26-12 and described in the paragraphs that follow the figures.

#### Note

In Figure 26-9 through Figure 26-12,  $n$  = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

Figure 26-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)

#### 26.3.6.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 26-10), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/  $\bar{W}$  bit. R/  $\bar{W}$  determines the direction of the data:

- R/  $\bar{W}$  = 0: The I2C master writes (transmits) data to the addressed slave. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/  $\bar{W}$  = 1: The I2C master reads (receives) data from the slave. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

Figure 26-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the slave after the first byte from the master, it is followed by  $n$  bits of data from the transmitter (master or slave, depending on the R/  $\bar{W}$  bit).  $n$  is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

### 26.3.6.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 26-11) is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and R/ $\bar{W}$ . The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

**Figure 26-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)**

### 26.3.6.3 Free Data Format

The free data format can be enabled by setting I2CMDR.FDF = 1.

In this format (see Figure 26-12), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

**Figure 26-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)**

#### Note

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

**Table 26-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR**

| MST | FDF | I2C Module State                             | Function of TRX   |
|-----|-----|--|---|
| 0   | 0   | In slave mode but not free data format mode  | TRX is a don't care. Depending on the command from the master, the I2C module responds as a receiver or a transmitter.  |
| 0   | 1   | In slave mode and free data format mode      | The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module:<br>TRX = 1: The I2C module is a transmitter.<br>TRX = 0: The I2C module is a receiver. |
| 1   | 0   | In master mode but not free data format mode | TRX = 1: The I2C module is a transmitter.<br>TRX = 0: The I2C module is a receiver.   |
| 1   | 1   | In master mode and free data format mode     | TRX = 0: The I2C module is a receiver.<br>TRX = 1: The I2C module is a transmitter.   |

### 26.3.6.4 Using a Repeated START Condition

I2C master can communicate with multiple slave addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, and free data formats. Figure 26-13 shows a repeated START condition in the 7-bit addressing format.

Figure 26-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)

#### Note

In Figure 26-13, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMR.

### 26.3.7 Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. Figure 26-14 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL is held low by the device with the longest low period. The other devices that finish their low periods must wait for SCL to be released, before starting their high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

Figure 26-14. Synchronization of Two I2C Clock Generators During Arbitration

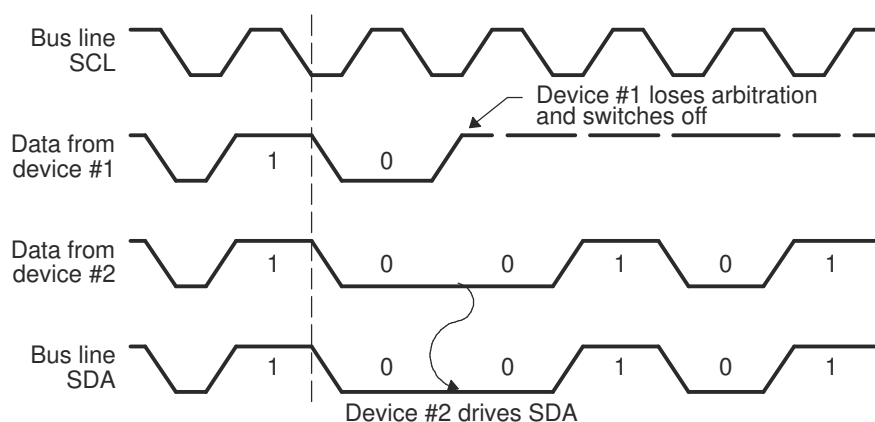

### 26.3.8 Arbitration

If two or more master-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 26-15 illustrates the arbitration procedure between two devices. The first master-transmitter that releases the SDA line high is overruled by another master-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, it switches to the slave-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

**Figure 26-15. Arbitration Procedure Between Two Master-Transmitters**

### 26.3.9 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

$$n = 8 * (\text{SYSCLK}) / (\text{I2C module clock (Fmod)})$$

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 26-16 shows the signal routing in digital loopback mode.

**Figure 26-16. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit**

#### Note

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

### 26.3.10 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. [Table 26-5](#) summarizes the various ways you can tell the I2C module to send a NACK bit.

**Table 26-5. Ways to Generate a NACK Bit**

| I2C Module Condition                                       | NACK Bit Generation Options  |
|--|--|
| Slave-receiver modes                                       | <ul style="list-style-type: none"> <li>• Allow an overrun condition (RSFULL = 1 in I2CSTR)</li> <li>• Reset the module (IRS = 0 in I2CMDR)</li> <li>• Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive</li> </ul>   |
| Master-receiver mode AND Repeat mode (RM = 1 in I2CMDR)    | <ul style="list-style-type: none"> <li>• Generate a STOP condition (STP = 1 in I2CMDR)</li> <li>• Reset the module (IRS = 0 in I2CMDR)</li> <li>• Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive</li> </ul>   |
| Master-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR) | <ul style="list-style-type: none"> <li>• If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition</li> <li>• If STP = 0, make STP = 1 to generate a STOP condition</li> <li>• Reset the module (IRS = 0 in I2CMDR). = 1 to generate a STOP condition</li> <li>• Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive</li> </ul> |

## 26.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in [Section 26.4.1](#).
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in [Section 26.4.2](#)

### 26.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in [Table 26-6](#). As shown in [Figure 26-17](#), all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, its flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

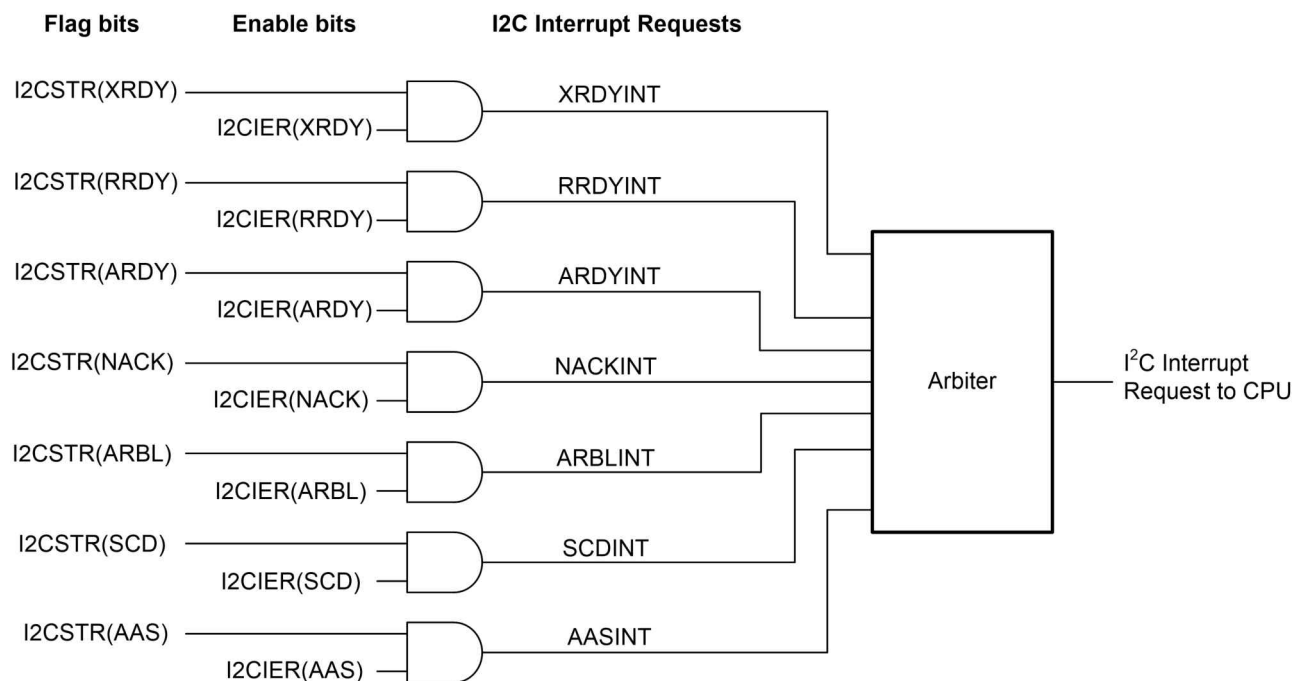

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if it is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A\_ISR). The I2CINT1A\_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A\_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to it.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

**Table 26-6. Descriptions of the Basic I2C Interrupt Requests**

| I2C Interrupt Request | Interrupt Source  |
|-----------------------|---|
| XRDYINT               | <p>Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR).</p> <p>As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.</p> |
| RRDYINT               | <p>Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR.</p> <p>As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.</p>  |
| ARDYINT               | <p>Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used.</p> <p>The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR.</p> <p>As an alternative to using ARDYINT, the CPU can poll the ARDY bit.</p>                           |
| NACKINT               | <p>No-acknowledgment condition: The I2C module is configured as a master-transmitter and did not received acknowledgment from the slave-receiver.</p> <p>As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.</p>   |
| ARBLINT               | <p>Arbitration-lost condition: The I2C module has lost an arbitration contest with another master-transmitter.</p> <p>As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.</p>  |
| SCDINT                | <p>Stop condition detected: A STOP condition was detected on the I2C bus.</p> <p>As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.</p>  |
| AASINT                | <p>Addressed as slave condition: The I2C has been addressed as a slave device by another master on the I2C bus.</p> <p>As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.</p>  |

**Figure 26-17. Enable Paths of the I2C Interrupt Requests**

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AASINT

The normal transmit interrupt timing makes it possible for stale data to remain in the transmit buffer if a transaction is aborted in the middle of a byte. To avoid this, set the FCM bit in the I2CEMDR register. When this bit is set, the transmit data ready interrupt is generated only when data is required for a bus transaction. In master mode, the interrupt is first generated when the ACK of the address byte is received. In slave mode, the interrupt is first generated when the address is matched. Further interrupts are generated when the data is ACKed. In this mode XRDY is asserted at the same time as the transmit ready interrupt.

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in [Figure 26-18](#) demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a slave-transmitter.

Slave Transmitter

Figure 26-18. Backwards Compatibility Mode and Forward Compactibility bit, Slave Transmitter

## 26.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 26-19 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

Figure 26-19. I2C\_FIFO\_interrupt

## 26.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMODR). All status bits (in I2CSTR) are forced to their default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the  $\overline{\text{XRS}}$  pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the  $\overline{\text{XRS}}$  pin is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

## 26.6 Software

### 26.6.1 I2C Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/i2c

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 26.6.1.1 I2C Digital Loopback with FIFO Interrupts

FILE: i2c\_ex1\_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

This pattern is repeated forever.

#### External Connections

- None

#### Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 26.6.1.2 I2C EEPROM

FILE: i2c\_ex2\_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, *i2cMsgOut*. The data read back will be contained in the message structure *i2cMsgIn*.

#### External Connections

- Connect external I2C EEPROM at address 0x50
- Connect DEVICE\_GPIO\_PIN\_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE\_GPIO\_PIN\_SCL on to external EEPROM SCL (serial clock) pin

#### Watch Variables

- *i2cMsgOut* - Message containing data to write to EEPROM
- *i2cMsgIn* - Message containing data read from EEPROM

### 26.6.1.3 I2C Digital External Loopback with FIFO Interrupts

FILE: i2c\_ex3\_external\_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

This pattern is repeated forever.

#### External Connections

- Connect SCLA(DEVICE\_GPIO\_PIN\_SCLA) to SCLB (DEVICE\_GPIO\_PIN\_SCLB)
- Connect SDAA(DEVICE\_GPIO\_PIN\_SDAA) to SDAB (DEVICE\_GPIO\_PIN\_SDAB)
- Connect DEVICE\_GPIO\_PIN\_LED1 to an LED used to depict data transfers.

#### Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

### 26.6.1.4 I2C EEPROM

FILE: i2c\_ex4\_eeprom\_polling.c

This program will show how to perform different EEPROM write and read commands using I2C polling method. EEPROM used for this example is AT24C256.

#### External Connections

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE\_GPIO\_PIN\_SCLA | SCL SDA | DEVICE\_GPIO\_PIN\_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

### 26.6.1.5 I2C Master Slave Communication using FIFO Interrupts

FILE: i2c\_ex5\_master\_slave\_interrupt.c

This program shows how to use I2CA and I2CB modules in both master and slave configuration. This example uses I2C FIFO interrupts and doesn't use polling.

Example1: I2CA as Master Transmitter and I2CB working Slave Receiver  
 Example2: I2CA as Master Receiver and I2CB working Slave Transmitter  
 Example3: I2CB as Master Transmitter and I2CA working Slave Receiver  
 Example4: I2CB as Master Receiver and I2CA working Slave Transmitter

*External Connections* on launchpad should be made as:

- Signal | I2CA | I2CB
- SCL | DEVICE\_GPIO\_PIN\_SCL\_A | DEVICE\_GPIO\_PIN\_SCL\_B
- SDA | DEVICE\_GPIO\_PIN\_SDA\_A | DEVICE\_GPIO\_PIN\_SDA\_B

*Watch Variables* in memory window

- I2CA\_TXdata
- I2CA\_RXdata
- I2CB\_TXdata
- I2CB\_RXdata stream for error checking

### 26.6.1.6 I2C EEPROM

FILE: i2c\_ex6\_eeprom\_interrupt.c

This program will show how to perform different EEPROM write and read commands using I2C interrupts. EEPROM used for this example is AT24C256.

*External Connections*

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM
- SCL | DEVICE\_GPIO\_PIN\_SCL\_A | SCL SDA | DEVICE\_GPIO\_PIN\_SDA\_A | SDA

Make sure to connect GND pins, if EEPROM and C2000 device are on different boards.

//Example 1: EEPROM Byte Write

//Example 2: EEPROM Byte Read

//Example 3: EEPROM word (16-bit) write

//Example 4: EEPROM word (16-bit) read

//Example 5: EEPROM Page write

//Example 6: EEPROM word Paged read

*Watch Variables*

- TX\_MsgBuffer - Message buffer that stores the data to be transmitted
- RX\_MsgBuffer - Message buffer that stores the data to be received

## 26.7 I2C Registers

This section describes the C28x I2C Module Registers.

### 26.7.1 I2C Base Address Table

**Table 26-7. I2C Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| I2caRegs       | I2C_REGS  | I2CA_BASE      | 0x0000_7300  | YES  | -   | YES | -   | YES                |
| I2cbRegs       | I2C_REGS  | I2CB_BASE      | 0x0000_7340  | YES  | -   | YES | -   | YES                |

## 26.7.2 I2C\_REGS Registers

Table 26-8 lists the memory-mapped registers for the I2C\_REGS registers. All register offset addresses not listed in Table 26-8 should be considered as reserved locations and the register contents should not be modified.

**Table 26-8. I2C\_REGS Registers**

| Offset | Acronym | Register Name               | Write Protection | Section            |
|--------|---------|-----------------------------|------------------|--------------------|
| 0h     | I2COAR  | I2C Own address             |                  | <a href="#">Go</a> |
| 1h     | I2CIER  | I2C Interrupt Enable        |                  | <a href="#">Go</a> |
| 2h     | I2CSTR  | I2C Status                  |                  | <a href="#">Go</a> |
| 3h     | I2CCLKL | I2C Clock low-time divider  |                  | <a href="#">Go</a> |
| 4h     | I2CCLKH | I2C Clock high-time divider |                  | <a href="#">Go</a> |
| 5h     | I2CCNT  | I2C Data count              |                  | <a href="#">Go</a> |
| 6h     | I2CDRR  | I2C Data receive            |                  | <a href="#">Go</a> |
| 7h     | I2CSAR  | I2C Slave address           |                  | <a href="#">Go</a> |
| 8h     | I2CDXR  | I2C Data Transmit           |                  | <a href="#">Go</a> |
| 9h     | I2CMDR  | I2C Mode                    |                  | <a href="#">Go</a> |
| Ah     | I2CISRC | I2C Interrupt Source        |                  | <a href="#">Go</a> |
| Bh     | I2CEMDR | I2C Extended Mode           |                  | <a href="#">Go</a> |
| Ch     | I2CPSC  | I2C Prescaler               |                  | <a href="#">Go</a> |
| 20h    | I2CFFTX | I2C FIFO Transmit           |                  | <a href="#">Go</a> |
| 21h    | I2CFFRX | I2C FIFO Receive            |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 26-9 shows the codes that are used for access types in this section.

**Table 26-9. I2C\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |

**Table 26-9. I2C\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description   |
|-------------|------|---|
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 26.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0h]

I2COAR is shown in [Figure 26-20](#) and described in [Table 26-10](#).

Return to the [Summary Table](#).

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMR), only bits 6-0 are used write 0s to bits 9-7.

**Figure 26-20. I2COAR Register**

|          |    |    |    |    |    |        |   |

| 9-0   | OAR      | R/W  | 0h    | In 7-bit addressing mode (XA = 0 in I2CMR):<br>00h-7Fh Bits 6-0 provide the 7-bit slave address of the I2C module.<br>Write 0s to bits 9-7.<br>In 10-bit addressing mode (XA = 1 in I2CMR):<br>000h-3FFh Bits 9-0 provide the 10-bit slave address of the I2C module.<br>Reset type: SYSRSn |

### 26.7.2.2 I2CIER Register (Offset = 1h) [Reset = 0h]

I2CIER is shown in [Figure 26-21](#) and described in [Table 26-11](#).

Return to the [Summary Table](#).

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

**Figure 26-21. I2CIER Register**

|          |        |        |        |        |        |        |        |

This is diagnostic register which needs to be explicitly cleared by Software. In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions.<br>Reset type: SYSRSn<br>0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events:<br>- It is manually cleared. To clear this bit, write a 1 to it.<br>- The I2C module is reset.<br>1h (R/W) = The I2C module has completed the transmission of a byte.                        |

**Table 26-12. I2CSTR Register Field Descriptions (continued)**

| Bit | Field | Type  | Reset | Description  |
|-----|-------|-------|-------|--|
| 5   | SCD   | R/W1C | 0h    | <p>Stop condition detected bit.</p> <p>SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit.</li> <li>- SCD is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = A STOP condition has been detected on the I2C bus.</p>   |
| 4   | XRDY  | R     | 1h    | <p>Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data.</p> <p>FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSr). The CPU can poll XRDY or use the XRDY interrupt request. When in FIFO mode, use TXFFINT instead.</p> <p>FCM=1: XRDY is asserted only when next data is required it gets de asserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR.</p> <p>1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSr.</p> <p>XRDY is also forced to 1 when the I2C module is reset.</p>   |
| 3   | RRDY  | R/W1C | 0h    | <p>Receive-data-ready interrupt flag bit.</p> <p>When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request. When in FIFO mode, use RXFFINT instead.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.</li> <li>- RRDY is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.</p>  |
| 2   | ARDY  | R/W1C | 0h    | <p>Register-access-ready interrupt flag bit (only Applicable when the I2C module is in the master mode).</p> <p>ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- The I2C module starts using the current register contents.</li> <li>- ARDY is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = The registers are ready to be accessed.</p> <p>In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0).</p> <p>In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.</p> |

**Table 26-12. I2CSTR Register Field Descriptions (continued)**

| Bit | Field | Type  | Reset | Description  |
|-----|-------|-------|-------|--|
| 1   | NACK  | R/W1C | 0h    | <p>No-acknowledgment interrupt flag bit.</p> <p>NACK applies when the I2C module is a master transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK) from the slave receiver. The CPU can poll NACK or use the NACK interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- An acknowledge bit (ACK) has been sent by the slave receiver.</li> <li>- NACK is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received.</p> <p>Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment.</p>  |
| 0   | ARBL  | R/W1C | 0h    | <p>Arbitration-lost interrupt flag bit (only applicable when the I2C module is a master-transmitter).</p> <p>ARBL primarily indicates when the I2C module has lost an arbitration contest with another mastertransmitter. The CPU can poll ARBL or use the ARBL interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- AL is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an</li> </ul> <p>AL interrupt. Emulator reads of the I2CISRC do not affect this bit.</p> <ul style="list-style-type: none"> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = Arbitration lost. AL is set by any one of the following events:</p> <ul style="list-style-type: none"> <li>- The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously.</li> <li>- The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1.</li> </ul> <p>When AL becomes 1, the MST and STP bits of I2CMR are cleared, and the I2C module becomes a slave-receiver.</p> |

#### 26.7.2.4 I2CCLKL Register (Offset = 3h) [Reset = 0h]

I2CCLKL is shown in [Figure 26-23](#) and described in [Table 26-13](#).

Return to the [Summary Table](#).

See the Clock Divider Registers section of the Introduction for details.<br>Note: These bits must be set to a non-zero value for proper I2C clock generation.<br>Reset type: SYSRSn |

### 26.7.2.6 I2CCNT Register (Offset = 5h) [Reset = 0h]

I2CCNT is shown in [Figure 26-25](#) and described in [Table 26-15](#).

Return to the [Summary Table](#).

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a master receiver. In the repeat mode (RM = 1), I2CCNT is not used.

The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the master mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

**Figure 26-25. I2CCNT Register**

I2CCNT indicates the number of data bytes to transfer or receive.</p> <p>If a STOP condition is specified (STP=1) then I2CCNT will decrease after each byte is sent until it reaches zero, which in turn will generate a STOP condition.</p> <p>The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1.</p> <p>The start value loaded to the internal data counter is 65536.</p> <p>The start value loaded to internal data counter is 1-65535.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = data count value is 65536</p> <p>1h (R/W) = data count value is 1</p> <p>2h (R/W) = data count value is 2</p> <p>FFFFh (R/W) = data count value is 65535</p> |

### 26.7.2.7 I2CDRR Register (Offset = 6h) [Reset = 0h]

I2CDRR is shown in [Figure 26-26](#) and described in [Table 26-16](#).

Return to the [Summary Table](#).

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.

If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.

When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

**Figure 26-26. I2CDRR Register**

### 26.7.2.8 I2CSAR Register (Offset = 7h) [Reset = 3FFh]

I2CSAR is shown in [Figure 26-27](#) and described in [Table 26-17](#).

Return to the [Summary Table](#).

The I2C slave address register (I2CSAR) is a 16-bit register for storing the next slave address that will be transmitted by the I2C module when it is a master. The SAR field of I2CSAR contains a 7-bit or 10-bit slave address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a slave, or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used write 0s to bits 9-7.

### 26.7.2.9 I2CDXR Register (Offset = 8h) [Reset = 0h]

I2CDXR is shown in [Figure 26-28](#) and described in [Table 26-18](#).

Return to the [Summary Table](#).

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.

When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

**Table 26-19. I2CMR Register Field Descriptions**

| Bit | Field    | Type | Reset | Description  |
|-----|----------|------|-------|--|
| 15  | NACKMOD  | R/W  | 0h    | <p>NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the slave-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit.</p> <p>In the master-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit</p> <p>1h (R/W) = In either slave-receiver or master-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared.</p> <p>Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.</p> |
| 14  | FREE     | R/W  | 0h    | <p>This bit controls the action taken by the I2C module when a debugger breakpoint is encountered.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = When I2C module is master:<br/>If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops.</p> <p>When I2C module is slave:<br/>A breakpoint forces the I2C module to stop when the current transmission/reception is complete.</p> <p>1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.</p>   |
| 13  | STT      | R/W  | 0h    | <p>START condition bit (only applicable when the I2C module is a master). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the master mode, STT is automatically cleared after the START condition has been generated.</p> <p>1h (R/W) = In the master mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus</p>   |
| 12  | RESERVED | R    | 0h    | Reserved   |

**Table 26-19. I2CMDR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description  |
|-----|-------|------|-------|--|
| 11  | STP   | R/W  | 0h    | <p>STOP condition bit (only applicable when the I2C module is a master).</p> <p>In the master mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions.</p> <p>Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STP is automatically cleared after the STOP condition has been generated</p> <p>1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.</p> |
| 10  | MST   | R/W  | 0h    | <p>Master mode bit.</p> <p>MST determines whether the I2C module is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I2C master generates a STOP condition</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Slave mode. The I2C module is a slave and receives the serial clock from the master.</p> <p>1h (R/W) = Master mode. The I2C module is a master and generates the serial clock on the SCL pin.</p>  |
| 9   | TRX   | R/W  | 0h    | <p>Transmitter mode bit.</p> <p>When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin.</p> <p>1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.</p>  |
| 8   | XA    | R/W  | 0h    | <p>Expanded address enable bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit slave addresses (from bits 6-0 of I2CSAR), and its own slave address has 7 bits (bits 6-0 of I2COAR).</p> <p>1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit slave addresses (from bits 9-0 of I2CSAR), and its own slave address has 10 bits (bits 9-0 of I2COAR).</p>   |
| 7   | RM    | R/W  | 0h    | <p>Repeat mode bit (only applicable when the I2C module is a master-transmitter).</p> <p>The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module.</p> <p>1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.</p>   |

**Table 26-19. I2CMDR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description  |
|-----|-------|------|-------|--|
| 6   | DLB   | R/W  | 0h    | <p>Digital loopback mode bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Digital loopback mode is disabled.</p> <p>1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the MST bit must be 1.</p> <p>In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where:<br/> <math>n = ((I2C \text{ input clock frequency} / \text{module clock frequency}) \times 8)</math></p> <p>The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR.</p> <p>Note: The free data format (FDF = 1) is not supported in the digital loopback mode.</p>   |
| 5   | IRS   | R/W  | 0h    | <p>I2C module reset bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values.</p> <p>1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.</p>   |
| 4   | STB   | R/W  | 0h    | <p>START byte mode bit. This bit is only applicable when the I2C module is a master. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C module is a slave, it ignores a START byte from a master, regardless of the value of the STB bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module is not in the START byte mode.</p> <p>1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates:</p> <ol style="list-style-type: none"> <li>1. A START condition</li> <li>2. A START byte (0000 0001b)</li> <li>3. A dummy acknowledge clock pulse</li> <li>4. A repeated START condition</li> </ol> <p>Then, as normal, the I2C module sends the slave address that is in I2CSAR.</p> |
| 3   | FDF   | R/W  | 0h    | <p>Free data format mode bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit.</p> <p>1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5.</p> <p>The free data format is not supported in the digital loopback mode (DLB=1).</p>   |
| 2-0 | BC    | R/W  | 0h    | <p>Bit count bits.</p> <p>BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits.</p> <p>Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 8 bits per data byte</p> <p>1h (R/W) = 1 bit per data byte</p> <p>2h (R/W) = 2 bits per data byte</p> <p>3h (R/W) = 3 bits per data byte</p> <p>4h (R/W) = 4 bits per data byte</p> <p>5h (R/W) = 5 bits per data byte</p> <p>6h (R/W) = 6 bits per data byte</p> <p>7h (R/W) = 7 bits per data byte</p>  |

### 26.7.2.11 I2CISRC Register (Offset = Ah) [Reset = 0h]

I2CISRC is shown in [Figure 26-30](#) and described in [Table 26-20](#).

Return to the [Summary Table](#).

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

**Figure 26-30. I2CISRC Register**

### 26.7.2.13 I2CPSC Register (Offset = Ch) [Reset = 0h]

I2CPSC is shown in [Figure 26-32](#) and described in [Table 26-22](#).

Return to the [Summary Table](#).

The I2C prescaler register (I2CPSC) is a 16-bit register (see [Figure 14-21](#)) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.

IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

**Figure 26-32. I2CPSC Register**

|          |    |    |    |    |    |   |   |

**Table 26-23. I2CFFTX Register Field Descriptions (continued)**

| Bit | Field  | Type | Reset | Description  |
|-----|--------|------|-------|--|
| 4-0 | TXFFIL | R/W  | 0h    | <p>Transmit FIFO interrupt level.</p> <p>These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels.</p> <p>Reset type: SYSRSn</p> |

### 26.7.2.15 I2CFFRX Register (Offset = 21h) [Reset = 0h]

I2CFFRX is shown in [Figure 26-34](#) and described in [Table 26-24](#).

Return to the [Summary Table](#).

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

**Figure 26-34. I2CFFRX Register**

|          |            |          |        |      |    |   |   |  |

## 27.1 Introduction

The PMBus module provides an interface between the microcontroller and devices compliant with the SMI Forum PMBus Specification Part I version 1.0 and Part II version 1.1. The PMBus is based on SMBus, which uses a similar physical layer to the I2C. This chapter assumes you are familiar with the PMBus, SMBus, and I2C bus specifications.

### 27.1.1 PMBUS Related Collateral

#### Expert Materials

- [9 things you need to know about PMBus Point-of-Load Power \(Video\)](#)

### 27.1.2 Features

The PMBus module has the following features:

- Compliance with the SMI Forum PMBus Specification (Part I v1.0 and Part II v1.1)
- Support for master and slave modes
- Support for I2C modes
- Support for three speeds:
  - Standard Mode: Up to 100 kHz
  - Fast Mode: Up to 400 kHz
- Packet error checking
- CONTROL and ALERT signals
- Clock high and low time-outs
- Four-byte transmit and receive buffers
- One maskable interrupt, which can be generated by several conditions:
  - Receive data ready
  - Transmit buffer empty
  - Slave address received
  - End of message
  - ALERT input asserted
  - Clock low time-out
  - Clock high time-out
  - Bus free

### 27.1.3 Block Diagram

[Figure 27-1](#) shows the block diagram for PMBus. The PMBus module handles the lower levels of the PMBus protocol. In addition to controlling signal levels and timing, parsing addresses, and buffering data, it also directly supports complex transactions such as Read Word and Process Call.

There are four PMBus signals:

- **SCL** is the bus clock. It is normally controlled by the master, but may be held low by a slave to delay a transaction and allow more time for processing.
- **SDA** is the bidirectional data line.
- **CONTROL** is a slave input that can trigger an interrupt. It can be used to tell a slave device to shut down.

- **ALERT** is a slave output/master input that allows a slave to request attention from the master.

The SDA and SCL timings produced by the module are derived from SYSCLK. To comply with the PMBus timing specs, the bit clock divider must be set by way of the PMBTIMCLK register to provide a bit clock of 10 MHz or less.

Figure 27-1. PMBus Module Block Diagram

## 27.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification is set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups are configured in the GPyPUD register.

### Note

The GPIO configuration register GPyODR must be set to normal mode when the PMBus is used. The open-drain operation for PMBus is managed by the PMBus module

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 27.3 Slave Mode Operation

This section describes the configuration and operation of the PMBus module in slave mode.

### 27.3.1 Configuration

To configure the module, write a suitable clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10 MHz. To activate slave mode, set the SLAVE\_EN bit in the PMBCTRL register. Next, set up the PMBSC register. The following options are configurable:

- Slave address and mask (SLAVE\_ADDR and SLAVE\_MASK): Sets the slave address and mask for message acceptance.

- Manual slave address acknowledgement (MAN\_SLAVE\_ACK): When enabled, allows software to decide whether to acknowledge (ACK) an address. When disabled, the decision to ACK is made automatically based on the slave address and mask.
- PEC enable (PEC\_ENA): Set this bit if Packet Error Checking (PEC) is used on the bus.
- Manual command byte acknowledgement (MAN\_CMD): Similar to manual slave acknowledgement, setting this bit allows software to decide whether to acknowledge (ACK) a command byte.
- Number of bytes to acknowledge automatically (RX\_BYTE\_ACK\_CNT): This is normally set to the max value, which allows the entire receive buffer to be used. However, smaller values may be used if the application requires that erroneous messages be detected and not acknowledged (NACKed) as soon as possible.

Manual acknowledgement is done by writing a one to the PMBACK register. Even with automatic acknowledgement, some writes to PMBACK are required. If the message (not including the address) is longer than 4 bytes, each packet of 4 bytes must be acknowledged. The PMBus module will stretch the clock (hold it low) until an ACK is issued. The module will then pull the data line low and release the clock, providing the ACK signal to the master.

If the complete message or the last part of the message is less than 4 bytes (or the RX\_BYTE\_ACK\_CNT limit), do not write to PMBACK.

Writing a zero to the PMBACK bit will send a NACK. This may only be done when the module is waiting for an acknowledgement. If a zero is written at any other time, the NACK will be issued during the next message.

### 27.3.2 Message Handling

This section describes some of the message types for PMBus and how to determine which message type is being received in slave mode. It is oriented toward the most efficient mode of operation – with automatic address and command acknowledgement. It is also oriented toward having Packet Error Checking (PEC) enabled.

If automatic address acknowledgement is disabled, all messages will start by setting the SLAVE\_ADDR\_READY register bit high. Read commands will have two instructions one for the read, and one for the write. If automatic command acknowledgement is enabled, the DATA\_READY bit will be set high, as well. If the message has no PEC, the number of bytes available will be n-1. For example, with PEC, a QUICK COMMAND will have one byte. With no PEC, a QUICK COMMAND will have zero bytes.

Note that the byte count does not increment as bytes arrive. No bits are set in the PMBST register until a stop message is received, the receive buffer is full, or a fault occurs. Then, all appropriate bit values are placed in the register together. All that is necessary to receive a quick command is to ACK the message by writing a one to the PMBACK register.

#### 27.3.2.1 Quick Command

Quick Commands (Figure 27-2) received by the PMBus module in slave mode require a simple acknowledgment of the received device address. In automatic address acknowledge mode, the module processes the quick command without firmware interaction. Upon receipt of the end of message, the firmware has the option to read the received address in the PMB\_HSA register. In manual address acknowledge mode, the address is acknowledged by writing to the PMBACK register.

**Figure 27-2. Quick Command Message**

### 27.3.2.2 Send Byte

A Send Byte message (Figure 27-3) consists of the device address, a single data byte, and an optional PEC byte. To process the PEC byte correctly, PEC processing must be enabled in the PMBSC register. In automatic address acknowledge mode, the data and optional PEC byte are acknowledged without firmware interaction. The module generates an End of Message interrupt, reads the status register and finds the data ready indication bit set. In manual mode, the address is acknowledged by the firmware, while the remaining data and PEC bytes are acknowledged by the module.

The PMBus module stores Data Byte #0 into the PMBRXBUF register. The data byte will be stored into bits 7-0. In non-PEC mode, the RX Byte Count in the PMBSTS register will indicate one byte received. If PEC processing is enabled, the PEC byte is also stored into the PMBRXBUF register, with the PEC byte residing in bits 15-8. The RX Byte Count in the PMBSTS register will indicate two bytes received. The PEC Valid bit in the PMBSTS register indicates the validity of the received PEC byte.

When a Send Byte message is received, the Data Ready bit is set along with the EOM and, assuming that the PEC is valid, the PEC valid bit. The read byte count (RD\_BYTE\_COUNT) register will contain a 2. All that is necessary to receive a send byte command is to ACK the message by writing a 1 to the PMBACK register. Before doing the ACK, read the byte from the lowest byte of the PMBRXBUF register.

**Figure 27-3. Send Byte Message With and Without PEC**

### 27.3.2.3 Receive Byte

A Receive Byte message (Figure 27-4) consists of the device address, a single data byte, and an optional PEC byte. In automatic address acknowledge mode, the firmware receives a data request interrupt following reception of the slave address. The data byte to be sent to the master is stored into bits 7-0 of the PMBTXBUF register and Transmit Byte Count bits within the PMBSC register are set to a value of 1. If PEC processing is enabled, the Transmit PEC bit (bit 19) within the PMBSC register is set to 1, along with the Enable PEC bit (bit 15). The module automatically appends the calculated PEC byte at the completion of the message.

**Figure 27-4. Receive Byte Message With and Without PEC**

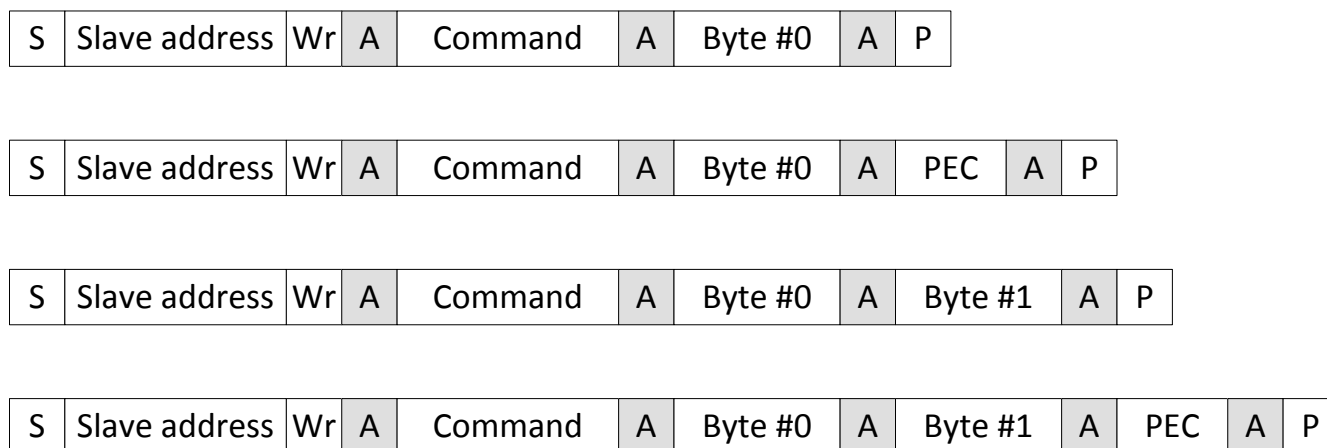

### 27.3.2.4 Write Byte/Word

The Write Byte and Write Word messages (Figure 27-5) consist of a slave address, a command word, transmitted data bytes and an optional PEC byte. In automatic address acknowledge mode, the data bytes and optional PEC byte are acknowledged without firmware interaction. The acknowledgment of the command word is configured through the PMBSC register. The firmware receives an End of Message interrupt in all cases except for Write Word with PEC message, reads the status register and finds the data ready indication bit set.

In the case of a Write Word with PEC byte message, the data ready interrupt is enabled after receiving 4 bytes (command byte, the 2 data bytes and the PEC byte). The firmware reads the data from the PMBRXBUF register and must write the PMBACK register to acknowledge back to the master. The PMBus module holds SCL low until the firmware responds to the received data.

In all other cases, the EOM interrupt is received and data can be read from the PMBRXBUF register. The firmware is not required to send an acknowledgement back to the master.

The Write Byte message will look exactly the same as the Send Byte, except the RD\_BYTE\_COUNT register will contain a 3. The Write Word message will have a RD\_BYTE\_COUNT of 4.

**Figure 27-5. Write Byte and Write Word Messages With and Without PEC**

### 27.3.2.5 Read Byte/Word

The Read Byte and Read Word messages (Figure 27-6) consist of a slave address, a command word, received data bytes from a slave, and an optional PEC byte. Address and command acknowledgment is configured through the PMBSC register. In automatic mode, the PMBus module provides a data ready and data request interrupt following receipt of a repeated start and slave address. The received command byte is found in bits 7-0 of the PMBRXBUF register. The firmware responds to the data request by programming the data bytes into the PMBTXBUF register and the TX Byte Count bits in the PMBSC register. If PEC processing is enabled, the Transmit PEC bit should also be asserted. An EOM interrupt indicates completion of the message to the Master.

When the repeated start (Sr) signal is received, the Data Ready bit will be asserted with a RD\_BYTE\_COUNT of 1. At this point, the operation cannot be distinguished from a group command Send Byte message. When the same device address is sent out with a read, the Data Request bit will be asserted. If data has already been written to the PMTXBUF register before the Device Addr is received, the Data Request bit will not be asserted. So if group commands are also expected, it is necessary to read the Data Ready with a RD\_BYTE\_COUNT of 1, and then wait and see whether the next event is an EOM or a Data Request. If it is an EOM, the command should be processed as a group send byte. If it is a Data Request, the command should be processed as a read. Depending on the command, it could be a read byte, word, or block. If the PMBus module is polled, both the Data Ready and the Data Request bits could possibly be set between polling intervals. This should be considered in the design of the firmware.

Once the read command is recognized, you must respond by writing data to the PMBTXBUF register. It is also necessary to make sure that the values in the PMBSC register are correct. The transmit byte count and PEC bit must be set appropriately. For a read byte, the transmit byte count can be loaded with a 1. If the transmission of a PEC byte is desired, the TX\_PEC bit must be set. After this, the data can be written to PMBTXBUF, which starts the transmission. All bytes should be written to PMBTXBUF at the same time. After the master receives the message, it will NACK the last byte to indicate that the correct number of bytes have been received. This will cause the EOM bit to be set in the PMBSTS register, indicating to the firmware that the Read Byte message is complete.

Figure 27-6. Read Byte and Read Word Messages With and Without PEC

### 27.3.2.6 Process Call

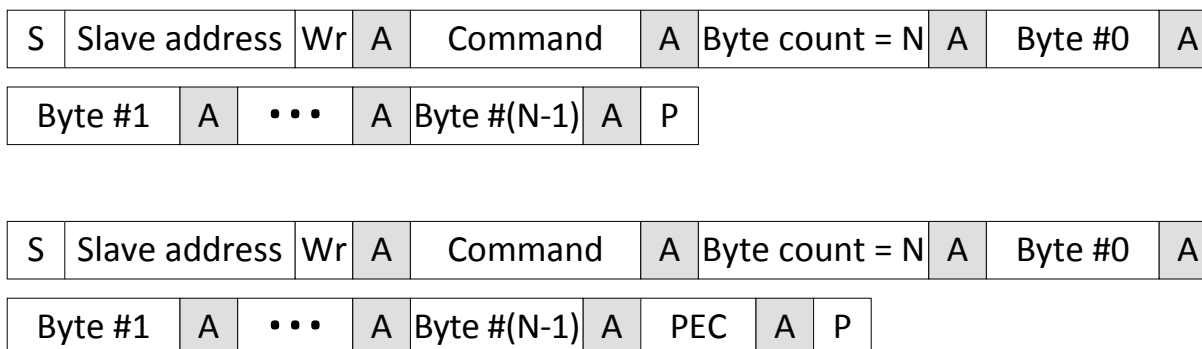

The Process Call (Figure 27-7) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. Address and command acknowledgement is configured through the PMBSC register. In automatic mode, following receipt of the repeated start and slave address, the PMBus module provides a data ready and a data request interrupt. The repeated start bit is set in the PMBSTS register to indicate the receipt of the first part of the Process Call message. The received command byte is found in bits 7-0 of the PMBRXBUF register, while the two data bytes received from the master can be found in bits 23-8. Upon receipt of the repeated start and a data request from the module, the firmware programs the PMBTXBUF with the 2 data bytes to be sent to the master. If PEC processing is enabled, the Transmit PEC bit within the PMBSC register is asserted. The EOM interrupt will indicate the read word portion of the Process Call message has been completed by the module.

**Figure 27-7. Process Call Message With and Without PEC**

### 27.3.2.7 Block Write

The Block Write (Figure 27-8) protocol is similar to Write Word in its structure, except that there are more than 2 data bytes in the message. Following the receipt of the command byte, the block length and 2 data bytes, the PMBus module provides a data ready interrupt. The module waits for the firmware to read the received data and program the acknowledge register. While waiting for an ACK from the firmware, the module will drive the clock line low, stalling the bus. The data ready interrupts will continue for the duration of the message at a frequency of every 4 data bytes. The number of bytes received can be found within the PMBSTS register. At the end of the message, less than 4 bytes may be stored in the PMBRXBUF register. The PEC Valid bit can be checked to determine if the received PEC value is accurate.

**Figure 27-8. Block Write Message With and Without PEC**

### 27.3.2.8 Block Read

The Block Read (Figure 27-9) protocol is similar to a Read Word in its structure, except that there are more than 2 data bytes in the message. Following the receipt of the repeated slave address, a data ready and data request interrupt is generated by the PMBus module. The command byte received from the master can be found in bits 7-0 of the PMBRXBUF register. The SCL line is held low until the firmware programs data bytes into the PMBTXBUF register. The firmware is required to load the block length into bits 7-0 of the PMBTXBUF register during the initial programming of the register. After 4 bytes have been transmitted, the module will issue a data request interrupt and hold SCL low again until the firmware has programmed additional data into the PMBTXBUF register.

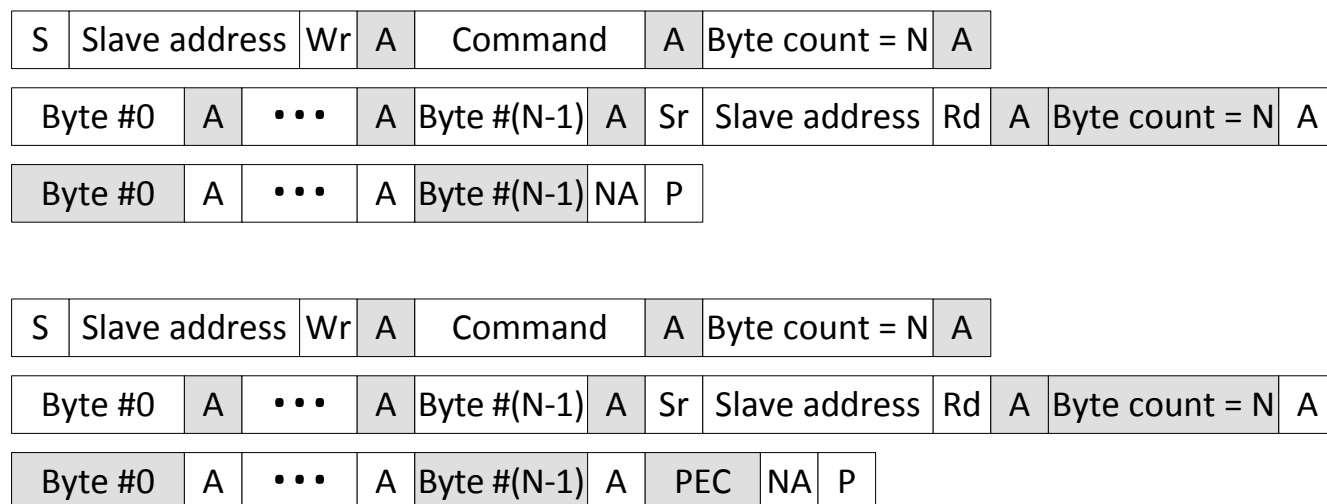

Block read starts the same as Read Word or Read Byte, but TX\_COUNT is loaded with a 4 the first time, and TX\_PEC is not set. Instead of waiting for an EOM after the first transmission, the firmware instead waits for a Data Request, indicating that the master is ready for more data. Until the last 4 or less bytes, the firmware simply writes a 4 to TX\_COUNT and then writes the 4 bytes to PMBTXBUF. TX\_PEC is left cleared. Then when the last 4 or fewer bytes are to be transmitted, the firmware writes out the appropriate byte count, sets the TX\_PEC bit, and writes the data to PMBTXBUF. The PMBus module will write out the data, followed by the PEC, and then the EOM bit will be set when the master NACKs the PEC.

**Figure 27-9. Block Read Message With and Without PEC**

### 27.3.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 27-10) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The processing of the Block Read-Block Write Process Call message is similar to the mode of operation for the Process Call message. After acknowledgement of the address and command bytes, the PMBus module generates a data ready interrupt upon detection of 4 data bytes or a repeated start condition. After receiving the repeated start, the firmware will be required to load transmit data to send to the master. Bits 7-0 of the initial programming of the PMBTXBUF register must represent the byte count of the block data sent to the master.

**Figure 27-10. Block Write-Block Read Process Call Message With and Without PEC**

### 27.3.2.10 Alert Response

The Alert Response Message (Figure 27-11) is utilized when the master detects an alert condition from a slave on the PMBus. In automatic address acknowledge mode, upon detection of the Alert Response Address, the PMBus module provides an acknowledgement to the master and sends the programmed slave address within the PMBSC register. The module only responds to the message if the Alert En bit within PMBCTRL register has been previously set. After receiving the Alert Response message, the module will clear the alert condition and enable bit within the PMBCTRL register.

In manual address acknowledge mode, the firmware must read the received address from the PMBRXBUF register and transmit the desired slave address back to the master. The PMBCTRL register must be reprogrammed to disable the Alert En bit used to initiate the Alert Response message from the master.

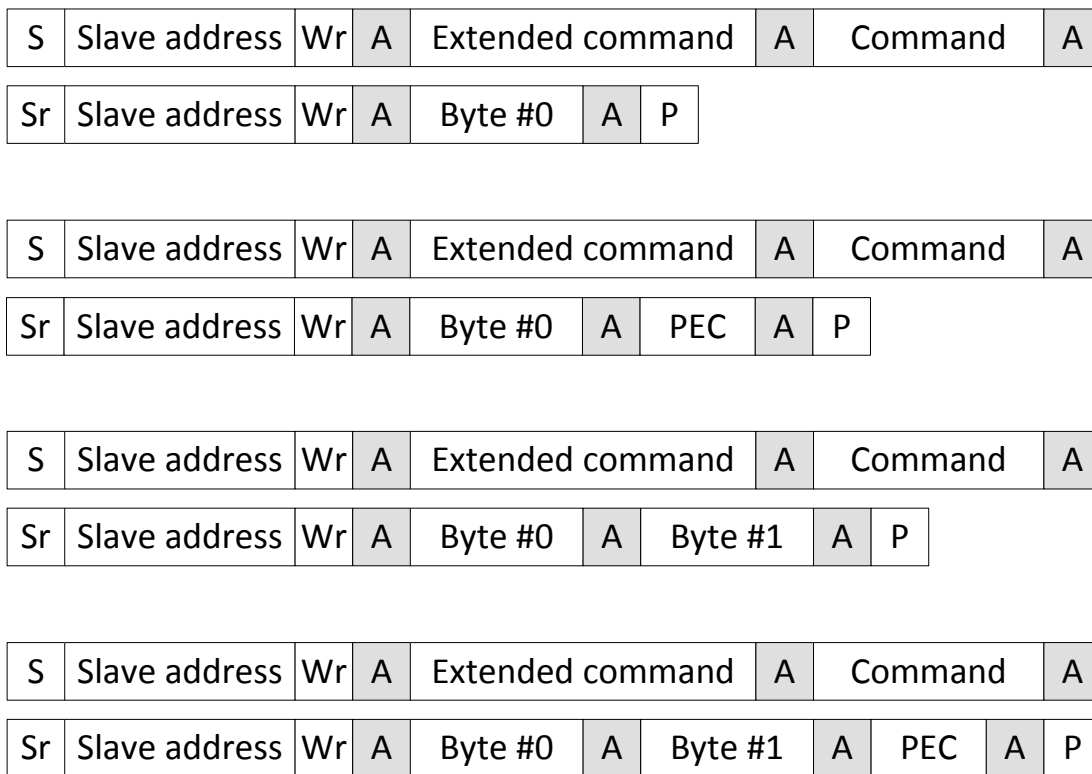

**Figure 27-11. Alert Response Message**

**27.3.2.11 Extended Command**

The PMBus module provides support for extended commands that allow for an extra 256 command codes. Both command bytes are stored in the PMBRXBUF register along with the data bytes. In recognizing the extended command messages, the Repeated Start bit and the Rd Byte Count Bits within the PMBSTS register are utilized. For Extended Command Write Byte/Write Word messages (Figure 27-12), the two command bytes are stored in bits 15-0 of the PMBRXBUF register. The initial command byte should hold the command extension code, representing utilization of the extended command protocol. The Repeated Start bit is also set, received after the retransmission of the device address. The Rd Byte Count equals 3 for an Ext Cmd Write Byte message and 4 for an Ext Cmd Write Word message.

For the Extended Command Read Byte/Read Word messages (Figure 27-13), the module will generate a data ready and data request interrupt following reception of the repeated device address. The two command bytes will be found in bits 15-0 of the PMBRXBUF register, with the initial command byte matching the command extension code. The firmware will be required to load transmit data to complete the message back to the master.

**Figure 27-12. Extended Command Write Byte and Write Word Messages With and Without PEC**

**Figure 27-13. Extended Command Read Byte and Read Word Messages With and Without PEC**

### 27.3.2.12 Group Command

The PMBus module supports the Group Command protocol. The Group Command (Figure 27-14) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. Following address and command acknowledgment, the module provides a data ready interrupt upon detection of 4 data bytes or the transmission of a repeated start on the bus. The firmware should wait for the EOM interrupt before processing the received command, as required by the use of the Group Command message.

For Group Commands, the data ready bit will be set as soon as the repeated start is received. The data can then be read into memory. But the data should not be acted upon until the EOM bit is set, which will occur when all of the messages have been received. Other than this delayed EOM, there is no difference for the slave firmware in receiving a Group Command than any other write message.

Figure 27-14. Group Command Message With and Without PEC

## 27.4 Master Mode Operation

This section describes the configuration and operation of the PMBus module in master mode.

### 27.4.1 Configuration

First, write a suitable clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10 MHz. To activate master mode, set the MASTER\_EN bit and clear the SLAVE\_EN bit in the PMBCTRL register. For each transaction, set up the PMBMC register. The following options are configurable:

- Slave address (SLAVE\_ADDR): Sets the slave address for the next transaction.
- PEC enable (PEC\_ENA): If Packet Error Checking (PEC) is used on the bus, set this bit.
- Extended command code enable (EXT\_CMD): When set, uses two bytes for commands.
- Command code enable (CMD\_ENA): When set, sends a command byte at the start of the transaction.
- Byte count (BYTE\_COUNT): Determines the number of data bytes to transfer. This does not include the block length byte, which is generated automatically when needed.
- Special command enables (GRP\_CMD and PRC\_CALL): Enables special behavior for group commands and process calls.

Writing to the PMBMC register will start a transfer.

Manual acknowledgement of received data is not needed.

### 27.4.2 Message Handling

This section describes the behavior and required configuration for each command type.

#### 27.4.2.1 Quick Command

Quick commands (Figure 27-15) are initiated in master mode by simply programming the desired slave device address into the PMBMC. The byte count within the PMBMC register is configured to 0 bytes by writing all zeros to bits 15-8. Upon transmission of the device address, the PMBus module will monitor the slave acknowledgement of the address. If the address is not acknowledged, the NACK bit within the status register is enabled and the PMBus module automatically sends a stop condition on the bus to terminate the message. If the address is acknowledged, a data request is issued to the processor. The firmware writes a zero to the PMBACK to terminate the message, forcing the PMBus modules to write a stop condition onto the bus.

**Figure 27-15. Quick Command Message**

### 27.4.2.2 Send Byte

A Send Byte message (Figure 27-16) consists of the device address, a single data byte, and an optional PEC byte. To initiate a Send Byte message, the data byte to be transmitted to the slave is loaded into bits 7-0 of the PMBTXBUF register. The PMBMC register is configured with the device address. To transmit a PEC byte with the message, the PEC\_EN bit within the PMBMC register is asserted high when the address is programmed.

After programming the PMBMC register, the PMBus module transmits the Send Byte message. The firmware can wait for an End of Message interrupt from the PMBus module. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify the slave properly acknowledged the transmitted data.

**Figure 27-16. Send Byte Message With and Without PEC**

### 27.4.2.3 Receive Byte

A Receive Byte message (Figure 27-17) consists of the device address, a single data byte, and an optional PEC byte. Data is being read from the slave in a Receive Byte message. To initiate a Receive Byte message, the firmware programs the device address, the R/W bit and the optional PEC\_EN into the PMBMC register. The R/W bit is enabled high to indicate a read message type (data transmitted from slave to master).

After programming the PMBMC register, the PMBus module transmits the Receive Byte message. The firmware can wait for an End of Message interrupt from the PMBus module to verify the accuracy of the message transmission. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify proper slave acknowledgement of the device address and to determine if any data is available for reading in the PMBRXBUF register. If PEC\_EN was asserted in the PMBMC register, the PEC\_VALID bit in the PMBSTS register is also checked to ensure a proper PEC byte was received from the slave with the received data.

**Figure 27-17. Receive Byte Message With and Without PEC**

#### 27.4.2.4 Write Byte/Word

The Write Byte and Write Word messages (Figure 27-18) consist of a device address, a command byte, transmitted data bytes, and an optional PEC byte. Write Byte messages include a single byte, while the Write Word messages support transmission of 2 bytes to the corresponding slave module. Similar to the Send Byte protocol, the PMBMC register is configured to send 1 or 2 bytes, the CMD\_EN bit is set to enable command byte transmission and the optional PEC\_EN bit is set.

With the command byte transmission enabled, the format of the PMBTXBUF register differs from the Send Byte protocol. In bits 7-0, the firmware must program the command byte to be sent to the slave. The data byte(s) are programmed into bits 15-8 and bits 23-16.

After programming the PMBMC register, the PMBus module transmits the Write Byte/Word message. The firmware can wait for an End of Message interrupt from the module to verify the accuracy of the message transmission. The PMBSTS register indicates if the slave acknowledged the message properly.

**Figure 27-18. Write Byte and Write Word Messages With and Without PEC**

### 27.4.2.5 Read Byte/Word

The Read Byte and Read Word messages (Figure 27-19) consist of a device address, a command byte, received data bytes from a slave, and an optional PEC byte. Read Byte messages include a single byte, while the Read Word message protocol supports receipt of 2 bytes from the slave. Similar to the Receive Byte Protocol, the PMBMC register is configured to receive 1 or 2 bytes, the CMD\_EN bit is set and the PEC\_EN is configured to expect or not expect a PEC byte appended to the message. The PMBus module will automatically terminate the message after the expected number of bytes is received from the slave or if the slave does not properly acknowledge any portion of the message.

In addition to programming the PMBMC register, the firmware is expected to load the command byte into bits 7-0 of the PMBTXBUF register. Any data received from the slave will be found in the PMBRXBUF register.

**Figure 27-19. Read Byte and Read Word Messages With and Without PEC**

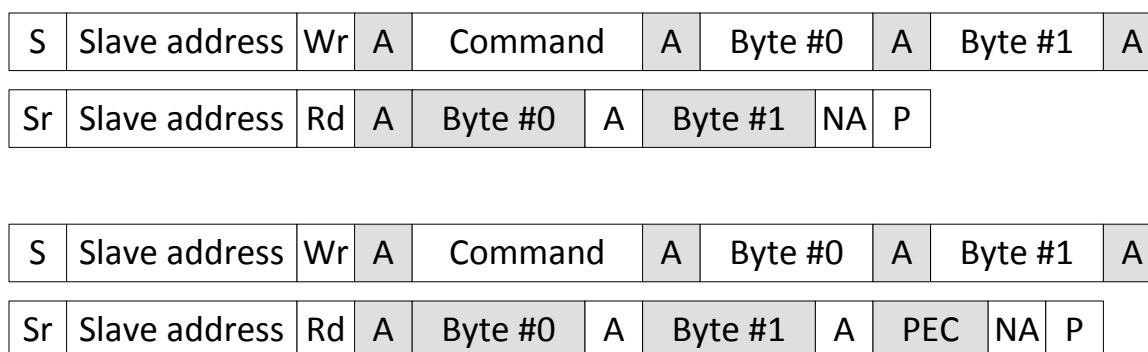

### 27.4.2.6 Process Call

The Process Call (Figure 27-20) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. A PEC byte can be appended to the read data from the slave as an option to the message protocol. The PMBMC register includes a PRC\_CALL bit, which enables the transmission of a Process Call message onto the PMBus. The PMBus module will automatically generate a repeated start condition and initiate the Read Word portion of the message when the process call bit is enabled.

To complete the Write Word portion of the Process Call, the PMBTXBUF register is loaded with the command byte in bits 7-0 and the data bytes are loaded into bits 23-8 of the register.

After programming the PMBMC register, the PMBus module transmits the Process Call Message. The firmware can wait for an End of Message interrupt from the module to determine the validity of the message. Upon the receipt of the EOM, the PMBSTS register should indicate the receipt of 2 bytes from the Read Word portion of the Process Call message and the status of the Slave acknowledgment of the transmit data. If PEC processing is enabled, the PEC\_VAL bit within the PMBSTS register indicates the accuracy of the PEC byte received from the slave during the Read Word part of the message.

The PRC\_CALL bit within the PMBMC register must be disabled for the next non-Process Call message. Please note that any write to the PMBMC register initiates a message, so reconfiguration of the master is not recommended until the firmware requires a new message to be transmitted.

**Figure 27-20. Process Call Message With and Without PEC**

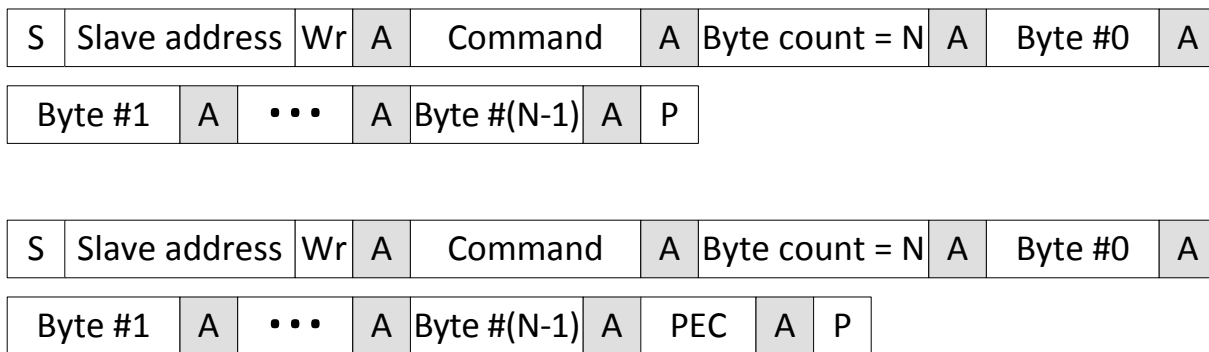

### 27.4.2.7 Block Write

The Block Write (Figure 27-21) protocol is similar to a Write Word in its structure, with the exception of transmission of more than 2 data bytes in the message. Additionally, the first data byte following the command byte specifies the length of the block of data bytes. As with a majority of the message protocols, the PEC byte can be appended to the end of the write data to the slave.

To initiate a Block Write message on the bus, the PMBMC register is programmed with the block length in the Byte Count bits. The block length is the number of data bytes, excluding the command byte and the first data byte that contains the block length. The PMBus module will automatically insert the block length into the message if the number of data bytes specified by the firmware exceeds 2. The initial write data is loaded into the PMBTXBUF register. With bits 7-0 representing the command byte, the remaining 3 bytes represent the first three data bytes following the block length.

Following programming of the PMBMC register, the Block Write message is transmitted. If the block length exceeds three bytes, the PMBus module will provide a data request interrupt, indicating the need for additional data bytes in the PMBTXBUF register. The PMBus module assumes that if more than 4 bytes are needed to complete the message, the firmware will utilize all 4 bytes when programming the PMBTXBUF register. If less than 4 bytes are needed to finish the Block Write message, the firmware only needs to program the appropriate bits of the PMBTXBUF register.

Upon completion of the message, the PMBus module issues an EOM interrupt. The PMBSTS register can be checked to verify the slave accepted the block of write data.

**Figure 27-21. Block Write Message With and Without PEC**

### 27.4.2.8 Block Read

The Block Read (Figure 27-22) protocol is similar to a Read Word in its structure, with the exception that there are more than 2 data bytes received from the slave. The first data byte transmitted by the slave represents the block length of the data being written by the slave. If PEC processing is enabled, the slave appends a PEC byte to the end of the message.

To initiate a Block Read message on the PMBus, the PMBMC register is programmed with the block length in the Byte Count bits. This count excludes the command byte, any slave address and the block length bytes in the message. The command byte to be transmitted to the slave is written into bits 7-0 of the PMBTXBUF register prior to the programming of the PMBMC register.

After configuring the PMBMC register, the Block Read message is transmitted. The module interrupts the firmware upon receipt of 4 data bytes from the slave. If the block length is 3, the EOM interrupt will be received concurrently with the data ready interrupt. Otherwise, only a data ready interrupt is asserted, indicating 4 bytes are ready for reading by the firmware. At the end of the message, less than 4 bytes may be stored in the PMBRXBUF register. The RX Byte Count bits in the PMBSTS register indicate the number of bytes available in the final data transfer. The firmware may verify the received PEC upon detection of the End of Message interrupt.

**Figure 27-22. Block Read Message With and Without PEC**

### 27.4.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 27-23) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The operation of the master is similar to a Block Write operation. Loading the block length into the byte count bits of the PMBMC register provides the length of the Block Write portion of the message. In addition, the PRC\_CALL bit within the PMBMC register must be enabled. Upon completion of the Block Write part of the message, the PMBus module will automatically issue a Repeated Start condition on the PMBus and start transmission of the Block Read portion of the message. Operation of the PMBus module after the Repeated Start condition is the same as it would be in a simple Block Read Message.

**Figure 27-23. Block Write-Block Read Process Call Message With and Without PEC**

### 27.4.2.10 Alert Response

The Alert Response Message (Figure 27-24) is utilized when the master detects an alert condition from a slave. In master mode, the Alert Response Message is simply a Receive Byte message with PEC disabled and the slave address set to 0xC (Alert Response address). The PMBus module detects the alert condition on an input and interrupts the firmware indicating the assertion of an alert condition (slave desires to communicate with master). Programming the PMBMC register with the Alert Response address initiates the Alert Response message and provides the device address of the slave requesting service. The device address will be found in the PMBRXBUF register following receipt of the EOM interrupt.

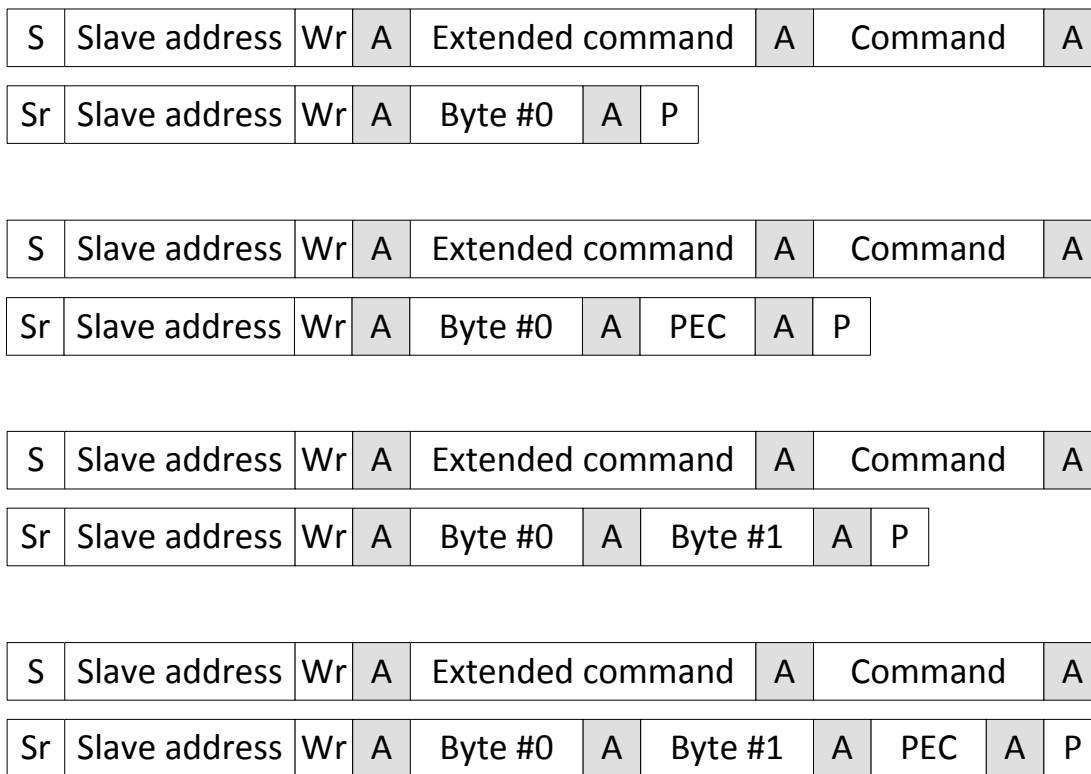

**Figure 27-24. Alert Response Message**

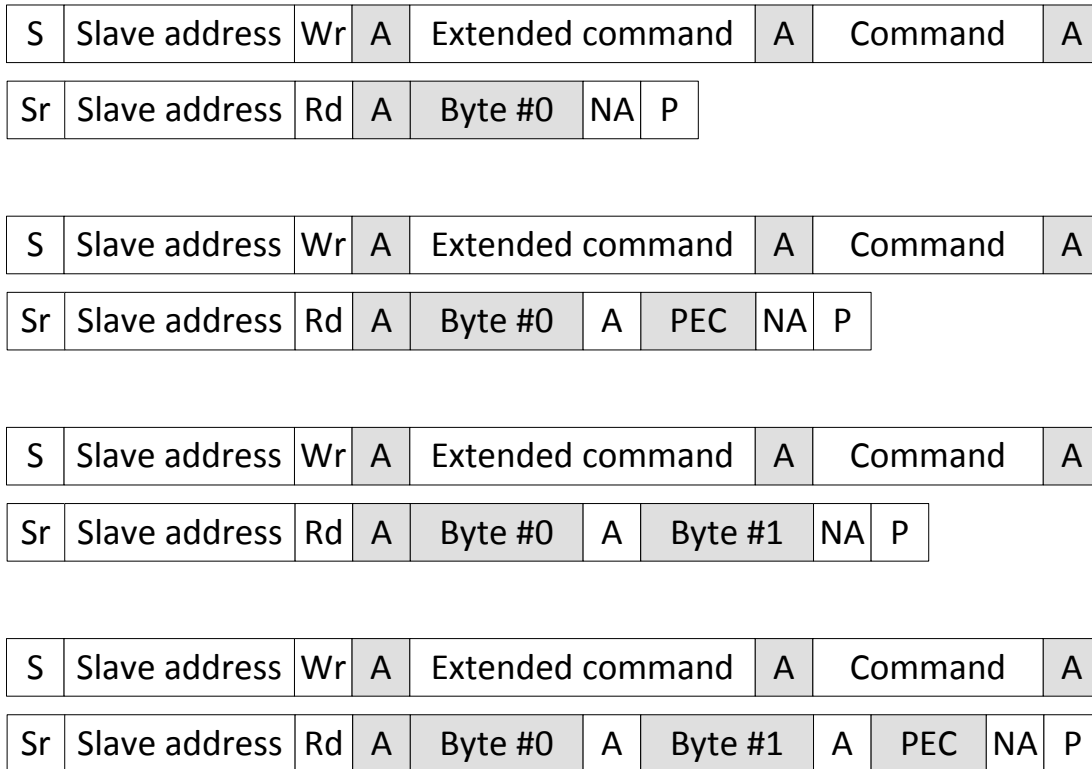

### 27.4.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. By asserting the EXT\_CMD bit within the PMBMC register, two command bytes are transmitted on the message protocol. Extended commands can be added to the Write Byte and Write Word (Figure 27-25) and the Read Byte and Read Word (Figure 27-26) protocols. Operation of the PMBus module in extended command mode is similar to these formats. In programming the write data or first part of the read message, the second command byte is loaded into bits 15-8 of the PMBTXBUF register with the remaining data bytes. The remaining operation of the module is identical to the previous protocols, except for the inclusion of a Repeated Start condition and slave address in the write messages. No support is required by firmware for these additional bytes in the write messages. The module will interpret the EXT\_CMD bit and make the appropriate format changes.

**Figure 27-25. Extended Command Write Byte and Write Word Messages With and Without PEC**

**Figure 27-26. Extended Command Read Byte and Read Word Messages With and Without PEC**

### 27.4.2.12 Group Command

The Group Command (Figure 27-27) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. To initiate a Group Command, the GRP\_CMD bit within the PMBMC register must be set when programming the slave address for the first device in the message. The rest of the message is processed as a write byte/word message. At the conclusion of the first part of the Group Command message, the firmware programs the next device address in the PMBMC register. The PMBus module will send a repeated start on the bus and begin the next part of the message. When programming the last device address of the Group Command message, the firmware must disable the GRP\_CMD bit when programming the PMBMC register.

Figure 27-27. Group Command Message With and Without PEC

## 27.5 PMBus Registers

This section describes the Power-Management Bus module Registers.

### 27.5.1 PMBUS Base Address Table

Table 27-1. PMBUS Base Address Table

| Bit Field Name |            | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|------------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure  |                |              |      |     |     |     |                    |
| PmbusaRegs     | PMBUS_REGS | PMBUSA_BASE    | 0x0000_6400  | YES  | YES | YES | YES | YES                |

## 27.5.2 PMBUS\_REGS Registers

Table 27-2 lists the memory-mapped registers for the PMBUS\_REGS registers. All register offset addresses not listed in Table 27-2 should be considered as reserved locations and the register contents should not be modified.

**Table 27-2. PMBUS\_REGS Registers**

| Offset | Acronym           | Register Name                           | Write Protection | Section            |
|--------|-------------------|---|------------------|--------------------|
| 0h     | PMBMC             | PMBUS Master Mode Control Register      | EALLOW           | <a href="#">Go</a> |
| 2h     | PMBTXBUF          | PMBUS Transmit Buffer                   |                  | <a href="#">Go</a> |
| 4h     | PMBRXBUF          | PMBUS Receive buffer                    |                  | <a href="#">Go</a> |
| 6h     | PMBACK            | PMBUS Acknowledge Register              |                  | <a href="#">Go</a> |
| 8h     | PMBSTS            | PMBUS Status Register                   |                  | <a href="#">Go</a> |
| Ah     | PMBINTM           | PMBUS Interrupt Mask Register           | EALLOW           | <a href="#">Go</a> |
| Ch     | PMBSC             | PMBUS Slave Mode Configuration Register | EALLOW           | <a href="#">Go</a> |
| Eh     | PMBHSA            | PMBUS Hold Slave Address Register       |                  | <a href="#">Go</a> |
| 10h    | PMBCTRL           | PMBUS Control Register                  | EALLOW           | <a href="#">Go</a> |
| 12h    | PMBTIMCTL         | PMBUS Timing Control Register           | EALLOW           | <a href="#">Go</a> |
| 14h    | PMBTIMCLK         | PMBUS Clock Timing Register             | EALLOW           | <a href="#">Go</a> |
| 16h    | PMBTIMSTSETUP     | PMBUS Start Setup Time Register         | EALLOW           | <a href="#">Go</a> |
| 18h    | PMBTIMBIDLE       | PMBUS Bus Idle Time Register            | EALLOW           | <a href="#">Go</a> |
| 1Ah    | PMBTIMLOWTIMEOUT  | PMBUS Clock Low Timeout Value Register  | EALLOW           | <a href="#">Go</a> |
| 1Ch    | PMBTIMHIGHTIMEOUT | PMBUS Clock High Timeout Value Register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 27-3 shows the codes that are used for access types in this section.

**Table 27-3. PMBUS\_REGS Access Type Codes**

| Access Type              | Code   | Description  |
|--------------------------|--------|--|
| Read Type                |        |  |
| R                        | R      | Read   |
| RC                       | R<br>C | Read<br>to Clear   |
| Write Type               |        |  |
| W                        | W      | Write  |
| Reset or Default Value   |        |  |
| -n                       |        | Value after reset or the default value   |
| Register Array Variables |        |  |
| i,j,k,l,m,n              |        | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |        | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 27.5.2.1 PMBMC Register (Offset = 0h) [Reset = 0h]

PMBMC is shown in [Figure 27-28](#) and described in [Table 27-4](#).

Return to the [Summary Table](#).

PMBUS Master Mode Control Register

**Figure 27-28. PMBMC Register**

|            |    |    |          |         |         |         |         |

**Table 27-10. PMBSC Register Field Descriptions**

| Bit   | Field           | Type | Reset | Description  |
|-------|-----------------|------|-------|--|
| 31-23 | RESERVED        | R    | 0h    | Reserved   |
| 22-21 | RX_BYTE_ACK_CNT | R/W  | 3h    | Configures number of data bytes to automatically acknowledge when receiving data in slave mode.<br>00 = 1 byte received by slave. Firmware is required to manually acknowledge every received byte.<br>01 = 2 bytes received by slave. Hardware automatically acknowledges the first received byte. Firmware is required to manually acknowledge after the second received byte.<br>10 = 3 bytes received by slave. Hardware automatically acknowledges the first 2 received bytes. Firmware is required to manually acknowledge after the third received byte.<br>11 = 4 bytes received by slave. Hardware automatically acknowledges the first 3 received bytes. Firmware is required to manually acknowledge after the fourth received byte<br>Reset type: SYSRSn |
| 20    | MAN_CMD         | R/W  | 0h    | 0 = Slave automatically acknowledges received command code<br>1 = Data Request flag generated after receipt of command code, firmware required to issue ACK to continue message<br>Reset type: SYSRSn  |
| 19    | TX_PEC          | R/W  | 0h    | Asserted when the slave needs to send a PEC byte at end of message.<br>PMBus Interface will transmit the calculated PEC byte after transmitting the number of data bytes indicated by TX Byte Cnt(Bits 18:16).<br>Reset type: SYSRSn   |

**Table 27-10. PMBSC Register Field Descriptions (continued)**

| Bit   | Field         | Type | Reset | Description   |
|-------|---------------|------|-------|---|
| 18-16 | TX_COUNT      | R/W  | 0h    | <p>0 = No bytes valid</p> <p>1 = One byte valid, Byte #0 (Bits 7:0 of Transmit Data Register)</p> <p>2 = Two bytes valid, Bytes #0 and #1 (Bits 15:0 of Transmit Data Register)</p> <p>3 = Three bytes valid, Bytes #0-2 (Bits 23:0 of Transmit Data Register)</p> <p>4 = Four bytes valid, Bytes #0-3 (Bits 31:0 of Transmit Data Register)</p> <p>Reset type: SYSRSn</p>  |
| 15    | PEC_ENA       | R/W  | 0h    | <p>0 = PEC processing disabled</p> <p>1 = PEC processing enabled</p> <p>Reset type: SYSRSn</p>  |
| 14-8  | SLAVE_MASK    | R/W  | 7Fh   | <p>Used in address detection, the slave mask enables acknowledgement of multiple device addresses by the slave. Writing a '0' to a bit within the slave mask enables the corresponding bit in the slave address to be either '1' or '0' and still allow for a match. Writing a '0' to all bits in the mask enables the PMBus Interface to acknowledge any device address. Upon power-up, the slave mask defaults to 7Fh, indicating the slave will only acknowledge the address programmed into the Slave Address (Bits 6-0).</p> <p>Reset type: SYSRSn</p> |
| 7     | MAN_SLAVE_ACK | R/W  | 0h    | <p>0 = Slave automatically acknowledges device address specified in SLAVE_ADDR, Bits 6:0</p> <p>1 = Enables the Manual Slave Address Acknowledgement Mode. Firmware is required to read received address and acknowledge on every message</p> <p>Note:<br/>When bit 31 (I2C_mode) of PMBCTRL register is set it is recommended to use manual acknowledging of slave address only (MAN_SLAVE_ACK =1).</p> <p>Reset type: SYSRSn</p>  |
| 6-0   | SLAVE_ADDR    | R/W  | 7Ch   | <p>Configures the current device address of the slave. Used in automatic slave address acknowledge mode (default mode). The PMBus Interface will compare the received device address with the value stored in the Slave Address bits and the mask configured in the Slave Mask bits. If matching, the slave will acknowledge the device address.</p> <p>Reset type: SYSRSn</p>  |

### 27.5.2.8 PMBHSA Register (Offset = Eh) [Reset = 0h]

PMBHSA is shown in [Figure 27-35](#) and described in [Table 27-11](#).

Return to the [Summary Table](#).

This page intentionally left blank.

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

Further information can be found in:

## 28.1 Introduction

This device uses the CAN IP known as DCAN.

### 28.1.1 DCAN Related Collateral

#### Foundational Materials

- [Automotive CAN Overview and Training](#) (Video)
- [C2000 Academy - Communications](#)
  - Refer to the DCAN section
- [CAN Physical layer](#) (Video)
- [CAN and CAN FD Overview](#) (Video)
- [CAN and CAN FD Protocol](#) (Video)

#### Expert Materials

- [Calculator for CAN Bit Timing Parameters Application Report](#)

### 28.1.2 Features

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1 Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably), each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard (11-bit) or extended (29-bit) identifier
  - Supports programmable identifier receive mask
  - Supports data and remote frames
  - Holds 0 to 8 bytes of data
  - Parity-checked configuration and data RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Message-RAM parity-check mechanism
- Two interrupt lines
- DMA support

---

#### Note

For a CAN bit clock of 120 MHz, the smallest bit rate possible is 4.6875 kbps.

Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data manual) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

---

### 28.1.3 Block Diagram

Figure 28-1 shows a block diagram of the CAN module. Following is a description of some of the main blocks.

Figure 28-1. CAN Block Diagram

### 28.1.3.1 CAN Core

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. It handles all ISO 118981 protocol functions.

### 28.1.3.2 Message Handler

The message handler is a state machine which controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. It also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

### 28.1.3.3 Message RAM

The CAN message RAM enables the storage of 32 CAN messages.

### 28.1.3.4 Registers and Message Object Access (IFx)

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through Interface registers.

Three Interface register sets control the CPU read and write accesses to the Message RAM. There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also [Section 28.13](#). The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

## 28.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests as well as the generation of interrupts or DMA requests.

The register set of the CAN may be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

### 28.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPYPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 28.2.2 Address/Data Bus Bridge

The CAN module uses a special addressing scheme to support byte accesses. It is recommended to only use 32-bit accesses to the CAN registers using the *HWREG\_BP()* macro that uses the *\_\_byte\_peripheral\_32()* intrinsic. If 16-bit accesses are to be used, the lower 16 bits should be written to the register's address, and the upper 16 bits should be written to the register's address, plus 2.

Because of the bus bridge, the view of the CAN module's register space through the Code Composer Studio™ (CCS) IDE memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses should be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view; odd addresses from the module are not displayed.

**Table 28-1. CAN Register Access from Software**

| CAN Register Space |          |            | C28x 8-Bit            |        | C28x 16-Bit       |        | C28x 32-Bit      |            |
|--------------------|----------|------------|-----------------------|--------|-------------------|--------|------------------|------------|
| Address            | Name     | Data       | Access                | Data   | Access            | Data   | Address          | Data       |
| 0x00               | CAN_CTL  | 0x33221100 | __byte((int *)0x00,0) | 0x0000 | *((short*)(0x00)) | 0x1100 | *((long*)(0x00)) | 0x33221100 |

## 28.3 Operating Modes

### 28.3.1 Initialization

The initialization mode is entered either by software (by setting the **Init** bit in the CAN\_CTL register), by hardware reset, or by going bus-off. While the **Init** bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN\_TX output is recessive (high). The CAN error counters are not updated. Setting the **Init** bit does not change any other configuration register.

To initialize the CAN Controller, the CPU has to configure the CAN Bit timing and those message objects which have to be used for CAN communication. Message objects which are not needed, can be deactivated with their **MsgVal** bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and **CCE** bits in the CAN Control register are set.

Clearing the **Init** bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before it can take part in bus activities and start the message transfer. For more details, see [Section 28.12](#).

The initialization of the message objects is independent of the **Init** bit; however, all message objects should be configured to particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering will be applied to it when the modified message object number is same or smaller than the previously found message object. This assures data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

### 28.3.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for communication.

Received messages are stored into their appropriate message objects if they pass acceptance filtering. The whole message (MSGID, DLC, and up to eight data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits which are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority. Messages may be updated or set to 'not valid' at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

#### 28.3.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting the DAR bit in the CAN Control register. Further details to this mode are provided in [Section 28.11.3](#).

#### 28.3.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module will stay in bus-off state.

The CAN provides an automatic auto-bus-on feature which is enabled by the ABO bit. If set, the CAN will automatically start the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

---

#### Note

If the CAN module goes Bus-Off due to multiple CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit is cleared by the application (or due to the auto-bus-on feature), the device will wait for 129 occurrences of Bus Idle (equal to  $129 * 11$  consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the Init bit. At the end of the bus-off recovery sequence, the error counters will be reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

---

### 28.3.3 Test Modes

The CAN module provides several test modes which are mainly intended for self-test purposes. Figure 28-2 aids in understanding the various test modes. It should be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. For the sake of brevity, this diagram does not include the GPIO muxing or the I/O buffers.

For all test modes, the Test bit in the CAN Control register needs to be set to 1 to enable write access to the CAN\_TEST register.

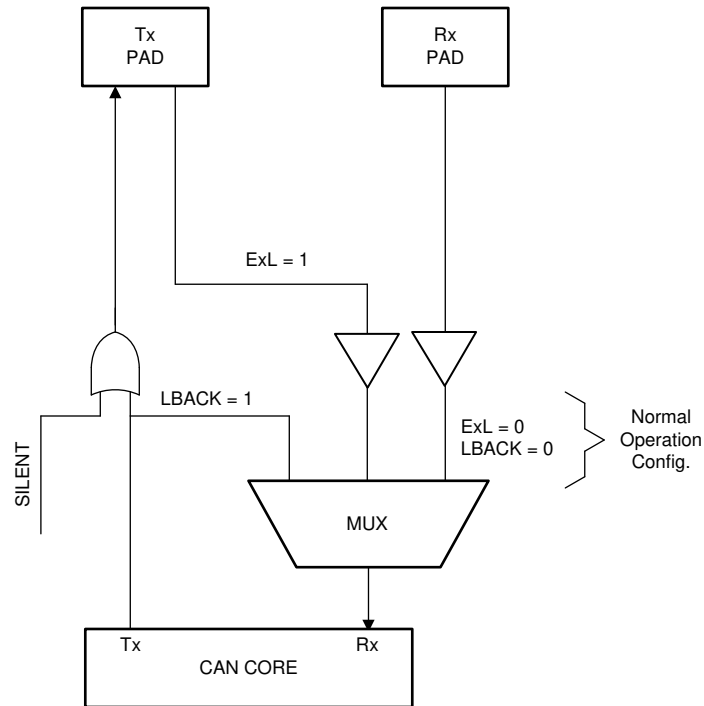

Figure 28-2. CAN\_MUX

### 28.3.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The CAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, the received frames are internally routed to the CAN Core.

Figure 28-3 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in test register (CAN\_TEST), to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 28-3. CAN Core in Silent Mode

### 28.3.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN\_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN\_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 28-4 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in loopback mode. Loopback mode can be activated by setting the LBack bit in the CAN\_TEST register to 1.

---

#### Note

In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see [Section 28.3.3.3](#).

---

**Figure 28-4. CAN Core in Loopback Mode**

### 28.3.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to the CAN Core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the ExL bit in Test Register to 1.

Figure 28-5 shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in external loopback mode.

**Note**

When loopback mode is active (LBack bit set), the ExL bit will be ignored.

Figure 28-5. CAN Core in External Loopback Mode

### 28.3.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN\_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN\_TX pin.

Figure 28-6 shows the connection of the signals CAN\_TX and CAN\_RX to the CAN Core in case of the combination of loopback mode with silent mode.

Figure 28-6. CAN Core in Loopback Combined with Silent Mode

## 28.4 Multiple Clock Source

The *System Control* chapter and the device data sheet provide for more information on how to configure the relevant clock source registers in the system module.

### Note

The CAN core has to be programmed to at least eight clock cycles per bit time. To achieve a transfer rate of 1 Mbps an oscillator frequency of 8 MHz or higher has to be used.

## 28.5 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt register. When no interrupt is pending, the register will hold the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk and LEC by reading the Error and Status Register, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID / INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine which reads the message from the interrupt source, may also read the message and reset the message object's IntPnd at the same time (CIntPnd bit in the IF1/IF2 Command register). When IntPnd is cleared, the Interrupt register will point to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN\_GLB\_INT\_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt via CAN\_GLB\_INT\_CLR and PIEACK.

### 28.5.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in [Section 28.14.1](#). Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

Note that writing to the IntPnd bit in the CAN\_IFnMCTL registers can force an interrupt.

### 28.5.2 Status Change Interrupts

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN\_CTL Register.

### 28.5.3 Error Interrupts

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT, which has to be enabled by setting IE0 in the CAN\_CTL register.

### 28.5.4 PIE Nomenclature for DCAN Interrupts

[Table 28-3](#) shows the PIE nomenclature for the interrupts.

**Table 28-3. PIE Nomenclature for Interrupts**

| Interrupt | CANA   | CANB   |
|-----------|--------|--------|
| CANINT0   | CANA_0 | CANB_0 |
| CANINT1   | CANA_1 | CANB_1 |

### 28.5.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in Figure 28-7 and Figure 28-8. Mailbox interrupts for transmit and receive operations can be routed to both CANINT0 and CANINT1. However, error and status interrupts can only be routed to CANINT0.

Figure 28-7. CAN Interrupt Topology 1

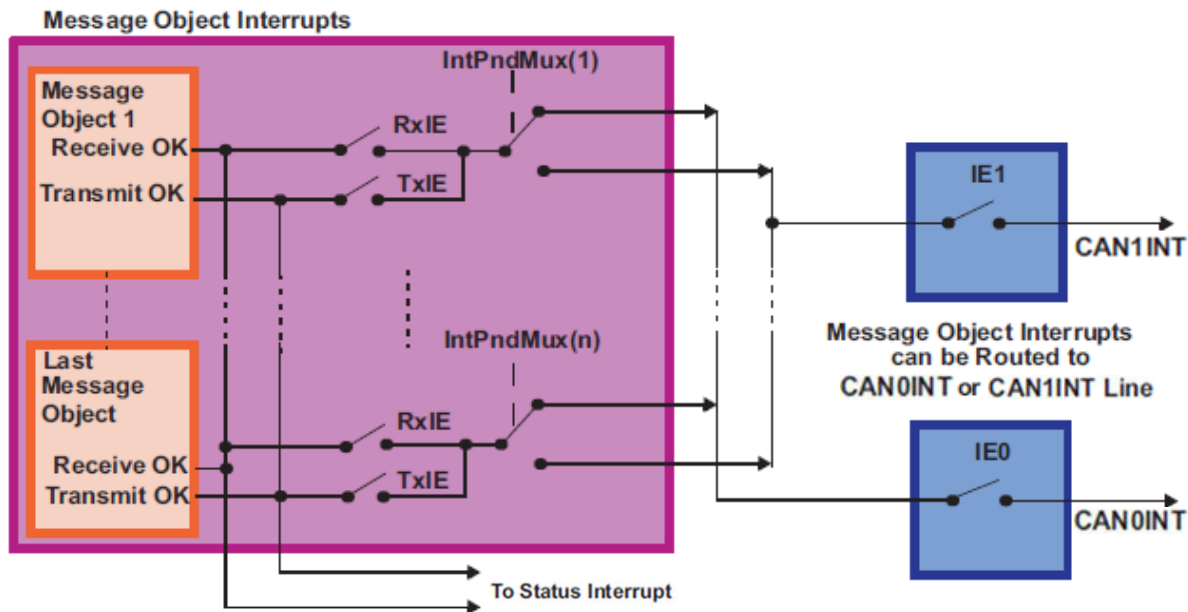

Figure 28-8. CAN Interrupt Topology 2

## 28.6 DMA Functionality

The CAN module provides three DMA trigger outputs, one for each of the three Interface Registers IF1, IF2 and IF3. These can be enabled using the DE1, DE2, and DE3 bits in the CAN\_CTL register.

The Update of IF1 and IF2 registers will be initiated by a write access to the IF1 and IF2 Command registers, respectively. Once enabled, setting the DMAActive bit in the IF1CMD or IF2CMD registers will cause a DMA request the next time the corresponding interface becomes available.

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update. That is, when IF3 DMA requests are enabled, all IF3 updates will trigger a DMA request.

When a DCAN internal IFx update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers; that is, DMA requests are cleared after the first read or write access to an IF register set.

## 28.7 Parity Check Mechanism

The CAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in Message RAM, one parity bit will be calculated.

Parity information is stored in the Message RAM on write accesses and will be checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN Control register. In case of a disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the CAN. A parity bit will be set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

### 28.7.1 Behavior on Parity Error

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object will be checked. If a parity error is detected, the PER bit in the Error and Status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

## 28.8 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit will wait until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect. Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization (see [Section 28.14.3](#)).

---

### Note

During debug mode, the Message RAM cannot be accessed via the IFx register sets.

Writing to control registers in Debug mode may influence the CAN state machine and further message handling.

---

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers (clear of DMA Active flag by read/write)

## 28.9 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects should be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see [Section 28.10](#).

For the configuration of the Bit Timing, see [Section 28.12.2](#).

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to '0' by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted via the CAN bus.

The CPU may enable the interrupt lines (setting IE0 and IE1 to '1') at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication may be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with IntPnd = '1'. It is updated even if the interrupt lines to the CPU are disabled (IE0 / IE1 are zero).

The CPU may poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData registers and the Transmission Request registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers; all Receive Objects are grouped at the high numbers.

## 28.10 Configuration of Message Objects

The entire Message RAM should be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

### 28.10.1 Configuration of a Transmit Object for Data Frames

Figure 28-9 shows how a transmit object can be initialized.

**Figure 28-9. Initialization of a Transmit Object**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE | TxIE  | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|------|-------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 1   | 0      | 0      | 0    | appl. | 0      | appl. | 0      |

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.
- The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.
- If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.
- If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.
- The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see [Section 28.11.8](#). Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

### 28.10.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object will cause the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

### 28.10.3 Configuration of a Single Receive Object for Data Frames

Figure 28-10 shows how a receive object for data frames can be initialized.

**Figure 28-10. Initialization of a Single Receive Object for Data Frames**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE  | TxIE | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|-------|------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 0   | 0      | 0      | appl. | 0    | 0      | 0     | 0      |

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- When the message handler stores a data frame in the message object, it will store the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.
- The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored data frame.
- If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = '1') for acceptance filtering.

## 28.10.4 Configuration of a Single Receive Object for Remote Frames

Figure 28-11 shows how a receive object for remote frames can be initialized.

**Figure 28-11. Initialization of a Single Receive Object for Remote Frames**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE  | TxIE | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|-------|------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 1   | 0      | 0      | appl. | 0    | 0      | 0     | 0      |

- Receive objects for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer, see [Section 28.10.5](#).
- UMask must be set to '1'. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see [Section 28.11.8](#).
- The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.
- If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

## 28.10.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to zero. The EoB bits of the last message object of a FIFO buffer is set to one, configuring it as the end of the block.

## 28.11 Message Handling

When initialization is finished, the CAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages that are received and accepted. Messages that are not read before the next messages are accepted for the same message object will be overwritten. Messages may be read interrupt-driven or after polling of NewDat.

### 28.11.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).
- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

### 28.11.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 28.11.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN Control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching Transmit Object the RmtEn bit is set.

#### 28.11.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MsgVal nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see [Section 28.11.3](#).

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

#### 28.11.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

---

#### Note

After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

---

### 28.11.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

### 28.11.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

### 28.11.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

1. Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'  
The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'  
The remote frame is ignored, this message object remains unchanged.
3. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'  
The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

### 28.11.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface registers, the data consistency is guaranteed by the message handler state machine.

Typically the CPU will write 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

### 28.11.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

### 28.11.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is '1'.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is '0' the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to '0', all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = '1') and therefore overwrite previous messages in this message object.

### 28.11.12 Reading from a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer. A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared. A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in [Figure 28-12](#).

---

#### Note

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality cannot be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

---

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

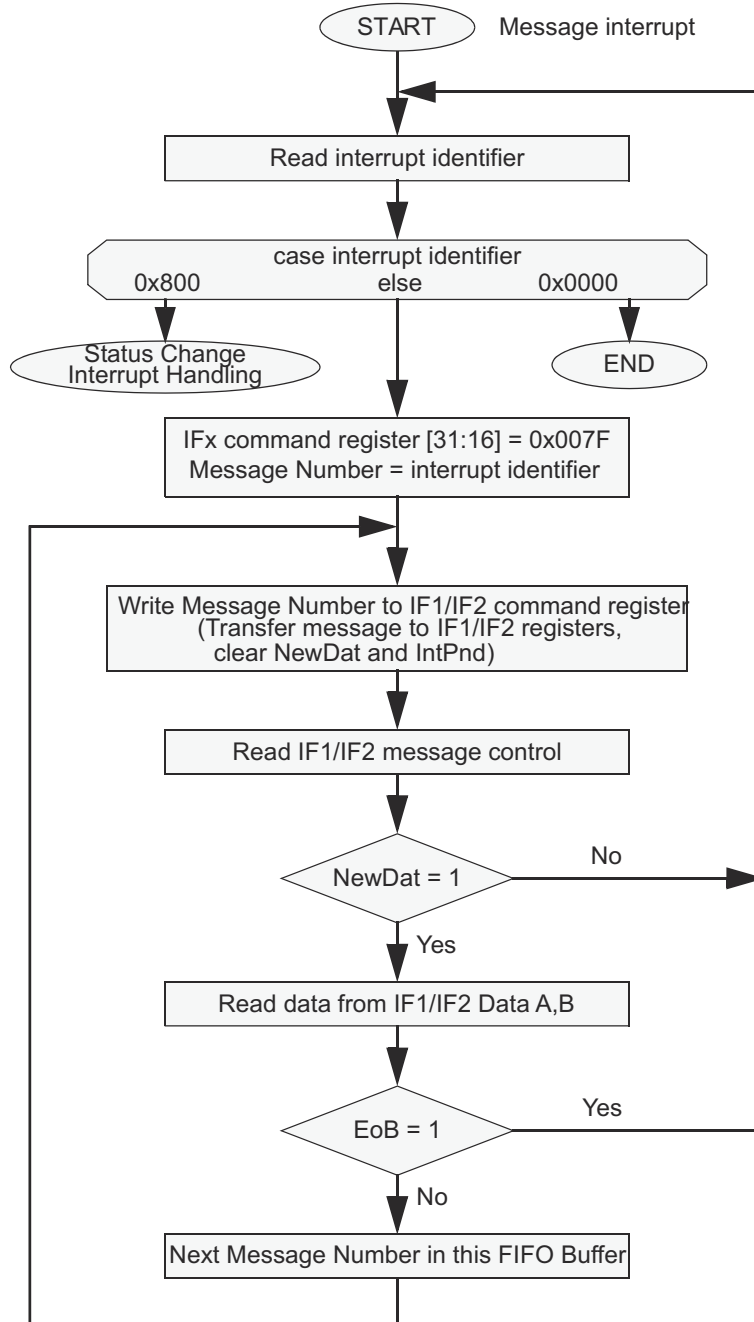

Figure 28-12. CPU Handling of a FIFO Buffer (Interrupt Driven)

## 28.12 CAN Bit Timing

The CAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods ( $F_{osc}$ ) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range ( $df$ ), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

### 28.12.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see [Figure 28-13](#)):

- Synchronization Segment (Sync\_Seg)
- Propagation Time Segment (Prop\_Seg)
- Phase Buffer Segment 1 (Phase\_Seg1)
- Phase Buffer Segment 2 (Phase\_Seg2)

**Figure 28-13. Bit Timing**

Each segment consists of a specific number of time quanta. The length of one time quantum ( $t_q$ ), which is the basic time unit of the bit time, is given by the CAN\_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate Prescaler} / \text{CAN\_CLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. [Table 28-4](#) describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

**Table 28-4. Programmable Ranges Required by CAN Protocol**

| Parameter                        | Range           | Remark   |
|----------------------------------|-----------------|--|
| Sync_Seg                         | 1 $t_q$ (fixed) | Synchronization of bus input to CAN_CLK            |
| Prop_Seg                         | [1 ... 8] $t_q$ | Compensates for the physical delay times           |
| Phase_Seg1                       | [1 ... 8] $t_q$ | May be lengthened temporarily by synchronization   |
| Phase_Seg2                       | [1 ... 8] $t_q$ | May be shortened temporarily by synchronization    |
| Synchronization Jump Width (SJW) | [1 ... 4] $t_q$ | May not be longer than either phase buffer segment |

**Note**

For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

**28.12.1.1 Synchronization Segment**

The Synchronization Segment (Sync\_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync\_Seg, its distance to the Sync\_Seg is called the phase error of this edge.

**28.12.1.2 Propagation Time Segment**

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 28-14 shows the phase shift and propagation times between two CAN nodes.

**Figure 28-14. The Propagation Time Segment**

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A\_to\_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay(B\_to\_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase\_Seg1. This condition defines the length of Prop\_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase\_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the Bit timing configuration (Prop\_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of  $1 t_q$ , requiring a longer Prop\_Seg.

### 28.12.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase\_Seg1 and Phase\_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync\_Seg, otherwise its distance to the Sync\_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync\_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame only resynchronizing is possible.

- Hard Synchronization

After a hard synchronization, the bit time is restarted with the end of Sync\_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge which causes resynchronization is positive, Phase\_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase\_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

When the phase error of the edge which causes resynchronization is negative, Phase\_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase\_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop\_Seg + Phase\_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The "leading" transmitter does not necessarily win the arbitration, therefore the receivers have to synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator's tolerance range.

The examples in Figure 28-15 show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

**Figure 28-15. Synchronization on Late and Early Edges**

In the first example, an edge from recessive to dominant occurs at the end of Prop\_Seg. The edge is "late" since it occurs after the Sync\_Seg. Reacting to the "late" edge, Phase\_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync\_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync\_Seg.

In the second example, an edge from recessive to dominant occurs during Phase\_Seg2. The edge is "early" since it occurs before a Sync\_Seg. Reacting to the "early" edge, Phase\_Seg2 is shortened and Sync\_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync\_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync\_Seg when synchronizing on an "early" edge because it cannot subsequently redefine that time quantum of Phase\_Seg2 where the edge occurs to be the Sync\_Seg.

The examples in Figure 28-16 show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop\_Seg and has the length of (Prop\_Seg + Phase\_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

**Figure 28-16. Filtering of Short Dominant Spikes**

### 28.12.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range  $df$  for an oscillator's frequency  $f_{osc}$  around the nominal frequency  $f_{nom}$  with:

$$(1 - df) \cdot f_{nom} \leq f_{osc} \leq (1 + df) \cdot f_{nom} \quad (28)$$

depends on the proportions of Phase\_Seg1, Phase\_Seg2, SJW, and the bit time. The maximum tolerance  $df$  is defined by two conditions (both shall be met):

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit\_time} \quad (29)$$

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop\_Seg = 1 and Phase\_Seg1 = Phase\_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8  $\mu$ s) with a bus length of 40 m.

### 28.12.2 Configuration of the CAN Bit Timing

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop\_Seg and Phase\_Seg1 (as TSEG1) is combined with Phase\_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see [Figure 28-17](#)).

In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1...n], values in the range of [0...n-1] are programmed. That way, for example, SJW (functional range of [1...4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values) [TSEG1 + TSEG2 + 3]  $t_q$  or (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2]  $t_q$ .

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP.

The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is  $0 t_q$  for the CAN.

Generally, the IPT is CAN controller specific, but may not be longer than  $2 t_q$ . The IPT length is the lower limit of the programmed length of Phase\_Seg2. In case of a synchronization, Phase\_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

Figure 28-17. Structure of the CAN Core's CAN Protocol Controller

### 28.12.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time ( $1 / \text{Bit rate}$ ) must be an integer multiple of the CAN clock period.

---

#### Note

8 MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1 MBit/s.

---

The bit time may consist of 8 to 25 time quanta. The length of the time quantum  $t_q$  is defined by the Baud Rate Prescaler with  $t_q = (\text{Baud Rate Prescaler}) / \text{CAN\_CLK}$ . Several combinations may lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop\_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop\_Seg is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The Sync\_Seg is  $1 t_q$  long (fixed), leaving  $(\text{bit time} - \text{Prop\_Seg} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length,  $\text{Phase\_Seg2} = \text{Phase\_Seg1}$ , else  $\text{Phase\_Seg2} = \text{Phase\_Seg1} + 1$ .

The minimum nominal length of Phase\_Seg2 has to be regarded as well. Phase\_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of  $[0 \dots 2] t_q$ .

The length of the synchronization jump width is set to its maximum value, which is the minimum of 4 and Phase\_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in [Section 28.12.1.4](#).

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

$(\text{Phase\_Seg2}-1) \& (\text{Phase\_Seg1} + \text{Prop\_Seg} - 1) \&$

$(\text{SynchronizationJumpWidth}-1) \& (\text{Prescaler}-1)$

### 28.12.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN\_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

|                           |         |   |   |
|---------------------------|---------|---|---|
| $t_q$                     | 100 ns  | = | $t_{CAN\_CLK}$  |
| delay of bus driver       | 90 ns   | = |   |
| delay of receiver circuit | 40 ns   | = |   |
| delay of bus line (40m)   | 220 ns  | = |   |
| $t_{Prop}$                | 700 ns  | = | $2 \cdot \text{delays} = 7 \cdot t_q$                               |
| $t_{SJW}$                 | 100 ns  | = | $1 \cdot t_q$   |
| $t_{TSeg1}$               | 800 ns  | = | $t_{Prop} + t_{SJW}$  |
| $t_{TSeg2}$               | 100 ns  | = | Information Processing Time + $1 \cdot t_q$                         |
| $t_{Sync-Seg}$            | 100 ns  | = | $1 \cdot t_q$   |
| bit time                  | 1000 ns | = | $t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$                              |
| tolerance for CAN_CLK     | 0.35 %  | = | $\frac{\min(Tseg1, Tseg2)}{2((13 \times \text{bit time}) - Tseg2)}$ |
|                           |         |   | $= \frac{0.1 \mu s}{2((13 \times 1 \mu s) - 0.1 \mu s)}$            |

In this example, the concatenated bit time parameters are  $(1-1)_3 \& (8-1)_4 \& (1-1)_2 \& (1-1)_6$ , so the Bit Timing Register is programmed to = 0x00000700.

### 28.12.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN\_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

|                           |            |   |   |
|---------------------------|------------|---|---|
| $t_q$                     | 1 $\mu s$  | = | $2 \cdot t_{CAN\_CLK}$  |
| delay of bus driver       | 200 ns     | = |   |
| delay of receiver circuit | 80 ns      | = |   |
| delay of bus line (40m)   | 220 ns     | = |   |
| $t_{Prop}$                | 1 $\mu s$  | = | $1 \cdot t_q$   |
| $t_{SJW}$                 | 4 $\mu s$  | = | $4 \cdot t_q$   |
| $t_{TSeg1}$               | 5 $\mu s$  | = | $t_{Prop} + t_{SJW}$  |
| $t_{TSeg2}$               | 4 $\mu s$  | = | Information Processing Time + $4 \cdot t_q$                         |
| $t_{Sync-Seg}$            | 1 $\mu s$  | = | $1 \cdot t_q$   |
| bit time                  | 10 $\mu s$ | = | $t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$                              |
| tolerance for CAN_CLK     | 1.58 %     | = | $\frac{\min(Tseg1, Tseg2)}{2((13 \times \text{bit time}) - Tseg2)}$ |
|                           |            |   | $= \frac{4 \mu s}{2((13 \times 10 \mu s) - 4 \mu s)}$               |

In this example, the concatenated bit time parameters are  $(4-1)_3 \& (5-1)_4 \& (4-1)_2 \& (2-1)_6$ , so the Bit Timing register is programmed to = 0x000034C1.

## 28.13 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modify-write cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see [Section 28.14.1](#)) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

That being said, there is one condition that can cause a write access to the message RAM to be lost. If `MsgVal = 1` for the message object which is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM may be lost. The reason for this is that it might happen that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when it is in the process of receiving a message for the same message object.

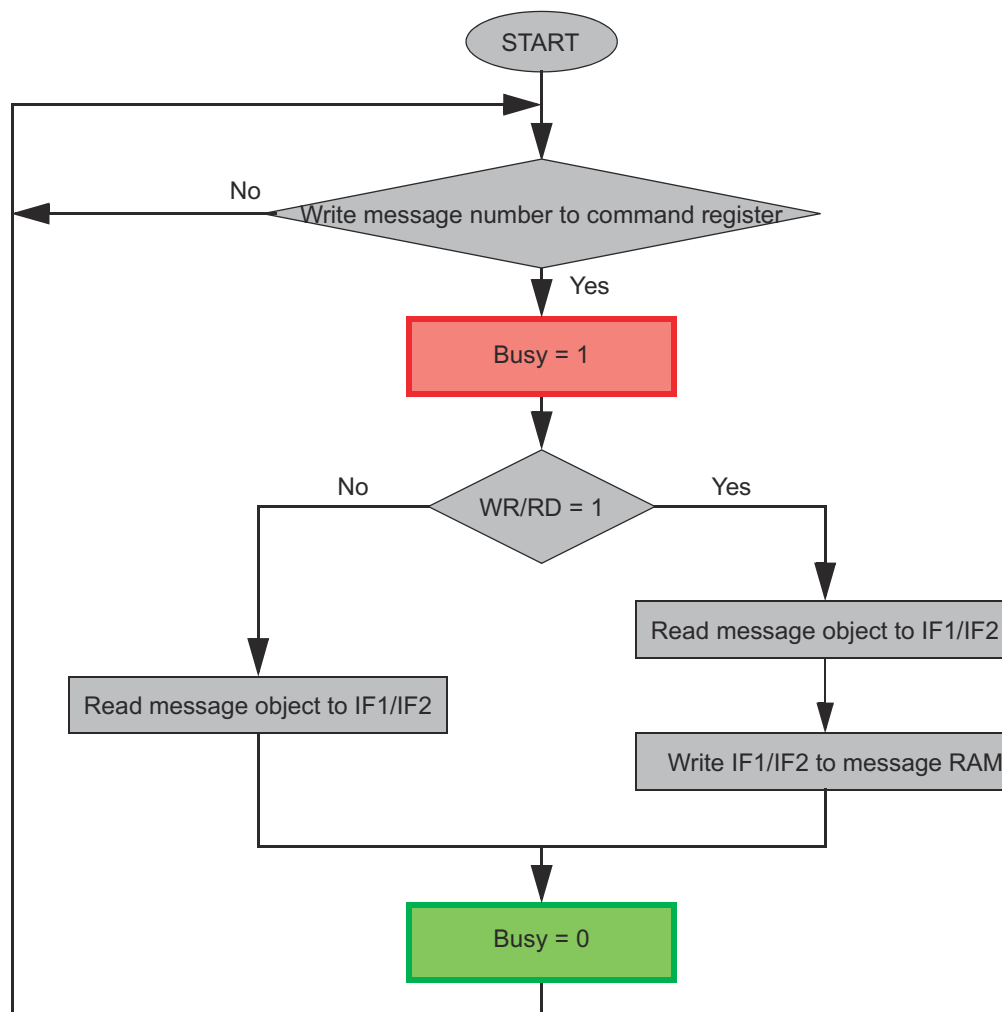

To avoid this issue with receive mail boxes, reset `MsgVal` before changing any of the following: `Id28-0`, `Xtd`, `Dir`, `DLC3-0`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`.

To avoid this issue with transmit mail boxes, reset `MsgVal` before changing any of the following: `Dir`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`. Other fields not listed above, like `Data`, may be changed without fear of losing a write to the message RAM.

### 28.13.1 Message Interface Register Sets 1 and 2 (IF1 and IF2)

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register will be overwritten by values taken from the other IFx registers. If the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register will be copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see [Figure 28-18](#)).

**Figure 28-18. Data Transfer Between IF1 / IF2 Registers and Message RAM**

### 28.13.2 Message Interface Register Set 3 (IF3)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA will be requested. The DMA request stays active until the first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in the CAN Control register.

#### Note

The IF3 register set can not be used for transferring data into message objects.

## 28.14 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed via the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

### 28.14.1 Structure of Message Objects

Figure 28-19 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Figure 28-19. Structure of a Message Object**

| Message Object |           |      |      |          |        |        |        |        |        |        |        |        |
|----------------|-----------|------|------|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| UMask          | Msk[28:0] | MXtd | MDir | EoB      | unused | NewDat | MsgLst | RxIE   | TxE    | IntPnd | RmtEn  | TxRqst |
| MsgVal         | ID[28:0]  | Xtd  | Dir  | DLC[3:0] | Data 0 | Data 1 | Data 2 | Data 3 | Data 4 | Data 5 | Data 6 | Data 7 |

**Table 28-5. Message Object Field Descriptions**

| Name     | Value                 | Description  |
|----------|-----------------------|--|
| MsgVal   | 0<br>1                | <p>Message valid</p> <p>The message object is ignored by the message handler.</p> <p>The message object is to be used by the message handler.</p> <p>Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code DLC[3:0] are changed.</p>  |
| UMask    | 0<br>1                | <p>Use Acceptance Mask</p> <p>Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.</p> <p>Mask bits are used for acceptance filtering.</p> <p>Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.</p> |
| ID[28:0] | ID[28:0]<br>ID[28:18] | <p>Message Identifier</p> <p>29-bit ("extended") identifier bits</p> <p>11-bit ("standard") identifier bits</p>  |

**Table 28-5. Message Object Field Descriptions (continued)**

| Name      | Value | Description  |
|-----------|-------|--|
| Msk[28:0] | 0     | The corresponding bit in the message identifier is not used for acceptance filtering (don't care).   |
|           | 1     | The corresponding bit in the message identifier is used for acceptance filtering.<br>Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28xx devices, where a "1" means the corresponding bit is NOT used for filtering, and "0" means it is used. |
| Xtd       | 0     | The 11-bit ("standard") identifier will be used for this message object.   |
|           | 1     | The 29-bit ("extended") identifier will be used for this message object.   |
| MXtd      | 0     | The extended identifier bit (IDE) has no effect on the acceptance filtering.   |
|           | 1     | The extended identifier bit (IDE) is used for acceptance filtering.<br>Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.                           |
| Dir       | 0     | Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.   |
|           | 1     | Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).  |
| MDir      | 0     | The message direction bit (Dir) has no effect on the acceptance filtering.   |
|           | 1     | The message direction bit (Dir) is used for acceptance filtering.  |
| EOB       | 0     | The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.  |
|           | 1     | The message object is a single message object or the last message object in a FIFO Buffer Block.<br>Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.  |
| NewDat    | 0     | No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.  |
|           | 1     | The message handler or the CPU has written new data into the data bytes of this message object.  |
| MsgLst    | 0     | Message Lost (only valid for Message Objects with direction = receive)<br>No message was lost since the last time when this bit was reset by the CPU.  |
|           | 1     | The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.   |
| RxIE      | 0     | Receive Interrupt Enable<br>IntPnd will not be triggered after the successful reception of a frame.  |
|           | 1     | IntPnd will be triggered after the successful reception of a frame.  |
| TxIE      | 0     | Transmit Interrupt Enable<br>IntPnd will not be triggered after the successful transmission of a frame.  |
|           | 1     | IntPnd will be triggered after the successful transmission of a frame.   |
| IntPnd    | 0     | Interrupt Pending<br>This message object is not the source of an interrupt.  |
|           | 1     | This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority.  |

**Table 28-5. Message Object Field Descriptions (continued)**

| Name     | Value | Description  |
|----------|-------|--|
| RmtEn    | 0     | Remote Enable<br>At the reception of a remote frame, TxRqst is not changed.  |
|          | 1     | At the reception of a remote frame, TxRqst is set.<br>Note: See <a href="#">Section 28.11.8</a> for details on the setup of RmtEn and UMask for remote frames.   |
| TxRqst   | 0     | Transmit Request<br>This message object is not waiting for a transmission.   |
|          | 1     | The transmission of this message object is requested and is not yet done.  |
| DLC[3:0] | 0-8   | Data length code<br>Data frame has 0-8 data bytes.   |
|          | 9-15  | Data frame has 8 data bytes.<br>Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.  |
| Data 0   |       | 1st data byte of a CAN data frame  |
| Data 1   |       | 2nd data byte of a CAN data frame  |
| Data 2   |       | 3rd data byte of a CAN data frame  |
| Data 3   |       | 4th data byte of a CAN data frame  |
| Data 4   |       | 5th data byte of a CAN data frame  |
| Data 5   |       | 6th data byte of a CAN data frame  |
| Data 6   |       | 7th data byte of a CAN data frame  |
| Data 7   |       | 8th data byte of a CAN data frame<br>Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values. |

### 28.14.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) \* 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

#### Note

'0' is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

Message Object number 1 has the highest priority.

**Table 28-6. Message RAM Addressing in Debug Mode**

| Message Object Number      | Offset From Base Address | Word Number | Debug Mode <sup>(1)</sup> |
|----------------------------|--------------------------|-------------|---------------------------|
| last implemented (here:32) | 0x0000                   | 1           | Parity                    |
|                            | 0x0004                   | 2           | MXtd,MDir,Mask            |
|                            | 0x0008                   | 3           | Xtd,Dir,ID                |
|                            | 0x000C                   | 4           | Ctrl                      |
|                            | 0x0010                   | 5           | Data Bytes 3-0            |
|                            | 0x0014                   | 6           | Data Bytes 7-4            |
| 1                          | 0x0020                   | 1           | Parity                    |
|                            | 0x0024                   | 2           | MXtd,MDir,Mask            |
|                            | 0x0028                   | 3           | Xtd,Dir,ID                |

(1) See [Section 28.14.3](#).

### 28.14.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

#### Note

During debug mode, the Message RAM cannot be accessed via the IFx register sets.

**Figure 28-20. Message RAM Representation in Debug Mode**

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

## 28.15 Software

### 28.15.1 CAN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/can

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 28.15.1.1 CAN External Loopback

FILE: can\_ex1\_loopback.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 2 byte message that contains an incrementing pattern.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Please refer to the appnote Programming Examples and Debug Strategies for the DCAN Module ([www.ti.com/lit/SPRACE5](http://www.ti.com/lit/SPRACE5)) for useful information about this example

##### *External Connections*

- None.

##### *Watch Variables*

- msgCount - A counter for the number of successful messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### 28.15.1.2 CAN External Loopback with Interrupts

FILE: can\_ex2\_loopback\_interrupts.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 4 byte message that contains an incrementing pattern. A CAN interrupt handler is used to confirm message transmission and count the number of messages that have been sent.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Please refer to the appnote Programming Examples and Debug Strategies for the DCAN Module ([www.ti.com/lit/SPRACE5](http://www.ti.com/lit/SPRACE5)) for useful information about this example

##### *External Connections*

- None.

##### *Watch Variables*

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- errorFlag - A flag that indicates an error has occurred

### 28.15.1.3 CAN External Loopback with DMA

FILE: can\_ex4\_loopback\_dma.c

This example sets up the CAN module to transmit and receive messages on the CAN bus. The CAN module is set to transmit a 4 byte message internally. An interrupt is used to assert the DMA request line which then triggers the DMA to transfer the received data from the CAN interface register to the receive buffer array. A data check is performed once the transfer is complete.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Refer to details of the External Loopback Test Mode in the *CAN Chapter*. Refer to the [Programming Examples and Debug Strategies for the DCAN Module Application Report](#) for useful information about this example.

#### External Connections

- None.

#### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

### 28.15.1.4 CAN Transmit and Receive Configurations

FILE: can\_ex5\_transmit\_receive.c

This example shows the basic setup of CAN in order to transmit or receive messages on the CAN bus with a specific Message ID. The CAN Controller is configured according to the selection of the define.

When the TRANSMIT define is selected, the CAN Controller acts as a Transmitter and sends data to the second CAN Controller connected externally. If TRANSMIT is not defined the CAN Controller acts as a Receiver and waits for message to be transmitted by the External CAN Controller. Refer to the [Programming Examples and Debug Strategies for the DCAN Module Application Report](#) for useful information about this example

CAN modules on the device need to be connected to via CAN transceivers.

#### Hardware Required

- A C2000 board with CAN transceiver.

#### External Connections

- ControlCARD CANA is on DEVICE\_GPIO\_PIN\_CANTXA (CANTXA)
- and DEVICE\_GPIO\_PIN\_CANRXA (CANRXA)

#### Watch Variables Transmit Configuration

- MSGCOUNT - Adjust to set the number of messages
- txMsgCount - A counter for the number of messages sent
- txMsgData - An array with the data being sent
- errorFlag - A flag that indicates an error has occurred
- rxMsgCount - Has the initial value as Number of Messages to be received and decrements with each message.

### 28.15.1.5 CAN Error Generation Example

FILE: can\_ex6\_error\_generation.c

This example demonstrates the ways of handling CAN Error conditions. It generates the CAN Packets and sends them over GPIO. It is looped back externally to be received in CAN module. The CAN Interrupt service routine reads the Error status and demonstrates how different Error conditions can be detected.

Change ERR\_CFG define to the different Error Scenarios and run the example. The corresponding Error Flag will be set in status variable of canISR() routine. Uses a CPU Timer (Timer 0) for periodic timer interrupt of CANBITRATE uSec. On the Timer interrupt it sends the required CAN Frame type with the specified error conditions. CAN modules on the device need to be connected to via CAN transceivers. Refer to the [Configurable Error Generator for Controller Area Network Application Report](#) for further details on this example.

#### External Connections

- ControlCARD GPIOTX\_PIN should be connected to
- DEVICE\_GPIO\_PIN\_CANRXA(CANRXA)

#### Watch Variables Transmit/Configuration

- status - variable in canISR for checking error Status

### 28.15.1.6 CAN Remote Request Loopback

FILE: can\_ex7\_loopback\_tx\_rx\_remote\_frame.c

This example shows the basic setup of CAN in order to transmit a remote frame and get a response for the remote frame and store it in a receive Object. The CAN peripheral is configured to transmit remote request frame and a remote answer frame messages with a specific CAN ID. Message object 3 is configured to transmit a remote request. Message object 2 is configured as a remote answer object with filter mask such that it accepts remote frame with any message ID and transmit's remote answer with message ID 7 and data length 8. Message object 1 is configured as a received object with filter message ID 7 so as to store the remote answer data transmitted by message object 2.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual.

#### External Connections

- None.

#### Watch Variables

- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

### 28.15.1.7 CAN Example that Illustrates the Usage of Mask Registers

FILE: can\_ex8\_mask.c

This example initializes CAN module A for Reception. When a frame with a matching filter criterion is received, the data will be copied in mailbox 1 and LED will be toggled a few times and the code gets ready for the next frame. If a message of any other MSGID is received, an ACK will be provided. Completion of reception is determined by polling CAN\_NDAT\_21 register. No interrupts are used. Refer to the [Programming Examples and Debug Strategies for the DCAN Module Application Report](#) for useful information about this example.

#### Hardware Required

- An external CAN node that transmits to CAN-A on the C2000 MCU

#### Watch Variables

- rxMsgCount - A counter for the number of messages received
- rxMsgData - An array with the data that was received

## 28.16 CAN Registers

This section describes the Controller Area Network registers.

### 28.16.1 CAN Base Address Table

**Table 28-7. CAN Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| CanaRegs       | CAN_REGS  | CANA_BASE      | 0x0004_8000  | YES  | YES | YES | -   | YES                |

## 28.16.2 CAN\_REGS Registers

Table 28-8 lists the memory-mapped registers for the CAN\_REGS registers. All register offset addresses not listed in Table 28-8 should be considered as reserved locations and the register contents should not be modified.

**Table 28-8. CAN\_REGS Registers**

| Offset (x8) | Offset (x16) | Acronym         | Register Name                          | Write Protection | Section            |
|-------------|--------------|-----------------|--|------------------|--------------------|
| 0h          | 0h           | CAN_CTL         | CAN Control Register                   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. [Table 28-9](#) shows the codes that are used for access types in this section.

**Table 28-9. CAN\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 28.16.2.1 CAN\_CTL Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 1401h]

CAN\_CTL is shown in [Figure 28-21](#) and described in [Table 28-10](#).

Return to the [Summary Table](#).

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

**Figure 28-21. CAN\_CTL Register**

It is set automatically during a bus off event. Clearing this bit will not shorten the bus recovery time.<br>0 CAN module processes messages normally<br>1 CAN module ignores bus activity<br>Reset type: SYSRSn |

### 28.16.2.2 CAN\_ES Register (Offset (x8) = 8h, Offset (x16) = 4h) [Reset = 7h]

CAN\_ES is shown in [Figure 28-22](#) and described in [Table 28-11](#).

Return to the [Summary Table](#).

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

**Figure 28-22. CAN\_ES Register**

**Table 28-11. CAN\_ES Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description   |
|-----|-------|------|-------|---|
| 4   | RxOk  | R    | 0h    | <p>Reception status Bit: This bit indicates the status of reception. The bit will be reset after the CPU reads the register.</p> <p>0 No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.</p> <p>1 A message has been successfully received since the last time when this bit was reset by a read access of the CPU. This bit will be set independent of the result of acceptance filtering.</p> <p>Reset type: SYSRSn</p>   |
| 3   | TxOk  | R    | 0h    | <p>Transmission status Bit: This bit indicates the status of transmission. The bit will be reset after the CPU reads the register.</p> <p>0 No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.</p> <p>1 A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was cleared by a read access of the CPU.</p> <p>Reset type: SYSRSn</p>  |
| 2-0 | LEC   | R    | 7h    | <p>Last Error Code</p> <p>The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register.</p> <p>0 No Error</p> <p>1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.</p> <p>2 Form Error: A fixed format part of a received frame has the wrong format.</p> <p>3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node.</p> <p>4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).</p> <p>7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'.</p> <p>Reset type: SYSRSn</p> |

### 28.16.2.3 CAN\_ERRC Register (Offset (x8) = 10h, Offset (x16) = 8h) [Reset = 0h]

CAN\_ERRC is shown in [Figure 28-23](#) and described in [Table 28-12](#).

Return to the [Summary Table](#).

This register reflects the value of the Transmit and Receive error counters

### 28.16.2.4 CAN\_BTR Register (Offset (x8) = 18h, Offset (x16) = Ch) [Reset = 2301h]

CAN\_BTR is shown in [Figure 28-24](#) and described in [Table 28-13](#).

Return to the [Summary Table](#).

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to 1024 CAN\_CLK periods.

**Figure 28-24. CAN\_BTR Register**

### 28.16.2.5 CAN\_INT Register (Offset (x8) = 20h, Offset (x16) = 10h) [Reset = 0h]

CAN\_INT is shown in [Figure 28-25](#) and described in [Table 28-14](#).

Return to the [Summary Table](#).

This register is used to identify the source of the interrupt(s).

**Figure 28-25. CAN\_INT Register**

The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.<br>Reset type: SYSRSn |

### 28.16.2.6 CAN\_TEST Register (Offset (x8) = 28h, Offset (x16) = 14h) [Reset = 0h]

CAN\_TEST is shown in [Figure 28-26](#) and described in [Table 28-15](#).

Return to the [Summary Table](#).

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

Note: Setting Tx[1:0] other than '00' will disturb message transfer.

Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

**Figure 28-26. CAN\_TEST Register**

|          |        |    |        |        |          |        |        |

### 28.16.2.7 CAN\_PERR Register (Offset (x8) = 38h, Offset (x16) = 1Ch) [Reset = 100h]

CAN\_PERR is shown in [Figure 28-27](#) and described in [Table 28-16](#).

Return to the [Summary Table](#).

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism

it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

**Figure 28-27. CAN\_PERR Register**

### 28.16.2.8 CAN\_RAM\_INIT Register (Offset (x8) = 80h, Offset (x16) = 40h) [Reset = 5h]

CAN\_RAM\_INIT is shown in [Figure 28-28](#) and described in [Table 28-17](#).

Return to the [Summary Table](#).

This register is used to initialize the Mailbox RAM. It clears the entire mailbox RAM, including the MsgVal bits.

**Figure 28-28. CAN\_RAM\_INIT Register**

|          |    |               |              |        |        |        |        |

### 28.16.2.12 CAN\_ABOTR Register (Offset (x8) = 100h, Offset (x16) = 80h) [Reset = 0h]

CAN\_ABOTR is shown in [Figure 28-32](#) and described in [Table 28-21](#).

Return to the [Summary Table](#).

This register is used to introduce a variable delay before the Bus-off recovery sequence is started.

**Figure 28-32. CAN\_ABOTR Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 28-21. CAN\_ABOTR Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description   |
|------|----------|------|-------|---|
| 31-0 | ABO_Time | R/W  | 0h    | Auto-Bus-On Timer<br>Number of clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. "Clock" refers to the input clock to the CAN module. This function has to be enabled by setting bit ABO in CAN Control Register.<br>The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO Time register after this phase.<br>NOTE: On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.<br>NOTE: During Debug mode, running Auto-Bus-On timer will be paused.<br>Reset type: SYSRSn |

### 28.16.2.13 CAN\_TXRQ\_X Register (Offset (x8) = 108h, Offset (x16) = 84h) [Reset = 0h]

CAN\_TXRQ\_X is shown in [Figure 28-33](#) and described in [Table 28-22](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN\_TXRQ\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

**Figure 28-33. CAN\_TXRQ\_X Register**

### 28.16.2.14 CAN\_TXRQ\_21 Register (Offset (x8) = 110h, Offset (x16) = 88h) [Reset = 0h]

CAN\_TXRQ\_21 is shown in [Figure 28-34](#) and described in [Table 28-23](#).

Return to the [Summary Table](#).

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

**Figure 28-34. CAN\_TXRQ\_21 Register**

### 28.16.2.16 CAN\_NDAT\_21 Register (Offset (x8) = 138h, Offset (x16) = 9Ch) [Reset = 0h]

CAN\_NDAT\_21 is shown in [Figure 28-36](#) and described in [Table 28-25](#).

Return to the [Summary Table](#).

This register holds the NewDat bits of all mailboxes. By reading out the NewDat bits, the CPU can check for which mailboxes the data portion was updated. The NewDat bit of a specific mailbox can be set/reset by the CPU via the IFx "Message Interface" Registers or by the Message Handler after reception of a Data Frame or after a successful transmission.

**Figure 28-36. CAN\_NDAT\_21 Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 28.16.2.18 CAN\_IPEN\_21 Register (Offset (x8) = 160h, Offset (x16) = B0h) [Reset = 0h]

CAN\_IPEN\_21 is shown in [Figure 28-38](#) and described in [Table 28-27](#).

Return to the [Summary Table](#).

This register holds the IntPnd bits of the mailboxes. By reading out these bits, the CPU can check for pending interrupts in the mailboxes. The IntPnd bit of a specific mailbox can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

**Figure 28-38. CAN\_IPEN\_21 Register**

### 28.16.2.19 CAN\_MVAL\_X Register (Offset (x8) = 180h, Offset (x16) = C0h) [Reset = 0h]

CAN\_MVAL\_X is shown in [Figure 28-39](#) and described in [Table 28-28](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Message Valid 2\_1 Register (CAN\_MVAL\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the MsgVal bits of these mailboxes are set, the corresponding bit in this register will be set.

### 28.16.2.20 CAN\_MVAL\_21 Register (Offset (x8) = 188h, Offset (x16) = C4h) [Reset = 0h]

CAN\_MVAL\_21 is shown in [Figure 28-40](#) and described in [Table 28-29](#).

Return to the [Summary Table](#).

This registers hold the MsgVal bits of all mailboxes. By reading out the MsgVal bits, the CPU can check which mailbox is valid. The MsgVal bit of a specific mailbox can be set/reset by the CPU via the IF1/2 "Message Interface" Registers.

**Figure 28-40. CAN\_MVAL\_21 Register**

### 28.16.2.21 CAN\_IP\_MUX21 Register (Offset (x8) = 1B0h, Offset (x16) = D8h) [Reset = 0h]

CAN\_IP\_MUX21 is shown in [Figure 28-41](#) and described in [Table 28-30](#).

Return to the [Summary Table](#).

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

**Figure 28-41. CAN\_IP\_MUX21 Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 28.16.2.22 CAN\_IF1CMD Register (Offset (x8) = 200h, Offset (x16) = 100h) [Reset = 1h]

CAN\_IF1CMD is shown in [Figure 28-42](#) and described in [Table 28-31](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 28.16.2.24 CAN\_IF1ARB Register (Offset (x8) = 210h, Offset (x16) = 108h) [Reset = 0h]

CAN\_IF1ARB is shown in [Figure 28-44](#) and described in [Table 28-33](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 29   | Dir   | R/W  | 0h    | Message Direction<br>0 Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, that frame is stored in this message object.<br>1 Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).<br>Note: This bit is write protected by Busy bit.<br>Reset type: SYSRSn |
| 28-0 | ID    | R/W  | 0h    | Message Identifier<br>ID[28:0] 29-bit Identifier ("Extended Frame")<br>ID[28:18] 11-bit Identifier ("Standard Frame")<br>Note: This bit is write protected by Busy bit.<br>Reset type: SYSRSn  |

**28.16.2.25 CAN\_IF1MCTL Register (Offset (x8) = 218h, Offset (x16) = 10Ch) [Reset = 0h]**

 CAN\_IF1MCTL is shown in [Figure 28-45](#) and described in [Table 28-34](#).

 Return to the [Summary Table](#).

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. This register has control/status bits pertaining to interrupts, acceptance mask, remote frames and FIFO option.
