### 28.16.2.26 CAN\_IF1DATA Register (Offset (x8) = 220h, Offset (x16) = 110h) [Reset = 0h]

CAN\_IF1DATA is shown in [Figure 28-46](#) and described in [Table 28-35](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 28.16.2.28 CAN\_IF2CMD Register (Offset (x8) = 240h, Offset (x16) = 120h) [Reset = 1h]

CAN\_IF2CMD is shown in [Figure 28-48](#) and described in [Table 28-37](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16-bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 28.16.2.30 CAN\_IF2ARB Register (Offset (x8) = 250h, Offset (x16) = 128h) [Reset = 0h]

CAN\_IF2ARB is shown in [Figure 28-50](#) and described in [Table 28-39](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 28.16.2.32 CAN\_IF2DATA Register (Offset (x8) = 260h, Offset (x16) = 130h) [Reset = 0h]

CAN\_IF2DATA is shown in [Figure 28-52](#) and described in [Table 28-41](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 28.16.2.34 CAN\_IF3OBS Register (Offset (x8) = 280h, Offset (x16) = 140h) [Reset = 0h]

CAN\_IF3OBS is shown in [Figure 28-54](#) and described in [Table 28-43](#).

Return to the [Summary Table](#).

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

### 28.16.2.40 CAN\_IF3UPD Register (Offset (x8) = 2C0h, Offset (x16) = 160h) [Reset = 0h]

CAN\_IF3UPD is shown in [Figure 28-60](#) and described in [Table 28-49](#).

Return to the [Summary Table](#).

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set. Note: IF3 Update enable should not be set for transmit objects.

**Figure 28-60. CAN\_IF3UPD Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

## **Modular Controller Area Network (MCAN)**

This chapter describes the Modular Controller Area Network (MCAN). MCAN supports both classic CAN and CAN FD protocols.

## 29.1 MCAN Overview

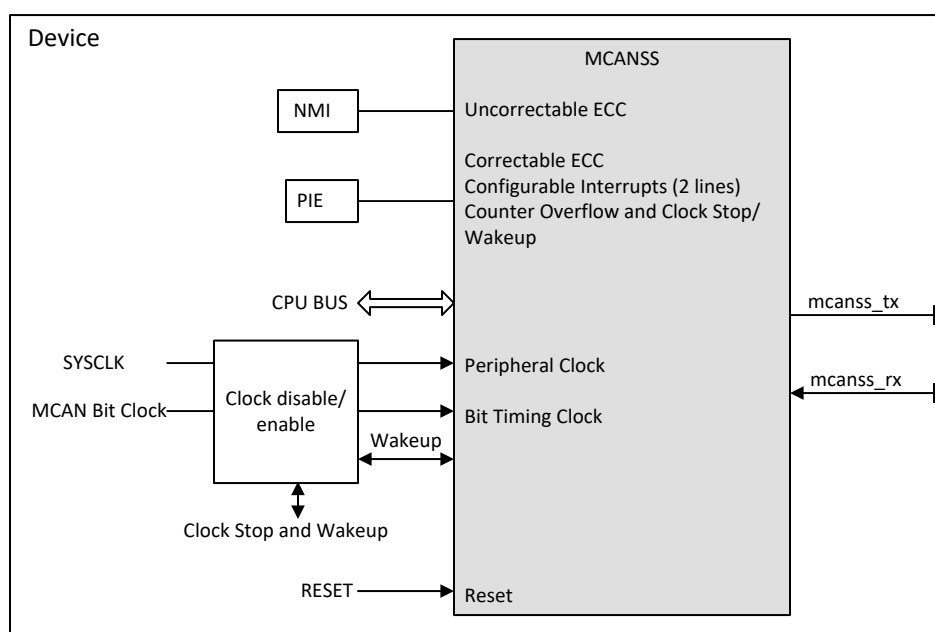

The Controller Area Network (CAN) is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. CAN has high immunity to electrical interference and the ability to detect various type of errors. In CAN, many short messages are broadcast to the entire network, which provides data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with flexible data-rate) protocols. The CAN FD feature allows higher throughput and increased payload per data frame. Classic CAN and CAN FD devices may coexist on the same network without any conflict provided that partial network transceivers, which can detect and ignore CAN FD without generating bus errors, are used by the classic CAN devices. The MCAN module is compliant to ISO 11898-1:2015.

### Note

The availability of the CAN FD feature is dependent on the device's part number. Refer to the device data manual for more information.

Figure 29-1 shows an overview of the MCAN module.

**Figure 29-1. MCAN Module Overview**

### 29.1.1 MCAN Related Collateral

#### Foundational Materials

- [C2000 Academy - Communications](#)
- [CAN and CAN FD Overview \(Video\)](#)
- [CAN and CAN FD Protocol \(Video\)](#)

### 29.1.2 MCAN Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit Event FIFO, up to 32 elements
- Up to 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Loop-back mode for self-test
- Maskable interrupt (two configurable interrupt lines, correctable ECC, counter overflow and clock stop/wakeup)
- Non-maskable interrupt (uncorrectable ECC)
- Two clock domains (CAN clock/host clock)
- ECC check for Message RAM
- Clock stop and wakeup support
- Timestamp counter

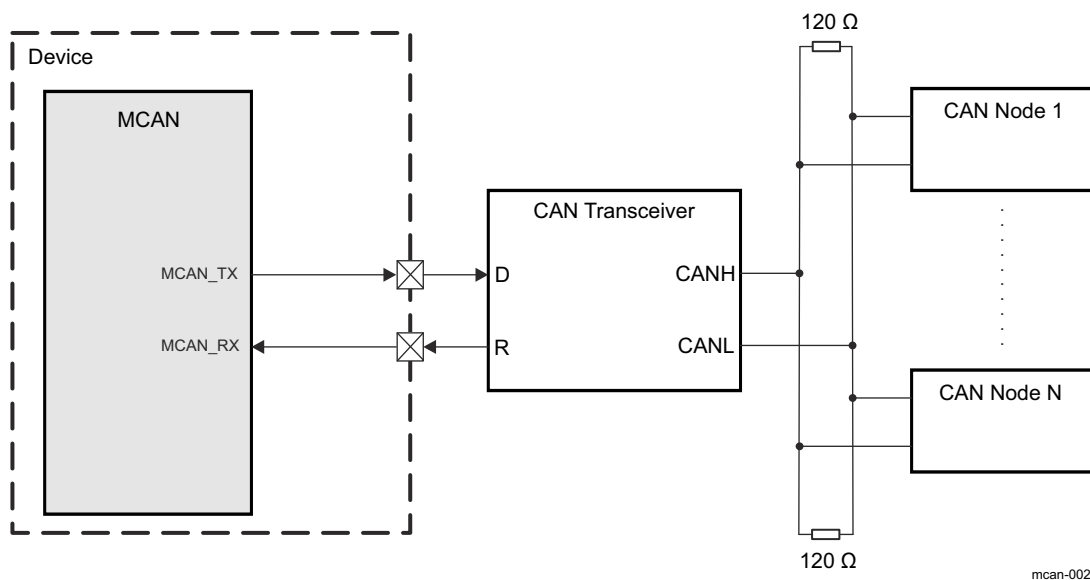

Non-supported features:

- Host bus firewall
- Clock calibration
- Debug over CAN

### 29.2 MCAN Environment

The CAN network physical layer consists of a two-wire differential bus, usually twisted pair, and provides a high level of interference immunity. An external CAN transceiver IC is needed to access the bus.

Figure 29-2 shows typical MCAN wiring.

**Figure 29-2. MCAN Typical Bus Wiring**

Table 29-1 describes the external signals of the MCAN module.

**Table 29-1. MCAN I/O Description**

| Module Signal | I/O    | Description                                      | Value at Reset |
|---------------|--------|--|----------------|
| MCAN_RX       | Input  | Serial data input from external CAN transceiver. | HiZ            |
| MCAN_TX       | Output | Serial data output to external CAN transceiver.  | 1              |

### Note

See the *Terminal Configurations and Functions* section in the device data manual and the *General-Purpose Input/Output (GPIO)* chapter in this TRM to configure this peripheral to be connected to the device pins.

## 29.3 CAN Network Basics

The network basics are:

- The CAN bus is a 2-wire differential bus using non-return-to-zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- When the bus is idle, any node can initiate a transmission to any other node(s). When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier-based, not address-based.
- The content of the message is labeled by the identifier that is unique throughout the network (for example: RPM, temperature, position, pressure, and so forth).
- All nodes on the network receive the message and each performs an acceptance test on the identifier. If the message is relevant, it is processed; otherwise, it is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

### 29.4 MCAN Integration

Figure 29-3 shows the integration of the MCAN module in the device.

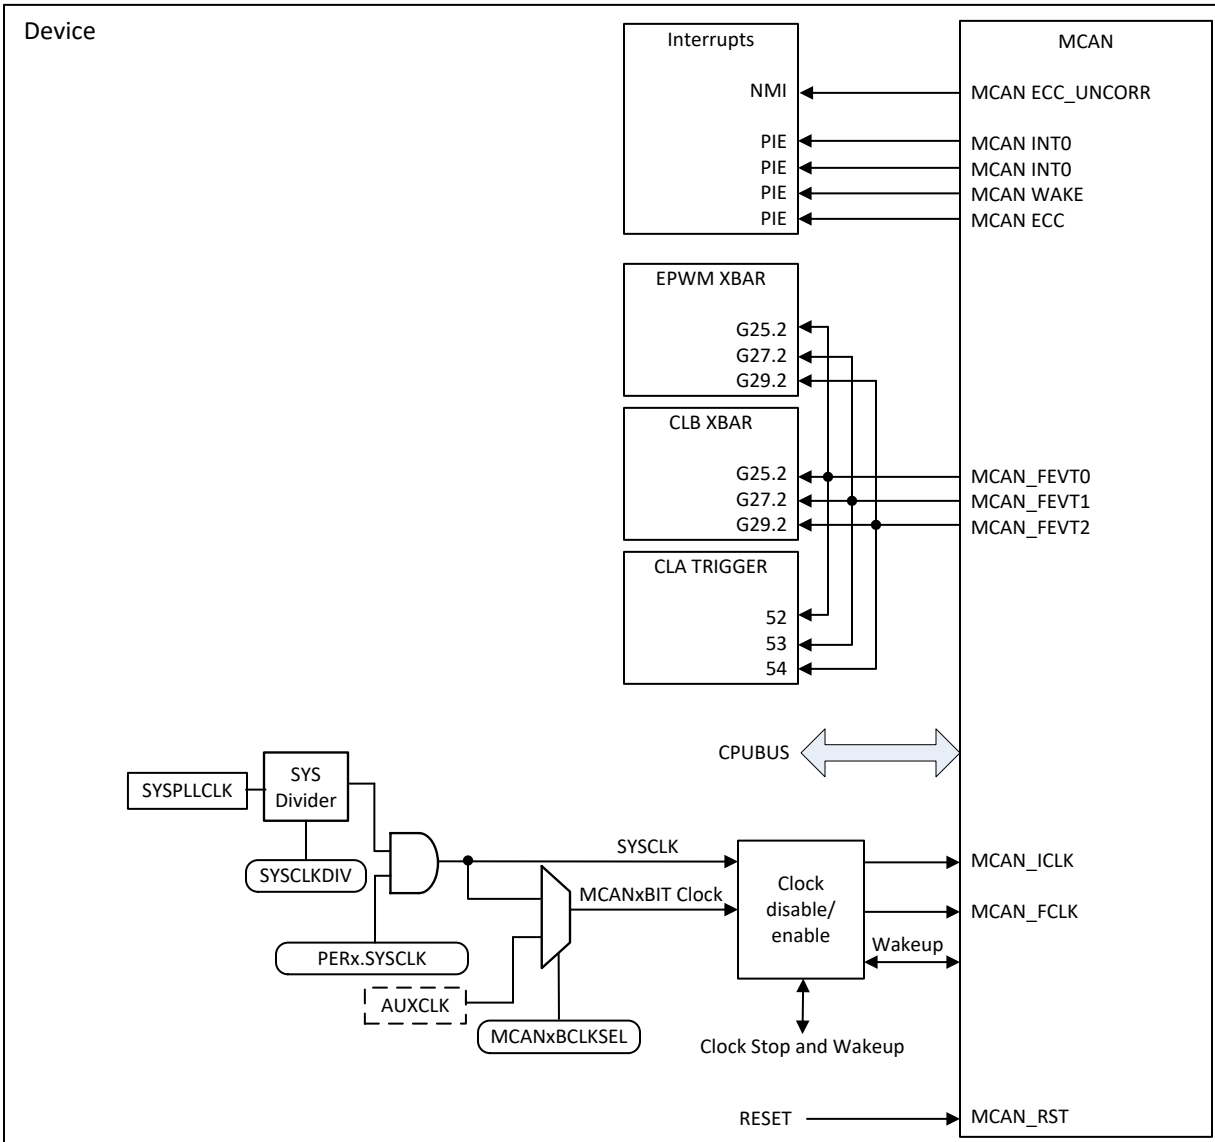

Figure 29-3. MCAN Integration

Table 29-2 and Table 29-3 summarize the integration of the MCAN module in the device.

**Table 29-2. MCAN Clocks and Resets**

| Destination Signal Name | Source Signal Name | Description                                  |
|-------------------------|--------------------|--|
| <b>Clocks</b>           |                    |  |

|                          | CLA Trigger      |               | 54              |                                     |

### Note

For more information about the CLA\_triggers, see the *Control Law Accelerator (CLA)* chapter.

For more information about the CLB XBAR, see the *Configurable Logic Block (CLB)* chapter.

For more information about the ePWM XBAR module, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

## 29.5 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values up to 5 Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 29-4 shows the MCAN module block diagram, followed by the description of the MCAN module blocks.

Figure 29-4. MCAN Block Diagram

- **CAN Core:** The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and Interrupt generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see [Section 29.5.16](#)).
- **Message RAM Interface:** enables a connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface:** The MCAN module registers are accessed by the user's software through a 32-bit peripheral bus interface.
- **Clocking:** Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN\_ICLK) and the peripheral asynchronous clock (functional clock - MCAN\_FCLK).
- **Extension Interface:** All selected internal status and control signals are routed to this interface (except for the indication signals of configuration change enable bit (MCAN\_CCCR.CCE) and Interrupt Register bits (MCAN\_IR).

### 29.5.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN\_ICLK) as the general module clock source, and
- the peripheral asynchronous clock (MCAN\_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module, there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and conversely, and between the reset signal (MCAN\_RST) to the Host clock domain and to the CAN clock domain.

---

#### Note

MCAN\_ICLK must always be higher or equal to MCAN\_FCLK, in order to achieve a stable functionality of the MCAN module:  $f_{ICLK} \geq f_{FCLK}$

---

The CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than the Classic CAN. For optimal performance, TI recommends using the lowest N-divider value that maintains a working PLL REF\_CLK for the system. Lower N-divider values increase the loop bandwidth of the PLL, which in turn improves timing margins for CAN-FD.

### 29.5.2 Interrupt Requests

The MCAN module generates interrupt requests. It is configured via the Host CPU. The Suspend mode prevents the interrupt requests from propagating to the Host CPU. The MCAN core has two interrupt lines and 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are 'level high' interrupts. The MCAN core provides two interrupt requests (MCANSS\_INT0 and MCANSS\_INT1).

For more information, see the following registers:

- Interrupt Register (MCAN\_IR)
- Interrupt Enable (MCAN\_IE)
- Interrupt Line Select (MCAN\_ILS)
- Interrupt Line Enable (MCAN\_ILE)

The MCAN module supports External Timestamp Counter. The External Timestamp Counter produces an interrupt when it rolls over (see [Section 29.5.10.1](#)).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS\_ICS)
- Interrupt Raw Status Register (MCANSS\_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS\_IECS)
- Interrupt Enable Register (MCANSS\_IE)
- Interrupt Enable Status Register (MCANSS\_IES)
- End Of Interrupt Register (MCANSS\_EOI)
- External Timestamp Prescaler Register (MCANSS\_EXT\_TS\_PRESCALER)
- External Timestamp Unserviced Interrupts Counter Register (MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR)

To clear IRQ\_INT0, IRQ\_INT1 and TS\_WAKE interrupts, write to the EOI bit field for the corresponding interrupt number that is described in the MCANSS\_EOI register. When MCAN is used by the C28x CPU, in addition to clearing the interrupt sources, it is necessary to clear the interrupt by writing '1' to PIEACK register in the bit position for group 9 (refer to PIE channel mapping) in order for successive MCAN interrupts to be recognized.

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write a 1 to the EOI registers (MCANERR\_SEC\_EOI.EOI\_WR/MCANERR\_DED\_EOI.EOI\_WR). For more information, see [Section 29.5.12.2](#).

### 29.5.3 Operating Modes

The operating modes are discussed in the following sections.

#### 29.5.3.1 Software Initialization

A software initialization begins when the MCAN\_CCCR.INIT bit is set to 1. This is done either by software or by a hardware reset, when an uncorrected bit error is detected in the Message RAM, or by going to a Bus\_Off state. While the MCAN\_CCCR.INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN\_CCCR.INIT bit does not change any configuration register. Resetting the MCAN\_CCCR.INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus\_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN\_CCCR.INIT and MCAN\_CCCR.CCE bits are set (write protection).

The MCAN\_CCCR.CCE bit can only be set/reset while the MCAN\_CCCR.INIT = 1. The MCAN\_CCCR.CCE bit is automatically reset when the MCAN\_CCCR.INIT bit is reset.

The following registers are reset when the MCAN\_CCCR.CCE bit is set:

- MCAN\_HPMS - High Priority Message Status
- MCAN\_RXF0S - Rx FIFO 0 Status
- MCAN\_RFX1S - Rx FIFO 1 Status
- MCAN\_TXFQS - Tx FIFO/Queue Status
- MCAN\_TXBRP - Tx Buffer Request Pending
- MCAN\_TXBTO - Tx Buffer Transmission Occurred
- MCAN\_TXBCF - Tx Buffer Cancellation Finished
- MCAN\_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN\_TOCV.TOC field is preset to the value configured by the MCAN\_TOCC.TOP field when the MCAN\_CCCR.CCE bit is set.

In addition, the Tx Handler and Rx Handler are held in idle state while MCAN\_CCCR.CCE = 1.

The following registers are only writeable while MCAN\_CCCR.CCE = 0

- MCAN\_TXBAR - Tx Buffer Add Request
- MCAN\_TXBCR - Tx Buffer Cancellation Request

MCAN\_CCCR.TEST and MCAN\_CCCR.MON bits can only be set by the Host CPU while MCAN\_CCCR.INIT = 1 and MCAN\_CCCR.CCE = 1. Both bits may be reset at any time. The MCAN\_CCCR.DAR bit can only be set/reset while MCAN\_CCCR.INIT = 1 and MCAN\_CCCR.CCE = 1.

Table 29-4 shows the steps to configure the MCAN module.

**Table 29-4. Steps to Configure MCAN Module**

| Step | Operation                              | Description  | Pseudo Code   |
|------|--|--|---|
| 1    | Initialize MCAN_CCCR                   | Set MCAN_CCCR.INIT bit and check that it has been set  | INIT = 1;<br>If INIT ≠ 1, wait until set                              |
| 2    | Unlock protected registers             | Set MCAN_CCCR.CCE bit                                  | CCE = 1;  |
| 3    | Configure CAN mode                     | Set MCAN_CCCR.FDOE bit to CAN FD                       | FDOE = 1 for CAN FD<br>FDOE = 0 for Classic CAN                       |
| 4    | Configure Bit Rate Switching           | Set MCAN_CCCR.BRSE bit                                 | BRSE = 1 for bit rate switching<br>BRSE = 0 for no bit rate switching |
| 5    | Set nominal bit timing                 | Set MCAN_NBTP register                                 |   |
| 6    | Lock protected registers               | Clear MCAN_CCCR.CCE bit                                | CCE = 0;  |
| 7    | Return MCAN module to normal operation | Clear MCAN_CCCR.INIT bit and check it has been cleared | INIT = 0;<br>If INIT ≠ 0, wait until set                              |

### 29.5.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN\_CCCR.INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

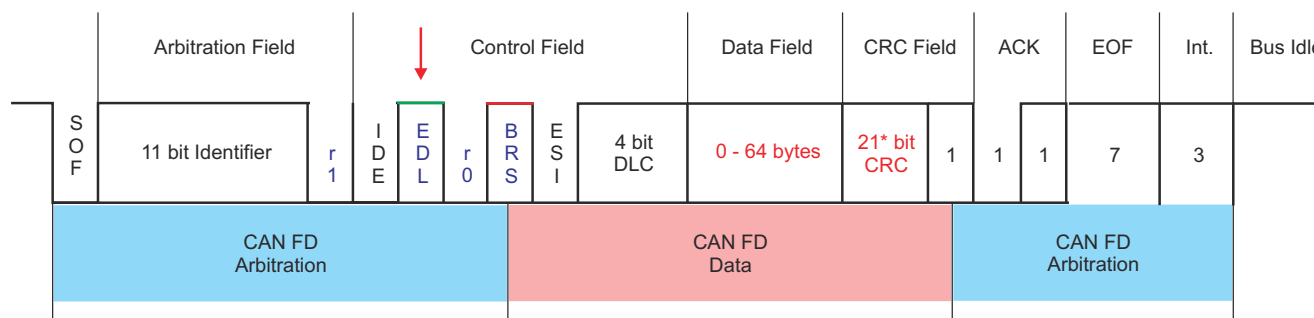

For messages to be transmitted, dedicated Tx buffers and/or a Tx FIFO or a Tx queue can be initialized or updated.

#### Note

Automated transmission upon reception of remote frames is not supported.

### 29.5.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 5 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 29-5, sets a data length of up to 8 or up to 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate compared to the arbitration phase) are enabled.

\* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

**Figure 29-5. CAN FD Frame**

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames, FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. If the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN\_PSR.PXE bit. When Protocol Exception Handling is enabled (MCAN\_CCCR.PXHD = 0), this causes the operation state to change from Receiver (MCAN\_PSR.ACT = 10) to Integrating (MCAN\_PSR.ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN\_CCCR.PXHD = 1), the MCAN will treat a recessive bit as an error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN\_CCCR.FDOE bit. If MCAN\_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN\_CCCR.FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN\_CCCR.FDOE and MCAN\_CCCR.BRSE bits can only be changed while the MCAN\_CCCR.INIT and MCAN\_CCCR.CCE bits are both set. With MCAN\_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN\_CCCR.FDOE = 1 and MCAN\_CCCR.BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN\_CCCR.FDOE = 1 and MCAN\_CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

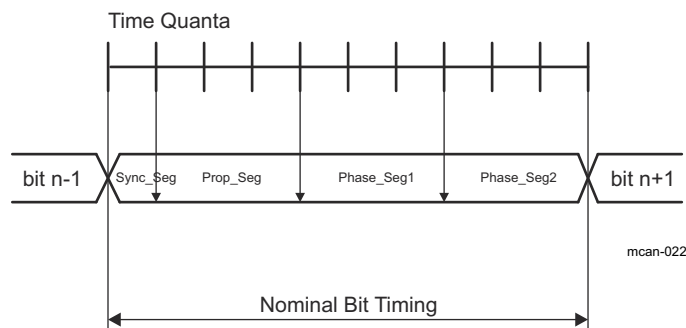

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to [Table 29-5](#).

**Table 29-5. DLC Coding in CAN FD**

| DLC                  | 9  | 10 | 11 | 12 | 13 | 14 | 15 |
|----------------------|----|----|----|----|----|----|----|
| Number of Data Bytes | 12 | 16 | 20 | 24 | 32 | 48 | 64 |

For CAN FD frames, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 29-6](#)) is used as configured by the Nominal Bit Timing and Prescaler Register (MCAN\_NBTP). In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register (MCAN\_DBTP). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

**Figure 29-6. CAN Bit Timing**

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN\_FCLK). Example: with MCAN\_FCLK = 20 MHz and the shortest configurable bit time of 4 t<sub>q</sub> (time quanta), the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the Error Status Indicator (ESI) bit depends on transmitter's error state (see MCAN\_PSR.RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag, the ESI bit is transmitted recessive, else it is transmitted dominant.

## 29.5.4 Transmitter Delay Compensation

### 29.5.4.1 Description

When only one CAN FD node is transmitting and all other nodes are receivers, the length of the bus line has no impact. When transmitting via the TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

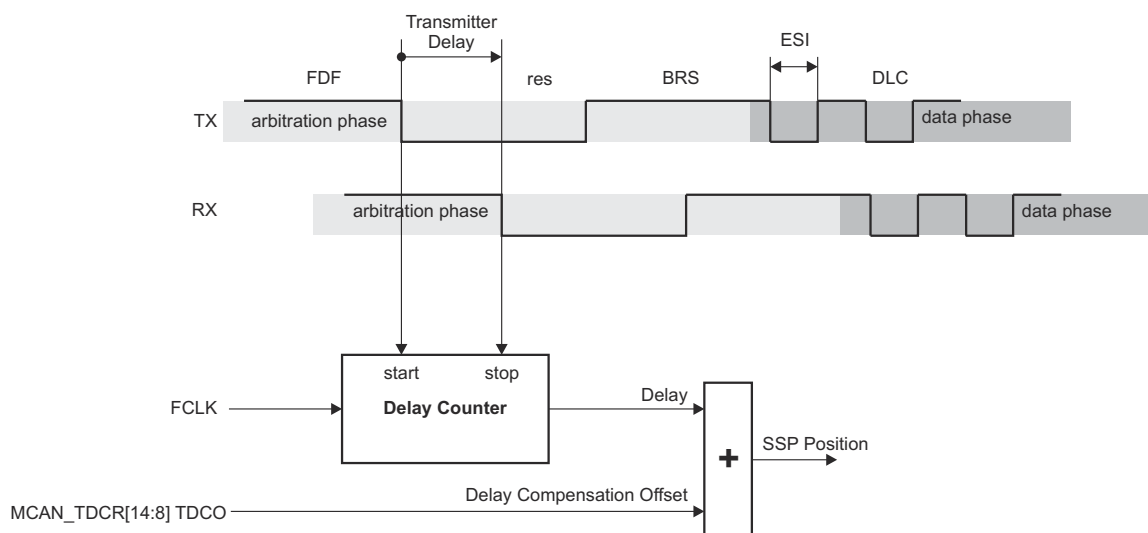

The MCAN module provides a delay compensation mechanism to compensate for the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN\_DBTP.TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN\_TDCR.TDCO field (see [Figure 29-7](#)). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN\_PSR.TDCV field. This field is cleared when the MCAN\_CCCR\_INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN\_DBTP.TDC bit is set.

mcan-005

**Figure 29-7. Transmitter Delay Measurement**

### 29.5.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming `MCAN_DBTP.TDC = 1`), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit `r0`. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see [Figure 29-7](#)). The mtq (minimum time quantum) dimension is equal to the CAN clock period (`MCAN_FCLK`).

The use of a transmitter delay compensation filter window can be enabled by programming the `MCAN_TDCR.TDCF` field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least `MCAN_TDCR.TDCF` field and the RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (`MCAN_TDCR.TDCO` field) has to be less than six bit times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (`MCAN_TDCR.TDCO`) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

### 29.5.5 Restricted Operation Mode

In restricted operation mode, the CAN node is able to receive data and remote frames and to give acknowledgment to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits; instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (`MCAN_ECR.REC` and `MCAN_ECR.TEC`) are frozen while CAN error logging (`MCAN_ECR.CEL`) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting the `MCAN_CCCR.ASM` bit. The bit can only be set by the Host CPU at any time when both `MCAN_CCCR.CCE` and `MCAN_CCCR.INIT` bits are set to 1.

The restricted operation mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave restricted operation mode, the Host CPU has to reset the `MCAN_CCCR.ASM` bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case, the application tests different bit rates and leaves the restricted operation mode after it has received a valid frame.

---

#### Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

---

### 29.5.6 Bus Monitoring Mode

Entering bus monitoring mode is done by setting the `MCAN_CCCR.MON` bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In bus monitoring mode the `MCAN_TXBRP` register is held in reset state. The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. [Figure 29-8](#) shows the connection of the TX and RX signals to the MCAN module in bus monitoring mode.

**Figure 29-8. Connection of Signals in Bus Monitoring Mode**

### 29.5.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN\_CCCR.DAR bit).

#### 29.5.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx buffer's Tx Request Pending (MCAN\_TXBRP[xx]) TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF[xx]) CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF[xx]) CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO[xx]) TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF[xx]) CFx bit is set

In the case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

### 29.5.8 Clock Stop Mode

Entering clock stop mode is controlled by the input clock stop request signal or MCAN\_CCCR.CSR bit. As long as the clock stop request signal is active, the MCAN\_CCCR.CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN\_CCCR.INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal to 1 and the MCAN\_CCCR.CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN\_CCCR.INIT bit will have no effect. Now the module clock inputs MCAN\_ICLK and MCAN\_FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN\_CCCR.CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN\_CCCR.CSA flag bit. Afterwards, the application can restart CAN communication by resetting MCAN\_CCCR.INIT bit.

Restoring the clocks from clock stop mode, needs to be done according to how the clock stop was initiated.

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN\_CCCR.INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits to 1 (for more information, see [Section 29.5.8.2](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN\_CCCR.INIT bit is performed to clear it.

### 29.5.8.1 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS\_CTRL.DBGSUSP\_FREE bit), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN\_CCCR.INIT bit will be set and the MCAN core will stay Idle. The suspend state can be verified by reading MCAN\_CCCR.INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits to 1 (for more information, see [Section 29.5.8.2](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN\_CCCR.INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN\_ECR.CEL
- MCAN\_PSR.LEC
- MCAN\_PSR.DLEC
- MCAN\_PSR.RESI
- MCAN\_PSR.RBRS
- MCAN\_PSR.RFDF
- MCAN\_PSR.PXE

### 29.5.8.2 Wakeup Request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN\_CCCR.INIT bit and the MCAN core will resume operation.

If the MCANSS\_CTRL.WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is de-asserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is de-asserted
- A reset is applied to the MCAN module

### 29.5.9 Test Modes

The MCAN\_TEST register write access is enabled by setting the test mode enable MCAN\_CCCR.TEST bit to 1. The MCAN\_TEST register allows the configuration of the test modes and test functions.

The CAN transmit TX pin has four output functions. One of those functions can be selected by programming the MCAN\_TEST.TX field. Additionally to its default function (the serial data output) it can drive the CAN sample point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive RX pin can be monitored from MCAN\_TEST.RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between the CAN clock (MCANx\_FCLK) and Host clock (MCANx\_ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN\_TEST.TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin by way of the MCAN\_TEST.RX bit.

---

#### Note

Test modes should be used for self-test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

---

#### 29.5.9.1 Internal Loop Back Mode

The MCAN module can be set into internal loop back mode by programming MCAN\_TEST.LBCK and MCAN\_CCCR.MON bits to 1. The internal loop back mode is used for a Hot Selftest. The Hot Selftest allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode, the RX pin is disconnected from the MCAN module and the TX pin is held recessive. Figure 29-9 shows the connection of the TX and RX pins to the MCAN module in internal loop back mode.

**Figure 29-9. Internal Loop Back Mode**

### 29.5.10 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN\_TSCC.TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable by way of the MCAN\_TSCV.TSC field. A write access to the MCAN\_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN\_IR.TSW flag

is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see [Section 29.5.16](#).

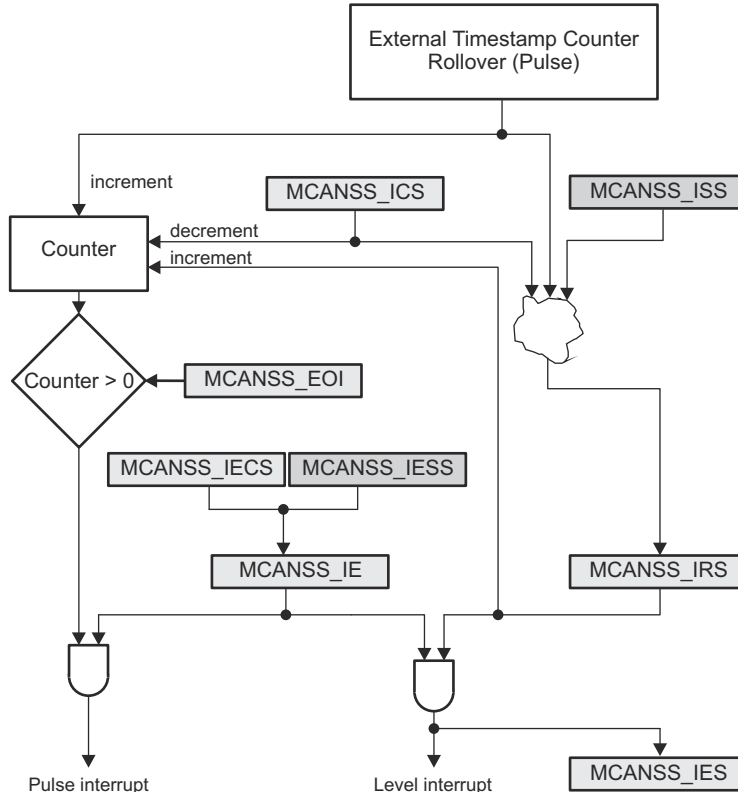

### 29.5.10.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an external timestamp counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN\_TSCC.TSS field.

The external timestamp counter uses the interface clock (MCANx\_ICLK) as a reference clock. The MCAN core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS\_EXT\_TS\_PRESCALER.PRESCALER bit field). The external timestamp counter can be enabled or disabled through the MCANSS\_CTRL.EXT\_TS\_CNTR\_EN bit. When disabled, the counter is reset back to zero. While enabled, the counter keeps incrementing. When the timestamp rolls over, the MCAN\_IRQ\_TS interrupt is generated.

When the timestamp rolls over, the MCANSS\_IRS register is set. The MCANSS\_IE register can be affected by writing to the MCANSS\_IESS register to set or to the MCANSS\_IECS register to clear. The MCANSS\_IESS register is a shadow register mapped to the same address as the MCANSS\_IE register. The level interrupt is a reflection of both MCANSS\_IRS and MCANSS\_IE being set. The MCANSS\_IES register reflects the level interrupt. When an rollover event occurs, the interrupt counter is incremented. Writing to the MCANSS\_ICS register to clear the MCANSS\_IRS register will also decrement the interrupt counter. Writing to the MCANSS\_EOI register will issue another pulse if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS\_ISS). The MCANSS\_ISS register is a shadow register mapped to the same address as the MCANSS\_IRS register.

mcan-021

**Figure 29-10. External Timestamp Counter Interrupt**

### 29.5.11 Timeout Counter

The MCAN module has integrated a 16-bit timeout counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The timeout counter is configured by way of the MCAN\_TOCC register. It is enabled by way of the MCAN\_TOCC.ETOC bit. The timeout counter operates as down-counter and uses the same prescaler programmed by the MCAN\_TSCC.TCP field as the timestamp counter. The actual counter value can be monitored from the MCAN\_TOCV.TOC field. The timeout counter can be started only when MCAN\_CCCR.INIT = 0 and stopped when MCAN\_CCCR.INIT = 1 (example: when the MCAN enters Bus\_Off state). The operation mode is selected by the MCAN\_TOCC.TOS field. When continuous mode is selected, the counter starts when MCAN\_CCCR.INIT = 0, a write to the MCAN\_TOCV register presets the counter to the value configured by the MCAN\_TOCC.TOP field and continues down-counting.

In case the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN\_TOCC.TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN\_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN\_IR.TOO flag is set.

In continuous mode, the counter is immediately restarted at the value configured by the MCAN\_TOCC.TOP field.

---

#### Note

The clock signal for the timeout counter is derived from the CAN core's sample point signal. Therefore the point in time where the timeout counter is decremented may vary due to the synchronization/re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

---

### 29.5.12 Safety

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC aggregator.

#### 29.5.12.1 ECC Wrapper

The ECC wrapper provides single error correction (SEC) and double error detection (DED) parity to the message memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

#### 29.5.12.2 ECC Aggregator

This section describes the functional details of the ECC aggregator module.

##### 29.5.12.2.1 ECC Aggregator Overview

The ECC aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

### 29.5.12.2.2 ECC Aggregator Registers

There are three groups of registers in the ECC aggregator module:

- **Global registers:** Aggregator Revision Register (MCANERR\_REV), ECC Vector Register (MCANERR\_VECTOR), Misc Status Register (MCANERR\_STAT), ECC Control Register (MCANERR\_CTRL), and ECC Wrapper Revision Register (MCANERR\_WRAP\_REV).
- **Control and status registers:** ECC Error Control Registers (MCANERR\_ERR\_CTRL1 and MCANERR\_ERR\_CTRL2) and ECC Error Status Registers (MCANERR\_ERR\_STAT1, MCANERR\_ERR\_STAT2, and MCANERR\_ERR\_STAT3).
- **Interrupt registers:** interrupt status, interrupt enable set, interrupt enable clear, and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANERR\_SEC\_EOI
  - MCANERR\_SEC\_STATUS
  - MCANERR\_SEC\_ENABLE\_SET
  - MCANERR\_SEC\_ENABLE\_CLR
  - MCANERR\_DED\_EOI
  - MCANERR\_DED\_STATUS
  - MCANERR\_DED\_ENABLE\_SET
  - MCANERR\_DED\_ENABLE\_CLR

### 29.5.12.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as:

- Software writes value (the ECC RAM ID) to the MCANERR\_VECTOR.ECC\_VECTOR field to select the ECC RAM for control or status.
- Software writes 1 to the MCANERR\_VECTOR.RD\_SVBUS bit to trigger a read.
- Software writes read address to the MCANERR\_VECTOR.RD\_SVBUS\_ADDRESS field.
- Software then polls the MCANERR\_VECTOR.RD\_SVBUS\_DONE bit to check if it is 1. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN\_ICLK) returns the read data.

### 29.5.12.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described:

- Software enables the interrupts for the ECC RAM by writing to the MCANERR\_SEC\_ENABLE\_SET/MCANERR\_DED\_ENABLE\_SET register.
- Software writes the ECC RAM ID in the MCANERR\_VECTOR.ECC\_VECTOR.
- Software writes the MCANERR\_VECTOR.RD\_SVBUS bit to trigger the read.
- Software writes the MCANERR\_ERR\_STAT1 register address to the MCANERR\_VECTOR.RD\_SVBUS\_ADDRESS field. Software will need to load the 'read message' in the rMCANERR\_VECTOR register again if it needs to read the MCANERR\_ERR\_STAT2 register.
- Software polls the MCANERR\_VECTOR.RD\_SVBUS\_DONE bit. When this bit is set, a read of the MCANERR\_ERR\_STAT1/MCANERR\_ERR\_STAT2 register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the MCANERR\_ERR\_STAT1.CLR\_ECC\_SEC or MCANERR\_ERR\_STAT1.CLR\_ECC\_DED bit depending on the type of the ECC error.
- Software has to poll the MCANERR\_ERR\_STAT1 register to guarantee that the status bit has been cleared.
- Software will write to the MCANERR\_SEC\_EOI/MCANERR\_DED\_EOI register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANERR\_SEC\_EOI.EOI\_WR/MCANERR\_DED\_EOI.EOI\_WR bits.

### 29.5.13 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

#### 29.5.13.1 Acceptance Filtering

The MCAN module employs two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic bit mask filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register
- Extended ID AND Mask (MCAN\_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 29.5.16](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN\_ICLK pulse.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN\_IR.HPM
- Set High Priority Message interrupt flag MCAN\_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32-bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer: New Data flag (MCAN\_NDAT1/MCAN\_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type, see MCAN\_PSR.LEC and MCAN\_PSR.DLEC fields, respectively).
- Rx FIFO: Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type, see MCAN\_PSR.LEC and MCAN\_PSR.DLEC fields, respectively). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 29.5.13.2.2](#) have to be considered.

---

#### Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

---

### 29.5.13.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 29.5.16.5](#) and [Section 29.5.16.6](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN\_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN\_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN\_XIDAM) is not used for Range Filtering.

### 29.5.13.1.2 Filter for Specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information, see [Section 29.5.16.5](#) and [Section 29.5.16.6](#).

### 29.5.13.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT = 10/Extended Filter Type EFT = 10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while the SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

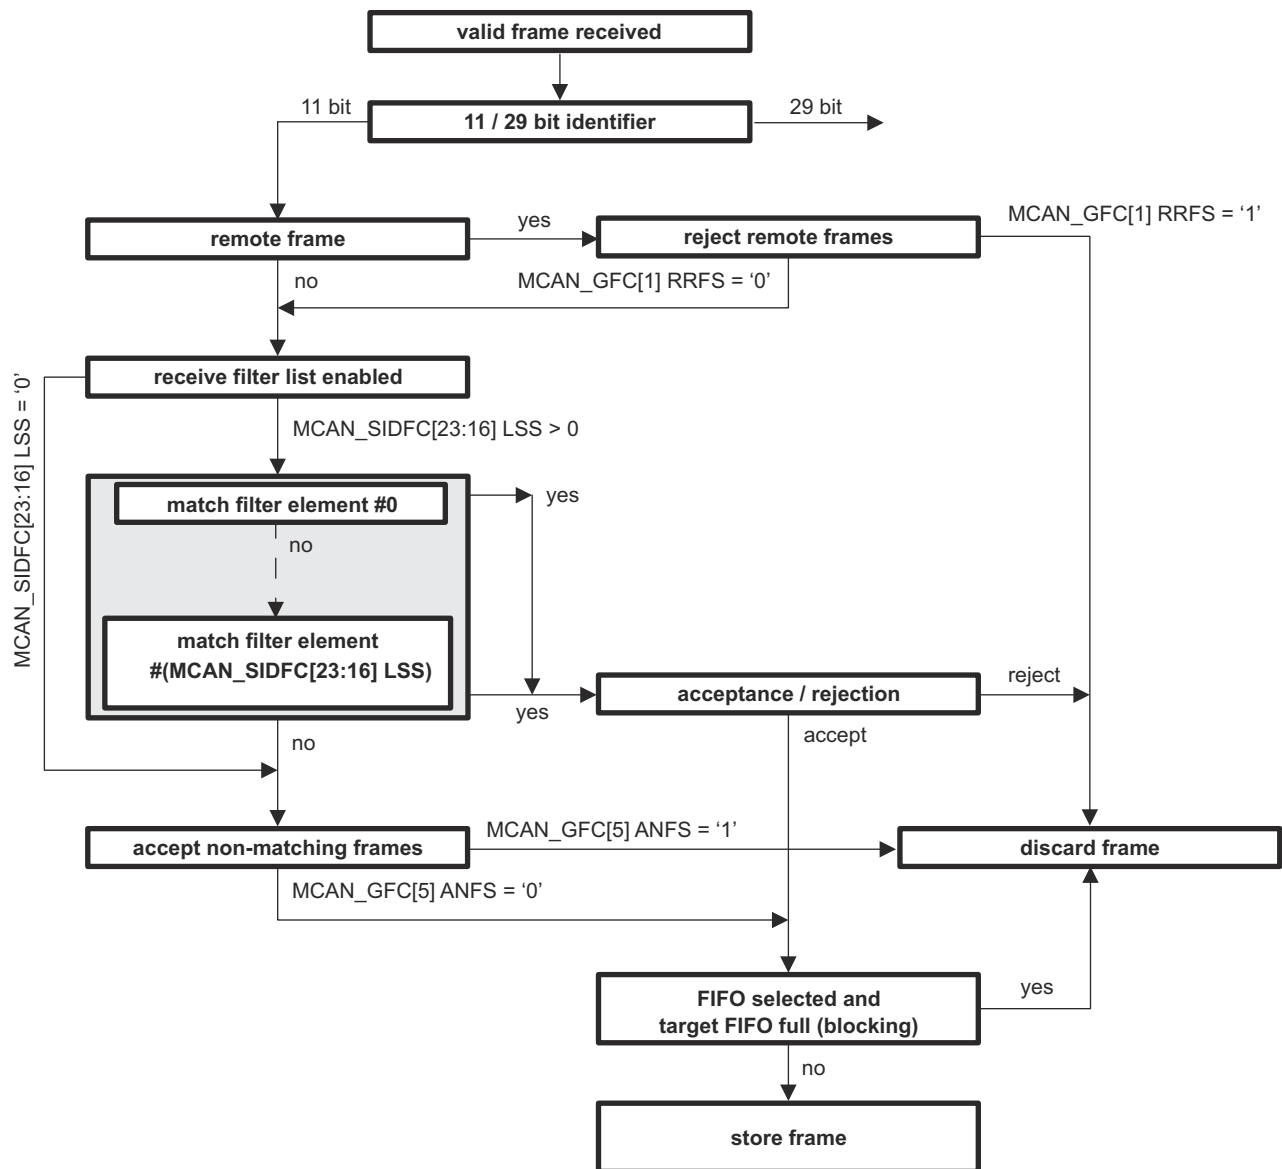

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

### 29.5.13.1.4 Standard Message ID Filtering

Figure 29-11 shows the standard Message ID (11-bit ID) filtering flow. Section 29.5.16.5 describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register

mcan-009

**Figure 29-11. Standard Message ID Filter Path**

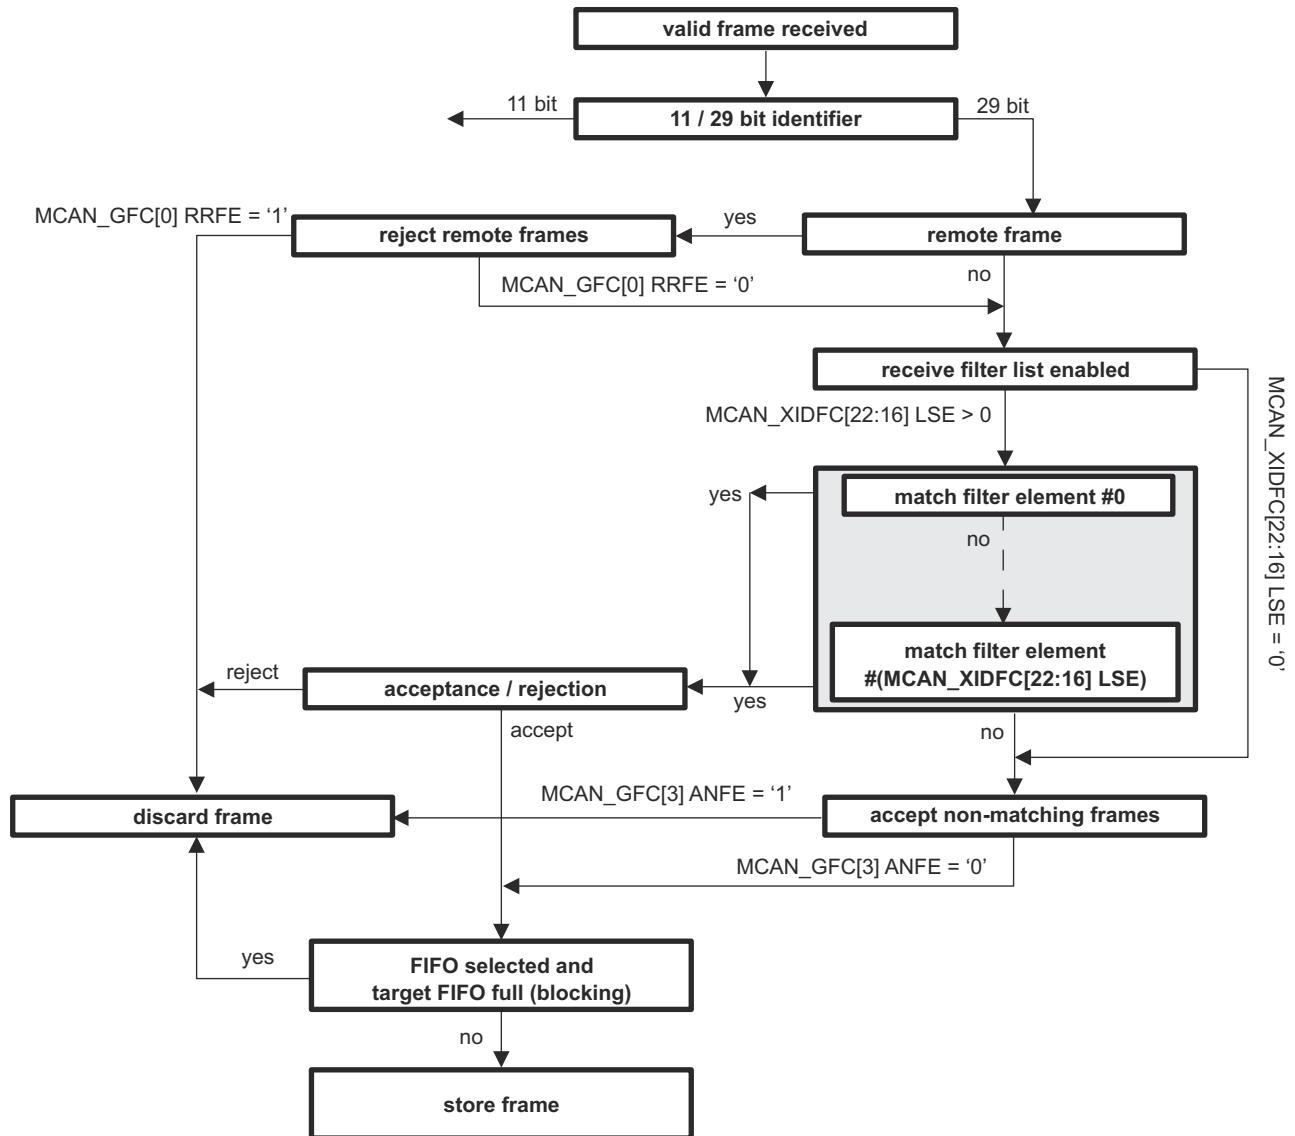

29.5.13.1.5 Extended Message ID Filtering

Figure 29-12 shows the extended Message ID (29-bit ID) filtering flow. Section 29.5.16.6 describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register

Note that before the filter list is executed, the received identifier is ANDed with the Extended ID AND Mask (MCAN\_XIDAM).

mcan-010

Figure 29-12. Extended Message ID Filter Path

### 29.5.13.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done by way of the MCAN\_RXF0C and MCAN\_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 are described in [Section 29.5.13.1](#). The Rx FIFO element is described in [Section 29.5.16.2](#).

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN\_RXFnC[30:24] FnWM filed (where: n = 0 or 1), an interrupt flag MCAN\_IR.RF0W/MCAN\_IR.RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN\_RXFnS[21:16] FnPI = MCAN\_RXFnS[13:8] FnGI), an Rx FIFO Full condition is signalled by the MCAN\_RXFnS[24] FnF status bit and interrupt flag MCAN\_IR.RF0F/MCAN\_IR.RF1F is set. [Figure 29-13](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN\_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

**Figure 29-13. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN\_RXFnC[15:2]FnSA field) has to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN\_RXFnS[13:8] FnGI). [Table 29-6](#) presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured by way of the MCAN\_RXESC register.

**Table 29-6. Rx Buffer/Rx FIFO Element Size**

| MCAN_RXESC Register<br>RBDS/F0DS/F1DS Bits | Data Field<br>[bytes] | FIFO Element Size<br>[RAM words] |
|--|-----------------------|----------------------------------|
| 000  | 8                     | 4                                |
| 001  | 12                    | 5                                |
| 010  | 16                    | 6                                |
| 011  | 20                    | 7                                |
| 100  | 24                    | 8                                |
| 101  | 32                    | 10                               |
| 110  | 48                    | 14                               |
| 111  | 64                    | 18                               |

### 29.5.13.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the `MCAN_RXFnC[31] FnOM = 0`.

If an Rx FIFO full condition is reached (`MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI`), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the `MCAN_RXFnS[24] FnF = 1` and interrupt flag `MCAN_IR.RF0F/MCAN_IR.RF1F` is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by `MCAN_RXFnS[25] RFnL = 1` and interrupt flag `MCAN_IR.RF0L/MCAN_IR.RF1L` is set.

### 29.5.13.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the `MCAN_RXFnC[31] FnOM = 1`. When an Rx FIFO full condition is reached (`MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI`) signalled by `MCAN_RXFnS[24] FnF = 1`, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode, if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. [Figure 29-14](#) shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

**Figure 29-14. Rx FIFO Overflow Handling**

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index `MCAN_RXFnA[5:0] FnAI`. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (`MCAN_RXFnS[24] FnF = 0`).

### 29.5.13.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx buffers. The start address of the Rx buffers section in the Message RAM is configured by way of the MCAN\_RXBC.RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see [Section 29.5.16.5](#) and [Section 29.5.16.6](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition, the flag MCAN\_IR.DRX (message stored in Dedicated Rx Buffer) is set.

[Table 29-7](#) shows an example filter configuration for Rx buffers.

**Table 29-7. Example Filter Configuration for Rx Buffers**

| Filter Element | SFID1[10:0]<br>EFID1[28:0] | SFID2[10:9]<br>EFID2[10:9] | SFID2[5:0]<br>EFID2[5:0] |
|----------------|----------------------------|----------------------------|--------------------------|
| 0              | ID message 1               | 00                         | 00 0000                  |
| 1              | ID message 2               | 00                         | 00 0001                  |
| 2              | ID message 3               | 00                         | 00 0010                  |

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN\_NDAT1/MCAN\_NDAT1 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

#### 29.5.13.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN\_IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

### 29.5.14 Tx Handling

The Tx handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx buffers. These Tx buffers can be configured as dedicated Tx buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx buffers/Tx FIFO or dedicated Tx buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 29.5.16.3](#) describes the Tx Buffer Element. [Table 29-8](#) shows the possible configurations for message transmission.

**Table 29-8. Possible Configurations for Message Transmission**

| MCAN_CCCR Register |      | Tx Buffer Element |         | Frame Transmission                |
|--------------------|------|-------------------|---------|-----------------------------------|
| BRSE               | FDOE | FDF               | BRS     |                                   |
| ignored            | 0    | ignored           | ignored | Classic CAN                       |
| 0                  | 1    | 0                 | ignored | Classic CAN                       |
| 0                  | 1    | 1                 | ignored | CAN FD without bit rate switching |
| 1                  | 1    | 0                 | ignored | Classic CAN                       |
| 1                  | 1    | 1                 | 0       | CAN FD without bit rate switching |
| 1                  | 1    | 1                 | 1       | CAN FD with bit rate switching    |

When the Tx Buffer Request Pending (MCAN\_TXBRP) register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with the lowest Message ID has highest priority.

---

**Note**

AUTOSAR requires at least three Tx Queue buffers and support of transmit cancellation.

---

### 29.5.14.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN\_CCCR.TXP bit. By default this bit is disabled (MCAN\_CCCR.TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

### 29.5.14.2 Dedicated Tx Buffers

Dedicated Tx buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done using the MCAN\_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 29-9 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates element size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN\_TXFQS.TFQP) × Element size to the Tx Buffer start address MCAN\_TXBC.TBSA field.

**Table 29-9. Tx Buffer/Tx FIFO/Tx Queue Element Size**

| MCAN_TXESC.TBDS | Data Field [bytes] | Element Size [RAM words] |
|-----------------|--------------------|--------------------------|
| 000             | 8                  | 4                        |
| 001             | 12                 | 5                        |
| 010             | 16                 | 6                        |
| 011             | 20                 | 7                        |
| 100             | 24                 | 8                        |
| 101             | 32                 | 10                       |
| 110             | 48                 | 14                       |
| 111             | 64                 | 18                       |

### 29.5.14.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN\_TXBC.TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN\_TXFQS.TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN\_TXFQS.TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS.TFQP field. After each Add Request (MCAN\_TXBAR[x] ARn = 1) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN\_TXFQS.TFQP = MCAN\_TXFQS.TFGI), Tx FIFO Full condition is signaled by bit MCAN\_TXFQS.TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx buffers as indicated by the Tx FIFO Free Level MCAN\_TXFQS.TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN\_TXFQS.TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates element size 32-bit words in the Message RAM (see [Table 29-9](#)). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC.TBSA field.

### 29.5.14.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN\_TXBC.TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS.TFQP field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN\_TXFQS.TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application may use the MCAN\_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates element size 32-bit words in the Message RAM (see [Table 29-9](#)). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC.TBSA field.

### 29.5.14.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN\_TXBC.NDTB field
- Tx FIFO: the number of Tx buffers assigned to the Tx FIFO is configured by the MCAN\_TXBC.TFQS field

If the MCAN\_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan Dedicated Tx buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN\_TXFQS.TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

[Figure 29-15](#) shows Mixed Dedicated Tx buffers/Tx FIFO example.

Figure 29-15. Mixed Dedicated Tx Buffers /Tx FIFO (example)

29.5.14.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN\_TXBC.NDTB field
- Tx Queue: the number of Tx buffers assigned to the Tx Queue is configured by the MCAN\_TXBC.TFQS field

If MCAN\_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan all Tx buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 29-16 shows Mixed Dedicated Tx buffers/Tx Queue example.

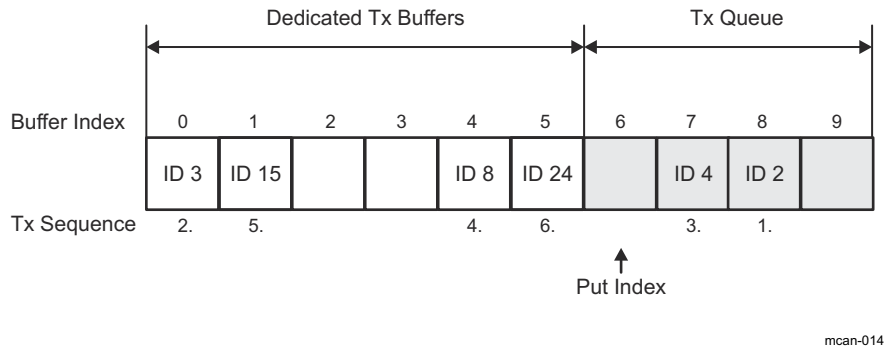

Figure 29-16. Mixed Dedicated Tx Buffers /Tx Queue (example)

29.5.14.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN\_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of the MCAN\_TXBCF register (MCAN\_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN\_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN\_TXBTO[n] TOn and MCAN\_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN\_TXBCF[n] CFn = 1.

---

**Note**

If pending transmission is canceled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message that may have a lower priority than the second message in this node.

---

**29.5.14.8 Tx Event Handling**

To support Tx Event Handling, the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. [Section 29.5.16.4](#) describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signaled by the MCAN\_IR.TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN\_TXEFS.EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN\_IR.TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN\_TXEFC.EFWM field, interrupt flag MCAN\_IR.TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN\_TXEFS.EFGI field has to be added to the Tx Event FIFO start address MCAN\_TXEFC.EFSA field.

**29.5.15 FIFO Acknowledge Handling**

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN\_RXF0A, MCAN\_RXF1A, and MCAN\_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

---

**Note**

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

---

**29.5.16 Message RAM**

The MCAN module has a Message RAM. The main purpose of the Message RAM is to store:

- Received Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

### 29.5.16.1 Message RAM Configuration

The MCAN module is configured to allocate up to 2048 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM is from 0x0005 8000 to 0x0005 9FFF.

The Message RAM is capable to include each of the sections listed in Figure 29-17. It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is no restriction with respect to the sequence of the sections. For parity checking or ECC, a respective number of bits has to be added to each word. When the MCAN module addresses the Message RAM, it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0, by way of the MCAN\_RXESC.F0DS field
- Rx FIFO, 1 by way of the MCAN\_RXESC.F1DS field
- Rx buffers, by way of the MCAN\_RXESC.RBDS field
- Tx buffers, by way of the MCAN\_TXESC.TBDS field

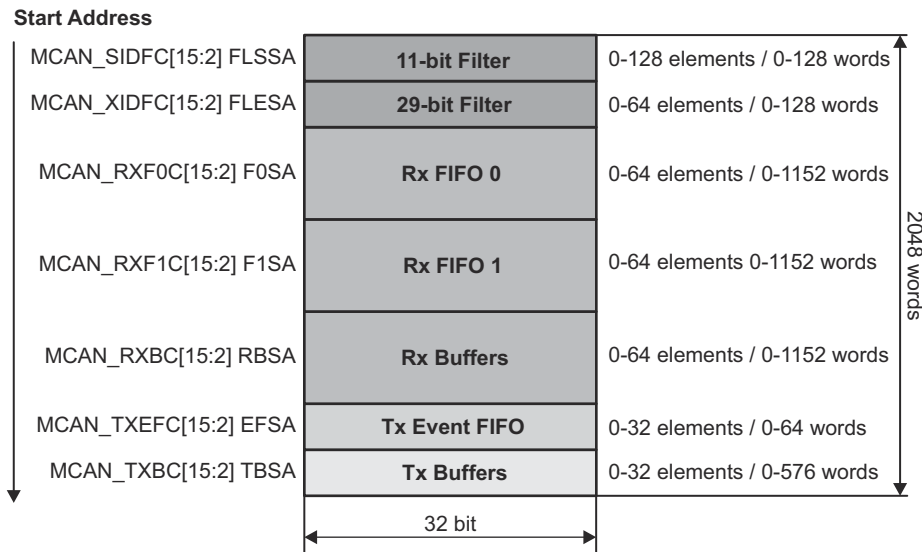

Figure 29-17. Message RAM Configuration

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

**Note**

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This prevents falsification or loss of data.

### 29.5.16.2 Rx Buffer and FIFO Element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN\_RXESC register.

Figure 29-18 shows Rx Buffer/Rx FIFO element structure.

**Figure 29-18. Rx Buffer/Rx FIFO Element Structure**

Table 29-10 shows Rx Buffer/Rx FIFO element field descriptions.

**Table 29-10. Rx Buffer/Rx FIFO Element Field Descriptions**

| Word | Bits | Field Name | Description   |

|      | 23:16 | DBm-1[7:0] | Data Byte m-1   |
|      | 15:8  | DBm-2[7:0] | Data Byte m-2   |
|      | 7:0   | DBm-3[7:0] | Data Byte m-3   |

**Note:** Depending on the configuration of the element size (MCAN\_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

**29.5.16.3 Tx Buffer Element**

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO/Tx Queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx buffers and Tx FIFO/Tx Queue by way of the MCAN\_TXBC.TFQS and MCAN\_TXBC.NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN\_TXESC register.

Figure 29-19 shows Tx Buffer element structure.

**Figure 29-19. Tx Buffer Element Structure**

Table 29-11 shows Tx Buffer element field descriptions.

**Table 29-11. Tx Buffer Element Field Descriptions**

| Word | Bits | Field Name | Description   |

|      | 15:8  | DBm-2[7:0] | Data Byte m-2   |
|      | 7:0   | DBm-3[7:0] | Data Byte m-3   |

**Note**

Depending on the configuration of the element size (MCAN\_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

### 29.5.16.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN\_TXEFS register.

Figure 29-20 shows Tx Event FIFO element structure.

mcan-018

**Figure 29-20. Tx Event FIFO Element Structure**

Table 29-12 shows Tx Event FIFO element field descriptions.

### 29.5.16.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN\_SIDFC.FLSSA field plus the index of the filter element (0-127).

[Figure 29-21](#) shows Standard Message ID Filter element structure.

**Figure 29-21. Standard Message ID Filter Element Structure**

[Table 29-13](#) shows Standard Message ID Filter element field descriptions.

**Table 29-13. Standard Message ID Filter Element Field Descriptions**

| Word | Bits  | Field Name  | Description  |
|------|-------|-------------|--|
|      | 31:30 | SFT[1:0]    | <p>Standard Filter Type</p> <ul style="list-style-type: none"> <li>0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1)</li> <li>0x1: Dual ID filter for SFID1 or SFID2</li> <li>0x2: Classic filter: SFID1 = filter; SFID2 = mask</li> <li>0x3: Filter element disabled</li> </ul> <p><b>Note:</b> With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = 000)</p>  |
|      | 29:27 | SFEC[2:0]   | <p>Standard Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0x0: Disable filter element</li> <li>0x1: Store in Rx FIFO 0 if filter matches</li> <li>0x2: Store in Rx FIFO 1 if filter matches</li> <li>0x3: Reject ID if filter matches</li> <li>0x4: Set priority if filter matches</li> <li>0x5: Set priority and store in FIFO 0 if filter matches</li> <li>0x6: Set priority and store in FIFO 1 if filter matches</li> <li>0x7: Store into Rx Buffer , configuration of SFT[1:0] ignored</li> </ul> |
| S0   | 26:16 | SFID1[10:0] | <p>Standard Filter ID 1</p> <p>When filtering for Rx buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.</p>  |
|      | 15:11 | RES         | Reserved   |

|      | 10:0  | SFID2[10:9] | <p>This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence.</p> <ul style="list-style-type: none"> <li>0x0: Store message into an Rx Buffer</li> <li>0x1: Debug Message A</li> <li>0x2: Debug Message B</li> <li>0x3: Debug Message C</li> </ul> <p><b>Note:</b> Debug feature is not supported.</p>  |
|      |       | SFID2[8:6]  | <p>This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches.</p> <p><b>Note:</b> Only two filter event pins are supported.</p>  |
|      |       | SFID2[5:0]  | <p>This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.</p>  |

### 29.5.16.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN\_XIDFC.FLESA field plus two times the index of the filter element (0-63).

Figure 29-22 shows Extended Message ID Filter element structure.

**Figure 29-22. Extended Message ID Filter Element Structure**

Table 29-14 shows Extended Message ID Filter element field descriptions.

**Table 29-14. Extended Message ID Filter Element Field Descriptions**

| Word | Bits  | Field Name  | Description  |
|------|-------|-------------|--|
| F0   | 31:29 | EFEC[2:0]   | Extended Filter Element Configuration<br>All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match. <ul style="list-style-type: none"> <li>• 0x0: Disable filter element</li> <li>• 0x1: Store in Rx FIFO 0 if filter matches</li> <li>• 0x2: Store in Rx FIFO 1 if filter matches</li> <li>• 0x3: Reject ID if filter matches</li> <li>• 0x4: Set priority if filter matches</li> <li>• 0x5: Set priority and store in FIFO 0 if filter matches</li> <li>• 0x6: Set priority and store in FIFO 1 if filter matches</li> <li>• 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored</li> </ul> |
|      | 28:0  | EFID1[28:0] | Extended Filter ID 1<br>First ID of extended ID filter element.<br>When filtering for Rx buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see <a href="#">Section 29.5.13.1.5</a> ) is used.  |

**Table 29-14. Extended Message ID Filter Element Field Descriptions (continued)**

| Word | Bits  | Field Name  | Description   |
|------|-------|-------------|---|
| F1   | 31:30 | EFT[1:0]    | Extended Filter Type <ul style="list-style-type: none"> <li>0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1)</li> <li>0x1: Dual ID filter for EFID1 or EFID2</li> <li>0x2: Classic filter: EFID1 = filter, EFID2 = mask</li> <li>0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied</li> </ul>  |
|      | 29    | RES         | Reserved  |
|      |       | EFID2[28:0] | Extended Filter ID 2<br>This bit field has a different meaning depending on the configuration of EFEC: <ul style="list-style-type: none"> <li>EFEC = 001 - 110: Second ID of extended ID filter element</li> <li>EFEC = 111: Filter for Rx buffers</li> </ul>   |
|      | 28:0  | EFID2[10:9] | This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> <li>0x0: Store message into an Rx Buffer</li> <li>0x1: Debug Message A</li> <li>0x2: Debug Message B</li> <li>0x3: Debug Message C</li> </ul> <b>Note:</b> Debug feature is not supported. |
|      |       | EFID2[8:6]  | This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICLK period in case the filter matches. <b>Note:</b> Only two filter event pins are supported.   |
|      |       | EFID2[5:0]  | This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.  |

## 29.6 Software

### 29.6.1 MCAN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/mcan

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 29.6.1.1 MCAN Internal Loopback with Interrupt

FILE: mcan\_ex1\_loopback.c

This example shows the MCAN Loopback functionality. The internal loopback mode is entered. The sent message should be received by the node. Use the last address of memory for Rx buffer.

##### External Connections

- None.

##### Watch Variables

- error - Checks if there is an error that occurred when the data was sent using internal loopback.

#### 29.6.1.2 MCAN Loopback with Interrupts Example Using SYSCONFIG Tool

FILE: mcan\_ex3\_loopback\_syscfg.c

This example illustrates the MCAN Loopback functionality. The internal loopback mode is entered. The message transmitted would be received by the node. The last address of memory is used for the Rx buffer. Peripheral configuration is done through SYSCONFIG

##### External Connections

- None.

##### Watch Variables

- error - Checks if there is an error that occurred when the data was sent using internal loopback.

#### 29.6.1.3 MCAN receive using Rx Buffer

FILE: mcan\_ex4\_receive.c

This example demonstrates the MCAN receive function. Communication is done between two CAN nodes. The transmitting node could be another MCU or a CAN bus analysis tool capable of transmitting CAN FD frames. The transmit and receive pins of the MCAN module should be connected to a CAN transceiver. Nominal Bit Rate of 500 kbps & Data bit rate of 1 Mbps is used

Only Standard frame with message ID 0x4 is received.

If another C2000 MCU is used as the transmitter, mcan\_ex3\_transmit.c can be run on it for the transmit function.

##### Hardware Required

- A C2000 board with CAN transceiver

##### External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE\_GPIO\_PIN\_CANRXA (MCANRXA)
- and DEVICE\_GPIO\_PIN\_CANTXA (MCANTXA)

##### Watch Variables

- rxMsg

#### 29.6.1.4 MCAN External Reception (with mask filter) into RX-FIFO1

FILE: mcan\_ex5\_mask\_filter\_receive.c

This example demonstrates Receiving, with mask filter configuration. The transmitting node could be a CAN FD capable controller or a CAN bus analysis tool capable of transmitting CAN FD frames. Bits 0, 1 & 3 of the identifier are masked. So these bits can have any value. This is achieved by using `stdFiltElem.sfid1 = 00000001111` and `stdFiltElem.sfid2 (mask 0 for X) = 11111110100`, which means any message with an ID of `0b0000000X1XX` are received and stored into the FIFO. Following STD IDs are received: `0x004`, `0x005`, `0x006`, `0x007`, `0x00C`, `0x00D`, `0x00E`, `0x00F`. All other IDs are not received. Classic bit-mask filter is used. This example may be used in conjunction with `mcan_ex3_transmit`.

The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used.

##### Hardware Required

- A C2000 board with CAN transceiver

##### External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on `DEVICE_GPIO_PIN_CANRXA (MCANRXA)`
- and `DEVICE_GPIO_PIN_CANTXA (MCANTXA)`

##### Watch Variables

- `rxMsg`

#### 29.6.1.5 MCAN Classic frames transmission using Tx Buffer

FILE: mcan\_ex7\_classic\_transmit.c

This simple example shows external communication between the MCAN module and another CAN node. It shows how to transmit classic CAN frames. The GPIOs of MCAN should be connected to a CAN Transceiver. Bit Rate is 500 kbps. Extended Identifier `0x15A5A5A5` is transmitted with 8 data bytes.

##### Hardware Required

- A C2000 board with CAN transceiver

##### External Connections

Both nodes should communicate through CAN transceivers.

- MCAN is on `DEVICE_GPIO_PIN_CANRXA (MCANRXA)`
- and `DEVICE_GPIO_PIN_CANTXA (MCANTXA)`

##### Watch Variables

- `txMsg`

### 29.6.1.6 MCAN External Reception (with RANGE filter) into RX-FIFO1

FILE: mcan\_ex8\_range\_filter.c

This example demonstrates Receiving, with RANGE filter configuration. The transmitting node could be a CAN FD capable controller or a CAN bus analysis tool capable of transmitting CAN FD frames. Only Extended IDs from 0x1FFFFFF23 to 0x1FFFFFF46 are received. Other IDs are not received. RXFIFO1 starts at an offset of 748 (2EC). MCAN Message RAM starts at 0x58000, so received messages will be copied starting at address 0x582EC. Note that as long as the ID matches, "classic" CAN frames will also be received.

The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used.

#### Hardware Required

- A C2000 board with CAN transceiver

#### External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE\_GPIO\_PIN\_CANRXA (MCANRXA)
- and DEVICE\_GPIO\_PIN\_CANTXA (MCANTXA)

#### Watch Variables

- rxMsg

### 29.6.1.7 MCAN External Transmit using Tx Buffer

FILE: mcan\_ex9\_transmit.c

This example demonstrates the MCAN External Transmit function. External communication is done between two CAN nodes. The receiving node could be another MCU or a CAN bus analysis tool capable of Receiving/ACKnowledging transmitted frames. The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used. Standard Identifier (STD ID) 0x4 is transmitted with 64 data bytes. #defines that are not required for this test case have been commented out. However, they have been left in the code should the scope of this code be expanded to include Receive and FIFO functions.

If another C2000 MCU is used as the receiver, mcan\_ex4\_receive.c can be run on it for the receive function.

#### Hardware Required

- A C2000 board with CAN transceiver

#### External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE\_GPIO\_PIN\_CANRXA (MCANRXA)
- and DEVICE\_GPIO\_PIN\_CANTXA (MCANTXA)

#### Watch Variables

- txMsg

## 29.7 MCAN Registers

This section describes the MCAN module registers.

### 29.7.1 MCAN Base Address Table

**Table 29-15. MCAN Base Address Table**

| Bit Field Name |                  | DriverLib Name   | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|------------------|------------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure        |                  |              |      |     |     |     |                    |
| McanaSsRegs    | MCANASS_REGS     | MCANASS_BASE     | 0x0005_C400  | YES  | -   | YES | -   | YES                |
| McanaRegs      | MCANA_REGS       | MCANA_BASE       | 0x0005_C600  | YES  | -   | YES | -   | YES                |
| McanaErrorRegs | MCANA_ERROR_REGS | MCANA_ERROR_BASE | 0x0005_C800  | YES  | -   | YES | -   | YES                |

## 29.7.2 MCANSS\_REGS Registers

Table 29-16 lists the memory-mapped registers for the MCANSS\_REGS registers. All register offset addresses not listed in Table 29-16 should be considered as reserved locations and the register contents should not be modified.

**Table 29-16. MCANSS\_REGS Registers**

| Offset (x8) | Offset (x16) | Acronym                                | Register Name   | Write Protection | Section            |
|-------------|--------------|--|---|------------------|--------------------|
| 0h          | 0h           | MCANSS_PID                             | MCAN Subsystem Revision Register                                |                  | <a href="#">Go</a> |
| 4h          | 2h           | MCANSS_CTRL                            | MCAN Subsystem Control Register                                 |                  | <a href="#">Go</a> |
| 8h          | 4h           | MCANSS_STAT                            | MCAN Subsystem Status Register                                  |                  | <a href="#">Go</a> |
| Ch          | 6h           | MCANSS_ICS                             | MCAN Subsystem Interrupt Clear Shadow Register                  |                  | <a href="#">Go</a> |
| 10h         | 8h           | MCANSS_IRS                             | MCAN Subsystem Interrupt Raw Status Register                    |                  | <a href="#">Go</a> |
| 14h         | Ah           | MCANSS_IECS                            | MCAN Subsystem Interrupt Enable Clear Shadow Register           |                  | <a href="#">Go</a> |
| 18h         | Ch           | MCANSS_IE                              | MCAN Subsystem Interrupt Enable Register                        |                  | <a href="#">Go</a> |
| 1Ch         | Eh           | MCANSS_IES                             | MCAN Subsystem Interrupt Enable Status                          |                  | <a href="#">Go</a> |
| 20h         | 10h          | MCANSS_EOI                             | MCAN Subsystem End of Interrupt                                 |                  | <a href="#">Go</a> |
| 24h         | 12h          | MCANSS_EXT_TS_PRESCALE<br>R            | MCAN Subsystem External Timestamp Prescaler 0                   |                  | <a href="#">Go</a> |
| 28h         | 14h          | MCANSS_EXT_TS_UNSERVICE<br>D_INTR_CNTR | MCAN Subsystem External Timestamp Unserviced Interrupts Counter |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 29-17 shows the codes that are used for access types in this section.

**Table 29-17. MCANSS\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| R-0                      | R-0  | Read Returns 0s  |
| Write Type               |      |  |
| W                        | W    | Write  |
| W1C                      | W1C  | Write 1 to clear   |
| W1S                      | W1S  | Write 1 to set   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |

**Table 29-17. MCANSS\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description   |
|-------------|------|---|
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 29.7.2.1 MCANSS\_PID Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 68E05101h]

MCANSS\_PID is shown in [Figure 29-23](#) and described in [Table 29-18](#).

Return to the [Summary Table](#).

MCAN Subsystem Revision Register

**Figure 29-23. MCANSS\_PID Register**

Complex bit access types are encoded to fit into small table cells. [Table 29-30](#) shows the codes that are used for access types in this section.

**Table 29-30. MCAN\_REGS Access Type Codes**

| Access Type              | Code         | Description  |
|--------------------------|--------------|--|
| Read Type                |              |  |
| R                        | R            | Read   |
| RC                       | R<br>C       | Read to Clear  |
| RS                       | R<br>S       | Read to Set  |
| Write Type               |              |  |
| W                        | W            | Write  |
| W1C                      | W<br>1C      | Write 1 to clear   |
| W1SQ                     | W<br>1S<br>Q | Write 1 to set Qualified. A condition must be met for this operation to occur.   |
| WQ                       | W<br>Q       | Write Qualified. A condition must be met for this operation to occur.  |
| Reset or Default Value   |              |  |
| -n                       |              | Value after reset or the default value   |
| Register Array Variables |              |  |
| i,j,k,l,m,n              |              | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |              | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 29.7.3.1 MCAN\_CREL Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 32380608h]

MCAN\_CREL is shown in [Figure 29-34](#) and described in [Table 29-31](#).

Return to the [Summary Table](#).

|------|-------|------|-----------|---|
| 31-0 | ETV   | R    | 87654321h | Endianness Test Value. Reading the constant value maintained in this register allows software to determine the endianness of the host CPU. Reset type: SYSRSn |

### 29.7.3.3 MCAN\_DBTP Register (Offset (x8) = Ch, Offset (x16) = 6h) [Reset = A33h]

MCAN\_DBTP is shown in [Figure 29-36](#) and described in [Table 29-33](#).

Return to the [Summary Table](#).

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32  $m\_can\_clk$  periods.  $tq = (DBRP + 1) mtq$ .

DTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. DTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] tq or (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

### 29.7.3.4 MCAN\_TEST Register (Offset (x8) = 10h, Offset (x16) = 8h) [Reset = X]

MCAN\_TEST is shown in [Figure 29-37](#) and described in [Table 29-34](#).

Return to the [Summary Table](#).

Write access to the Test Register has to be enabled by setting bit CCCR.TEST to '1'. All Test Register functions are set to their reset values when bit CCCR.TEST is reset.

Loop Back Mode and software control of the internal CAN TX pin are hardware test modes. Programming of TX ≠ "00" may disturb the message transfer on the CAN bus.

**Table 29-36. MCAN\_CCCR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description  |
|-----|-------|------|-------|--|
| 0   | INIT  | R/W  | 1h    | Initialization<br>0 Normal Operation<br>1 Initialization is started<br>Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.<br>Reset type: SYSRSn |

### 29.7.3.7 MCAN\_NBTP Register (Offset (x8) = 1Ch, Offset (x16) = Eh) [Reset = 06000A03h]

MCAN\_NBTP is shown in [Figure 29-40](#) and described in [Table 29-37](#).

Return to the [Summary Table](#).

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512  $m\_can\_clck$  periods.  $tq = (NBRP + 1) mtq$ .

NTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. NTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the MCAN for a bit rate of 500 kBit/s.

| Bit  | Field | Type | Reset | Description   |
|------|-------|------|-------|---|
| 10-8 | DLEC  | RS   | 7h    | Data Phase Last Error Code. Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.<br>Reset type: SYSRSn                                   |
| 7    | BO    | R    | 0h    | Bus_Off Status<br>0 The M_CAN is not Bus_Off<br>1 The M_CAN is in Bus_Off state<br>Reset type: SYSRSn   |
| 6    | EW    | R    | 0h    | Warning Status<br>0 Both error counters are below the Error_Warning limit of 96<br>1 At least one of error counter has reached the Error_Warning limit of 96<br>Reset type: SYSRSn  |
| 5    | EP    | R    | 0h    | Error Passive<br>0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected<br>1 The M_CAN is in the Error_Passive state<br>Reset type: SYSRSn  |
| 4-3  | ACT   | R    | 0h    | Node Activity. Monitors the module's CAN communication state.<br>00 Synchronizing - node is synchronizing on CAN communication<br>01 Idle - node is neither receiver nor transmitter<br>10 Receiver - node is operating as receiver<br>11 Transmitter - node is operating as transmitter<br>Note: ACT is set to "00" by a Protocol Exception Event.<br>Reset type: SYSRSn |

**Table 29-43. MCAN\_PSR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description   |
|-----|-------|------|-------|---|
| 2-0 | LEC   | RS   | 7h    | <p>Last Error Code. The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.</p> <p>0 No Error: No error occurred since LEC has been reset by successful reception or transmission.</p> <p>1 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.</p> <p>2 Form Error: A fixed format part of a received frame has the wrong format.</p> <p>3 AckError: The message transmitted by the MCAN was not acknowledged by another node.</p> <p>4 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>5 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>6 CRCErr: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.</p> <p>7 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.</p> <p>Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.</p> <p>Note: The Bus_Off recovery sequence (see ISO 11898-1:2015) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences.</p> <p>Reset type: SYSRSn</p> |

### 29.7.3.14 MCAN\_TDCR Register (Offset (x8) = 48h, Offset (x16) = 24h) [Reset = 0h]

MCAN\_TDCR is shown in [Figure 29-47](#) and described in [Table 29-44](#).

Return to the [Summary Table](#).

| 14-8  | TDCO     | R/WQ | 0h    | Transmitter Delay Compensation Offset. Offset value defining the distance between the measured delay from the internal CAN TX signal to the internal CAN RX signal and the secondary sample point. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn   |
| 7     | RESERVED | R    | 0h    | Reserved   |
| 6-0   | TDCF     | R/WQ | 0h    | Transmitter Delay Compensation Filter Window Length. Defines the minimum value for the SSP position, dominant edges on the internal CAN RX signal that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn |

### 29.7.3.15 MCAN\_IR Register (Offset (x8) = 50h, Offset (x16) = 28h) [Reset = 8000000h]

MCAN\_IR is shown in [Figure 29-48](#) and described in [Table 29-45](#).

Return to the [Summary Table](#).

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signalled.

### 29.7.3.17 MCAN\_ILS Register (Offset (x8) = 58h, Offset (x16) = 2Ch) [Reset = 0h]

MCAN\_ILS is shown in [Figure 29-50](#) and described in [Table 29-47](#).

Return to the [Summary Table](#).

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE.EINT0 and ILE.EINT1.

**Figure 29-50. MCAN\_ILS Register**

| 28-0  | EIDM     | R/WQ | 1FFFFFFFh | Extended ID Mask. For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'.<br>Reset type: SYSRSn |

### 29.7.3.23 MCAN\_HPMS Register (Offset (x8) = 94h, Offset (x16) = 4Ah) [Reset = 0h]

MCAN\_HPMS is shown in [Figure 29-56](#) and described in [Table 29-53](#).

Return to the [Summary Table](#).

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

**Figure 29-56. MCAN\_HPMS Register**

### 29.7.3.35 MCAN\_TXFQS Register (Offset (x8) = C4h, Offset (x16) = 62h) [Reset = 0h]

MCAN\_TXFQS is shown in [Figure 29-68](#) and described in [Table 29-65](#).

Return to the [Summary Table](#).

The Tx FIFO/Queue status is related to the pending Tx requests listed in register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

**Figure 29-68. MCAN\_TXFQS Register**

**Table 29-67. MCAN\_TXBRP Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description  |
|-----|-------|------|-------|--|
| 0   | TRP0  | R    | 0h    | <p>Transmission Request Pending 0.</p> <p>Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR.</p> <p>TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).</p> <p>A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset.</p> <p>After a cancellation has been requested, a finished cancellation is signalled via TXBCF</p> <ul style="list-style-type: none"> <li>- after successful transmission together with the corresponding TXBTO bit</li> <li>- when the transmission has not yet been started at the point of cancellation</li> <li>- when the transmission has been aborted due to lost arbitration</li> <li>- when an error occurred during frame transmission</li> </ul> <p>In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions.</p> <p>0 No transmission request pending<br/>1 Transmission request pending</p> <p>Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.</p> <p>Reset type: SYSRSn</p> |

### 29.7.3.38 MCAN\_TXBAR Register (Offset (x8) = D0h, Offset (x16) = 68h) [Reset = 0h]

MCAN\_TXBAR is shown in [Figure 29-71](#) and described in [Table 29-68](#).

Return to the [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. Table 29-78 shows the codes that are used for access types in this section.

**Table 29-78. MCAN\_ERROR\_REGS Access Type Codes**

| Access Type | Code | Description     |
|-------------|------|-----------------|
| Read Type   |      |                 |
| R           | R    | Read            |
| R-0         | R-0  | Read Returns 0s |

**Table 29-78. MCAN\_ERROR\_REGS Access Type Codes (continued)**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| WD                       | W<br>D  | Write<br>Decrement. Decrements the<br>specified bit field by the amount<br>written.  |
| WI                       | W<br>I  | Write<br>Increment. Increments the<br>specified bit field by the amount<br>written.  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default<br>value  |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in<br>a register name, an offset, or an<br>address, they refer to the value of<br>a register array where the register<br>is part of a group of repeating<br>registers. The register groups<br>form a hierarchical structure and<br>the array is represented with a<br>formula. |
| y                        |         | When this variable is used in a<br>register name, an offset, or an<br>address it refers to the value of<br>a register array.   |

### 29.7.4.1 MCANERR\_REV Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 66A0EA00h]

MCANERR\_REV is shown in [Figure 29-80](#) and described in [Table 29-79](#).

Return to the [Summary Table](#).

MCAN Error Aggregator Revision Register

### 29.7.4.2 MCANERR\_VECTOR Register (Offset (x8) = 8h, Offset (x16) = 4h) [Reset = 0h]

MCANERR\_VECTOR is shown in [Figure 29-81](#) and described in [Table 29-80](#).

Return to the [Summary Table](#).

Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC\_VECTOR field, together with the RD\_SVBUS trigger and RD\_SVBUS\_ADDRESS bit field. This initiates the serial read which consummates by setting the RD\_SVBUS\_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address.

**Table 29-86. MCANERR\_ERR\_STAT1 Register Field Descriptions**

| Bit   | Field              | Type  | Reset | Description   |
|-------|--------------------|-------|-------|---|
| 31-16 | ECC_BIT1           | R     | 0h    | ECC Error Bit Position. Indicates the bit position in the RAM data that is in error on an SEC error. Only valid on an SEC error.<br>0 Bit 0 is in error<br>1 Bit 1 is in error<br>2 Bit 2 is in error<br>3 Bit 3 is in error<br>...<br>31 Bit 31 is in error<br>>32 Invalid<br>Reset type: SYSRSn   |
| 15    | CLR_CTRL_REG_ERROR | R/W1S | 0h    | Writing a '1' clears the CTRL_REG_ERROR bit<br>Reset type: SYSRSn   |
| 14-13 | RESERVED           | R/WD  | 0h    | Reserved  |
| 12    | CLR_ECC_OTHER      | R/W1C | 0h    | Writing a '1' clears the ECC_OTHER bit.<br>Reset type: SYSRSn   |
| 11-10 | CLR_ECC_DED        | R/WD  | 0h    | Clear ECC_DED. A write of a non-zero value to this bit field decrements the ECC_DED bit field by the value provided.<br>Reset type: SYSRSn  |
| 9-8   | CLR_ECC_SEC        | R/WD  | 0h    | Clear ECC_SEC. A write of a non-zero value to this bit field decrements the ECC_SEC bit field by the value provided.<br>Reset type: SYSRSn  |
| 7     | CTRL_REG_ERROR     | R/W1S | 0h    | Control Register Error. A bit field in the control register is in an ambiguous state. This means that the redundancy registers have detected a state where not all values are the same and has defaulted to the reset state. S/W needs to re-write these registers to a known state. A write of 1 will set this interrupt flag.<br>Reset type: SYSRSn |
| 6-5   | RESERVED           | R/WI  | 0h    | Reserved  |

**Table 29-86. MCANERR\_ERR\_STAT1 Register Field Descriptions (continued)**

|-----|-----------|-------|-------|---|
| 4   | ECC_OTHER | R/W1S | 0h    | SEC While Writeback Error Status<br>0 No SEC error while writeback pending<br>1 Indicates that successive single-bit errors have occurred while a writeback is still pending<br>Reset type: SYSRSn  |
| 3-2 | ECC_DED   | R/WI  | 0h    | Double Bit Error Detected Status. A 2-bit saturating counter of the number of DED errors that have occurred since last cleared.<br>0 No double-bit error detected<br>1 One double-bit error was detected<br>2 Two double-bit errors were detected<br>3 Three double-bit errors were detected<br>A write of a non-zero value to this bit field increments it by the value provided.<br>Reset type: SYSRSn  |
| 1-0 | ECC_SEC   | R/WI  | 0h    | Single Bit Error Corrected Status. A 2-bit saturating counter of the number of SEC errors that have occurred since last cleared.<br>0 No single-bit error detected<br>1 One single-bit error was detected and corrected<br>2 Two single-bit errors were detected and corrected<br>3 Three single-bit errors were detected and corrected<br>A write of a non-zero value to this bit field increments it by the value provided.<br>Reset type: SYSRSn |

### 29.7.4.9 MCANERR\_ERR\_STAT2 Register (Offset (x8) = 24h, Offset (x16) = 12h) [Reset = 0h]

MCANERR\_ERR\_STAT2 is shown in [Figure 29-88](#) and described in [Table 29-87](#).

Return to the [Summary Table](#).

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

**Figure 29-88. MCANERR\_ERR\_STAT2 Register**

This page intentionally left blank.

This chapter describes the local interconnect network (LIN) module. Since this module can also operate like a conventional serial communications interface (SCI) port, it is referred to as the SCI/LIN module in this document. In SCI compatibility mode, it is functionally compatible to the standalone SCI module. However, since the SCI/LIN module uses a different register/bit structure, code written for this module cannot be directly ported to the standalone SCI module and vice versa.

This module can be configured to operate in either SCI (UART) or LIN mode.

## 30.1 Introduction

The SCI/LIN is compliant to the LIN protocol specified in the *LIN Specification Package*. The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The SCI's hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter (UART) that implements the standard non-return to zero format.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-master/multiple-slave with a message identification for multi-cast transmission between any network nodes.

Throughout the chapter, Compatibility Mode refers to SCI Mode functionality of the SCI/LIN Module. [Section 30.2](#) explains about the SCI functionality and [Section 30.3](#) explains about the LIN functionality. Though the registers are common for LIN and SCI, the register descriptions has notes to identify the register/bit usage in different modes.

### 30.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard non-return to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- At 100-MHz peripheral clock, 3.125 Mbits/s is the Max Baud Rate achievable
- Five error flags and Seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multi-buffered receive and transmit units

---

#### Note

The SCI/LIN module is functionally compatible with the C2000™ SCI modules, but not directly software compatible due to different register control structures.

The SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general-purpose I/O pin.

The SCI/LIN module does not support isosynchronous mode as there is no SCICLK pin.

---

### 30.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3 protocols
- Configurable Baud Rate up to 20 kpbs
- Two external pins: LINRX and LINTX.
- Multi-buffered receive and transmit units
- Identification masks for message filtering
- Automatic master header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Slave automatic synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- Wake up on LINRX dominant level from transceiver
- Automatic wake up support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- 2 Interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

### 30.1.3 Block Diagram

The SCI/LIN module contains the core SCI block with added sub-blocks to support LIN protocol.

The three major components of the SCI Module are:

- **Transmitter (TX)** contains two major registers to perform the double-buffering:
  - The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
  - The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.
- **Baud Clock Generator**
  - A programmable baud generator produces a baud clock scaled from the input clock VCLK
- **Receiver (RX)** contains two major registers to perform the double-buffering:
  - The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
  - The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. [Figure 30-1](#) shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multi-buffered receiver and transmitter. The SCI interface, the DMA control subblocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. [Figure 30-2](#) shows the SCI/LIN block diagram.

## 30.2 Serial Communications Interface Module

### 30.2.1 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The configuration options are:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

#### 30.2.1.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

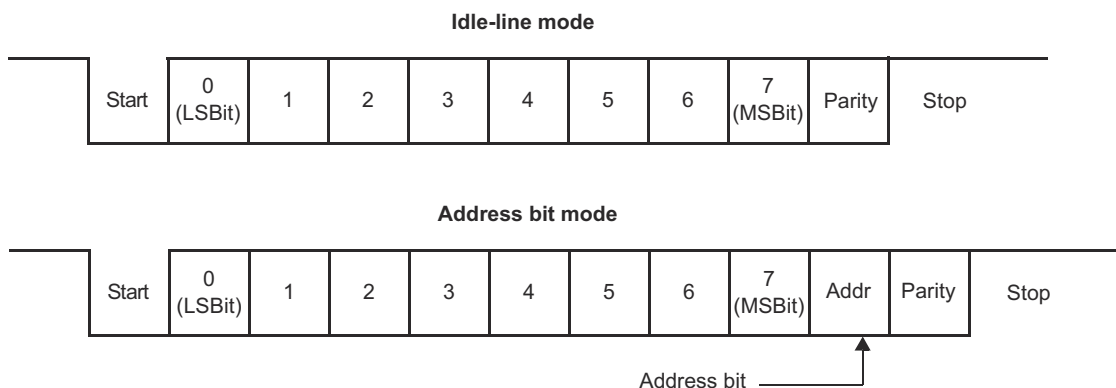

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 30-3](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 30-3](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 30-3](#) use one stop bit per frame.

**Figure 30-3. Typical SCI Data Frame Formats**

### 30.2.1.2 SCI Asynchronous Timing Mode

The SCI can be configured to use the asynchronous timing mode using TIMING MODE bit in SCIGCR1 register.

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 30-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

**Figure 30-4. Asynchronous Communication Bit Timing**

### 30.2.1.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value in the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{SCICLK Frequency} = \frac{\text{VCLK Frequency}}{P + 1 + \frac{M}{16}}$$

$$\text{Asynchronous baud value} = \frac{\text{SCICLK Frequency}}{16}$$

For P = 0,

$$\text{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (30)$$

**Table 30-1. P and M Values for Standard Bit Rates**

| 100 MHz Device, LIN Module Input Clock = 50 MHz |                 |                  |         |         |
|---|-----------------|------------------|---------|---------|
| Desired Bit Rate                                | Actual Bit Rate | Percentage Error | P Value | M Value |
| 115200  | 115207.4        | 0.0064           | 26      | 2       |
| 57600   | 57603.69        | 0.0064           | 53      | 4       |
| 38400   | 38402.46        | 0.0064           | 80      | 6       |
| 19200   | 19201.23        | 0.0064           | 161     | 12      |
| 9600  | 9600.61         | 0.0064           | 324     | 8       |

| 2400  | 2400.04         | 0.0016           | 1301    | 1       |
| 1200  | 1199.99         | 0.0008           | 2603    | 1       |

### 30.2.1.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the superfractional divider uses an additional 3-bit modulating value (see [Table 30-3](#)). The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ . If the character length is more than 10, then the modulation table will be a rolled-over version of the original table ([Table 30-2](#)), as shown in [Table 30-3](#).

The baud rate will vary over a data field to average according to the BRS[30:28] value by a “d” fraction of the peripheral internal clock:  $0 < d < 1$ . See [Figure 30-5](#) for a simple Average “d” calculation based on “U” value (BRS[30:28]).

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (31)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (32)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

**Table 30-2. Superfractional Bit Modulation for SCI Mode (Normal Configuration)**

| Normal Configuration = Start Bit + 8 Data Bits + Stop Bit |           |      |      |      |      |      |      |      |      |          |

### 30.2.1.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

**30.2.1.4.1 Idle-Line Multiprocessor Modes**

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 30-6 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

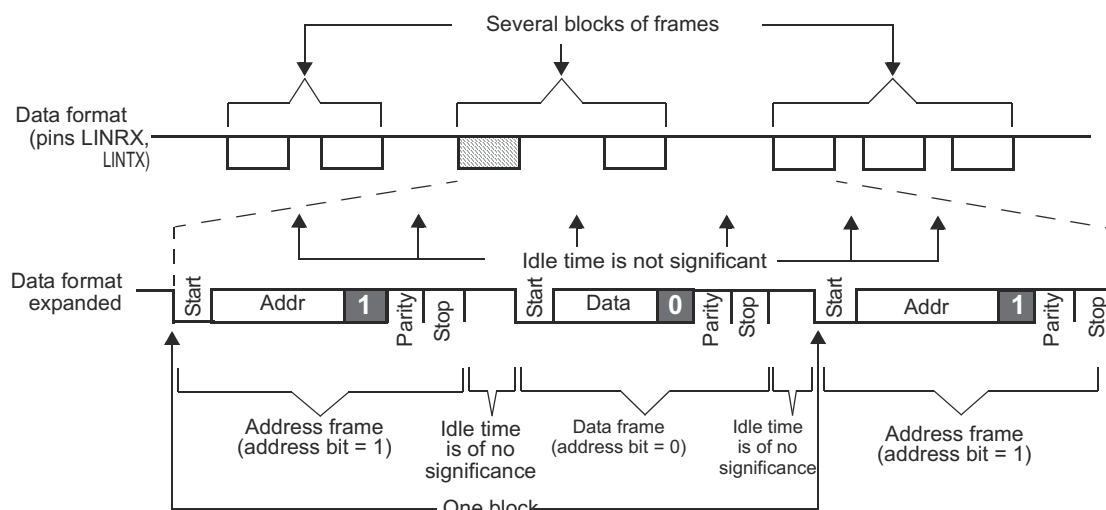

**Figure 30-6. Idle-Line Multiprocessor Communication Format**

### 30.2.1.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 30-7 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 30-7. Address-Bit Multiprocessor Communication Format**

### 30.2.1.5 SCI Multi Buffered Mode

To reduce CPU load when Receiving or Transmitting data in interrupt mode or DMA mode, the SCI/LIN module has eight separate receive and transmit buffers. Multi buffered mode is enabled by setting the MBUF MODE bit.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. the LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1 registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a DMA request (TXDMA) could occur after transmitting a response.

Figure 30-8 and Figure 30-9 show the receive and transmit multi-buffer functional block diagram, respectively.

Figure 30-8. Receive Buffers

Figure 30-9. Transmit Buffers

### 30.2.2 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 30-10](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISSETINT and SCICLRINT registers, respectively.

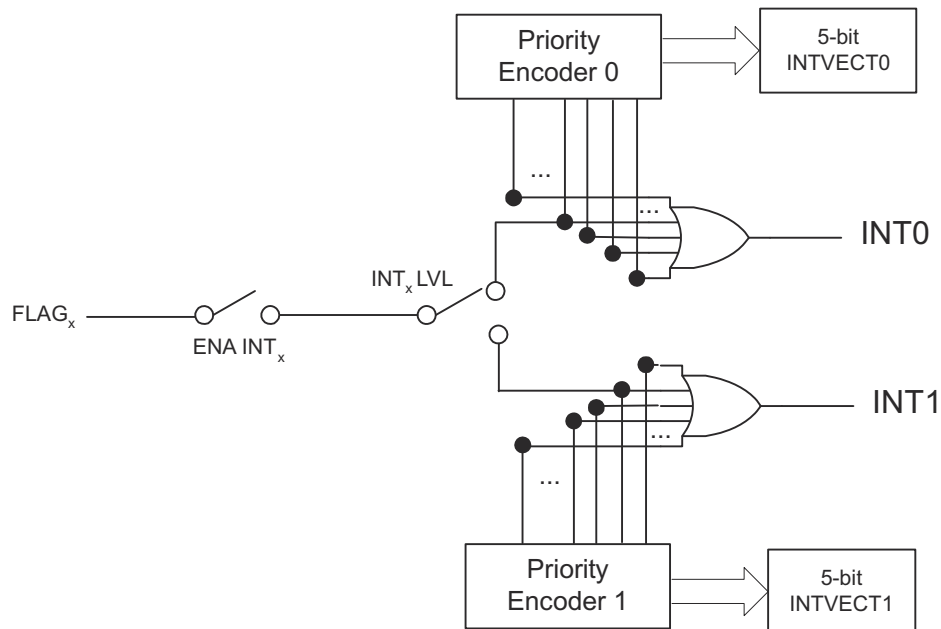

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level 1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 30-10. General Interrupt Scheme**

**Figure 30-11. Interrupt Generation for Given Flags**

### 30.2.2.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD before any interrupt gets generated. To transmit further data, data can be written to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 30.2.2.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

### 30.2.2.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

### 30.2.2.4 Error Interrupts

The following error detections are supported with an interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver, if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register.

There are 16 interrupt sources in the SCI/LIN module. In SCI mode, 8 interrupts are supported, as listed in [Table 30-6](#).

**Table 30-6. SCI/LIN Interrupts**

| Offset <sup>(1)</sup> | Interrupt                                  | Applicable to SCI | Applicable to LIN |
|-----------------------|--|-------------------|-------------------|
| 0                     | No interrupt                               | -                 | -                 |
| 1                     | Wakeup                                     | Yes               | Yes               |
| 2                     | Inconsistent-sync-field error              | No                | Yes               |
| 3                     | Parity error                               | Yes               | Yes               |
| 4                     | ID   | No                | Yes               |
| 5                     | Physical bus error                         | No                | Yes               |
| 6                     | Frame error                                | Yes               | Yes               |
| 7                     | Break detect                               | Yes               | No                |
| 8                     | Checksum error                             | No                | Yes               |
| 9                     | Overrun error                              | Yes               | Yes               |
| 10                    | Bit error (BE)                             | Yes               | Yes               |
| 11                    | Receive                                    | Yes               | Yes               |
| 12                    | Transmit                                   | Yes               | Yes               |
| 13                    | No-response error                          | No                | Yes               |
| 14                    | Timeout after wakeup signal (150 ms)       | No                | Yes               |
| 15                    | Timeout after three wakeup signals (1.5 s) | No                | Yes               |
| 16                    | Timeout (Bus Idle, 4s)                     | No                | Yes               |

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

**Table 30-7. SCI Receiver Status Flags**

| SCI Flag | Register | Bit | Value After Reset <sup>(1)</sup> |
|----------|----------|-----|----------------------------------|
| CE       | SCIFLR   | 29  | 0                                |
| ISFE     | SCIFLR   | 28  | 0                                |
| NRE      | SCIFLR   | 27  | 0                                |
| FE       | SCIFLR   | 26  | 0                                |
| OE       | SCIFLR   | 25  | 0                                |
| PE       | SCIFLR   | 24  | 0                                |
| RXWAKE   | SCIFLR   | 12  | 0                                |
| RXRDY    | SCIFLR   | 9   | 0                                |
| BUSY     | SCIFLR   | 3   | 0                                |
| IDLE     | SCIFLR   | 2   | 1                                |
| WAKEUP   | SCIFLR   | 1   | 0                                |
| BRKDT    | SCIFLR   | 0   | 0                                |

(1) The flags are frozen with their reset value while SWnRST = 0.

**Table 30-8. SCI Transmitter Status Flags**

| SCI Flag | Register | Bit | Value After Reset <sup>(1)</sup> |
|----------|----------|-----|----------------------------------|
| BE       | SCIFLR   | 31  | 0                                |
| PBE      | SCIFLR   | 30  | 0                                |
| TXWAKE   | SCIFLR   | 10  | 0                                |
| TXEMPTY  | SCIFLR   | 11  | 1                                |
| TXRDY    | SCIFLR   | 8   | 1                                |

(1) The flags are frozen with their reset value while SWnRST = 0.

### 30.2.3 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA transfers depending on whether multi-buffer mode bit (MBUF MODE) is enabled or not enabled.

#### 30.2.3.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

In Multi-Buffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RX DMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

#### 30.2.3.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

In Multi-Buffered SCI mode once TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

### 30.2.4 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see [Section 30.2.4.1](#) or [Section 30.2.4.2](#)).

#### 30.2.4.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffer Mode

After a valid idle period is detected, data is automatically received as it arrives on the LINRX pin.

##### 30.2.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

### 30.2.4.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling or interrupt method to read the data. The SCI clears the RXRDY bit after the new data in SCIRD has been read.

### 30.2.4.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffered or Buffered SCI Mode

#### 30.2.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit), or by disabling the transmitter (clear TXENA bit).

---

#### Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

#### 30.2.4.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling or interrupt method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. SCI waits for data to be written to the SCITD register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

### 30.2.5 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

---

#### Note

##### Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

#### 30.2.5.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 30-7](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

## 30.3 Local Interconnect Network Module

### 30.3.1 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls, and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling LIN MODE bit in SCIGCR1 register.

---

#### Note

The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10. For the START bit, the first three samples are used.

---

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see [Section 30.7](#).

#### 30.3.1.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

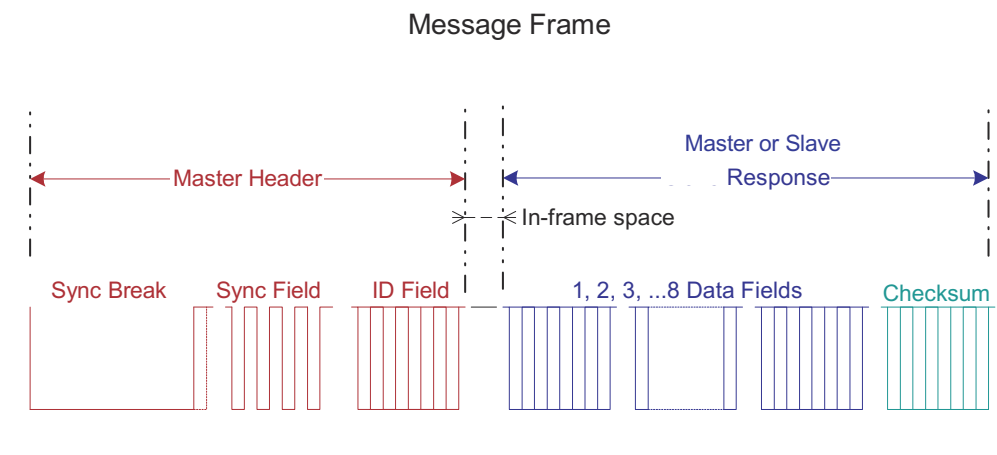

1. Support for LIN 2.0 checksum
2. Enhanced synchronizer FSM support for frame processing
3. Enhanced handling of extended frames
4. Enhanced baud rate generator
5. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware.

### 30.3.1.2 Message Frame

The LIN protocol defines a message frame format, illustrated in Figure 30-12. Each frame includes one master header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces may be 0.

**Figure 30-12. LIN Protocol Message Frame Format: Master Header and Slave Response**

There is no arbitration in the definition of the LIN protocol; therefore, multiple slave nodes responding to a header might be detected as an error.

The LIN bus is a single channel wired-AND. The bus has a binary level: either dominant for a value of 0, or recessive for a value of 1.

#### 30.3.1.2.1 Message Header

The header of a message is initiated by a master (see Figure 30-13) and consists of a three field-sequence:

- The sync break field signaling the beginning of a message
- The sync field conveying bit rate information of the LIN bus
- The ID field denoting the content of a message

**Figure 30-13. Header 3 Fields: Sync Break, Sync, and ID**

30.3.1.2.2 Response

The format of the response is as illustrated in Figure 30-14. There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

Figure 30-14. Response Format of LIN Message Frame

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames (Section 30.3.1.6). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see Table 30-9, or by LENGTH value in SCIFORMAT[18:16] register; see Table 30-10. The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

Table 30-9. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than v1.3

| ID5 | ID4 | Number of Data Bytes |
|-----|-----|----------------------|
| 0   | 0   | 2                    |
| 0   | 1   | 2                    |
| 1   | 0   | 4                    |
| 1   | 1   | 8                    |

Table 30-10. Response Length with SCIFORMAT[18:16] Programming

| SCIFORMAT[18:16] | Number of Bytes |
|------------------|-----------------|
| 000              | 1               |
| 001              | 2               |
| 010              | 3               |
| 011              | 4               |
| 100              | 5               |
| 101              | 6               |
| 110              | 7               |
| 111              | 8               |

### 30.3.1.3 Synchronizer

The synchronizer has three major functions in the messaging between master and slave nodes. It generates the master header data stream, it synchronizes to the LIN bus for responding, and it locally detects timeouts. A bit rate is programmed using the prescalers in the BRSR register to match the indicated LIN\_speed value in the LIN description file.

The LIN synchronizer will perform the following functions: master header signal generation, slave detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

### 30.3.1.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time  $T_{bit}$ . The bit time is derived from the fields P and M in the baud rate selection register (BRSR).

The ranges for the prescaler values in the BRSR register are:

$$P = 0, 1, 2, 3, \dots, 2^{24} - 1$$

$$M = 0, 1, 2, \dots, 15$$

The P values in the BRSR register are user programmable. The P and M dividers could be used for both SCI mode and LIN mode to select a baud rate. If the ADAPT bit is set and the LIN slave is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as follows:

$$1\text{kHz} \leq F_{LINCLK} \leq 20\text{kHz}$$

All transmitted bits are shifted in and out at  $T_{bit}$  periods.

#### 30.3.1.4.1 Fractional Divider

The M field of the BRSR register modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time,  $T_{bit}$  is expressed in terms of the VCLK period  $T_{VCLK}$  as follows:

For all P other than 0, and all M,

$$T_{bit} = 16 \left( P + 1 + \frac{M}{16} \right) T_{VCLK}$$

For P= 0 :  $T_{bit} = 32T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{\text{LINCLK}} = \frac{F_{\text{VCLK}}}{16(P+1 + \frac{M}{16})} \quad \text{For all } P \text{ other than zero}$$

$$F_{\text{LINCLK}} = \frac{F_{\text{VCLK}}}{32} \quad \text{For } P = 0$$

### 30.3.1.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN master mode (sync field + identifier field + response field + checksum field)
- LIN slave mode (response field + checksum field)

#### 30.3.1.4.2.1 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRSR[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in [Table 30-11](#). The sync field (0x55), the identifier field, and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table will have an additional VCLK period added to their  $T_{\text{bit}}$ . In LIN master mode, bit modulation applies to sync field + identifier field + response field. In LIN slave mode, bit modulation applies to identifier field + response field.

**Table 30-11. Superfractional Bit Modulation for LIN Master Mode and Slave Mode**

| BRSR[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |
|-------------|-----------|------|------|------|------|------|------|------|------|----------|
| 0h          | 0         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0        |
| 1h          | 1         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 1    | 0        |
| 2h          | 1         | 0    | 0    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 3h          | 1         | 0    | 1    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 4h          | 1         | 0    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 0        |
| 5h          | 1         | 1    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 1        |
| 6h          | 1         | 1    | 1    | 0    | 1    | 1    | 1    | 0    | 1    | 1        |
| 7h          | 1         | 1    | 1    | 1    | 1    | 1    | 1    | 0    | 1    | 1        |

The baud rate will vary over a LIN data field to average according to the BRSR[30:28] value by a  $d$  fraction of the peripheral internal clock:  $0 < d < 1$ .

The instantaneous bit time is expressed in terms of  $T_{\text{VCLK}}$  as follows:

For all  $P$  other than 0, and all  $M$  and  $d$  (0 or 1),

$$T^{\text{bit}} = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{\text{VCLK}}$$

For  $P = 0$ ,  $T_{\text{bit}} = 32T_{\text{VCLK}}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a bit} = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK}$$

For P = 0,  $T_{bit} = 32T_{VCLK}$

### 30.3.1.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the DMA will trigger a message header generation and the LIN state machine will handle the generation itself. A master node initiates header generation on CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the master to initiate a LIN communication and consists of three fields: break field, synchronization field, and identification field, as seen in [Figure 30-15](#).

#### Note

The LIN protocol uses the parity bits in the identifier. The control length bits are optional to the LIN protocol.

**Figure 30-15. Message Header in Terms of  $T_{bit}$**

- The break field consists of two components:
  - The synchronization break (SYNC BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The sync break length may be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The sync break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNC FIELD) consists of one start bit, byte 0x55, and a stop bit. It is used to convey  $T_{bit}$  information and resynchronize LIN bus nodes.
- The identifier field's ID byte may use six bits as an identifier, with optional length control and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITY ENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See [Figure 30-16](#) for an illustration of the ID field.

---

**Note**
**Optional Control Length Bits**

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

---

**Figure 30-16. ID Field**

---

**Note**

If the LIN module, configured as Slave in multi-buffer mode, is in the process of transmitting data while a new header comes in, the module might end up in responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario the following procedure could be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Sync Break).
  2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise TD0/TD1 might be written twice for one ID.
  3. Once the complete ID is received, based on the match, the newly configured data will be transmitted by the node.
-

### 30.3.1.5.1 Event Triggered Frame Handling

The LIN 2.0 protocol uses event-triggered frames that may occasionally cause collisions. Event-triggered frames have to be handled in software.

If no slave answers to an event triggered frame header, the master node will set the NRE flag, and a NRE interrupt will occur if enabled. If a collision occurs, a frame error and checksum error may arise before the NRE error. Those errors are flagged and the appropriate interrupts will occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding slaves. If the slaves are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The bus busy flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision the flag is cleared in the same cycle as the NRE flag is set.

Software could implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the bus busy flag to get set or NRE flag to get set.
- If bus busy flag is not set before NRE flag, then it is a true no response case (no data has been transmitted onto the bus).
- If bus busy flag gets set, then wait for NRE flag to get set or for successful reception. If NRE flag is set, then in this case a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

### 30.3.1.5.2 Header Reception and Adaptive Baud Rate

A slave node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a slave measures the baud rate during detection of the sync field. If ADAPT bit is set, then the measured baud rate is compared to the slave node's programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The LIN synchronizer determines two measurements: BRK\_count and BAUD\_count (Figure 30-17). These values are always calculated during the Header reception for sync field validation (Figure 30-18).

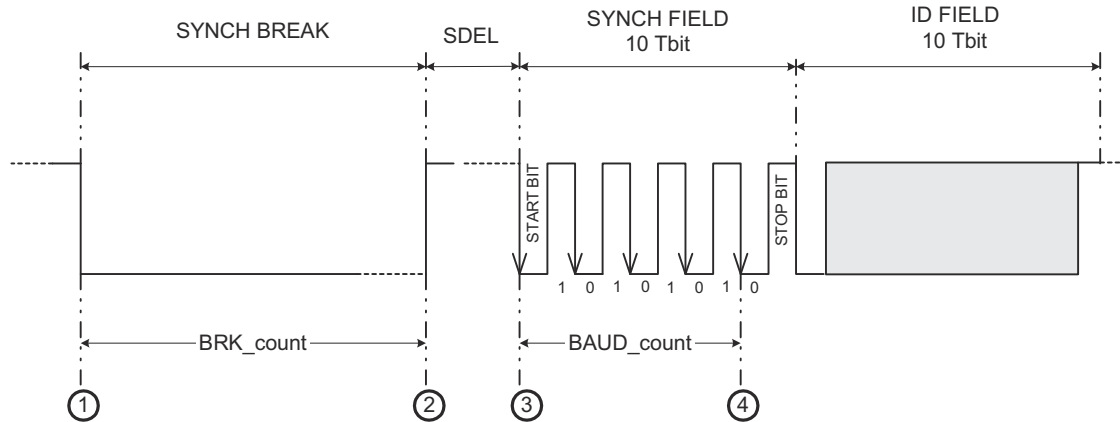

Figure 30-17. Measurements for Synchronization

By measuring the values BRK\_count and BAUD\_count, a valid sync break sequence can be detected as described in Figure 30-18. The four numbered events in Figure 30-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the sync break relative to the detecting node  $T_{bit}$ . For a slave node receiving the sync break, a threshold of  $11 T_{bit}$  is used as required by the LIN protocol. For detection of the dominant data stream of the sync break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the sync break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD\_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A slave node can calculate a single  $T_{bit}$  time by division of BAUD\_count by 8. In addition, for consistency between the detected edges the following is evaluated:

$$BAUD\_count + BAUD\_count \gg 2 + BAUD\_count \gg 3 \leq BRK\_count$$

The BAUD\_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a  $T_{bit}$  unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in Figure 30-18, if the measured BRK\_count value is less than  $11 T_{bit}$ , the sync break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK\_count and BAUD\_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

#### Note

In adaptive mode the MBRS divider should be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte could mistakenly be detected as a sync break.

The break-threshold relative to the slave node is  $11 T_{bit}$ . The break is  $13 T_{bit}$  as specified in LIN v1.3.

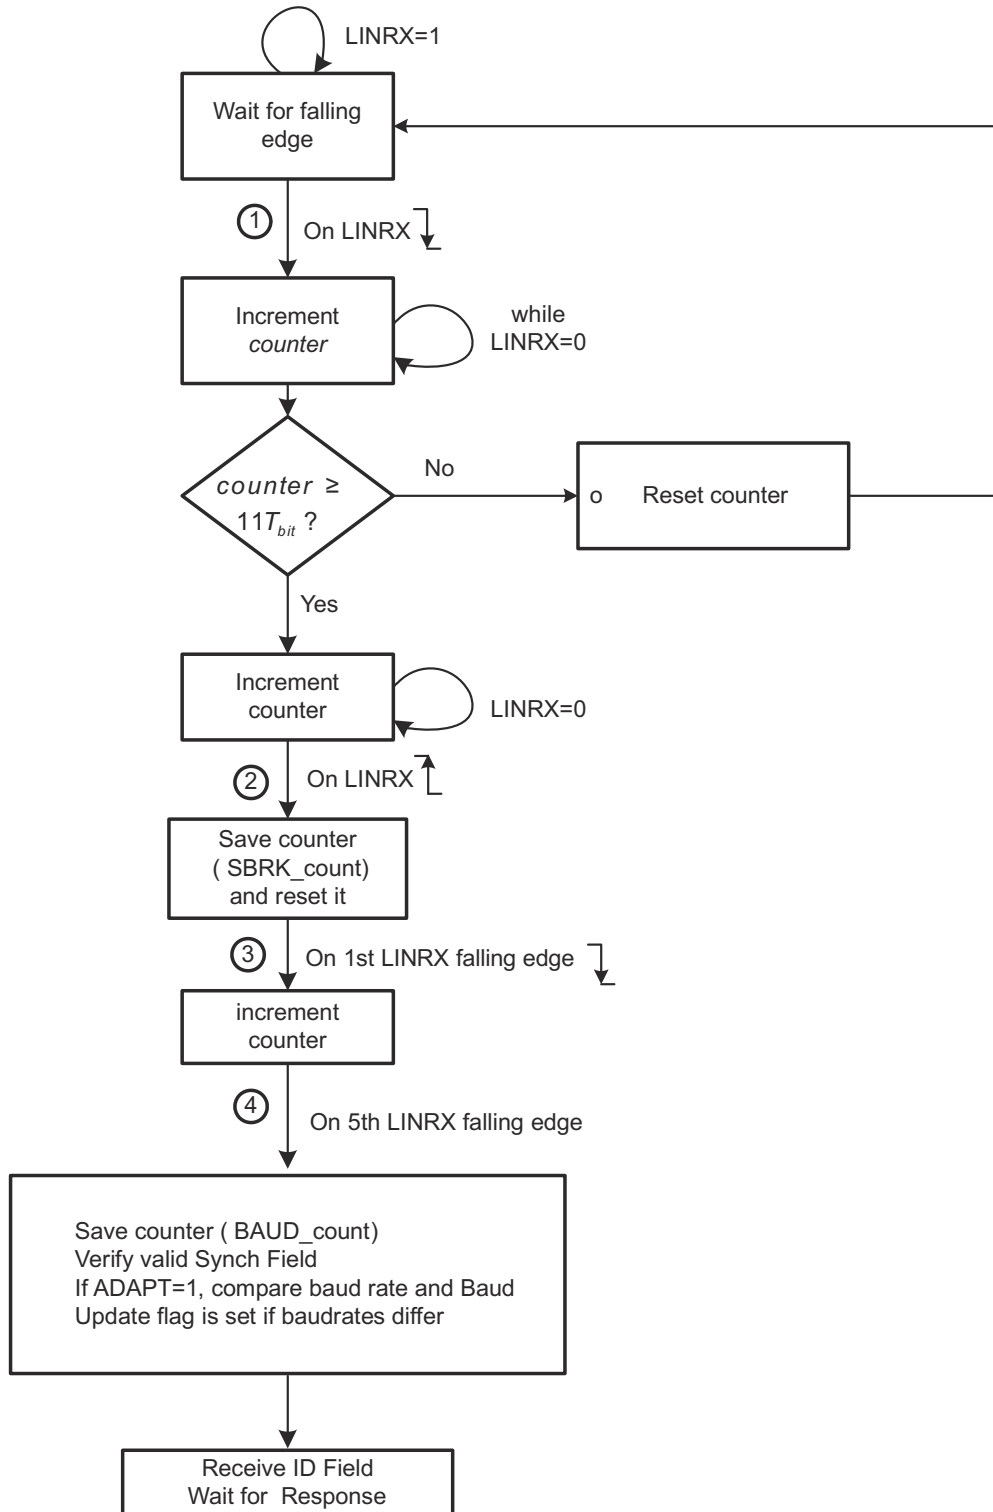

Figure 30-18. Synchronization Validation Process and Baud Rate Adjustment

If the sync field is not detected within the given tolerances, the inconsistent-sync-field-error (ISFE) flag will be set. An ISFE interrupt will be generated, if enabled by its respective bit in the SCISSETINT register. The ID byte should be received after the sync field validation was successful. Any time a valid break (larger than  $11 T_{bit}$ ) is detected, the receiver's state machine should reset to reception of this new frame. This reset condition is only valid during response state, not if an additional sync break occurs during header reception.

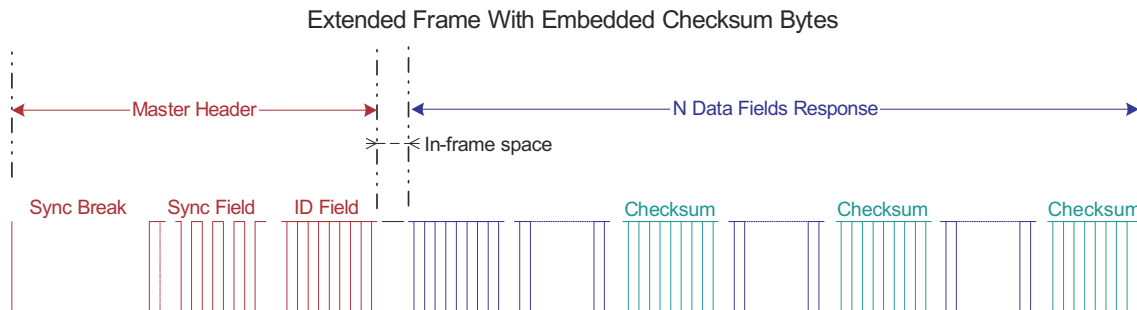

**Note**

When an inconsistent sync field (ISFE) error occurs, suggested action for the application is to Reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to their normal states.

**30.3.1.6 Extended Frames Handling**

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user-defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier will be set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see [Figure 30-19](#). Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

**Figure 30-19. Optional Embedded Checksum in Response for Extended Frames**

An ID interrupt will be generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC will initiate an automatic send of the checksum byte. The last data field should always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see [Figure 30-20](#).

**Note**

The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

**Figure 30-20. Checksum Compare and Send for Extended Frames**

### 30.3.1.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a master node could flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

#### 30.3.1.7.1 No-Response Error (NRE)

The no-response error will occur when any node expecting a response waits for  $T_{\text{FRAME\_MAX}}$  time and the message frame is not fully completed within the maximum length allowed,  $T_{\text{FRAME\_MAX}}$ . After this time a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{\text{FRAME\_MIN}} = T_{\text{HEADER\_MIN}} + T_{\text{DATA\_FIELD}} + T_{\text{CHECKSUM\_FIELD}} = 44 + 10N$$

where  $N$  = number of data fields.

And the maximum time frame is given by:

$$T_{\text{FRAME\_MAX}} = T_{\text{FRAME\_MIN}} * 1.4 = (44 + 10N) * 1.4$$

The timeout value  $T_{\text{FRAME\_MAX}}$  is derived from the  $N$  number of data fields value see [Table 30-12](#). The  $N$  value is either embedded in the header's ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register, will indicate the value for  $N$ .

#### Note

The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE will not be handled by the LIN controller hardware.

**Table 30-12. Timeout Values in  $T_{bit}$  Units**

| N | $T_{DATA\_FIELD}$ | $T_{FRAME\_MIN}$ | $T_{FRAME\_MAX}$ |
|---|-------------------|------------------|------------------|
| 1 | 10                | 54               | 76               |
| 2 | 20                | 64               | 90               |
| 3 | 30                | 74               | 104              |
| 4 | 40                | 84               | 118              |
| 5 | 50                | 94               | 132              |
| 6 | 60                | 104              | 146              |
| 7 | 70                | 114              | 160              |
| 8 | 80                | 124              | 174              |

### 30.3.1.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 s (this is 80,000  $F_{LINCLK}$  cycles with the fastest bus rate of 20 kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, then it can be assumed that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

#### Note

After the timeout was flagged, a SWnRESET should be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame was on the bus before the idle period.

### 30.3.1.7.3 Timeout After Wakeup Signal and Timeout After Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup should expect a header from the master within a defined amount of time: timeout after wakeup signal. See [Section 30.4.3](#) for more details.

### 30.3.1.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

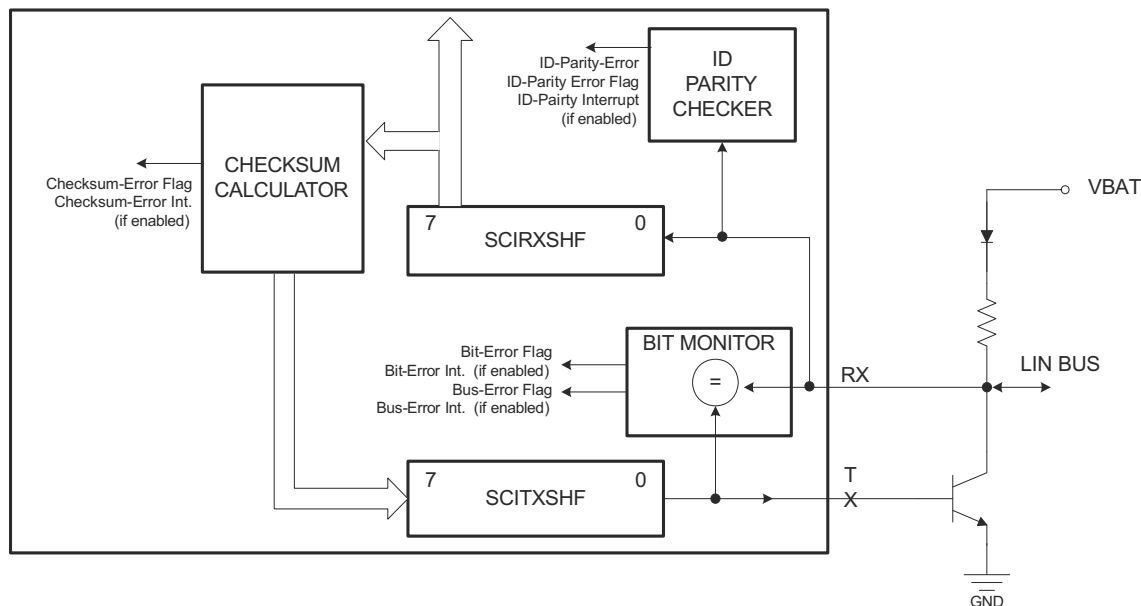

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

### 30.3.1.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor ensures that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in [Figure 30-21](#).

#### Note

If a bit occurs due to receiving a header during a slave response, NRE/TIMEOUT flag will not be set for the new frame.

**Figure 30-21. TXRX Error Detector**

### 30.3.1.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a master if no valid message can be generated on the bus (Bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Sync Break can be generated (for example, because of a bus shortage to VBAT) or if no sync break delimiter can be generated (for example, because of a bus shortage to GND). Once the Sync Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

### 30.3.1.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm:

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \text{ (even Parity)}$$

$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \text{ (odd Parity)}$$

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See [Section 30.3.1.9](#) for details.

### 30.3.1.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end if the calculated modulo-256 sum over all received data bytes (including the ID byte if it is the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of its resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see Figure 30-22) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see Figure 30-23) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation should always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit will be overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

Figure 30-22. Classic Checksum Generation at Transmitting Node

Figure 30-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node

### 30.3.1.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes will participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used as shown in Figure 30-24. During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in Figure 30-16) to determine whether they transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See Figure 30-24. All nodes compare the received ID to the identifier stored in the ID-SlaveTask BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there will be an ID TX flag and an interrupt will be triggered if enabled in the SCISSETINT register.

The masked bits become don't cares for the comparison. To build a mask for a set of identifiers, an XOR function could be used.

Figure 30-24. ID Reception, Filtering and Validation

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most significant bits (MSBs) and filter 3 least significant bits (LSBs), the acceptance mask could be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07$$

A mask of all zeros will compare all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF will always cause a match. A mask of all 1s will filter all bits of the received identifier, and thus there will be an ID match regardless of the content of the ID-SlaveTask BYTE field in the LINID register.

---

#### Note

When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. A mask of all 0s will compare all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s will filter all bits of the received identifier and there will be no match.

---

#### If HGEN CTRL = 1:

- Received ID is compared with the ID-Slave-Task byte, using the RXID mask and the TXID mask.
- A mask of all ones will always result in a match.
- A mask of all zeroes means all the bits must be the same to result in a match.
- If a mask has some bits which are ones, then those bits will not be used for the filtering criterion.

#### If HGEN CTRL = 0:

- Received ID is compared with the ID byte, using the RXID mask and the TXID mask.
- A mask of all ones will result in no match.
- A mask of all zeroes means all the bits must be the same to result in a match.
- If a mask has some bits which are ones, then those bits will not be used for the filtering criterion.

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU may read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

---

#### Note

When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

---

In multi-buffer mode, the TXRDY flag will be set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multi-buffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multi-buffer mode, the TXEMPTY flag is set when both the transmit buffer(s) TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In nonmulti-buffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all slave receiving nodes will validate the identifier using all eight bits of the received ID byte. The SCI/LIN will flag a corrupted identifier if an ID-parity error is detected.

### 30.3.1.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers. [Figure 30-8](#) illustrates the receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt will be generated if enabled in the SCISSETINT register.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multi-buffer mode is enabled, or to RD0 if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the ID BYTE field does not convey message length (see *Note: Optional Control Length Bits* in [Section 30.3.1.5](#)), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A receive interrupt, and a receive ready RXRDY flag as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte will be compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multi-buffer mode is enabled or not (MBUF MODE bit).

---

#### Note

In multi-buffer mode following are the scenarios associated with clearing the "RXRDY" flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
  2. For LENGTH less than or equal to 4, Read to RD0 register will clear the "RXRDY" flag.
  3. For LENGTH greater than 4, Read to RD1 register will clear the "RXRDY" flag.
-

### 30.3.1.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with  $N = 1-8$ ) response in interrupt mode or DMA mode, the SCI/LIN module has eight transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TXy transmit buffers. Optionally, a DMA transfer could be done on a byte-per-byte basis when multi-buffer mode is not enabled (MBUF MODE bit). [Figure 30-9](#) illustrates the transmit buffers.

The multi-buffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multi-buffer mode is enabled, or from TD0 to SCITXSHF if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note: Optional Control Length Bits* in [Section 30.3.1.5](#)), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A transmit interrupt (TX interrupt) and a transmit ready flag (TXRDY flag), as well as a DMA request (TXDMA) could occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multi-buffer mode is enabled or not (MBUF MODE bit).

The checksum byte will be automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multi-buffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

---

#### Note

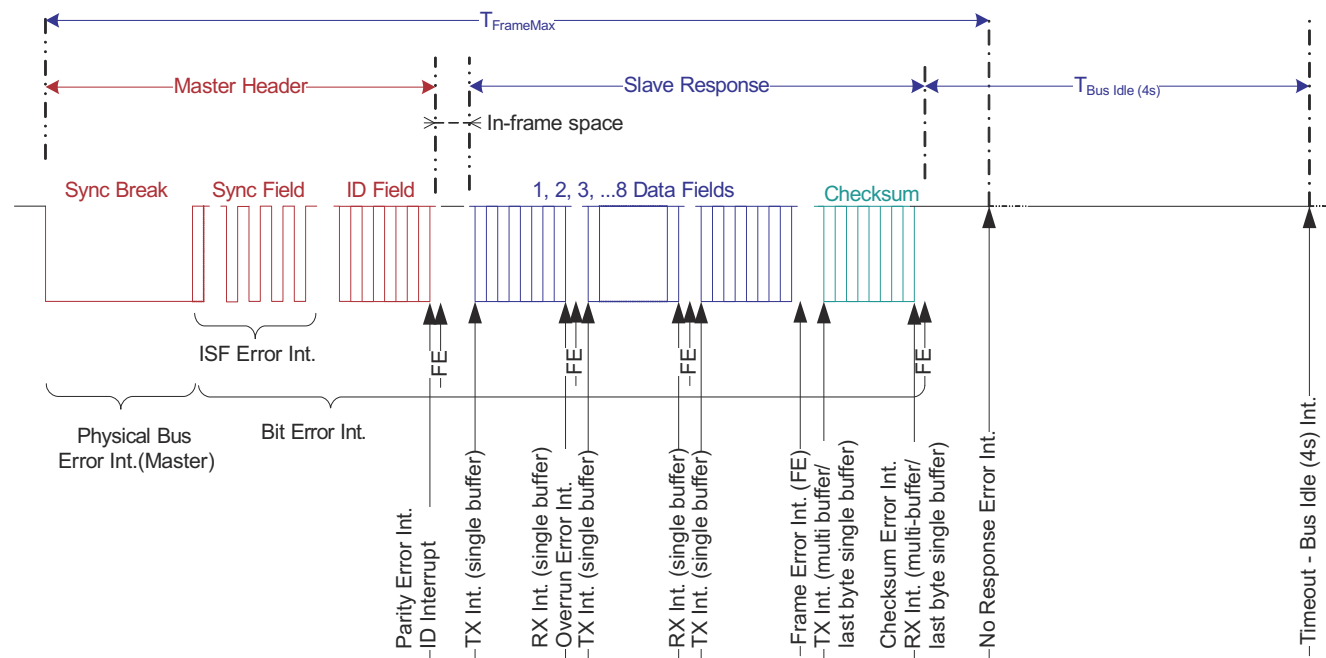

The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLRINT register or by disabling the transmitter via the TXENA bit.

---

### 30.3.2 LIN Interrupts

LIN and SCI mode have a common Interrupt block as explained in [Section 30.2.2](#). There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in [Table 30-6](#).

A LIN message frame indicating the timing and sequence of the LIN interrupts that could occur is shown in [Figure 30-25](#).

**Figure 30-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence**

### 30.3.3 Servicing LIN Interrupts

When servicing an interrupt, clear the corresponding flag in the flag register (SCIFLR) before clearing the global interrupt flag (LIN\_GLB\_INT\_CLR). The ISR should follow the guidelines below. This will prevent any spurious or duplicate interrupt from occurring.

- Clear the LIN interrupt flag in the SCIFLR register.
- Read the LIN interrupt status register to make sure the flag is cleared.
- Clear the global interrupt flag bit in LIN\_GLB\_INT\_CLR.

#### Note

The transmit interrupt is generated before the LIN transmitter is ready to accept new data. Inside of the LIN transmit ISR, the software should wait until the buffer is completely empty before loading the next data. This can be done by polling for the Bus Busy Flag (SCIFLR.BUSY) to be 0.

### 30.3.4 LIN DMA Interface

LIN DMA Interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multi-buffer mode is enabled or not via the multi-buffer enable control bit (MBUF MODE).

---

### Note

Do not use the DMA to transmit data to multiple slave IDs. Writing to the LINID register will initiate a new transmission. The DMA will write to the LINID register before the LIN state machine is ready to accept the new ID. Doing so will cause the LIN to miss this transmission.

---

#### 30.3.4.1 LIN Receive DMA Requests

In LIN mode, when the multi-buffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled and disabled using the SET RX DMA and CLR RX DMA bits, respectively.

#### 30.3.4.2 LIN Transmit DMA Requests

In LIN mode with the multi-buffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled and disabled using the SET TX DMA and CLR TX DMA bits, respectively.

#### 30.3.5 LIN Configurations

The following list details the configuration steps that software should perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting RESET bit.
- Clear SWnRST to 0 before configuring the LIN.
- Enable the LINRX and LINTX pins by setting the RX FUNC and TX FUNC bits.
- Select LIN mode by programming LIN MODE bit.
- Select Master or Slave mode by programming the CLOCK bit.
- Select the desired frame format (checksum, parity, length control) by programming SCIGCR1.
- Select multi-buffer mode by programming MBUF MODE bit.
- Select the baud rate to be used for communication by programming BRSR.
- Set the maximum baud rate to be used for communication by programming MBRSR.
- Set the CONT bit to make LIN not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit to connect the transmitter to the receiver internally if needed (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit if data is to be received.
- Select the transmit enable TXENA bit if data is to be transmitted.
- Select the RX ID MASK and the TX ID MASK fields in the LINMASK register.
- Set SWnRST to 1 after the LIN is configured.
- Perform Receive or Transmit data (see [Section 30.3.1.9](#), [Section 30.3.5.1](#), and [Section 30.3.5.2](#)).

---

### Note

If TXENA is set and the SWnRST is released, the LIN will only generate a new DMA request. The LIN hardware will not generate a new Transmit interrupt request. If using interrupts, the first transmission must be started by software by writing the data to transmit followed by writing to LIN TX to initiate the transmission.

---

#### 30.3.5.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The ID RX FLAG is set after a valid LIN ID is received with RX Match. An ID interrupt is generated, if enabled.

#### 30.3.5.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when it transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt method. To use the interrupt method, the SET RX INT bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum will be compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit will be cleared once the checksum is received. A CE will immediately be flagged if there is a checksum error.

#### 30.3.5.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, DMA, or interrupt method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit will be cleared once the checksum is received and compared.

#### 30.3.5.2 Transmitting Data

The LIN transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The ID TX flag is set after a valid LIN ID is received with TX Match. An ID interrupt is generated, if enabled.

#### 30.3.5.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX

INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte will be sent after the current byte transmission. The SC bit will be cleared after the checksum byte has been transmitted.

---

#### Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

#### 30.3.5.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. Like single-buffer mode, you can use the polling or interrupt method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum will be sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit will be cleared after the checksum byte has been transmitted.

### 30.4 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The LIN module may enter low-power mode either when there was no activity on the LINRX pin for more than 4s (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal will terminate the sleep mode of the LIN bus.

---

#### Note

#### Enabling Local Low-Power Mode During Receive and Transmit

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wake-up interrupt to clear the powerdown bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

---

#### 30.4.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic master request frame with identifier 0x3C (60), with the first data field as 0x00. There should be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

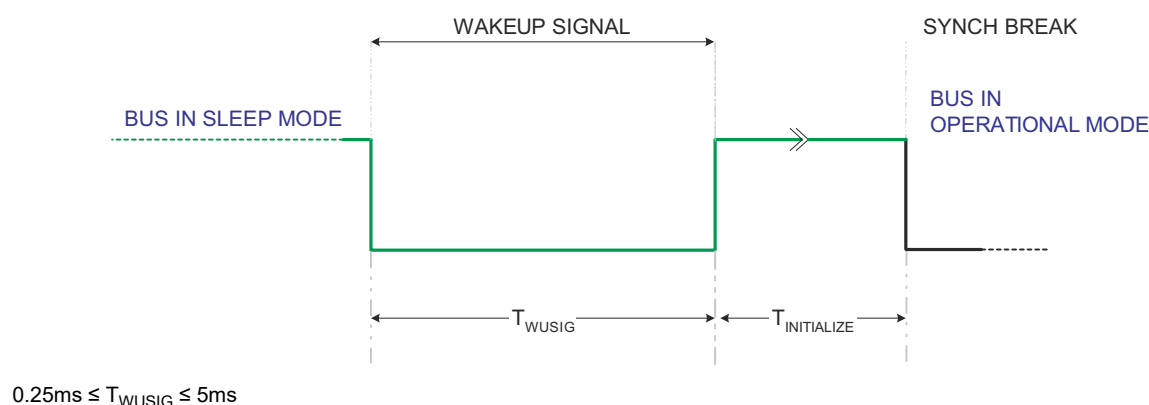

### 30.4.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit a low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

#### Note

If the wakeup interrupt is disabled, then the SCI/LIN enters low-power mode whenever it is requested to do so, but a low level on the receive RX pin does NOT cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal; see [Figure 30-26](#). A slave node that detects the bus in sleep mode, and with a wakeup request pending, will send a wakeup signal. The wakeup signal is a dominant value on the LIN bus for  $T_{WUSIG}$ ; this is at least  $5 T_{bits}$  for the LIN bus baud rates. The wakeup signal is generated by sending a 0xF0 byte containing 5 dominant  $T_{bits}$  and 5 recessive  $T_{bits}$ .

**Figure 30-26. Wakeup Signal Generation**

Assuming a perfect bus with no noise or loading effects, a write of 0xF0 to TD0 will load the transmitter to meet the wakeup signal timing requirement for  $T_{WUSIG}$ . Then, setting the GENWU bit will transmit the preloaded value in TD0 for a wakeup signal transmission.

#### Note

The GENWU bit can be set/reset only when SWnRST is set to '1' and the node is in power down mode. The bit will be cleared on a valid sync break detection. A master sending a wakeup request, will exit power down mode upon reception of the wakeup pulse. The bit will be cleared on a SWnRST. This can be used to stop a master from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, will translate it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, it will generate a wakeup interrupt if enabled in the SCISSETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150 ms will detect it as a wakeup request. The LIN controller's slave is ready to listen to the bus in less than 100 ms ( $T_{INITIALIZE} < 100\text{ms}$ ) after a dominant-to-recessive edge (end-of-wakeup signal).

### 30.4.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the master to send a header. If no sync field is detected before 150 ms (3,000 cycles at 20 kHz) after a wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5 s (30,000 cycles at 20 kHz) period after three breaks.

---

#### Note

To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to assure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup should set the MBRS register accordingly to meet the targeted time as  $128 \text{ Tbits} \times \text{programmed prescaler}$ .

The LIN controller handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

---

### 30.5 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. when set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register will not have any effect on the flags in the SCIFLR register.

---

#### Note

When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

---

## 30.6 Software

### 30.6.1 LIN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/lin

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 30.6.1.1 LIN Internal Loopback with Interrupts

FILE: lin\_ex1\_loopback\_interrupts.c

This example configures the LIN module in master mode for internal loopback with interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Upon reception of an ID header, an interrupt is triggered on line 0 and an interrupt service routine (ISR) is called. The received data is then checked for accuracy.

The example can be adjusted to use interrupt line 1 instead of line 0 by uncommenting "LIN\_setInterruptLevel1()".

##### *External Connections*

- None.

##### *Watch Variables*

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)
- level0Count - The number of line 0 interrupts
- level1Count - The number of line 1 interrupts

#### 30.6.1.2 LIN SCI Mode Internal Loopback with Interrupts

FILE: lin\_ex2\_sci\_loopback.c

This example configures the LIN module in SCI mode for internal loopback with interrupts. The LIN module performs as a SCI with a set character and frame length in a non-multi-buffer mode. The module is setup to continuously transmit a character, wait to receive that character, and repeat.

##### *External Connections*

- None.

##### *Watch Variables*

- rxCount - The number of RX interrupts
- transmitChar - The character being transmitted
- receivedChar - The character received

### 30.6.1.3 LIN SCI MODE Internal Loopback with DMA

FILE: lin\_ex3\_sci\_dma.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in multi-buffer mode. When the transmit buffers in the LINTD0 and LINTD1 registers have enough space, the DMA will transfer data from global variable sData into those transmit registers. Once the received buffers in the LINRD0 and LINRD1 registers contain data, the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

#### External Connections

- None

#### Watch Variables

- sData - Data to send
- rData - Received data

### 30.6.1.4 LIN Internal Loopback without Interrupts (polled mode)

FILE: lin\_ex4\_loopback\_polling.c

This example configures the LIN module in master mode for internal loopback without interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Waits for reception of an ID header. The received data is then checked for accuracy.

#### External Connections

- None.

#### Watch Variables

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)

### 30.6.1.5 LIN Internal Loopback with Interrupts using Sysconfig

FILE: lin\_ex5\_syscfg.c

This example is similar to ex1 but using syscfg tool to configure the LIN Module parameters. The file lin\_ex5\_syscfg.syscfg can be updated using the GUI tool to update the configuration parameters.

This example configures the LIN module in master mode for internal loopback with interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Upon reception of an ID header, an interrupt is triggered on line 0 and an interrupt service routine (ISR) is called. The received data is then checked for accuracy.

#### External Connections

- None.

#### Watch Variables

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)
- level0Count - The number of line 0 interrupts
- level1Count - The number of line 1 interrupts

### 30.6.1.6 LIN Incomplete Header Detection

FILE: lin\_ex6\_detect\_incomplete\_header.c

This example demonstrates how an error in the header field of a LIN frame can be detected. It configures the LIN module in slave mode and waits till new frame is received. It configures an external interrupt to trigger by a falling edge in the LIN Rx pin confirming start of frame. In the ISR of XINT, a timer is configured to trigger after max time consumed by reception of a complete LIN frame. If a LIN frame is successfully received the timer is disabled before getting triggered in the LIN ISR else the timer ISR is called which indicates an error in header frame.

#### External Connections

- LINATX/RX to host node via transceiver.

#### Watch Variables

- linHeaderError - Number of times header error was detected
- rxData - An array with the data that was received if successful reception
- xint1Count - Number of timer XINT triggered

### 30.6.1.7 LIN External Loopback without Interrupts (polled mode)

FILE: lin\_ex7\_external\_loopback.c

This example configures the LINA module in master mode and LINB module in slave mode. Master transmits 8 byte data to the slave with a matching ID configured in slave Receive ID. The received data is then checked for accuracy.

#### External Connections

- Connect LINA TX/RX with LINB TX/RX via transceiver.

#### Watch Variables

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)

## 30.7 SCI/LIN Registers

The SCI/LIN module registers are based on the SCI registers, with added functionality registers enabled by the LIN MODE bit in the SCIGCR1 register.

These registers are accessible in 32-bit reads or writes. The SCI/LIN is controlled and accessed through the registers listed in the following sections. Among the features that can be programmed are the LIN protocol mode, communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

### 30.7.1 LIN Base Address Table

**Table 30-13. LIN Base Address Table**

| Bit Field Name |           | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure |                |              |      |     |     |     |                    |
| LinaRegs       | LIN_REGS  | LINA_BASE      | 0x0000_6A00  | YES  | YES | YES | YES | YES                |
| LinbRegs       | LIN_REGS  | LINB_BASE      | 0x0000_6B00  | YES  | YES | YES | YES | YES                |

### 30.7.2 LIN\_REGS Registers

Table 30-14 lists the memory-mapped registers for the LIN\_REGS registers. All register offset addresses not listed in Table 30-14 should be considered as reserved locations and the register contents should not be modified.

**Table 30-14. LIN\_REGS Registers**

| Offset | Acronym         | Register Name                        | Write Protection | Section            |
|--------|-----------------|--------------------------------------|------------------|--------------------|
| 0h     | SCIGCR0         | Global Control Register 0            |                  | <a href="#">Go</a> |
| 4h     | SCIGCR1         | Global Control Register 1            |                  | <a href="#">Go</a> |
| 8h     | SCIGCR2         | Global Control Register 2            |                  | <a href="#">Go</a> |
| Ch     | SCISSETINT      | Interrupt Enable Register            |                  | <a href="#">Go</a> |
| 10h    | SCICLEARINT     | Interrupt Disable Register           |                  | <a href="#">Go</a> |
| 14h    | SCISSETINTLVL   | Set Interrupt Level Register         |                  | <a href="#">Go</a> |
| 18h    | SCICLEARINTLVL  | Clear Interrupt Level Register       |                  | <a href="#">Go</a> |
| 1Ch    | SCIFLR          | Flag Register                        |                  | <a href="#">Go</a> |
| 20h    | SCIINTVECT0     | Interrupt Vector Offset Register 0   |                  | <a href="#">Go</a> |
| 24h    | SCIINTVECT1     | Interrupt Vector Offset Register 1   |                  | <a href="#">Go</a> |
| 28h    | SCIFORMAT       | Length Control Register              |                  | <a href="#">Go</a> |
| 2Ch    | BRSR            | Baud Rate Selection Register         |                  | <a href="#">Go</a> |
| 30h    | SCIED           | Emulation buffer Register            |                  | <a href="#">Go</a> |

| 6Ch    | LINMASK         | Acceptance mask register             |                  | <a href="#">Go</a> |
| 70h    | LINID           | LIN ID Register                      |                  | <a href="#">Go</a> |
| 74h    | LINTD0          | Transmit Data Register 0             |                  | <a href="#">Go</a> |
| 78h    | LINTD1          | Transmit Data Register 1             |                  | <a href="#">Go</a> |
| 7Ch    | MBSR            | Maximum Baud Rate Selection Register |                  | <a href="#">Go</a> |
| 90h    | IODFTCTRL       | IODFT for LIN                        |                  | <a href="#">Go</a> |
| E0h    | LIN_GLB_INT_EN  | LIN Global Interrupt Enable Register |                  | <a href="#">Go</a> |
| E4h    | LIN_GLB_INT_FLG | LIN Global Interrupt Flag Register   |                  | <a href="#">Go</a> |
| E8h    | LIN_GLB_INT_CLR | LIN Global Interrupt Clear Register  |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 30-15 shows the codes that are used for access types in this section.

**Table 30-15. LIN\_REGS Access Type Codes**

| Access Type | Code    | Description         |
|-------------|---------|---------------------|
| Read Type   |         |                     |
| R           | R       | Read                |
| Write Type  |         |                     |
| W           | W       | Write               |
| W1C         | W<br>1C | Write<br>1 to clear |

**Table 30-15. LIN\_REGS Access Type Codes  
(continued)**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default<br>value  |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in<br>a register name, an offset, or an<br>address, they refer to the value of<br>a register array where the register<br>is part of a group of repeating<br>registers. The register groups<br>form a hierarchical structure and<br>the array is represented with a<br>formula. |
| y                        |         | When this variable is used in a<br>register name, an offset, or an<br>address it refers to the value of<br>a register array.   |

### 30.7.2.1 SCIGCR0 Register (Offset = 0h) [Reset = 0h]

SCIGCR0 is shown in [Figure 30-26](#) and described in [Table 30-16](#).

Return to the [Summary Table](#).

The SCIGCR0 register defines the module reset.

**Figure 30-26. SCIGCR0 Register**

This bit affects the reset state of the SCI/LIN module.<br>Reset type: SYSRSn<br>0h (R/W) = SCI/LIN module is in held in reset.<br>1h (R/W) = SCI/LIN module is out of reset. |

### 30.7.2.2 SCIGCR1 Register (Offset = 4h) [Reset = 0h]

SCIGCR1 is shown in [Figure 30-27](#) and described in [Table 30-17](#).

Return to the [Summary Table](#).

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI.

**Figure 30-27. SCIGCR1 Register**

|          |         |              |          |        |           |            |          |

| 25    | TXENA    | R/W  | 0h    | Transmit enable.<br>This bit is effective in LIN and SCI modes. Data is transferred from SCITD or the TDy (with y=0, 1,...7) buffers in LIN mode to the SCITXSHF shift out register only when the TXENA bit is set.<br>Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent (including the checksum byte in LIN mode).<br>Reset type: SYSRSn<br>0h (R/W) = Disable transfers from SCITD or TDy to SCITXSHF<br>1h (R/W) = Enable transfers of data from SCITD or TDy to SCITXSHF |

**Table 30-17. SCIGCR1 Register Field Descriptions (continued)**

| Bit   | Field        | Type | Reset | Description   |
|-------|--------------|------|-------|---|
| 24    | RXENA        | R/W  | 0h    | <p>Receive enable.</p> <p>This bit is effective in LIN or SCI-compatible mode. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multibuffers.</p> <p>Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 7) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.</p> <p>Note: If RXENA is cleared before the time the reception of a frame is complete, the data from the frame is not transferred into the receive buffer.</p> <p>Note: If RXENA is set before the time the reception of a frame is complete, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame</p> <p>Reset type: SYSRSn<br/>           0h (R/W) = Prevents the receiver from transferring data from the shift buffer to the receive buffer or multi-buffers<br/>           1h (R/W) = Allows the receiver to transfer data from the shift buffer to the receive buffer or multi-buffers</p> |
| 23-18 | RESERVED     | R    | 0h    | Reserved  |
| 17    | CONT         | R/W  | 0h    | <p>Continue on suspend.</p> <p>This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI/LIN operates when the program is suspended. This bit affects the LIN counters. When this bit is set, the counters are not stopped during debug. When this bit is cleared, the counters are stopped during debug.</p> <p>Reset type: SYSRSn<br/>           0h (R/W) = When debug mode is entered, the SCI/LIN state machine is frozen. Transmissions and LIN counters are halted and resume when debug mode is exited.<br/>           1h (R/W) = When debug mode is entered, the SCI/LIN continues to operate until the current transmit and receive functions are complete.</p>   |
| 16    | LOOPBACK     | R/W  | 0h    | <p>Loopback bit.</p> <p>This bit is effective in LIN or SCI-compatible mode. The self-checking option for the SCI/LIN can be selected with this bit. If the LINTX and LINRX pins are configured with SCI/LIN functionality, then the LINTX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINTX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result.</p> <p>Reset type: SYSRSn<br/>           0h (R/W) = Loopback mode is disabled.<br/>           1h (R/W) = Loopback mode is enabled.</p>   |
| 15-14 | RESERVED     | R    | 0h    | Reserved  |
| 13    | STOPEXTFRAME | R/W  | 0h    | <p>Stop extended frame communication.</p> <p>This bit is effective in LIN mode only. This bit can be written only during extended frame communication. When the extended frame communication is stopped, this bit is cleared automatically.</p> <p>Reset type: SYSRSn<br/>           0h (R/W) = No effect<br/>           1h (R/W) = Extended frame communication will be stopped, once current frame transmission/reception is completed.</p>   |

**Table 30-17. SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field    | Type | Reset | Description   |
|-----|----------|------|-------|---|
| 12  | HGENCTRL | R/W  | 0h    | <p>HGEN control bit.</p> <p>This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = ID filtering using ID-Byte.</p> <p>RECEIVEDID and IDBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in NO match.</p> <p>1h (R/W) = ID filtering using ID-SLAVETask byte (Recommended).</p> <p>RECEIVEDID and IDSLAVETASKBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in ALWAYS match</p>  |
| 11  | CTYPE    | R/W  | 0h    | <p>Checksum type.</p> <p>This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Classic checksum is used.</p> <p>This checksum is compatible with LIN 1.3 Slave nodes. The classic checksum contains the modulo-256 sum with carry over all data bytes. Frames sent with Identifier 60 (0x3C) to 63 (0x3F) must always use the classic checksum.</p> <p>1h (R/W) = Enhanced checksum is used.</p> <p>The enhanced checksum is compatible with LIN 2.0 and newer Slave nodes. The enhanced checksum contains the modulo-256 sum with carry over all data bytes AND the protected Identifier.</p>  |
| 10  | MBUFMODE | R/W  | 0h    | <p>Multibuffer mode.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The multi-buffer mode is disabled.</p> <p>1h (R/W) = The multi-buffer mode is enabled.</p>   |
| 9   | ADAPT    | R/W  | 0h    | <p>Adapt mode enable.</p> <p>This mode is effective in LIN mode only. This bit has an effect during the detection of the Sync Field. There are two LIN protocol bit rate modes that could be enabled with this bit according to the Node capability file definition: automatic or select. Software and network configuration will decide which of the previous two modes. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a LIN Slave node detecting the baudrate will compare it to the prescalers in BRSR register and update it if they are different. The BRSR register will be updated with the new value. If this bit is not set there will be no adjustment to the BRSR register. This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Automatic baudrate adjustment is disabled.</p> <p>1h (R/W) = Automatic baudrate adjustment is enabled.</p> |
| 8   | SLEEP    | R/W  | 0h    | <p>SCI sleep.</p> <p>SCI compatibility mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p>The receiver still operates when the SLEEP bit is set however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition. The SLEEP bit is not automatically cleared when an address byte is detected.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Sleep mode is disabled.</p> <p>1h (R/W) = Sleep mode is enabled.</p>               |

**Table 30-17. SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description   |
|-----|------------|------|-------|---|
| 7   | SWnRST     | R/W  | 0h    | <p>Software reset (active low).<br/>This bit is effective in LIN or SCI-compatible mode. The SCI/LIN should only be configured while SWnRST = 0.<br/>Only the following configuration bits can be changed in runtime (i.e., while SWnRESET = 1):</p> <ul style="list-style-type: none"> <li>- STOP EXT Frame (SCIGCR1[13])</li> <li>- CC bit (SCIGCR2[17])</li> <li>- SC bit (SCIGCR2[16])</li> </ul> <p>Reset type: SYSRSn<br/>0h (R/W) = The SCI/LIN is in its reset state<br/>no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags. All affected logic is held in the reset state until a 1 is written to this bit.<br/>1h (R/W) = The SCI/LIN is in its ready state<br/>transmission and reception can occur. After this bit is set to 1, the configuration of the module should not change.</p> |
| 6   | LINMODE    | R/W  | 0h    | <p>LIN mode<br/>This bit controls the mode of operation of the module.<br/>Reset type: SYSRSn<br/>0h (R/W) = LIN mode is disabled<br/>SCI compatibility mode is enabled.<br/>1h (R/W) = LIN mode is enabled<br/>SCI compatibility mode is disabled.</p>   |
| 5   | CLK_Master | R/W  | 0h    | <p>SCI internal clock enable or LIN Master/Slave configuration.<br/>In the SCI mode, this bit enables the clock to the SCI module. In LIN mode, this bit determines whether a LIN node is a Slave or Master.<br/>Reset type: SYSRSn<br/>0h (R/W) = SCI-compatible mode: Reserved.<br/>LIN mode: The module is in Slave mode.<br/>1h (R/W) = SCI-compatible mode: Enable clock to the SCI module.<br/>LIN mode: The node is in Master mode.</p>  |
| 4   | STOP       | R/W  | 0h    | <p>SCI number of stop bits.<br/>This bit is effective in SCI-compatible mode only.<br/>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.<br/>This field is writable in SCI mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = One stop bit is used.<br/>1h (R/W) = Two stop bits are used.</p>  |
| 3   | PARITY     | R/W  | 0h    | <p>SCI parity odd/even selection.<br/>This bit is effective in SCI-compatible mode only. If the PARITY ENA bit (SCIGCR1.2) is set, PARITY designates odd or even parity. The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.<br/>This field is writable in SCI mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = Odd parity is used. The SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.<br/>1h (R/W) = Even parity is used. The SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</p>  |

**Table 30-17. SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description  |
|-----|------------|------|-------|--|
| 2   | PARITYENA  | R/W  | 0h    | Parity enable.<br>Enables or disables the parity function.<br>Reset type: SYSRSn<br>0h (R/W) = SCI-compatible mode: Parity disabled<br>no parity bit is generated during transmission or is expected during reception.<br>LIN mode: ID-parity verification is disabled.<br>1h (R/W) = SCI compatible mode: Parity enabled. A parity bit is generated during transmission and is expected during reception.<br>LIN mode: ID-parity verification is enabled. |
| 1   | TIMINGMODE | R/W  | 0h    | SCI timing mode bit.<br>This bit is effective in SCI-compatible mode only. It must be set to 1 when the SCI mode is used. This bit configures the SCI for asynchronous operation.<br>Reset type: SYSRSn<br>0h (R/W) = Reserved.<br>1h (R/W) = Must be set to 1 when module is configured for SCI operation   |
| 0   | COMMMODE   | R/W  | 0h    | SCI/LIN communication mode bit.<br>In compatibility mode, it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5.<br>Reset type: SYSRSn<br>0h (R/W) = SCI-compatible mode: Idle-line mode is used.<br>LIN mode: ID4 and ID5 are not used for length control.<br>1h (R/W) = SCI-compatible mode: Address-bit mode is used.<br>LIN mode: ID4 and ID5 are used for length control.                 |

### 30.7.2.3 SCIGCR2 Register (Offset = 8h) [Reset = 0h]

SCIGCR2 is shown in [Figure 30-28](#) and described in [Table 30-18](#).

Return to the [Summary Table](#).

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module.

**Figure 30-28. SCIGCR2 Register**

|-------|----------|------|-------|---|
| 31-18 | RESERVED | R    | 0h    | Reserved  |
| 17    | CC       | R/W  | 0h    | <p>Compare Checksum.</p> <p>This mode is effective in LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. The user will initiate this transaction by writing a one to this bit.</p> <p>In non multibuffer mode, once the CC bit is set, the checksum will be compared on the byte that is currently being received, expected to be the checkbyte.</p> <p>During Multi-buffer mode, following are the scenarios associated with the CC bit :</p> <ul style="list-style-type: none"> <li>- If CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed no. of data bytes indicated by SCIFORMAT[18:16], is treated as a checksum byte.</li> <li>- If CC bit is set during the IDLE period (i.e. during inter-frame space), then the next immediate byte will be treated as a checksum byte.</li> </ul> <p>A CE will immediately be flagged if there is a checksum error.</p> <p>This bit is automatically cleared once the checksum is successfully compared.</p> <p>Reset type: SYSRSn<br/>           0h (R/W) = No effect<br/>           1h (R/W) = Compare checksum on expected checkbyte</p> |

**Table 30-18. SCIGCR2 Register Field Descriptions (continued)**

| Bit  | Field     | Type | Reset | Description   |
|------|-----------|------|-------|---|
| 16   | SC        | R/W  | 0h    | <p>Send Checksum</p> <p>This mode is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checkbyte. In non multibuffer mode the checkbyte will be sent after the current byte transmission. In multibuffer mode the checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]).</p> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No checkbyte will be sent.</p> <p>1h (R/W) = A checkbyte will be sent. This bit will automatically get cleared after the checkbyte is transmitted. The checksum will not be sent if this bit is set before transmitting the very first byte, that is, during interframe space.</p> |
| 15-9 | RESERVED  | R    | 0h    | Reserved  |
| 8    | GENWU     | R/W  | 0h    | <p>Generate wakeup signal.</p> <p>This bit controls the generation of a wakeup signal, by transmitting the TDO buffer value. This bit is cleared on reception of a valid sync break.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No effect</p> <p>1h (R/W) = Transmit TDO for wakeup. This bit will be cleared on a SWnRST (SCIGCR1.7)</p>  |
| 7-1  | RESERVED  | R    | 0h    | Reserved  |
| 0    | POWERDOWN | R/W  | 0h    | <p>Power down.</p> <p>This bit is effective in LIN or SCI-compatible mode. When the powerdown bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay low-power mode from being entered until completion of reception. In LIN mode the user may set the POWERDOWN bit on Sleep Command reception or on idle bus detection (more than 4 seconds, i.e. 80,000 cycles at 20kHz)</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Normal operation</p> <p>1h (R/W) = Request local low-power mode</p>   |

### 30.7.2.4 SCISSETINT Register (Offset = Ch) [Reset = 0h]

SCISSETINT is shown in [Figure 30-29](#) and described in [Table 30-19](#).

Return to the [Summary Table](#).

The SCISSETINT register is used to enable the various interrupts available in the LIN module.

|-----|-------------|-------|-------|--|
| 0   | SETBRKDTINT | R/W1S | 0h    | Set break-detect interrupt.<br>This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an interrupt if a break condition is detected on the LINRX pin.<br>This field is writable in SCI mode only.<br>Reset type: SYSRSn<br>0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect.<br>1h (R/W) = Interrupt is enabled. |

### 30.7.2.5 SCICLEARINT Register (Offset = 10h) [Reset = 0h]

SCICLEARINT is shown in [Figure 30-30](#) and described in [Table 30-20](#).

Return to the [Summary Table](#).

The SCICLEARINT register is used to disable the enabled interrupts without accessing the SCISSETINT register.

**Figure 30-30. SCICLEARINT Register**

### 30.7.2.7 SCICLEARINTLVL Register (Offset = 18h) [Reset = 0h]

SCICLEARINTLVL is shown in [Figure 30-32](#) and described in [Table 30-22](#).

Return to the [Summary Table](#).

The SCICLEARINTLVL register is used to map individual interrupt sources to the INT0 line.

**Figure 30-32. SCICLEARINTLVL Register**

| Bit | Field | Type  | Reset | Description  |
|-----|-------|-------|-------|--|
| 29  | CE    | R/W1C | 0h    | <p>Checksum Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is checksum error detected by a receiving node. The type of checksum to be used depends on the SCIGCR1.CTYPE bit. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No Checksum error detected.<br/>1h (R/W) = Checksum error detected.</p>  |
| 28  | ISFE  | R/W1C | 0h    | <p>Inconsistent Sync Field Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there has been an inconsistent Sync Field error detected by the synchronizer during header reception. See the "Header Reception and Adaptive Baudrate" section for more information. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No Inconsistent Sync Field error detected.<br/>1h (R/W) = Inconsistent Sync Field error detected.</p>    |
| 27  | NRE   | R/W1C | 0h    | <p>No-Response Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is no response to a Master's header completed within TFRAME_MAX. This timeout period is applied for message frames of unknown length (identifiers 0 to 61). This error is detected by the synchronizer of the module. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No No-Response error detected.<br/>1h (R/W) = No-Response error detected.</p> |

**Table 30-23. SCIFLR Register Field Descriptions (continued)**

| Bit   | Field    | Type  | Reset | Description  |
|-------|----------|-------|-------|--|
| 26    | FE       | R/W1C | 0h    | <p>Framing error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatible mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt if the RXERR INT ENA bit is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>- Reception of a new character (SCI-compatible mode), or frame (LIN mode)</p> <p>In multibuffer mode the frame is defined in the SCIFORMAT register.</p> <p>Reset type: SYSRSn<br/>0h (R/W) = No framing error detected.<br/>1h (R/W) = Framing error detected.</p>  |
| 25    | OE       | R/W1C | 0h    | <p>Overrun error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit is one. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>Reset type: SYSRSn<br/>0h (R/W) = No overrun error detected.<br/>1h (R/W) = Overrun error detected.</p>  |
| 24    | PE       | R/W1C | 0h    | <p>Parity error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. For more information on parity checking, see the "SCI Global Control Register (SCIGCR1)" description. If the parity function is disabled (that is, SCIGCR1.2 = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Reception of a new character (SCI-compatible mode) or frame (LIN mode)</li> <li>- Writing a 1 to this bit</li> </ul> <p>Reset type: SYSRSn<br/>0h (R/W) = No parity error or parity disabled.<br/>1h (R/W) = Parity error detected.</p> |

| Bit | Field    | Type  | Reset | Description   |
|-----|----------|-------|-------|---|
| 14  | IDRXFLAG | R/W1C | 0h    | <p>Identifier On Receive Flag.</p> <p>This bit is effective in LIN mode only. This flag is set once an identifier is received with an RX match and no ID-parity error. See the "Message Filtering and Validation" section for more details. When this flag is set it indicates that a new valid identifier has been received on an RX match. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVTECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Reading the LINID register</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No valid ID received.<br/>1h (R/W) = Valid ID RX received in LINID[23:16] on RX match.</p> |
| 13  | IDTXFLAG | R/W1C | 0h    | <p>Identifier On Transmit Flag.</p> <p>This bit is effective in LIN mode only. This flag is set once an identifier is received with a TX match and no ID-parity error. See the "Message Filtering and Validation" section for more details. When this flag is set it indicates that a new valid identifier has been received on a TX match. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVTECT0/1 register</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting SWnRESET</li> <li>- System reset</li> <li>- Reading the LINID register</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No valid ID received.<br/>1h (R/W) = Valid ID received in LINID[23:16] on TX match.</p>                         |
| 12  | RXWAKE   | R     | 0h    | <p>Receiver wakeup detect flag.</p> <p>This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- System reset</li> <li>- Receipt of a data frame</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The data in SCIRD is not an address.<br/>1h (R/W) = The data in SCIRD is an address.</p> <p>See [1] Section 3.4.4, Sleep Mode for Multiprocessor Communication, on page 16 for more information on using the RXWAKE bit with sleep mode.</p>   |

**Table 30-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field   | Type  | Reset | Description  |
|-----|---------|-------|-------|--|
| 11  | TXEMPTY | R     | 1h    | <p>Transmitter Empty flag.</p> <p>The value of this flag indicates the contents of the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF). In multibuffer mode, this flag indicates the value of the TDx registers and shift register (SCITXSHF). In non multibuffer mode, this flag indicates the value of LINTD0 (byte) and shift register (SCITXSHF). This bit is set by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- System reset.</li> </ul> <p>Note: This bit does not cause an interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Compatible mode or LIN with no multibuffer:<br/>Transmitter buffer or shift register (or both) are loaded with data.</p> <p>In LIN mode using multibuffer mode:<br/>Multibuffer or shift register (or all) are loaded with data.</p> <p>1h (R/W) = Compatible mode or LIN with no multibuffer:<br/>Transmitter buffer and shift registers are both empty.</p> <p>In LIN mode using multibuffer mode:<br/>Multibuffer and shift registers are all empty.</p>                                       |
| 10  | TXWAKE  | R/W   | 0h    | <p>SCI transmitter wakeup method select.</p> <p>This bit is effective in SCI-compatible mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. TXWAKE is not cleared by the SWnRESET bit (SCIGCR1.7).</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Address-bit mode: Frame to be transmitted will be data (address bit = 0).</p> <p>Idle-line mode: Frame to be transmitted will be data.</p> <p>1h (R/W) = Address-bit mode:<br/>Frame to be transmitted will be an address (address bit=1).</p> <p>Idle-line mode:<br/>Following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).</p>  |
| 9   | RXRDY   | R/W1C | 0h    | <p>Receiver ready flag.</p> <p>In SCI compatibility mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In LIN mode, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In non multibuffer mode RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set (SCISSETINT.9). RXRDY is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reading SCIRD in while in SCI compatibility mode</li> <li>- Reading last data byte RDy of the response in LIN mode</li> </ul> <p>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No new data in SCIRD/RDy.</p> <p>1h (R/W) = New data ready to be read from SCIRD.</p> |

**Table 30-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field    | Type  | Reset | Description  |
|-----|----------|-------|-------|--|
| 8   | TXRDY    | R     | 1h    | <p>Transmitter buffer register ready flag.</p> <p>When set, this bit indicates that the transmit buffer(s) register (SCITD in compatibility mode and LINTD0, LINTD1 in MBUF mode) is/are ready to get another character from a CPU write.</p> <p>In SCI compatibility mode, writing data to SCITD automatically clears this bit. In LIN mode, this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer are shifted into the SCITXSHF register. This event can trigger a transmit DMA event if the DMA enable bit is set. This bit is set to 1 by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET (SCIGCR1.7)</li> <li>- System reset</li> </ul> <p>Note: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>Note: The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disaLING the corresponding interrupt via the SCICLEARINT register or by disaLING the transmitter via the TXENA bit (SCIGCR1.25=0).</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Compatible mode: SCITD is full.</p> <p>LIN mode: The multibuffers are full.</p> <p>1h (R/W) = Compatible mode: SCITD is ready to receive the next character.</p> <p>LIN mode: The multibuffers are ready to receive the next character(s).</p> |
| 7   | TOA3WUS  | R/W1C | 0h    | <p>Timeout After 3 Wakeup Signals flag.</p> <p>This bit is effective in LIN mode only. This flag is set if there is no Sync Break received after 3 wakeup signals and a period of 1.5 seconds have passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No timeout after 3 wakeup signals.</p> <p>1h (R/W) = Timeout after 3 wakeup signals and 1.5s time.</p>  |
| 6   | TOAWUS   | R/W1C | 0h    | <p>Timeout After Wakeup Signal flag.</p> <p>This bit is effective in LIN mode only. This bit is set if there is no Sync Break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No timeout after one wakeup signal (150 ms).</p> <p>1h (R/W) = Timeout after one wakeup signal.</p>   |

**Table 30-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field   | Type  | Reset | Description   |
|-----|---------|-------|-------|---|
| 4   | TIMEOUT | R/W1C | 0h    | <p>LIN Bus IDLE timeout flag.</p> <p>This bit is effective in LIN mode only. This bit is set if there is no LIN bus activity for at least 4 seconds. LIN bus activity being a transition from recessive to dominant. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No bus idle detected.<br/>1h (R/W) = LIN bus idle detected.</p>   |
| 3   | BUSY    | R     | 0h    | <p>Bus BUSY flag.</p> <p>This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the BUSY bit is cleared. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver but can be cleared by:</p> <ul style="list-style-type: none"> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset.</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Receiver is not currently receiving a frame.<br/>1h (R/W) = Receiver is currently receiving a frame.</p> |
| 2   | IDLE    | R     | 1h    | <p>SCI receiver in idle state.</p> <p>This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters this state:</p> <ul style="list-style-type: none"> <li>- After a system reset</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- After coming out of power down</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Idle period detected, the SCI is ready to receive.<br/>1h (R/W) = Idle period not detected, the SCI will not receive any data.</p>  |
| 1   | WAKEUP  | R/W1C | 0h    | <p>Wake-up flag.</p> <p>This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT.1) is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit.</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Do not wake up from power-down mode.<br/>1h (R/W) = Wake up from power-down mode.</p>   |

**Table 30-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field | Type  | Reset | Description   |
|-----|-------|-------|-------|---|
| 0   | BRKDT | R/W1C | 0h    | <p>SCI break-detect flag.</p> <p>This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- By writing a 1 to this bit.</li> </ul> <p>This bit is writable in SCI mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No break condition detected.<br/>1h (R/W) = Break condition detected.</p> |

### 30.7.2.9 SCIINTVECT0 Register (Offset = 20h) [Reset = 0h]

SCIINTVECT0 is shown in [Figure 30-34](#) and described in [Table 30-24](#).

Return to the [Summary Table](#).

The SCIINTVECT0 register indicates the offset for the INT0 interrupt line.

**Figure 30-34. SCIINTVECT0 Register**

| Bit   | Field    | Type | Reset | Description   |
|-------|----------|------|-------|---|
| 31-19 | RESERVED | R    | 0h    | Reserved  |
| 18-16 | LENGTH   | R/W  | 0h    | <p>Frame length control bits.</p> <p>In LIN mode, these bits indicate the number of bytes in the response field from 1 to 8 bytes. In buffered SCI mode, these bits indicate the number of characters. When these bits are used to indicate LIN response length (SCIGCR1[0] = 1), then when there is an ID RX match, this value should be updated with the expected length of the response. In buffered SCI mode, these bits indicate the number of characters with SCIFORMAT[2:0] bits per character. i.e. these bits indicate the transmitter/receiver format for the number of characters: 1 to 8. There can be up to eight characters with eight bits each.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The response field has 1 bytes/characters.<br/>                     1h (R/W) = The response field has 2 bytes/characters.<br/>                     2h (R/W) = The response field has 3 bytes/characters.<br/>                     3h (R/W) = The response field has 4 bytes/characters.<br/>                     4h (R/W) = The response field has 5 bytes/characters.<br/>                     5h (R/W) = The response field has 6 bytes/characters.<br/>                     6h (R/W) = The response field has 7 bytes/characters.<br/>                     7h (R/W) = The response field has 8 bytes/characters.</p> |
| 15-3  | RESERVED | R    | 0h    | Reserved  |
| 2-0   | CHAR     | R/W  | 0h    | <p>Character length control bits.</p> <p>These bits are effective in SCI compatible mode only. These bits set the SCI character length from 1 to 8 bits.</p> <p>Note: In compatibility mode or buffered SCI mode, when data of fewer than eight bits in length is received, it is left justified in SCIRD/RDy and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified.</p> <p>Note: Data written to the SCITD should be right justified but does not need to be padded with leading zeros.</p> <p>These bits are writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The character is 1 bits long.<br/>                     1h (R/W) = The character is 2 bits long.<br/>                     2h (R/W) = The character is 3 bits long.<br/>                     3h (R/W) = The character is 4 bits long.<br/>                     4h (R/W) = The character is 5 bits long.<br/>                     5h (R/W) = The character is 6 bits long.<br/>                     6h (R/W) = The character is 7 bits long.<br/>                     7h (R/W) = The character is 8 bits long.</p>  |

### 30.7.2.12 BRSR Register (Offset = 2Ch) [Reset = 0h]

BRSR is shown in [Figure 30-37](#) and described in [Table 30-27](#).

Return to the [Summary Table](#).

The BRSR register is used to configure the baud rate of the LIN module.

**Figure 30-37. BRSR Register**

### 30.7.2.13 SCIED Register (Offset = 30h) [Reset = 0h]

SCIED is shown in [Figure 30-38](#) and described in [Table 30-28](#).

Return to the [Summary Table](#).

The SCIED register is a duplicate copy of SCIRD register that has no affect on the RXRDY flag for use with an emulator.

**Figure 30-38. SCIED Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17   | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED |    |    |    |    |    |    |    |    |    |    |    |    |    | ED   |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    | R-0h |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 30-28. SCIED Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 31-8 | RESERVED | R    | 0h    | Reserved   |
| 7-0  | ED       | R    | 0h    | Receiver Emulation Data.<br>This bit is effective in SCI-compatible mode only. Reading SCIED(7-0) does not clear the RXRDY flag. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag.<br>Reset type: SYSRSn |

### 30.7.2.14 SCIRD Register (Offset = 34h) [Reset = 0h]

SCIRD is shown in [Figure 30-39](#) and described in [Table 30-29](#).

Return to the [Summary Table](#).

The SCIRD register is where received data is stored and can be read from.

**Figure 30-39. SCIRD Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17   | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED |    |    |    |    |    |    |    |    |    |    |    |    |    | RD   |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    | R-0h |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 30-29. SCIRD Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description   |
|------|----------|------|-------|---|
| 31-8 | RESERVED | R    | 0h    | Reserved  |
| 7-0  | RD       | R    | 0h    | Received Data.<br>This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if RX INT ENA (SCISSETINT0.9) is set. When the data is read from SCIRD, the RXRDY flag is automatically cleared.<br>When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified.<br>Reset type: SYSRSn |

### 30.7.2.15 SCITD Register (Offset = 38h) [Reset = 0h]

SCITD is shown in [Figure 30-40](#) and described in [Table 30-30](#).

Return to the [Summary Table](#).

The SCITD register is where data to be transmitted is written to by application software.

**Figure 30-40. SCITD Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17     | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED |    |    |    |    |    |    |    |    |    |    |    |    |    | TD     |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    | R/W-0h |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 30-30. SCITD Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 31-8 | RESERVED | R    | 0h    | Reserved   |
| 7-0  | TD       | R/W  | 0h    | Transmit data<br>This bit is effective in SCI-compatible mode only. Data to be transmitted is written to this register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag (SCIFLR.23), which indicates that SCITD is ready to be loaded with another byte of data. Note: If TX INT ENA (SCISSETINT.8) is set, this data transfer also causes an interrupt.<br>Note: Data written to the SCIRD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.<br>Reset type: SYSRSn |

### 30.7.2.16 SCIPIO0 Register (Offset = 3Ch) [Reset = 0h]

SCIPIO0 is shown in [Figure 30-41](#) and described in [Table 30-31](#).

Return to the [Summary Table](#).

The SCIPIO0 register is used to enable the LINTX and LINRX pins.

**Figure 30-41. SCIPIO0 Register**

|          |    |    |    |    |        |        |          |

### 30.7.2.17 SCIPIO2 Register (Offset = 44h) [Reset = 0h]

SCIPIO2 is shown in [Figure 30-42](#) and described in [Table 30-32](#).

Return to the [Summary Table](#).

The SCIPIO2 register indicates the current status of the LINTX and LINRX pins.

**Figure 30-42. SCIPIO2 Register**

### 30.7.2.20 LINRD1 Register (Offset = 68h) [Reset = 0h]

LINRD1 is shown in [Figure 30-45](#) and described in [Table 30-35](#).

Return to the [Summary Table](#).

The LINRD1 register contains the upper 4 bytes of the received LIN frame data.

**Figure 30-45. LINRD1 Register**

|      |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|------|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|

| 23-16 | RD5   | R    | 0h    | 8-bit Receive Buffer 5.<br>Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received.<br>Reset type: SYSRSn |
| 15-8  | RD6   | R    | 0h    | 8-bit Receive Buffer 6.<br>Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received.<br>Reset type: SYSRSn |
| 7-0   | RD7   | R    | 0h    | 8-bit Receive Buffer 7.<br>Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received.<br>Reset type: SYSRSn |

### 30.7.2.21 LINMASK Register (Offset = 6Ch) [Reset = 0h]

LINMASK is shown in [Figure 30-46](#) and described in [Table 30-36](#).

Return to the [Summary Table](#).

The LINMASK register is used to configure the masks used for filtering incoming ID messages for receive and transmit frames.

**Figure 30-46. LINMASK Register**

|          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |          |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|----------|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED |    |    |    |    |    |    |    | RXIDMASK |    |    |    |    |    |    |    | RESERVED |    |    |    |    |    |   |   | TXIDMASK |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    | R/W-0h   |    |    |    |    |    |    |    | R-0h     |    |    |    |    |    |   |   | R/W-0h   |   |   |   |   |   |   |   |

**Table 30-36. LINMASK Register Field Descriptions**

| Bit   | Field    | Type | Reset | Description   |
|-------|----------|------|-------|---|
| 31-24 | RESERVED | R    | 0h    | Reserved  |
| 23-16 | RXIDMASK | R/W  | 0h    | Receive ID mask.<br>This field is effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and compare it to the ID-byte. A compare match of the received ID with the RX ID mask will set the ID RX flag and trigger an ID interrupt if enabled. A 0 bit in the mask indicates that that bit is compared to the ID-byte. A 1 bit in the mask indicates that that bit is filtered and therefore not used in the compare.<br>When HGENCTRL is set to 1, this field must be set to 0xFF.<br>Reset type: SYSRSn |
| 15-8  | RESERVED | R    | 0h    | Reserved  |
| 7-0   | TXIDMASK | R/W  | 0h    | Transmit ID mask.<br>This field is effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and compare it to the ID-byte. A compare match of the received ID with the TX ID Mask will set the ID TX flag and trigger an ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore not used for the compare.<br>When HGENCTRL is set to 1, this field must be set to 0xFF.<br>Reset type: SYSRSn         |

### 30.7.2.22 LINID Register (Offset = 70h) [Reset = 0h]

LINID is shown in [Figure 30-47](#) and described in [Table 30-37](#).

Return to the [Summary Table](#).

The LINID register contains the identification fields for LIN communication.

NOTE: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

**Figure 30-47. LINID Register**

|                 |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

| R/W-0h          |    |    |    |    |    |    |    | R/W-0h     |    |    |    |    |    |    |    |

**Table 30-37. LINID Register Field Descriptions**

| Bit   | Field           | Type | Reset | Description   |
|-------|-----------------|------|-------|---|
| 31-24 | RESERVED        | R    | 0h    | Reserved  |
| 23-16 | RECEIVEDID      | R    | 0h    | Received ID.<br>This bit is effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match.<br>Note: If a framing error (FE) is detected during ID reception, the received ID will also not be copied to the LINID register.<br>Reset type: SYSRSn |
| 15-8  | IDSLAVETASKBYTE | R/W  | 0h    | ID Slave Task byte.<br>This field is effective in LIN mode only. This byte contains the identifier to which the received ID of an incoming header will be compared in order to decide whether a RX response, a TX response, or no action needs to be done by the LIN node.<br>These bits are writable in LIN mode only.<br>Reset type: SYSRSn   |
| 7-0   | IDBYTE          | R/W  | 0h    | ID byte.<br>This field is effective in LIN mode only. This byte is the LIN mode message ID. On a Master node, a write to this register by the CPU initiates a header transmission. For a Slave task, this byte is used for message filtering when HGENCTRL (SCIGCR1.12) is '0'.<br>These bits are writable in LIN mode only.<br>Reset type: SYSRSn  |

### 30.7.2.23 LINTD0 Register (Offset = 74h) [Reset = 0h]

LINTD0 is shown in [Figure 30-48](#) and described in [Table 30-38](#).

Return to the [Summary Table](#).

The LINTD0 register contains the lower 4 bytes of the data to be transmitted.

NOTE: TD<x-1> is equivalent to Data byte <x> of the LIN frame.

**Figure 30-48. LINTD0 Register**

|        |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |        |   |   |   |   |   |   |   |

**Table 30-38. LINTD0 Register Field Descriptions**

| Bit   | Field | Type | Reset | Description  |
|-------|-------|------|-------|--|
| 31-24 | TD0   | R/W  | 0h    | 8-bit Transmit Buffer 0.<br>Byte 0 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Once byte 0 is written in TDO buffer, transmission will be initiated.<br>Reset type: SYSRSn |
| 23-16 | TD1   | R/W  | 0h    | 8-bit Transmit Buffer 3.<br>Byte 1 to be transmitted is written into this register and then copied to SCITXSHF for transmission.<br>Reset type: SYSRSn   |
| 15-8  | TD2   | R/W  | 0h    | 8-bit Transmit Buffer 2.<br>Byte 2 to be transmitted is written into this register and then copied to SCITXSHF for transmission.<br>Reset type: SYSRSn   |
| 7-0   | TD3   | R/W  | 0h    | 8-bit Transmit Buffer 3.<br>Byte 3 to be transmitted is written into this register and then copied to SCITXSHF for transmission.<br>Reset type: SYSRSn   |

### 30.7.2.24 LINTD1 Register (Offset = 78h) [Reset = 0h]

LINTD1 is shown in [Figure 30-49](#) and described in [Table 30-39](#).

Return to the [Summary Table](#).

The LINTD1 register contains the upper 4 bytes of the data to be transmitted.

NOTE: TD<x-1> is equivalent to Data byte <x> of the LIN frame.

**Figure 30-49. LINTD1 Register**

|        |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |        |   |   |   |   |   |   |   |

| 15-8  | TD6   | R/W  | 0h    | 8-bit Transmit Buffer 6.<br>Byte 6 to be transmitted is written into this register and then copied to SCITXSHF for transmission.<br>Reset type: SYSRSn |
| 7-0   | TD7   | R/W  | 0h    | 8-bit Transmit Buffer 7.<br>Byte 7 to be transmitted is written into this register and then copied to SCITXSHF for transmission.<br>Reset type: SYSRSn |

### 30.7.2.25 MBRSR Register (Offset = 7Ch) [Reset = DACH]

MBRSR is shown in [Figure 30-50](#) and described in [Table 30-40](#).

Return to the [Summary Table](#).

The MBRSR register is used to configure the expected maximum baud rate of the LIN network.

**Figure 30-50. MBRSR Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 30-40. MBRSR Register Field Descriptions**

| Bit   | Field    | Type | Reset | Description  |
|-------|----------|------|-------|--|
| 31-13 | RESERVED | R    | 0h    | Reserved   |
| 12-0  | MBR      | R/W  | DACH  | <p>Maximum Baud Rate Prescaler.</p> <p>This field is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see the "Header Reception and Adaptive Baudrate" section) of a Slave module if the ADAPT bit is set. In this way, a SCI/LIN Slave using an automatic or select bit rate modes detects any LIN bus legal rate automatically.</p> <p>The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise a s 0x00 data byte could mistakenly be detected as sync break.</p> <p>The default value is for a 70MHz LINCLK (0xDAC).</p> <p>This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20kHz rate.</p> <p>Reset type: SYSRSn</p> |

### 30.7.2.26 IODFTCTRL Register (Offset = 90h) [Reset = 500h]

IODFTCTRL is shown in [Figure 30-51](#) and described in [Table 30-41](#).

Return to the [Summary Table](#).

The IODFTCTRL register is used to emulate various error and test conditions.

**Figure 30-51. IODFTCTRL Register**

|          |          |         |               |          |         |         |                 |

## 31.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, they can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to ensure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, refer to the [Fast Serial Interface \(FSI\) Skew Compensation Application Report](#).

### 31.1.2 FSI Features

The FSI module includes the following features:

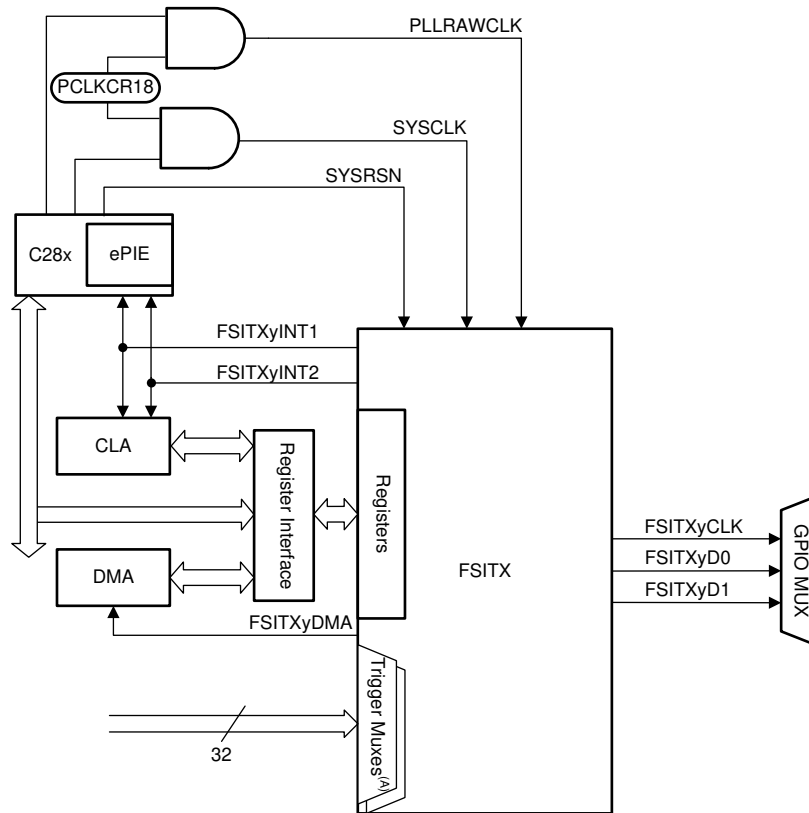

- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- FSI-SPI compatibility mode (limited features available)
- Tag match notifications

### 31.2 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features may require additional configuration of modules that are not within the scope of this chapter, the details can be found elsewhere in this TRM.

#### 31.2.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.

A. The signals connected to the trigger muxes are described in [Section 31.2.5](#).

**Figure 31-1. FSI Transmitter (FSITX) CPU Interface**

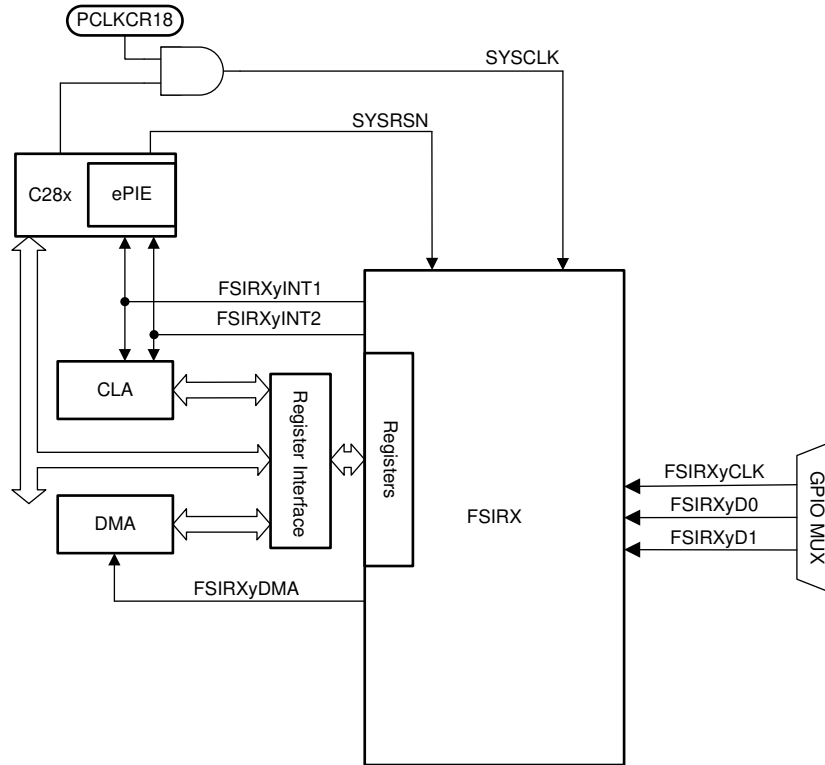

Figure 31-2. FSI Receiver (FSIRX) CPU Interface

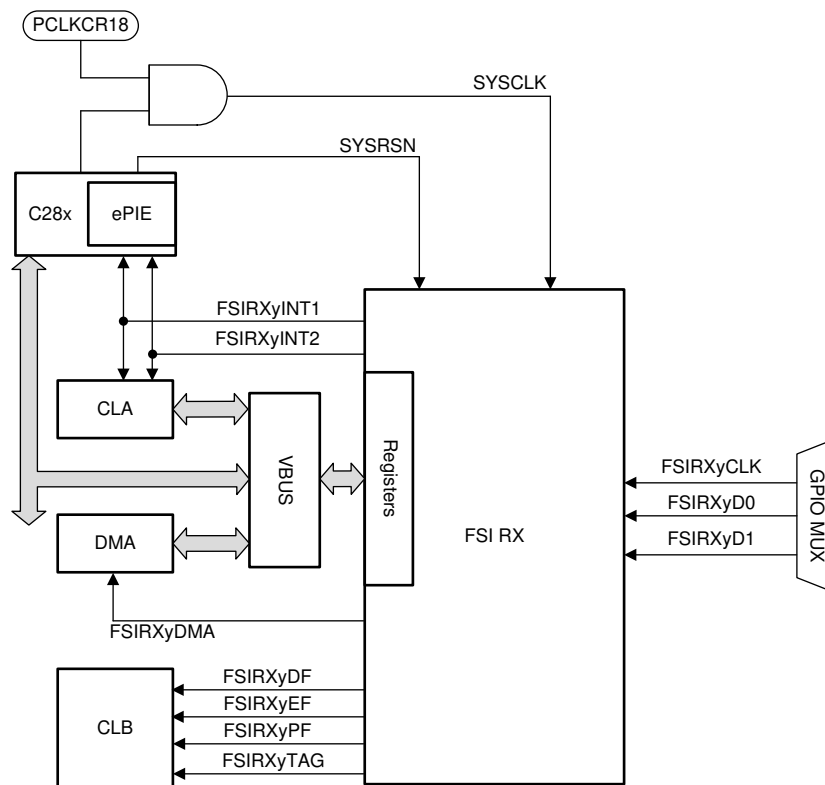

Figure 31-3. FSI Receiver (FSIRX) CPU Interface with CLB

### 31.2.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core will communicate directly to a single FSI receiver core. Similarly, an FSI receiver core will receive data from a single FSI transmitter core.

Each FSI core has three signals associated with it: one clock and two data signals. Data is always transmitted or received with the most significant bit of each frame field being first. If multi-lane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and their GPIOs repurposed for other application needs. [Table 31-1](#) and [Table 31-2](#) describe the various signals that can be selected by the PADCONFIG register to be brought out to device pins.

#### CAUTION

The maximum RXCLK rate is SYSCLK/2 and should not exceed this limit.

**Table 31-1. FSI Receiver Core Signals**

| Signal Name | Direction | Description   | Inactive Level <sup>(1)</sup> |
|-------------|-----------|---|-------------------------------|
| RXCLK       | Input     | This is the receive clock input signal for the FSI receive module.<br>This must should be connected to TXCLK of the transmitting FSI module.                        | Logic High                    |
| RXD0        | Input     | This is the primary data input line for reception. This should be connected to the TXD0 of the transmitting FSI module.   | Logic High                    |
| RXD1        | Input     | This is an additional data input line for reception. This signal should be connected to the TXD1 of the transmitting FSI module if multi-lane transmission is used. | Logic High                    |

(1) Inactive level refers to the state of the pin while the module is not actively receiving data.

**Table 31-2. FSI Transmitter Core Signals**

| Signal Name | Direction | Description   | Inactive Level <sup>(1)</sup> |
|-------------|-----------|---|-------------------------------|
| TXCLK       | Output    | This is the transmit clock. It is driven by the FSI transmit module.<br>During a transmission, four clock edges will be transmitted before the start of frame phase (preamble) and four clock edges will follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock.<br>In FSI-SPI compatibility mode, the preamble and the post frame clock edges will not be transmitted. Data is transmitted only on one edge of the clock. Data will transmit on rising edge and received on falling edge of the clock. | Logic High                    |
| TXD0        | Output    | This is the primary data output line for transmission. This signal is driven by the FSI transmit module.<br>When the FSI is configured for multi-lane transmission, TXD0 will contain all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame will be transmitted in full.   | Logic High                    |
| TXD1        | Output    | This is an additional data output line for transmission if the FSI is configured for multi-lane transmission. This signal is driven by the FSI transmit module.<br>During transmission, the data bits are split between TXD0 and TXD1. TXD1 will contain all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line will be identical to TXD0.                            | Logic High                    |

(1) Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

### 31.2.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See the *General Purpose Input-Output (GPIO)* chapter for more details on the GPIO mux and settings.

### 31.2.3 FSI Interrupts

Each FSI module contains multiple interrupt sources which can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT\_STS, EVT\_FRC, and the EVT\_CLR registers, respectively.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX\_INT\_CTRL register. The receiver events are assigned an interrupt vector using RX\_INT1\_CTRL and RX\_INT2\_CTRL registers. If an interrupt is not required, ensure the bit is not set in the respective INT\_CTRL register.

#### 31.2.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME\_DONE):** This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF\_UNDERRUN):** This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet be written to by the CPU, or DMA.
- **Buffer Overrun (BUF\_OVERRUN):** The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun may occur if a piece of data is overwritten before it has been transmitted.
- **Ping Frame Triggered (PING\_TRIGGERED):** The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit will be set when the ping counter has timed out or an external ping trigger event has occurred.

### 31.2.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events:

- **Ping Watchdog Timeout (PING\_WD\_TO):** This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX\_PING\_WD\_REF register.
- **Frame Watchdog Timeout (FRAME\_WD\_TO):** This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX\_FRAME\_WD\_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter will start counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog will time out and this event will be generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **CRC Error (CRC\_ERR):** This error indicates that a CRC error has occurred. A CRC error will be generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE\_ERR):** This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **End-of-Frame Error (EOF\_ERR):** This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **Receive Buffer Overrun (BUF\_OVERRUN):** This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF\_UNDERRUN):** This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads the buffer while it is empty.
- **Frame Done (FRAME\_DONE):** This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR\_FRAME):** This event indicates that an error frame has been received.
- **Ping Frame Received (PING\_FRAME):** This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME\_OVERRUN):** This event indicates that a new frame has been received while the FRAME\_DONE flag was still set.
- **Data Frame Received (DATA\_FRAME):** This event indicates that a data frame has been received.
- **Ping Tag Matched (PING\_TAG\_MATCH):** This event indicates that a ping frame with a matching tag has been received.
- **Data Tag Matched (DATA\_TAG\_MATCH):** This event indicates that a data frame with a matching tag has been received.
- **Error Tag Matched (ERROR\_TAG\_MATCH):** This event indicates that an error frame with a matching tag has been received.

### 31.2.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application should select the interrupt vector for each desired event using the TX\_INT\_CTRL register for the transmitter, and RX\_INT1\_CTRL and RX\_INT2\_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

---

#### Note

If an event is registered for both interrupt vectors, both interrupts will fire. There are no hardware checks for overlapping interrupt vector assignments.

---

### 31.2.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user should clear the event flag using the EVT\_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt will be generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This may cause the application to miss events that may be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine will be similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX\_EVT\_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events that require action.
- Perform the necessary actions for each of the events seen in the snapshot.
- Write to the receive event and error clear register (RX\_EVT\_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag may still be set at the end of the ISR. As soon as the ISR completes, a new interrupt will be generated and this flag will still be set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR may cause race conditions which will cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both are handled within the same interrupt line, the software may only respond to one of the events if they both occur close in time.

### 31.2.4 DMA Interface

Both the transmitter and receiver are capable of using the DMA for automatic data transfers. The DMA trigger is independent from the interrupt signals. DMA events are only triggered on the completion of a data frame.

The transmitter DMA trigger is enabled by setting TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. The transmitter must also set TX\_OPER\_CTRL\_LO.START\_MODE to 0x2 to allow either a write to the TX\_FRAME\_CTRL.START bit or to the TX\_FRAME\_TAG\_UDATA register to start the transmission.

The receiver DMA trigger is enabled by setting RX\_DMA\_CTRL.DMA\_EVT\_EN to 1.

Refer to [Section 31.3.2](#) and [Section 31.3.3](#) for more DMA information specific to each FSI Module.

### 31.2.5 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and/or generic frames. These muxes are independently configured for each type of frame. The application may select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX\_PING\_CTRL.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_PING\_CTRL.EXT\_TRIG\_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX\_OPER\_CTRL\_HI.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x1 in order for a frame to be transmitted by an external trigger.

---

#### Note

Triggers generated by the CLB and EPWM XBAR are asynchronous and must be at least 3 SYSCLKs wide.

---

**Table 31-3. External Trigger Sources and Their Index**

| Index | External Trigger Source |
|-------|-------------------------|
| 0     | EPWM XBAR0-TRIP4        |

### 31.3 FSI Functional Description

#### 31.3.1 FSI Functional Description

The Fast Serial Interface Transmitter and Receiver modules (FSI\_TX/FSI\_RX) are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

### 31.3.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU and the DMA.

The transmitter has the following features:

- Automated ping frame generation
- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data
- DMA support

Figure 31-4 shows the high-level block diagram of the FSI transmitter. Figure 31-5 shows the block diagram of the transmitter core submodule.

The following sections describe the various aspects of the FSI transmitter in detail.

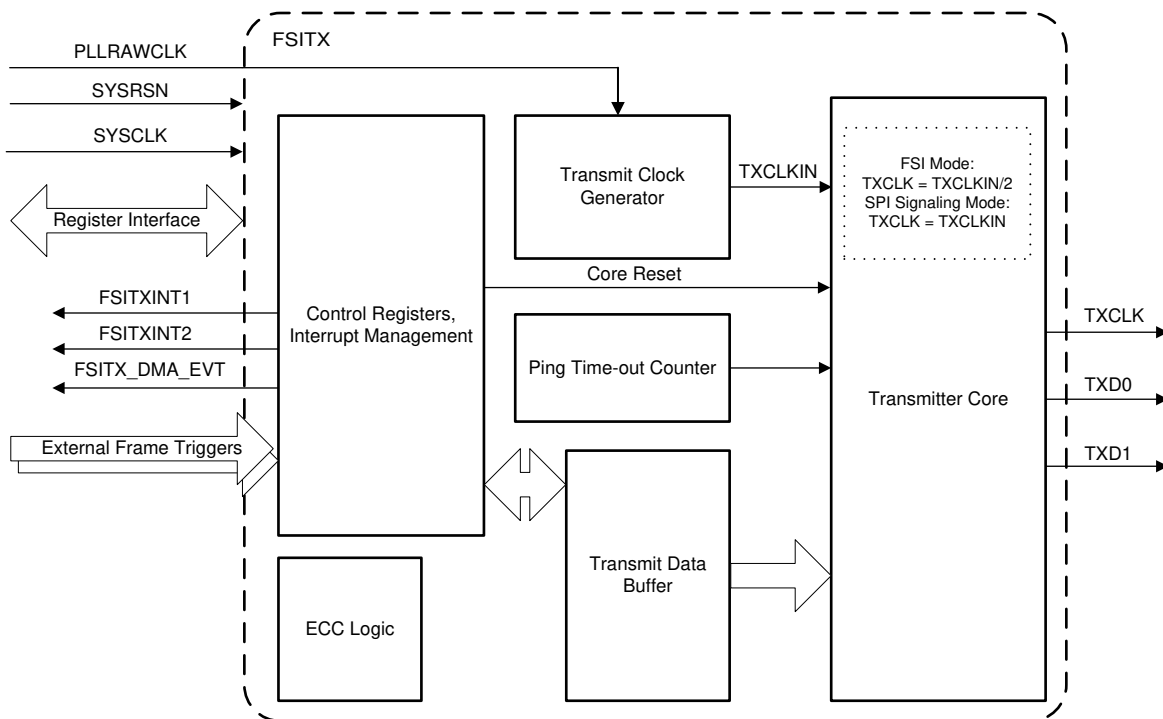

Figure 31-4. FSI Transmitter Block Diagram

**Figure 31-5. FSI Transmitter Core Block Diagram**

### 31.3.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module should execute the following initialization sequence in order to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX\_CLK\_CTRL.CLK\_RST to 1 and subsequently clearing it.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX\_OPER\_CTRL\_LO.SEL\_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX\_CLK\_CTRL.PRESCALE\_VAL.
4. Enable the transmitter clock divider by setting TX\_CLK\_CTRL.CLK\_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX\_MASTER\_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX\_MASTER\_CTRL.

After initialization and configuration, the transmitter module should synchronize with receiver module before transmitting. The synchronization sequence is described in [Section 31.4.1](#).

#### **CAUTION**

Do not change TX\_CLK\_CTRL.PRESCALE\_VAL while the clock is enabled (TX\_CLK\_CTRL.CLK\_EN = 1). Doing so may cause undefined behavior.

### 31.3.2.2 FSI\_TX Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX\_CLK\_CTRL.PRESCALE\_VAL) then setting the clock divider enable bit (TX\_CLK\_CTRL.CLK\_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0x0 or 0x1) through 255 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

#### CAUTION

TXCLK should never be configured to be faster than SYSCLK/2.

### 31.3.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps may be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
  - Set the user data
  - Write to the data buffer
  - Set the word length if the frame is a software defined frame length
4. Set the start condition

---

#### Note

Transmit Frame Start Restriction:

A new frame transmission can be initiated by one of the methods selected in the TX\_OPER\_CTRL\_LO.START\_MODE bits. If there is already a PING frame transmission taking place, due to a hardware initiated PING timer, the new frame transmission will begin as soon as the on-going PING transmission is completed.

Once a START of frame has been initiated, the next START of frame will be recognized when the first frame has started transmitting the End-of-Frame (EOF) field. If a new START trigger arrives before the current transmission has reached the EOF field, the trigger will be lost without a notification.

---

#### Note

There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior will be as follows:

- The transmitted frame structure will be exactly like an NWORD data frame. The size of the data frame will be determined by the value in the TX\_FRAME\_CTRL.N\_WORDS register.
- The frame type field of the transmitted data frame will be transmitted as programmed. If this is received by an FSI receiver, it will generate a Type error.

This mechanism can be used to force a Type error in a received frame for testing purposes.

---

The following sections describe the specific configuration for each frame type and start condition.

### 31.3.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps should be executed. Steps 1-6 may be executed in any order before setting TX\_FRAME\_CTRL.START. Some fields may not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and will be re-transmitted in the subsequent frame unless they are modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX\_FRAME\_CTRL.FRAME\_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX\_FRAME\_CTRL.N\_WORDS to 1 less than the number of words to be transmitted if TX\_FRAME\_CTRL.FRAME\_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words will be transmitted, N = 16, set TX\_FRAME\_CTRL.N\_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware will calculate the CRC to be transmitted. If TX\_OPER\_CTRL\_LO.SW\_CRC is 1, the application may calculate a custom CRC value and then set TX\_USER\_CRC to the result.
5. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired tag.
6. Set TX\_FRAME\_TAG\_UDATA.USER\_DATA to the desired user data.
7. Set TX\_FRAME\_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

### 31.3.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See [Section 31.2.5](#) for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in [Section 31.3.2.3.1](#). The only difference is that in Step 7, the start condition will be automatically set when the external trigger condition is met rather than by software.

It is important to note that by externally triggering frames, the frame information to be sent will be pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX will take the data as is, and the application software should ensure that this data has been updated as necessary.

Using TX\_EVT\_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

### 31.3.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

#### 31.3.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX\_PING\_CTRL.CNT\_RST.
2. Set the desired ping tag to TX\_PING\_TAG.TAG.
3. Set the ping timer reference value to TX\_PING\_TO\_REF.TO\_REF.
4. Enable the ping timer by writing 1 to TX\_PING\_CTRL.TIMER\_EN.

The ping timer is a free-running counter which will count up from 0. The current value of the ping timer counter is found in TX\_PING\_TO\_CNT. When the current value of TX\_PING\_TO\_CNT matches the reference value TX\_PING\_TO\_REF.TO\_REF, TX\_EVT\_STS.PING\_TRIGGERED will be set. TX\_PING\_TO\_CNT will reset to 0 and resume counting until the next match has occurred or the ping timer is halted by software (TX\_PING\_CTRL.TIMER\_EN is set to 0).

### 31.3.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX\_FRAME\_CTRL.FRAME\_TYPE to 0000'b to denote that the frame being sent will be a Ping Frame.
2. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired value.
3. Write 1 to TX\_FRAME\_CTRL.START. This will start the transmission.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

### 31.3.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers may be selected. See [Section 31.2.5](#) for the list of input sources.

#### CAUTION

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX\_PING\_CTRL.EXT\_TRIG\_EN is set to 1, it will take precedence and the ping timer will be ignored.

### 31.3.2.3.4 Transmitting Frames with DMA

The FSI transmitter can send data which is continuously fed with the DMA. A DMA trigger will be generated every time a data frame transmission is completed. This is concurrent with the FRAME\_DONE signal that sets the TX\_EVT\_STS.FRAME\_DONE flag.

In order to transmit continuous data with the DMA, some configurations need to be made on the transmitter:

First, set TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This will allow the DMA trigger to propagate to the DMA module. Next, TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX\_FRAME\_CTRL.START or TX\_FRAME\_TAG\_UDATA..

The DMA must also be configured properly for the FSI to send the data. One possible solution of using the DMA to continuously feed the transmit buffer is shown below:

- Set up two DMA channels to be triggered by the same FSI transmitter and DMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps the after 16 words are copied.

#### Note

Because the frame tag and user data must be written in to in order to initiate the transmission of the frame, use two consecutive DMA channels. This ensures that the DMA channels are always executed in sequence. The DMA channel servicing the data buffer should be the lower numbered channel and the tag/user data channel should be the next. For example, configure DMA channel 3 to service the data buffer, and configure DMA channel 4 to service the tag and user data.

### 31.3.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer from which it pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. This mode of operation is the only way in which the overrun, underrun, and pointer status are meaningful. If data is being sourced by the DMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, it means that the buffer went out of sync. This would not only affect the current transfer, but all future transfers also could not be guaranteed due to the ring buffer. Under such conditions, the underrun would need a soft reset to cleanly recover. Alternately, the software could manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and will guarantee a full reset of the control registers.

Due to the flexibility of the transmit buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields may be ignored without adversely affecting the transmitter capability. Additionally, the CURR\_WORD\_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX\_BUF\_PTR\_LOAD. This will force the transmitter to start picking the data from the indicated location in the buffer.

### 31.3.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX\_OPER\_CTRL\_LO.SW\_CRC appropriately.

If hardware CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial  $0x7 (x^8 + x^2 + x + 1)$ . The transmitter module will automatically compute the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC Submodule, refer to [Section 31.3.7](#).

If software CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 1), the CRC must be computed by software and placed in the TX\_USER\_CRC register. The next frame to be transmitted will use the value placed in the TX\_USER\_CRC register in place of the CRC value generated by the hardware.

As the TX\_USER\_CRC register is software-programmable, the application may use this field as an extra data field for application specific purposes. If TX\_USER\_CRC is used in this manner, the CRC detection on the receiver will not be valid and should be ignored.

### 31.3.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt may or may not require a soft reset in order to resume proper operation. This determination is up to the application software. Refer to [Section 31.3.2.4](#) for more information on the transmit buffer.

### 31.3.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX\_MASTER\_CTRL.CORE\_RST.

A module reset will cause the registers to be reset to their default state.

### 31.3.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after they pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU and the DMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- DMA support
- FSI-SPI compatibility mode

Figure 31-6 provides a high-level overview of the internal modules present in the FSI receiver. Figure 31-7 shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

The following sections describe the various aspects of the FSI receiver module.

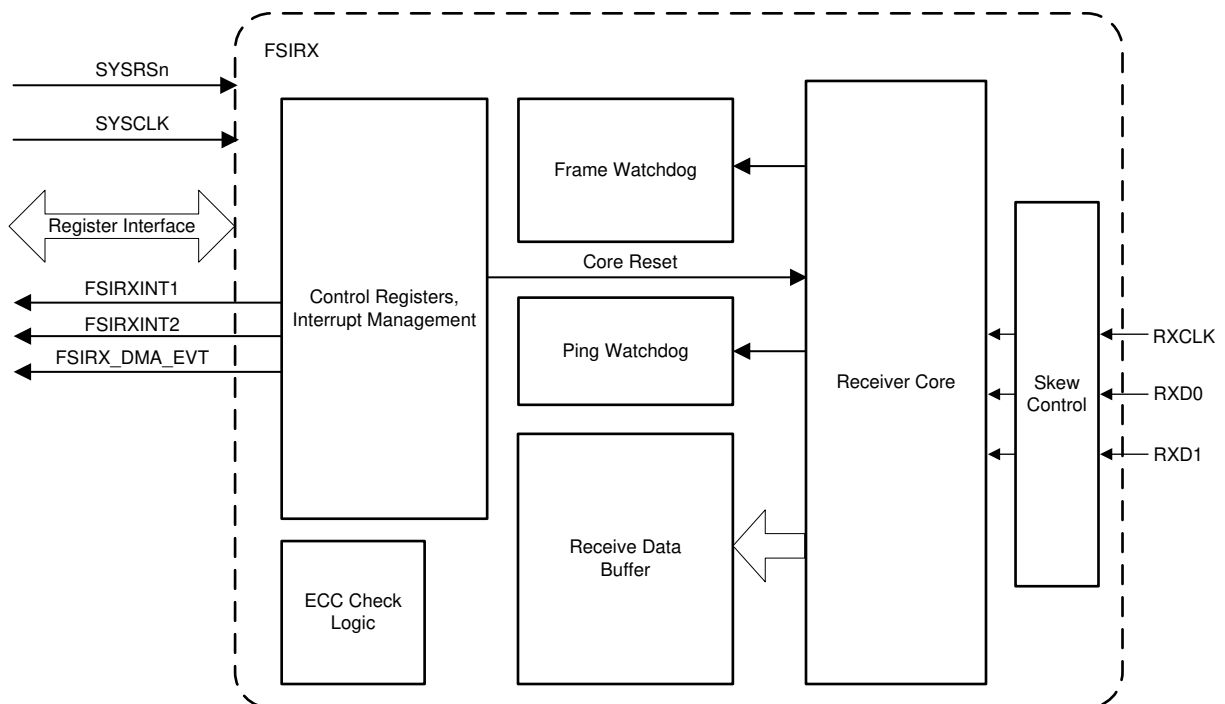

Figure 31-6. FSI Receiver Block Diagram

**Figure 31-7. FSI Receiver Core Block Diagram**

### 31.3.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module should assert and release the receiver core reset bit (RX\_MASTER\_CTRL.CORE\_RST) prior to any other initialization. Once the receiver module is initialized, the following steps may be executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See [Section 31.3.3.4](#) for configuration details.
3. If required, configure the frame watchdog to ensure that each frame is received within a predetermined window. See [Section 31.3.3.5](#) for configuration details.
4. Initialize the receive buffer pointer by writing to the RX\_BUF\_PTR\_LOAD register. Received data will be placed into the buffer starting with the address loaded in this register.
5. Ensure all errors and flags have been cleared from the RX\_EVT\_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX\_EVT\_STS register for various conditions. For example, when the RX\_EVT\_STS.FRAME\_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application should configure the various features such as the ping and frame watchdogs, DMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in [Section 31.4.1](#).

### 31.3.3.2 FSI\_RX Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

#### CAUTION

RXCLK should never be faster than SYSCLK.

### 31.3.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. It is important to note that there is no equivalent to a chip select signal to gate incoming data. Every valid clock edge will latch data into the receiver.

The header information of the received frame will be placed in their respective register fields.

- RX\_FRAME\_INFO.FRAME\_TYPE will contain the received frame type.
- RX\_FRAME\_TAG\_UDATA.FRAME\_TAG will contain the received frame tag.
- RX\_FRAME\_TAG\_UDATA.USER\_DATA will contain the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag will be set in the RX\_EVT\_STS register.

#### Note

If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The following errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

#### 31.3.3.3.1 Receiving Frames with DMA

The FSI receiver can continuously receive data and move it from the receiver buffer with the DMA. A DMA trigger will be generated every time a data frame has been received. This is concurrent with the FRAME\_DONE signal that sets the RX\_EVT\_STS.FRAME\_DONE flag. In order to receive continuous data with the DMA, some configurations need to be made on the receiver.

First, set RX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This will allow the DMA trigger to propagate to the DMA module. The receiver is now able to trigger a DMA event upon the reception of a data frame.

The DMA must also be configured properly for the FSI to receive the data. One possible solution for using the receiver to continuously feed the DMA is show below:

- Set up two DMA channels to be triggered by the FSI Receiver DMA Trigger.
- Configure one DMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next DMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the DMA channel which is handling the data buffer, execute before the DMA channel handling the received tag and user data.

#### 31.3.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event will be triggered which can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter which is reset and restarted upon the successful reception of a ping frame. The watchdog counter will be incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting `RX_PING_WD_CTRL.PING_WD_RST` to 1 and then subsequently clearing it to 0.
2. Set `RX_OPER_CTRL.PING_WD_RST_MODE` to the desired watchdog reset event, either 0 for ping frames only, or 1 for any frame.
3. Set `RX_PING_WD_REF` to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting `RX_PING_WD_CTRL.PING_EN` to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the `RX_PING_WD_CNT` value reaches the value programmed in `RX_PING_WD_REF`, the `RX_EVT_STS.PING_WD_TO` flag will be set. If configured, an interrupt can be generated on this event.

#### 31.3.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration that it takes for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog will be triggered which can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting `RX_FRAME_WD_CTRL.FRAME_WD_CNT_RST` to 1 and then subsequently clearing it to 0.
2. Set `RX_FRAME_WD_REF.FRAME_WD_REF` to the maximum number of SYSCLK cycles expected to be in the longest frame that may be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting `RX_FRAME_WD_CTRL.FRAME_WD_CNT_EN` to 1.

The frame watchdog is now enabled and can detect a failed frame.

If the `RX_FRAME_WD_CNT` reaches the value programmed in `RX_FRAME_WD_REF`, the `RX_EVT_STS.FRAME_WD_TO` flag will be set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

### 31.3.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX\_DLY\_LINE\_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values should only be adjusted while the FSIRX is held in soft reset, ensuring that there are no active transmissions during this process. Figure 31-8 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits will behave similarly.

Figure 31-8. Delay Line Control Circuit

For more information on skew compensation, refer to the [Fast Serial Interface \(FSI\) Skew Compensation Application Report](#).

The FSITX module also has delay line control circuitry that is placed before the FSITX signals (TXCLK, TXD0, and TXD1) are sent to the TDM signal selection mux (controlled by the SEL\_TDM\_PATH signal). The TX\_DLY\_LINE\_CTRL register determines the length of the delay for each output line.

### 31.3.3.7 Buffer Management

The FSI receiver has a 16-word buffer into which the data is copied to when it has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no guaranteed receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer guarantee which values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields may be ignored without adversely affecting the receiver capability. Additionally, the CURR\_WORD\_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX\_BUF\_PTR\_LOAD. This will force the receiver to start storing the received data starting at the indicated location in the buffer.

### 31.3.3.8 CRC Submodule

The receive module will automatically calculate the CRC on the incoming data. The received CRC value is placed into `RX_CRC_INFO.RX_CRC`. The CRC value calculated by hardware on the received data is placed into `RX_CRC_INFO.CALC_CRC`. These values are compared by hardware and will set `RX_EVT_STS.CRC_ERROR` if there is a mismatch. The receiver can generate an interrupt based on `RX_EVT_STS.CRC_ERROR` if enabled.

Since the CRC is only used in data frames, the values found in `RX_CRC_INFO.RX_CRC` and `RX_CRC_INFO.CALC_CRC` are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to [Section 31.3.7](#).

If the transmitting module is sending a software-defined CRC value (`FSITX.TX_OPER_CTRL_LO.SW_CRC = 1`) the receiver module will trigger a CRC Error event if the received value does not match the hardware-calculated value. As this is an application level decision, the FSIRX can safely disregard the CRC error event. Application software will need to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field may have also been used as an application-specific value, not a CRC, the application can use the `RX_CRC_INFO.RX_CRC` as required. All CRC errors and flags can be ignored in this situation.

### 31.3.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (`RX_FRAME_TAG_UDATA`) register and receiver ping tag (`RX_PING_TAG`) register) have the Least Significant Bit is set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions which can be called depending on the tag value. A function pointer needs a 32-bit storage space and hence each successive pointer will be offset by 2. If the first pointer is at address  $x$ , then the second pointer will be at address  $x+2$ , the third at address  $x+4$  and so on. By keeping the LSB 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

### 31.3.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver will receive data on every clock edge. While there are specific patterns which determine the a start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset in order to ensure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver may be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (`RX_VIS_1.RX_CORE_STS`) can be monitored to determine if it has entered into an error state requiring a soft reset in order to resume communication. Incorrect frame type and end of frame errors will always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout will always require a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. `RX_CORE_STS` can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also will not cause `RX_CORE_STS` to be set. Similar to the frame watchdog, a corrupt receiver may not be the reason for the ping frame to have timed out. The transmitter may have gone offline and never sent a ping frame. Alternately, during idle time, a noise event may have occurred, thereby putting the receiver into a corrupt state. As the receiver will be able to detect this during the ping frame watchdog timeout interrupt handler, this type of event will not be lost and the application can act appropriately.

As the receiver is clocked by `RXCLK`, not `SYSCLK`, a noisy clock or data line may cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Ensure that the clock and data

lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the data manual for this device. Failure to do so may cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application should check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun may warrant a soft reset in order to resynchronize with the local application software. Refer to [Section 31.3.3.8](#) for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device should stop transmitting and begin a new synchronization phase.

### 31.3.3.11 FSI\_RX Reset

The receiver module and its registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX\_MASTER\_CTRL.CORE\_RST.

A module reset will cause the registers to be reset to their default state. After a module reset, the receiver module must be re-initialized, and the data link re-established.

### 31.3.4 Frame Format

The FSI module transmits and receives information in frames. Each frame will contain multiple phases where different information can be found. The number of phases as well as the total length of the frame will vary depending on the frame type being transmitted. Frames may be as short as 16 bits long for a ping or error frame or 288 bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown below. Each phase of the frame (such as start-of-frame, frame type, and so on) will be transmitted with the most significant bit first. [Table 31-4](#) describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

**Table 31-4. Basic Frame Structure**

| Idle State | Preamble | Start of Frame | Frame Type | User Data | Data Words | CRC Byte | Frame Tag | End of Frame | Postamble | Idle State |
|------------|----------|----------------|------------|-----------|------------|----------|-----------|--------------|-----------|------------|
|            | 1111     | 1001           | 4 bits     | 8 bits    | 1-16 words | 8 bits   | 4 bits    | 0110         | 1111      |            |

The FSI also supports a FSI-SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to [Section 31.3.13](#) for more information on how to configure and use the FSI-SPI compatibility mode.

---

#### Note

One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI.

---

### 31.3.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail.

- **Idle State:** During the idle state, the clock and data lines will be driven high, the inactive state.
- **Preamble:** The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare it for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame:** The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type:** The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in [Section 31.3.4.2](#). The transmitter must set the TX\_FRAME\_CTRL.FRAME\_TYPE field before transmitting a frame. The received frame type is stored in the RX\_FRAME\_INFO.FRAME\_TYPE.
- **User Data:** The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX\_FRAME\_TAG\_UDATA.USER\_DATA. The received user data is stored in RX\_FRAME\_TAG\_UDATA.USER\_DATA.
- **Data:** The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and will be placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames is found in [Section 31.3.4.2.3](#).
- **CRC Byte:** The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX\_OPER\_CTRL\_LO.SW\_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag:** The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX\_FRAME\_TAG\_UDATA.FRAME\_TAG bits for data frames. Ping frames use the tag defined in TX\_PING\_TAG.TAG. The receiver can access the received frame tag in RX\_FRAME\_TAG\_UDATA.FRAME\_TAG.
- **End of Frame:** The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble:** The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines will be driven high, their inactive state. This phase is not present in FSI-SPI compatibility mode.

### 31.3.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

[Table 31-5](#) provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

**Table 31-5. Frame Types and Their 4-bit Codes**

| Frame Type  | 4-bit Frame Code          | Description   |
|-------------|---------------------------|---|
| PING        | 0000                      | This is the ping frame that can be sent either by software or automatically by hardware.  |
| ERROR       | 1111                      | This should be used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software is at liberty to use this for any purpose. |
| DATA_1_WORD | 0100                      | 1 word data packet (16 bits of data)  |
| DATA_2_WORD | 0101                      | 2 word data packet (32 bits of data)  |
| DATA_4_WORD | 0110                      | 4 word data packet (64 bits of data)  |
| DATA_6_WORD | 0111                      | 6 word data packet (96 bits of data)  |
| DATA_N_WORD | 0011                      | N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules should have the same value programmed.                |
| Reserved    | 0001, 0010, and 1000-1110 | Reserved  |

#### 31.3.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. [Table 31-6](#) shows the structure of the ping frames.

**Table 31-6. Ping Frame**

| Idle State | Preamble | SOF  | Frame Type | Frame Tag | EOF  | Postamble | Idle State |
|------------|----------|------|------------|-----------|------|-----------|------------|
|            | 1111     | 1001 | 0000       | xxxx      | 0110 | 1111      |            |

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to ensure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See [Section 31.3.2.3.3](#) for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between it and the transmitter has been broken. See [Section 31.3.3.4](#) for information on how the receiver handles ping frames.

### 31.3.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. [Table 31-7](#) shows the structure of an error frame.

**Table 31-7. Error Frame**

| Idle State | Preamble | SOF  | Frame Type | Frame Tag | EOF  | Postamble | Idle State |
|------------|----------|------|------------|-----------|------|-----------|------------|
|            | 1111     | 1001 | 1111       | xxxx      | 0110 | 1111      |            |

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX\_FRAME\_TAG\_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX\_FRAME\_TAG\_UDATA register and act on up to 16 different conditions.

### 31.3.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. [Table 31-8](#) shows the general structure of data frames.

**Table 31-8. Data Frame**

| Idle State | Preamble | SOF  | Frame Type | User Data | Data Words | CRC Byte  | Frame Tag | EOF  | Postamble | Idle State |
|------------|----------|------|------------|-----------|------------|-----------|-----------|------|-----------|------------|
|            | 1111     | 1001 | 0xxx       | xxxx xxxx | 1-16 words | xxxx xxxx | xxxx      | 0110 | 1111      |            |

The frame type field will reflect the 4-bit code of the frame type. A list of frame types can be seen in [Table 31-5](#). The number of the data words transmitted will be determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N\_WORDS field of the transmitter’s TX\_FRAME\_CTRL register and receiver’s RX\_OPER\_CTRL register.

### 31.3.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits will be split between the data lines while the start of frame, frame type, frame tag, and end of frame fields will be identical and complete on each line. The user data, data, and CRC fields will be split between the data lines. Starting with the most significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the following example, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12...d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

**Table 31-9. Multi-Lane Frame Format**

| Idle State | Preamble | SOF  | Frame Type | User Data   | Data Words  | CRC Byte  | Frame Tag | EOF  | Postamble | Idle State |
|------------|----------|------|------------|---|---|---|-----------|------|-----------|------------|
| TXD0       | 1111     | 1001 | 0011       | u <sup>7</sup> u <sup>5</sup> u <sup>3</sup> u <sup>1</sup> | d <sup>15</sup> d <sup>13</sup> ...d <sup>1</sup> | c <sup>7</sup> c <sup>5</sup> c <sup>3</sup> c <sup>1</sup> | xxxx      | 0110 | 1111      |            |
| TXD1       | 1111     | 1001 | 0011       | u <sup>6</sup> u <sup>4</sup> u <sup>2</sup> u <sup>0</sup> | d <sup>14</sup> d <sup>12</sup> ...d <sup>0</sup> | c <sup>6</sup> c <sup>4</sup> c <sup>2</sup> c <sup>0</sup> | xxxx      | 0110 | 1111      |            |

### 31.3.5 Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before it can receive and decode frames. The receiver core has an asynchronous reset mechanism which will allow the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset will be released synchronous to the receive clock (RXCLK). Thus, the receiver will require five full clock pulses to be able to come out of reset. Sending the flush pattern will ensure that these clock edges are received and any subsequent frames sent to the receiver will be correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI will have the same effect as a flush sequence.

Figure 31-9 shows a sample plot of the flush sequence.

**Figure 31-9. Flush Sequence Signals**

### 31.3.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting `RX_MASTER_CTRL.INT_LOOPBACK` to 1. Internal loopback routes the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter.

Figure 31-10 shows the signal connections with internal loopback.

**Figure 31-10. FSI with Internal Loopback**

### 31.3.7 CRC Generation

The FSI uses CRC-8 with the polynomial `0x07` for the internal hardware CRC generation. This polynomial is also represented as  $x^8+x^2+x+1$ .

For example, for a 2-word data packet the following calculation would occur:

Data-1 = `0x4433`

Data-0 = `0x2211`

User Data = `0xAA`

The CRC would be computed with the bytes being taken in the following order (first to last):

`0xAA` – Byte 0, User Data

`0x11` – Byte 1, Data-0, Least-significant byte

`0x22` – Byte 2, Data-0, Most-significant byte

`0x33` – Byte 3, Data-1, Least-significant byte

`0x44` – Byte 4, Data-1, Most-significant byte

### 31.3.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX\_OPER\_CTRL\_HI.ECC\_SEL to 1.
2. Write the data to the TX\_ECC\_DATA register as well as the transmit buffer.
3. Read TX\_ECC\_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX\_ECC\_VAL to TX\_FRAME\_TAG\_UDATA.USER\_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX\_ECC\_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX\_FRAME\_TAG\_UDATA.USER\_DATA to the RX\_ECC\_VAL register.
3. Read the RX\_ECC\_LOG register. This contains the result of the ECC computation using the RX\_ECC\_DATA and RX\_ECC\_VAL registers.
  - a. If no ECC errors were detected, RX\_ECC\_LOG will be 0. The correct data will be available in RX\_ECC\_SEC\_DATA.
  - b. If a single bit error was detected, RX\_ECC\_LOG.SBE will be 1. The autocorrected data will be available in RX\_ECC\_SEC\_DATA.
  - c. If multiple bit errors occurred, RX\_ECC\_LOG.MBE will be set to 1. The data in RX\_ECC\_SEC\_DATA is invalid and should not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame and allocate one of the data words to be the ECC value.

### 31.3.9 Tag Matching

The FSI receiver core has the capability of generating an interrupt when the received data or ping frame's tag matches the reference tag in RX\_FRAME\_TAG\_CMP or RX\_PING\_TAG\_CMP, respectively.

Each tag compare register allows the user to not only select a reference tag (TAG\_REF) but also set up a mask (TAG\_MASK) to ignore specified bits in the reference tag. In order for tag matching to be enabled, the CMP\_EN bit must be set. When the tag compare is enabled and a successful match occurs, the PING\_TAG\_MATCH, the DATA\_TAG\_MATCH or the ERROR\_TAG\_MATCH in RX\_EVT\_ERR\_STATUS will be set. The corresponding match register status can be cleared by writing to RX\_EVT\_ERR\_CLEAR. Also, if it is required to set the match register status in software, the user must do so by writing to the RX\_EVT\_ERR\_SET register.

The tag matching scheme is NOT a filtering scheme. Tag matching is only a notification scheme to alert the user when a specific tag is detected in a data or ping frame. Both RX\_INTR\_EVT\_CTRL\_1 and RX\_INTR\_EVT\_CTRL\_2 interrupts can be set up to generate an interrupt when a tag match event occurs.

Another feature used when tag matching is enabled, is the broadcast feature. The broadcast feature can be enabled by setting the BRDCST\_EN in RX\_FRAME\_TAG\_CMP or RX\_PING\_TAG\_CMP. When broadcast mode is enabled, the third bit of the tag will be treated as a broadcast bit. If the received tag has its third bit set, then it will be treated as a match regardless of the other tag bit comparisons. It is important to note that, a match caused by TAG\_REF and TAG\_MASK will also be considered a match.

It is important to reiterate that the tag matching scheme is not a filtering scheme. For example, if tag matching is enabled and a frame is received with a non matching tag, the frame is still saved in the buffer and the corresponding event status bits (FRAME\_DONE, DATA\_FRAME\_RCVD etc.) will be set.

Tag matching should be used in TDM configuration described in [Section 31.3.11](#). However it can be used in single slave configurations as needed.

### 31.3.10 User Data Filtering (UDATA Matching)

The FSI receiver core has the capability of filtering data frames and only receive packets when received data's UDATA (user data) matches the reference UDATA in RX\_UDATA\_FILTER.

UDATA filter compare register allows the user to not only select a reference UDATA (UDATA\_REF) but also set up a mask (UDATA\_MASK) to ignore specified bits in the reference user data. In order for user data filtering to be enabled, the RX\_MASTER\_CTRL.DATA\_FILTER\_EN bit must be set. When the user data filtering is enabled, only a successful match would allow the packet to be received in the FSIRX circular buffer, all non-matching packets are ignored.

The user data matching scheme **is a filtering scheme**.

User data filtering should be used in multi-slave configuration as described in [Section 31.3.11](#); however, it can be used in single-slave configurations as needed.

### 31.3.11 TDM Configurations

The FSI module in this device supports multi-slave configurations, whereas a single master can control multiple slave devices.

In order to use the FSI module in the multi-slave configuration described, the slave device must utilize tag matching and user data filtering.

This multi-slave configuration is supported in the FSI module through time-division multiplexing. When TDM is enabled, each slave must also have tag matching enabled. [Figure 31-11](#) shows a scheme where a single master is communicating with multiple slaves. All FSI receive modules in the slave devices are directly connected to the master device's transmit module. The transmit modules of the slave devices are chained serially such that each transmit module is connected to the next slave device and the last slave device's output connects to the master device's receive module. Each slave device will decide, based on the received frame's tag, whether to transmit their own data, or to enter bypass mode where they directly connect the previous slave device's transmit module to the next slave device. This is done by using the FSI transmit module's TDM\_IN.

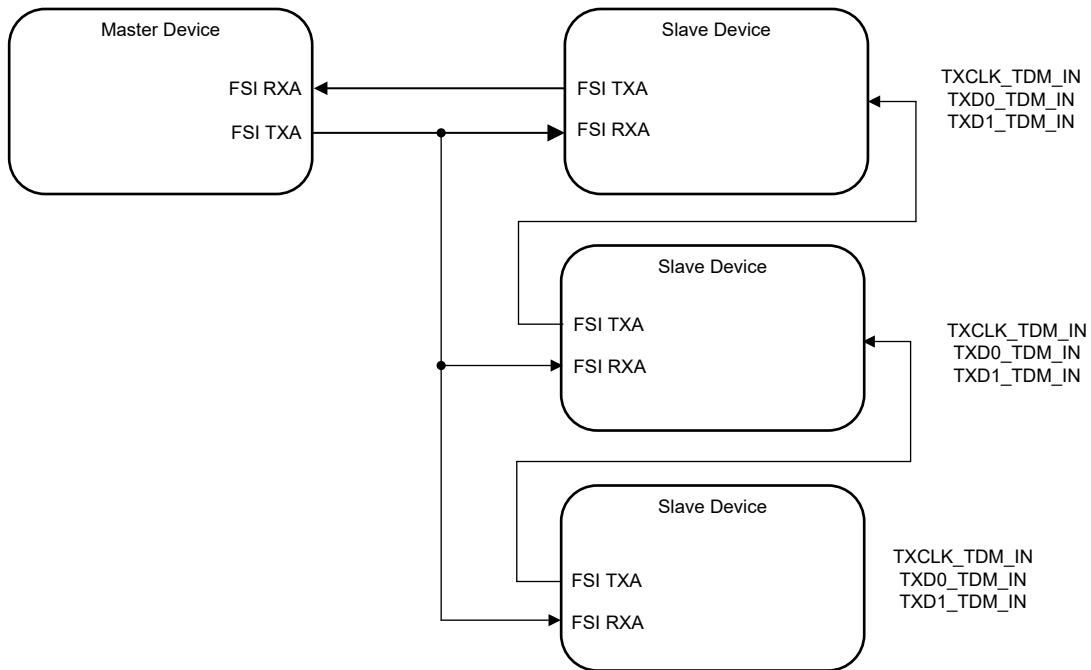

Figure 31-11. FSI Multi-Slave Configuration

When an FSI transmitter module is used in TDM mode, TXCLK\_TDM\_IN, TXD0\_TDM\_IN and TXD1\_TDM\_IN pins are used if the transmitter is required to enter bypass mode. Figure 31-12 shows how the FSI module operates when in multi-slave TDM mode.

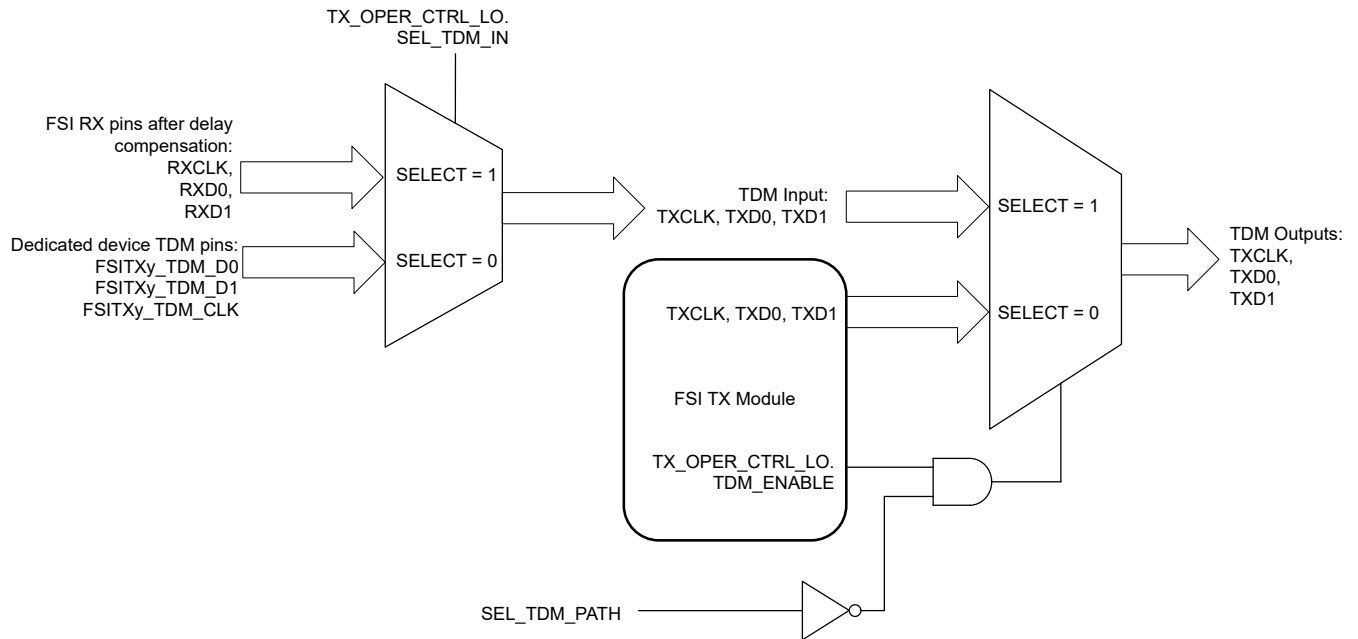

Figure 31-12. FSI Transmitter Multi-Slave Multiplexing

The SEL\_TDM\_PATH signal is sourced from the RX\_TRIG0 signal (after being stretched by the programmable width module). The RX\_TRIGx signal will also generate the transmit trigger for the FSI transmitter. The RX\_TRIGx signal must be configured to decide when to generate the FSI transmit trigger based on the status of the data, ping, and frame tag match generated by the FSI receiver module. The FSITX module must be configured to transmit on an external trigger and the corresponding RX\_TRIGx trigger input must be selected. In a broadcast scenario (FSI tag match will notify all slave devices that a match has occurred), the RX\_TRIG0 signal inside each slave will generate a trigger and SEL\_TDM\_PATH signal. The main key here is that the trigger and the SEL\_TDM\_PATH signal must be generated at a different time interval in a non-overlapping manner. Figure 31-13 shows an example of FSI transmit triggers and the multi-slave SEL\_TDM\_PATH signals generated by the RX\_TRIGx signal or the CLB module of the slave devices in a broadcast scenario.

Figure 31-13. Generated Signals for FSI Multi-Slave Configuration

When using TDM mode, the user has the option of using the device dedicated TDM\_IN pins or FSIRX pins. When the FSITX module is put in bypass mode, the TX\_OPER\_CTRL.SEL\_TDM\_IN bit determines which set of signals, FSIRX input signals or TDM\_IN signals, is internally connected to the FSITX output signals.

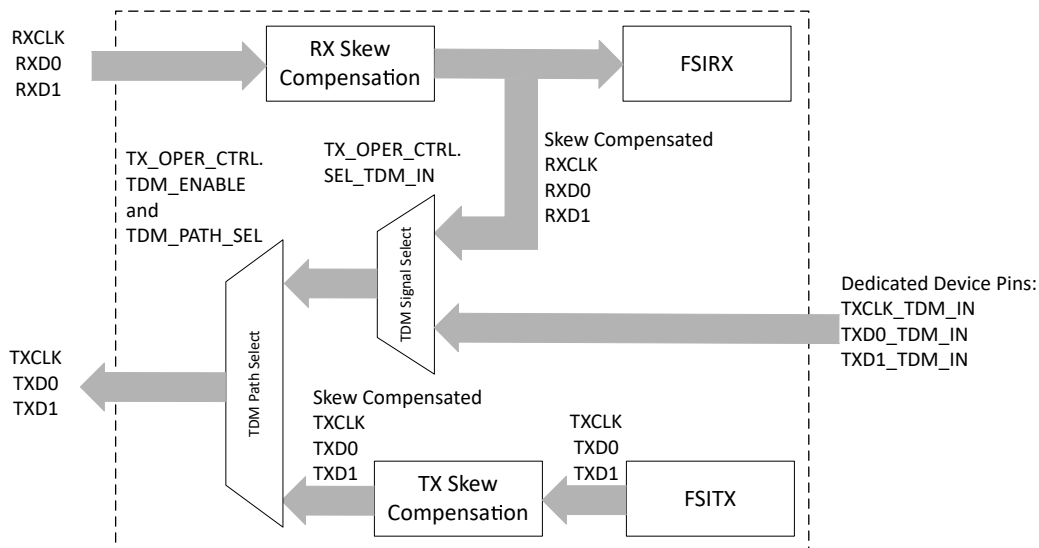

Figure 31-14. TDM Signal Selection

### 31.3.12 FSI Trigger Generation

The RX\_TRIGx external trigger can be used to initiate FSITX transmission. RX\_TRIG0 must be used if TDM mode (multi-slave configuration) is required. RX\_TRIG0 must be used as the trigger source for start of transmission while the programmable stretch width RX\_TRIG0 signal is used as the SEL\_TDM\_PATH signal (which decides whether the local FSITX is active or put in bypass mode).

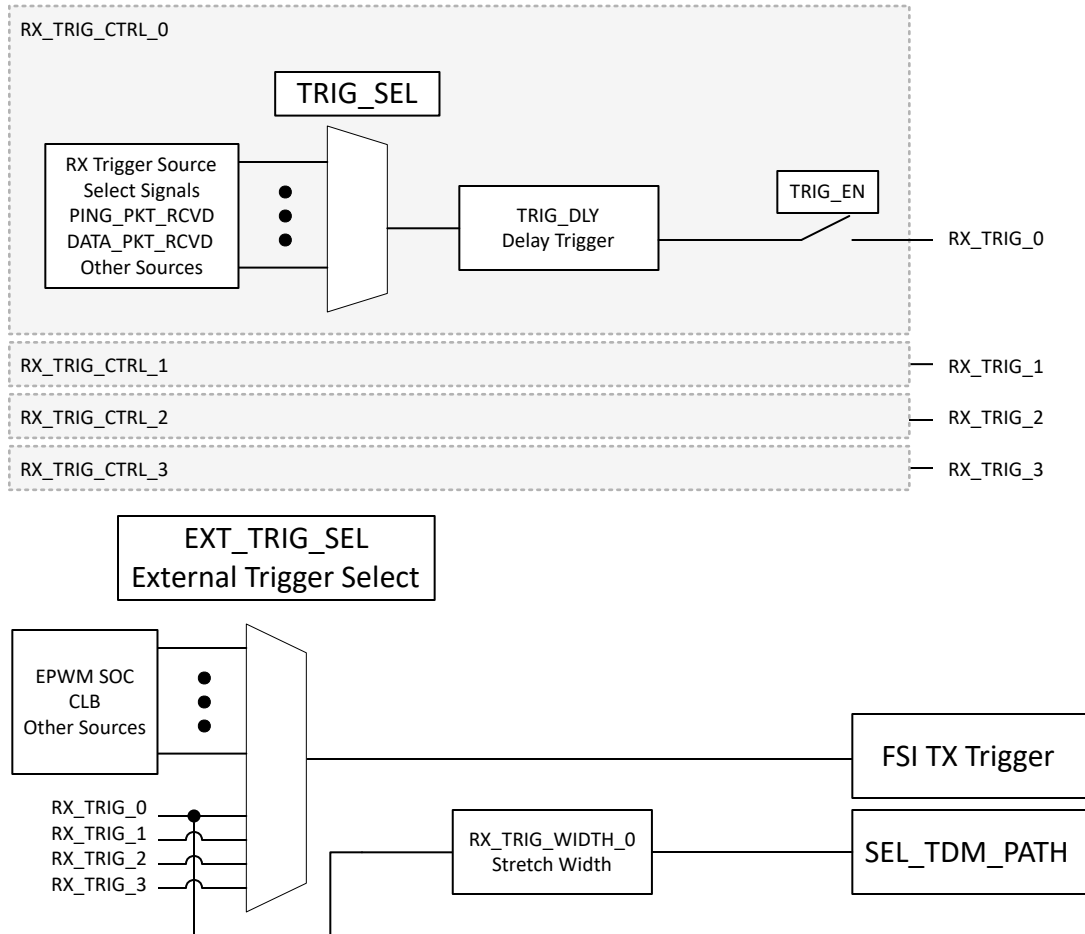

Figure 31-15. RX\_TRIGx FSI Trigger

The signal source for the RX\_TRIGx signal is selected through the RX\_TRIG\_CTRL\_x.TRIG\_SEL bits, as listed in Table 31-10.

Table 31-10. RX\_TRIGx Trigger Select Signals

| RX_TRIG_CTRLx.TRIG_SEL | Selected Signal               |
|------------------------|-------------------------------|
| 0                      | Ping Packet Received          |
| 1                      | Data Packet Received          |
| 2                      | Error Packet Received         |
| 3                      | Ping Frame Tag Match Occured  |
| 4                      | Data Frame Tag Match Occured  |
| 5                      | Error Frame Tag Match Occured |
| 6                      | Frame Done                    |
| 7                      | Reserved                      |
| 8 to 15                | Reserved                      |

The RX\_TRIGx signals can optionally be delayed (this can be used in TDM scenarios) through the RX\_TRIG\_CTRL\_x.TRIG\_DLY.

### 31.3.13 FSI-SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode follow:

- Data will transmit on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 will be driven like an active-low, chip-select signal. The signal will be low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks will be transmitted. All signals return to the IDLE state after the frame phase is finished.
- It is not possible to transmit in the SPI slave configuration because the FSI TXCLK cannot take an external clock source.

Table 31-11 lists the frame structure of the FSI-SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI slave, the standard SPI must encode the transmission to be sent.

**Table 31-11. FSI-SPI Compatibility Frame Structure**

| Idle State | Start of Frame | Frame Type | User Data | Data Words | CRC byte <sup>(1)</sup> | Frame Tag | End of Frame | Idle State |
|------------|----------------|------------|-----------|------------|-------------------------|-----------|--------------|------------|
|            | 1001           | 4 bits     | 8 bits    | 1-16 words | 8 bits                  | 4 bits    | 0110         |            |

(1) The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data would be arranged in the following manner. The example provided in Table 31-12 assumes a DATA\_2\_WORD frame has been sent.

**Table 31-12. Contents of Data Received by a Standard SPI**

| SPI Data   | Data Contents                    |
|------------|----------------------------------|
| SPI word 0 | 1001, 0100, 8-bit User Data      |
| SPI word 1 | Data word 1                      |
| SPI word 2 | Data word 2                      |
| SPI word 3 | 8-bit CRC, 4-bit Frame Tag, 0110 |

### 31.3.13.1 Available SPI Modes

There are a few wiring schemes available for the FSI to use when communicating with an SPI module.

#### 31.3.13.1.1 FSITX as SPI Master, Transmit Only

The FSITX can operate as an independent SPI Master module. In this condition, TXCLK will be connected to SPICLK, TXD0 will be connected to SPISIMO, and TXD1 will be connected to  $\overline{\text{SPISTE}}$ , the chip select.

**Figure 31-16. FSITX as SPI Master, Transmit Only**

When the FSI is a SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver will require some software to act upon this information.

**Table 31-13. FSI as Master Transmitter, SPI as Slave Receiver**

| Capability  | Availability | Comment  |
|---|--------------|--|
| Framing checks on the data frames                     | Yes          | Can be implemented in software on the SPI receiver.  |
| Ability to detect line breaks                         | Yes          | Can be implemented in software on the SPI receiver but will require additional software overhead such as a timer, or watchdog. |
| CRC check   | Yes          | Can be implemented in software on the SPI receiver. For devices that have VCRC , this will be more efficient.                  |
| ECC on data   | Yes          | Can be implemented in software in the SPI receiver   |
| Detection of abruptly terminated frames               | No           |  |
| Double edge data rate                                 | No           |  |
| Recovery from glitches on signal lines between frames | No           |  |
| Skew adjustment on signal lines                       | No           |  |

#### 31.3.13.1.1.1 Initialization

To configure the FSITX module to be a SPI master for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX\_OPER\_CTRL\_LO.SPI\_MODE to 1. This will enable the SPI clocking scheme and signaling structure.

#### 31.3.13.1.1.2 Operation

The operation of the FSITX module in FSI-SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to [Section 31.3.2](#) for more information on each of these features.

### 31.3.13.1.2 FSIRX as SPI Slave, Receive Only

The FSIRX can operate as an independent SPI slave module. In the usage, RXCLK will be connected to SPICLK, and RXD0 will be connected to SPISIMO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence will be required to resynchronize the FSIRX module with the Master.

**Figure 31-17. FSIRX as SPI Slave, Receive Only**

When the FSI is a SPI receiver communicating with a SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

**Table 31-14. SPI as Master Transmitter, FSI as Slave Receiver**

| Capability  | Availability | Comment   |
|---|--------------|---|
| Framing checks on the data frames                     | Yes          | Standard on FSI   |
| Ability to detect line breaks                         | Yes          | Can be implemented in software in the SPI transmitter. But will have to use some timer or watchdog in the transmitting SPI device   |
| CRC check   | Yes          | Can be implemented in software in the SPI transmitter.  |
| ECC on data   | Yes          | Can be implemented in software in the SPI transmitter.  |
| Detection of abruptly terminated frames               | Yes          | This is accomplished with the FSI setting up the frame watchdog counter.  |
| Double edge data rate                                 | No           |   |
| Recovery from glitches on signal lines between frames | Yes          | Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame will discard the effects of these glitches and will cause the receiver to resynchronize when the real "start-of-frame" pattern is seen. So, the ability to reject glitches in between frames is hence very high. |
| Skew adjustment on signal lines                       | Yes          | The FSI receiver has the ability to add delays to the incoming signal lines.  |

#### 31.3.13.1.2.1 Initialization

To configure the FSIRX module to be a SPI slave for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set `RX_OPER_CTRL.SPI_MODE` to 1. This will enable the SPI clocking scheme and signaling structure.

#### 31.3.13.1.2.2 Operation

The operation of the FSIRX module in FSI-SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to [Section 31.3.3](#) for more information on each of these features.

### 31.3.13.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Master

In this configuration, the FSITX is the clock master. The FSITX module will drive TXCLK (SPICLK), TXD0 (SPISIMO), and TXD1 (SPISTE/chip select), to the SPI slave. The SPISOMI signal will be connected back to the RXD0 signal. RXCLK can be fed either internally using the internal SPI pairing feature or wired externally, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX could also be thought of as an additional SPI slave. Some software logic will be required in order for the FSI to emulate a SPI master fully.

Figure 31-18. FSITX and FSIRX as SPI Master, Full Duplex

#### 31.3.13.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI master operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set their respective SPI\_MODE bits. This will enable the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX\_MASTER\_CTRL.SPI\_PAIRING to 1. This will internally connect TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK may be reallocated to other application requirements.

If the application requires an external clock loopback, ensure that TXCLK is connected to RXCLK. This may be required if the SPI Slave is across an isolation barrier and there is latency between TXCLK being launched and SPISOMI data being received on RXD0.

#### 31.3.13.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI master module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

## 31.4 FSI Programming Guide

This section describes various operational sequences and features for the FSI.

### 31.4.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules may exchange data. Since the receiver will accept data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example provides a suggested approach for establishing a clean communication link on two separate devices that may power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to ensure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 31-19 shows the connection of the devices in this example. While there is no true concept of a master or a slave node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

**Figure 31-19. Point to Point Connection**

Device 1 is the master node; it will be the driver of the initialization sequence. Device 2 is the slave node; it will respond to the master's commands. In this example, as well as in a real world use-case, neither the master nor the slave may know precisely when the other is ready to receive communication.

Sample sequences for both the master device and slave device are provided in the following subsections.

### 31.4.1.1 Establishing the Communication Link from the Master

The following sequence is an example of how the master node can establish the communication link with the slave without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
  - Send the flush sequence.
  - Send a ping frame with the frame tag 0000.
  - Wait for some time. (determined by application)
  - If the FSIRX has received a valid ping frame, continue; else iterate the loop again.
  - If the received ping frame tag was 0001, continue; else iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point both the master transmit and receive channels have successfully received a frame from their slave counterparts. The link has been established and standard application communication may begin.

### 31.4.1.2 Establishing the Communication Link from the Slave

The following sequence is an example of how the slave node can establish the communication link with the master without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else return to step 4.
6. If the received frame tag was 0000, continue; else discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else return to step 4.
11. If the received ping frame tag was 0001, continue; else if the received frame tag was 0000, return to step 9.  
This can happen if a second ping frame was already in transit before receiving the slave's response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from their master counterparts. The link has been established and regular communication may now proceed. The application may configure periodic ping frames from the transmitter, initialize the receiver's ping and frame watchdogs and begin the communication required by the application.

### 31.4.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a master register lock. These protections ensure that no spurious writes or unintentional modifications to these registers are accepted. For the list of registers with write protections available and the register and bit descriptions, refer to [Section 31.6](#).

#### EALLOW Protection

EALLOW is a device-level register protection, refer to [Section 3.1.3](#) for more information on EALLOW. For those registers with EALLOW protection, the EALLOW bit should be set before modifying the register. The application should then clear the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

#### Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. In order to write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX\_MASTER\_CTRL.CORE\_RST must be set. To do this, write 0xA501 to TX\_MASTER\_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE\_RESET bit. Refer to the register descriptions for more information on which registers have write keys added.

#### Control Register Lock Protection

There also exists a master lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the register descriptions section. The control register lock will prevent any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX\_LOCK\_CTRL and TX\_LOCK\_CTRL for the receiver and transmitter respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV\_CFG\_REGS.SOFTPRESx) for the FSI module. Refer to [Section 31.3.2.7](#) for more information on SYSRSn.

### 31.4.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores will always be in free running mode. CPU halts will not have any effect on the operation of the FSI. However, reads of registers and data buffers by the debugger will not affect any flags, or status of the data buffers.

If you want to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

## 31.5 Software

### 31.5.1 FSI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/fsi

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 31.5.1.1 FSI Loopback:CPU Control

FILE: fsi\_ex1\_loopback\_cpucontrol.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Automatic (hardware triggered) Ping frame transmission is also setup along with data.

User can edit some of configuration parameters as per use case. These are as below. Default values can be referred in code where these globals are defined

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

For any errors during transfers, that is, *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time(detected through software counters - txTimeOutCntr and rxTimeOutCntr)

#### External Connections

For FSI internal loopback (EXTERNAL\_FSI\_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL\_FSI\_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

#### Watch Variables

- *dataFrameCntr* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.2 FSI Loopback CLA Control

FILE: fsi\_ex2\_loopback\_clacontrol.c

Example sets up infinite data frame transfers where trigger happens through CLA. Automatic (hardware triggered) Ping frame transmission is also setup along with data. This example is similar to fsi\_ex1\_loopback\_cpucontrol and only different in the sense that data frame transfer are triggered from a CLA task. Using CLA will release some of load from CPU and help it in providing time for other tasks.

User can edit some of configuration parameters as per use case. These are as below. Default values can be referred in code where these globals are defined.

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

For any errors during transfers, that is, *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time(detected through software counters - txTimeOutCntr and rxTimeOutCntr)

#### External Connections

For FSI internal loopback (EXTERNAL\_FSI\_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL\_FSI\_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

#### Watch Variables

- *dataFrameCntr* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.3 FSI DMA Frame Transfers:DMA Control

FILE: fsi\_ex3\_loopback\_dmacontrol.c

Example sets up infinite data frame transfers where DMA trigger happens once through CPU and then DMA takes control to transfer data iteratively. This example demonstrates the FSI feature about triggering DMA events which in turn can copy data and trigger next transfer.

Two DMA channels are setup for FSI Tx operation and two for Rx. Four areas in GSx memories are also setup as source and sink for data and tag values of frame under transmission.

Automatic (hardware triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### *External Connections*

For FSI internal loopback (`EXTERNAL_FSI_ENABLE == 0`), no external connections needed

For FSI external loopback (`EXTERNAL_FSI_ENABLE == 1`), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

#### *Watch Variables*

- *countDMAtransfers* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.4 FSI Data Transfer by External Trigger

FILE: fsi\_ex4\_loopback\_epwmtrigger.c

FSI frame transfer can be triggered by external sources. It can connect up to 32 trigger sources but as of now, only 16 ePWMx-SOCy(x-1:8, y-A:B) are supported. FSI supports external trigger for both PING and DATA frame transfers and in this example we demonstrate how to setup infinite DATA transfers using selectable ePWM-SOC as a trigger source. The TB counter for ePWM operation is in up/down count mode for this example.

Automatic (hardware triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI internal loopback (EXTERNAL\_FSI\_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL\_FSI\_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

#### Watch Variables

- *dataFrameCnt* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.5 FSI Data Transfers upon CPU Timer Event

FILE: fsi\_ex5\_periodic\_frame.c

Example sets up infinite data frame transfers where trigger comes from ISR handling the periodic CPU Timer event. Automatic (hardware triggered) Ping frame transmission is also setup along with data.

CPU Timer0 is chosen for setting up periodic timer events. User can choose any other Timer-1/Timer-2 as well.

Automatic (hardware triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI internal loopback (`EXTERNAL_FSI_ENABLE == 0`), no external connections needed

For FSI external loopback (`EXTERNAL_FSI_ENABLE == 1`), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

#### Watch Variables

- *dataFrameCntr* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.6 FSI and SPI Communication(*fsi\_ex6\_spi\_master\_tx*)

FILE: fsi\_ex6\_spi\_master\_tx.c

FSI supports SPI compatibility mode to talk to the devices not having FSI but SPI module. Example sets up infinite data frame transfers where FSI acts like master Tx and SPI as slave Rx. API to decode FSI frame received at SPI end is implemented and checks are made to ensure received details(frame tag/type, userdata, data) match with transferred frame.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI <-> SPI communication, make below connections in GPIO settings:

- GPIO\_27 -> GPIO\_3 :: To connect FSITX\_CLK with SPICLK
- GPIO\_26 -> GPIO\_2 :: To connect FSITX\_TX0 with SPISIMOA
- GPIO\_25 -> GPIO\_0 :: To connect FSITX\_TX1 with SPISTEA

#### Watch Variables

- *dataFrameCntr* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.7 FSI and SPI Communication(*fsi\_ex7\_spi\_slave\_rx*)

FILE: *fsi\_ex7\_spi\_slave\_rx.c*

FSI supports SPI compatibility mode to talk to the devices not having FSI but SPI module. Example sets up infinite data frame transfers where FSI acts like slave Rx and SPI as master Rx. API to build the FSI frame at SPI end before transfer is implemented in SW and checks are made to ensure received details(frame tag/type, userdata, data) on FSI Rx match with transferred data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI(Rx) <-> SPI(Tx) communication, make connections in GPIO settings:

There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge.

- GPIO\_13 -> GPIO\_3 :: To connect FSIRXCLK with SPICLK\_A
- GPIO\_12 -> GPIO\_2 :: To connect FSIRX0 with SPISIMOA

#### Watch Variables

- *dataFrameCnt* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.8 FSI P2Point Connection:Rx Side

FILE: *fsi\_ex8\_ext\_p2pconnection\_rx.c*

Example sets up FSI receiving device in a point to point connection to the FSI transmitting device. Example code to set up FSI transmit device is implemented in a separate file.

In a real scenario two separate devices may power up in arbitrary order and there is a need to establish a clean communication link which ensures that receiver side is flushed to properly interpret the start of a new valid frame.

There is no true concept of a master or a slave node in the FSI protocol, but to simplify the data flow and connection we can consider transmitting device as master and receiving side as slave. Transmitting side will be driver of initialization sequence.

Handshake mechanism that must take place before actual data transmission can be use case specific; points described below can be taken as an example on how to implement the handshake from receiving side.

- Setup the receiver interrupts to detect PING type frame reception
- Begin the first PING loop
  - Wait for receiver interrupt
  - If the FSI Rx has received a PING frame with *FSI\_FRAME\_TAG0*, come out of loop. Otherwise iterate the loop again.
- Begin the second PING loop
  - Send the Flush sequence
  - Send the PING frame with tag *FSI\_FRAME\_TAG1*
  - Wait for receiver interrupt
  - If the FSI Rx has received a PING frame with *FSI\_FRAME\_TAG1*, come out of loop. Otherwise iterate the loop again.

Now, the receiver side has received the acknowledged PING frame (tag1), so it is ready for normal operation further.

After above synchronization steps, FSI Rx can be configured as per use case, that is, nWords, lane width, enabling events etc and start the infinite transfers. More details on establishing the communication link can be found in device TRM.

User can edit some of configuration parameters as per use case, similar to other examples.

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

### External Connections

For FSI external P2P connection, external connections are required to be made between two devices. Device 1's FSI TX and RX pins need to be connected to device 2's FSI RX and TX pins, respectively. See below for external connections to make and GPIOs used:

External connections required between independent RX and TX devices:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

### Watch Variables

- *dataFrameCntr* Number of Data frame received
- *error* Non zero for transmit/receive data mismatch

### 31.5.1.9 FSI P2Point Connection:Tx Side

FILE: `fsi_ex8_ext_p2pconnection_tx.c`

Example sets up FSI transmitting device in a point to point connection to the FSI receiving device. Example code to set up FSI receiving device is implemented in a separate file.

In a real scenario two separate devices may power up in arbitrary order and there is a need to establish a clean communication link which ensures that receiver side is flushed to properly interpret the start of a new valid frame.

There is no true concept of a master or a slave node in the FSI protocol, but to simplify the data flow and connection we can consider transmitting device as master and receiving side as slave. Transmitting side will be driver of initialization sequence.

Handshake mechanism which must take place before actual data transmission can be use case specific; points described below can be taken as an example on how to implement the handshake from transmitting side.

- Setup the receiver interrupts to detect PING type frame reception
- Begin the PING loop
  - Send the Flush sequence
  - Send a PING frame with the frame tag *FSI\_FRAME\_TAG0*
  - Wait for some time (determined by application)
  - If the FSI Rx has received a PING frame with *FSI\_FRAME\_TAG1*, come out of loop. Otherwise iterate the loop again

Send a PING frame with the frame tag *FSI\_FRAME\_TAG1*

After above synchronization steps, FSI Tx can be configured as per use case, that is, *nWords*, lane width, enabling events etc and start the infinite transfers. More details on establishing the communication link can be found in device TRM.

User can edit some of configuration parameters as per use case, similar to other examples.

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

### External Connections

For FSI external P2P connection, external connections are required to be made between two devices. Device 1's FSI TX and RX pins need to be connected to device 2's FSI RX and TX pins, respectively. See below for external connections to make and GPIOs used:

External connections required between independent RX and TX devices:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1

ControlCard FSI Header GPIOs:

- GPIO\_27 -> FSITX\_CLK
- GPIO\_26 -> FSITX\_TX0
- GPIO\_25 -> FSITX\_TX1
- GPIO\_13 -> FSIRX\_CLK
- GPIO\_12 -> FSIRX\_RX0
- GPIO\_11 -> FSIRX\_RX1

### Watch Variables

- *dataFrameCntr* Number of Data frame transmitted
- *error* Non zero for transmit/receive data mismatch

## 31.6 FSI Registers

This section describes the Fast Serial Interface Registers. The FSI module contains two distinct sets of registers. One for the FSI receiver and one for the FSI transmitter.

### 31.6.1 FSI Base Address Table

**Table 31-15. FSI Base Address Table**

| Bit Field Name |             | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-------------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure   |                |              |      |     |     |     |                    |
| FsiTxaRegs     | FSI_TX_REGS | FSITXA_BASE    | 0x0000_6600  | YES  | YES | YES | YES | YES                |
| FsiRxaRegs     | FSI_RX_REGS | FSIRXA_BASE    | 0x0000_6680  | YES  | YES | YES | YES | YES                |

### 31.6.2 FSI\_TX\_REGS Registers

Table 31-16 lists the memory-mapped registers for the FSI\_TX\_REGS registers. All register offset addresses not listed in Table 31-16 should be considered as reserved locations and the register contents should not be modified.

**Table 31-16. FSI\_TX\_REGS Registers**

| Offset        | Acronym            | Register Name                                   | Write Protection | Section            |
|---------------|--------------------|---|------------------|--------------------|
| 0h            | TX_MASTER_CTRL     | Transmit main control register                  | EALLOW           | <a href="#">Go</a> |
| 2h            | TX_CLK_CTRL        | Transmit clock control register                 | EALLOW and LOCK  | <a href="#">Go</a> |
| 4h            | TX_OPER_CTRL_LO    | Transmit operation control register low         | EALLOW and LOCK  | <a href="#">Go</a> |
| 5h            | TX_OPER_CTRL_HI    | Transmit operation control register high        | EALLOW and LOCK  | <a href="#">Go</a> |
| 6h            | TX_FRAME_CTRL      | Transmit frame control register                 |                  | <a href="#">Go</a> |
| 7h            | TX_FRAME_TAG_UDATA | Transmit frame tag and user data register       |                  | <a href="#">Go</a> |
| 8h            | TX_BUF_PTR_LOAD    | Transmit buffer pointer control load register   | EALLOW           | <a href="#">Go</a> |
| 9h            | TX_BUF_PTR_STS     | Transmit buffer pointer control status register |                  | <a href="#">Go</a> |
| Ah            | TX_PING_CTRL       | Transmit ping control register                  | EALLOW and LOCK  | <a href="#">Go</a> |
| Bh            | TX_PING_TAG        | Transmit ping tag register                      |                  | <a href="#">Go</a> |
| Ch            | TX_PING_TO_REF     | Transmit ping timeout counter reference         | EALLOW and LOCK  | <a href="#">Go</a> |
| Eh            | TX_PING_TO_CNT     | Transmit ping timeout current count             |                  | <a href="#">Go</a> |
| 10h           | TX_INT_CTRL        | Transmit interrupt event control register       | EALLOW and LOCK  | <a href="#">Go</a> |
| 11h           | TX_DMA_CTRL        | Transmit DMA event control register             | EALLOW and LOCK  | <a href="#">Go</a> |
| 12h           | TX_LOCK_CTRL       | Transmit lock control register                  | EALLOW and LOCK  | <a href="#">Go</a> |
| 14h           | TX_EVT_STS         | Transmit event and error status flag register   |                  | <a href="#">Go</a> |
| 16h           | TX_EVT_CLR         | Transmit event and error clear register         | EALLOW           | <a href="#">Go</a> |
| 17h           | TX_EVT_FRC         | Transmit event and error flag force register    | EALLOW           | <a href="#">Go</a> |
| 18h           | TX_USER_CRC        | Transmit user-defined CRC register              |                  | <a href="#">Go</a> |
| 20h           | TX_ECC_DATA        | Transmit ECC data register                      |                  | <a href="#">Go</a> |
| 22h           | TX_ECC_VAL         | Transmit ECC value register                     |                  | <a href="#">Go</a> |
| 24h           | TX_DLYLINE_CTRL    | Transmit delay Line control register            | EALLOW and LOCK  | <a href="#">Go</a> |
| 40h + formula | TX_BUF_BASE_y      | Base address for transmit buffer                |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 31-17 shows the codes that are used for access types in this section.

**Table 31-17. FSI\_TX\_REGS Access Type Codes**

| Access Type            | Code | Description |
|------------------------|------|-------------|
| Read Type              |      |             |
| R                      | R    | Read        |
| Write Type             |      |             |
| W                      | W    | Write       |
| Reset or Default Value |      |             |

**Table 31-17. FSI\_TX\_REGS Access Type Codes  
(continued)**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| <i>-n</i>                |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| <i>i,j,k,l,m,n</i>       |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| <i>y</i>                 |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 31.6.2.1 TX\_MASTER\_CTRL Register (Offset = 0h) [Reset = 0h]

TX\_MASTER\_CTRL is shown in [Figure 31-20](#) and described in [Table 31-18](#).

Return to the [Summary Table](#).

Transmit main control register

**Figure 31-20. TX\_MASTER\_CTRL Register**

|          |    |    |    |    |    |        |          |
|----------|----|----|----|----|----|--------|----------|
| 15       | 14 | 13 | 12 | 11 | 10 | 9      | 8        |
| KEY      |    |    |    |    |    |        |          |
| W-0h     |    |    |    |    |    |        |          |
| 7        | 6  | 5  | 4  | 3  | 2  | 1      | 0        |
| RESERVED |    |    |    |    |    | FLUSH  | CORE_RST |
| R-0h     |    |    |    |    |    | R/W-0h | R/W-0h   |

**Table 31-18. TX\_MASTER\_CTRL Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 15-8 | KEY      | W    | 0h    | Write Key<br>In order to write to any bit in this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register.<br>Reset type: SYSRSn   |
| 7-2  | RESERVED | R    | 0h    | Reserved   |
| 1    | FLUSH    | R/W  | 0h    | Flush Operation Start bit<br>This bit will cause the transmitter to initiate a flush pattern of a single toggle on the TXD0 and TXD1 followed by five full cycles of TXCLK. This bit should be written only when the CORE_RST bit is 0 and the clock to the Transmitter core is turned on.<br>0h (R/W) = Clear this bit.<br>1h (R/W) = Setting this bit will initiate flush sequence.<br>To properly execute a flush sequence, Set FLUSH to 1, wait for five TXCLK cycles then clear FLUSH to 0.<br>Note: The KEY field must contain 0xA5 for any write to this bit to take effect. The software must keep this bit set to 1 for at least five TXCLK cycles before setting it back to 0.<br>Reset type: SYSRSn |
| 0    | CORE_RST | R/W  | 0h    | Transmitter Main Core Reset bit<br>This bit controls the transmitter main core reset. In order to send any frame, this bit must be cleared.<br>0h (R/W) = Transmitter core is not in reset and can transmit frames.<br>1h (R/W) = Transmitter core is held in reset.<br>Note: The KEY field must contain 0xA5 for any write to this bit to take effect.<br>Reset type: SYSRSn  |

### 31.6.2.2 TX\_CLK\_CTRL Register (Offset = 2h) [Reset = 0h]

TX\_CLK\_CTRL is shown in [Figure 31-21](#) and described in [Table 31-19](#).

Return to the [Summary Table](#).

Transmit clock control register

**Table 31-26. TX\_PING\_CTRL Register Field Descriptions**

| Bit  | Field        | Type | Reset | Description  |
|------|--------------|------|-------|--|
| 15-9 | RESERVED     | R    | 0h    | Reserved   |
| 8-3  | EXT_TRIG_SEL | R/W  | 0h    | External Trigger Select bits<br>This bitfield will select one of the 64 external trigger inputs to be the source to generate a ping frame. A ping frame will only be generated if the EXT_TRIG_EN bit is set.<br>0h (R/W) = Trigger 1 will be used to generate a ping frame.<br>1h (R/W) = Trigger 2 will be used to generate a ping frame.<br>..<br>3Fh (R/W) = Trigger 64 will be used to generate a ping frame.<br>Reset type: SYSRSn   |
| 2    | EXT_TRIG_EN  | R/W  | 0h    | External Trigger Enable bit<br>This bit will allow the external trigger logic to generate a ping frame.<br>0h (R/W) = External triggers will not be used to generate ping frames.<br>1h (R/W) = The selected external trigger (selected by EXT_TRIG_SEL bits) will be able to generate a ping frame. The ping timer will be ignored if this bit is set.<br>Reset type: SYSRSn  |
| 1    | TIMER_EN     | R/W  | 0h    | Ping Timer Enable bit<br>This bit will enable the ping timer for generating periodic ping frames.<br>0h (R/W) = The ping timer is disabled and will not generate ping frames.<br>1h (R/W) = The ping timer is enabled and can be used to generate ping frames. Once the timer count reaches the value set by the TX_PING_TO_REF register, it will initiate a ping frame transmission.<br>Note: If the ping timer is used, EXT_TRIG_EN should not be set as it will override this function.<br>Reset type: SYSRSn |
| 0    | CNT_RST      | R/W  | 0h    | Ping Counter Reset bit<br>Writing a 1 to this bit will reset the ping counter to 0. The counter will stay in reset as long as this bit is set to 1. This bit needs to be cleared to 0 to use the counter.<br>0h (R/W) = Clear the CNT_RST.<br>1h (R/W) = The ping counter will be reset to 0.<br>Reset type: SYSRSn  |

### 31.6.2.10 TX\_PING\_TAG Register (Offset = Bh) [Reset = 0h]

TX\_PING\_TAG is shown in [Figure 31-29](#) and described in [Table 31-27](#).

Return to the [Summary Table](#).

Transmit ping tag register

**Figure 31-29. TX\_PING\_TAG Register**

|          |    |    |    |        |    |   |   |

Complex bit access types are encoded to fit into small table cells. [Table 31-42](#) shows the codes that are used for access types in this section.

**Table 31-42. FSI\_RX\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Write Type               |      |  |
| W                        | W    | Write  |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 31.6.3.1 RX\_MASTER\_CTRL Register (Offset = 0h) [Reset = 0h]

RX\_MASTER\_CTRL is shown in [Figure 31-43](#) and described in [Table 31-43](#).

Return to the [Summary Table](#).

Receive main control register

**Figure 31-43. RX\_MASTER\_CTRL Register**

|          |    |    |                |               |             |              |          |
|----------|----|----|----------------|---------------|-------------|--------------|----------|

| R-0h     |    |    | R/W-0h         | R/W-0h        | R/W-0h      | R/W-0h       | R/W-0h   |

**Table 31-43. RX\_MASTER\_CTRL Register Field Descriptions**

| Bit  | Field          | Type | Reset | Description  |
|------|----------------|------|-------|--|
| 15-8 | KEY            | W    | 0h    | Write Key.<br>In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register.<br>Reset type: SYSRSn   |
| 7-5  | RESERVED       | R    | 0h    | Reserved   |
| 4    | DATA_FILTER_EN | R/W  | 0h    | Data Filter Enable Bit.<br>0h (R/W) = Data filtering is disabled.<br>1h (R/W) = Data filtering is enabled.<br>Reset type: SYSRSn   |
| 3    | INPUT_ISOLATE  | R/W  | 0h    | When set to 1, the FSI RX inputs (RXCLK, RXD0 and RXD1) will be isolated from what is driven from the device pins and will be held at inactive level of '1'. This isolation facilitates the user to switch the RX inputs to a different set of device pins and hence any potential glitch that could occur during the process of switching will not affect the RX module itself.<br>Reset type: SYSRSn   |
| 2    | SPI_PAIRING    | R/W  | 0h    | Clock Pairing for SPI-like Behavior Enable bit<br>This bit enables the internal clock pairing with the FSI TX module. This feature internally connects the TXCLK to RXCLK allowing the FSI TX module, acting as a SPI controller, to clock data into the receiver and out of the transmitter like a standard SPI module. This configuration is valid when the Module is in SPI mode only (RX_OPER_CTRL.SPI_MODE = 1)<br>0h (R/W) = SPI clock pairing is not enabled.<br>1h (R/W) = SPI clock pairing is enabled. The RXCLK will be internally connected to the TXCLK of the corresponding FSI module.<br>Note: The KEY field must contain 0xA5 for any write to this bit to take effect.<br>Reset type: SYSRSn |

**Table 31-43. RX\_MASTER\_CTRL Register Field Descriptions (continued)**

| Bit | Field        | Type | Reset | Description  |
|-----|--------------|------|-------|--|
| 1   | INT_LOOPBACK | R/W  | 0h    | <p>Internal Loopback Enable bit</p> <p>This bit enables the internal loopback functionality of the FSI receiver. By enabling this bit, a mux will select the signals coming directly from the corresponding FSI transmitter module rather than from the pins.</p> <p>0h (R/W) = Internal loopback is disabled. The FSI RX module will receive signals coming from the pins.</p> <p>1h (R/W) = Internal loopback is enabled. The FSI RX module will receive signals from the directly from FSI TX module rather than the pins.</p> <p>Note: The KEY field must contain 0xA5 for any write to this bit to take effect.</p> <p>Reset type: SYSRSn</p> |
| 0   | CORE_RST     | R/W  | 0h    | <p>Receiver Main Core Reset bit</p> <p>This bit controls the receiver main core reset. In order to receive any frame, this bit must be cleared.</p> <p>Note: For reset to take effect, the FSI RX module must be held in reset for at least 4 SYSCLK cycles.</p> <p>0h (R/W) = Receiver core is not in reset and can receive frames.</p> <p>1h (R/W) = Receiver core is held in reset.</p> <p>Note: The KEY field must contain 0xA5 for any write to this bit to take effect.</p> <p>Reset type: SYSRSn</p>  |

### 31.6.3.2 RX\_OPER\_CTRL Register (Offset = 4h) [Reset = 0h]

RX\_OPER\_CTRL is shown in [Figure 31-44](#) and described in [Table 31-44](#).

Return to the [Summary Table](#).

Receive operation control register

|-----|---------------|------|-------|---|
| 10  | FRAME_OVERRUN | R    | 0h    | <p>Frame Overrun Flag</p> <p>This bit indicates that a frame overrun condition has occurred. This bit gets set to 1 when a new DATA/ERROR frame is received and the corresponding DATA_FRAME_RCVD/ERROR_FRAME_RCVD flag is still set to 1. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Frame overrun has not occurred.<br/>1h (R) = Frame overrun has occurred.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p> |
| 9   | PING_FRAME    | R    | 0h    | <p>Ping Frame Received Flag</p> <p>This bit indicates that an ping frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = No ping frame has been received.<br/>1h (R) = A ping frame has been received.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>   |
| 8   | ERR_FRAME     | R    | 0h    | <p>Error Frame Received Flag</p> <p>This bit indicates that an error frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = No error frame has been received.<br/>1h (R) = An error frame has been received.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>  |
| 7   | BUF_UNDERRUN  | R    | 0h    | <p>Receive Buffer Underrun Flag</p> <p>This bit indicates that a buffer underrun condition has occurred in the receive buffer. This will happen when software reads the buffer which is empty and has no valid data. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Receive Buffer Underrun has not occurred.<br/>1h (R) = Receive Buffer Underrun has occurred.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>   |
| 6   | FRAME_DONE    | R    | 0h    | <p>Frame Done Flag</p> <p>This bit indicates that a frame has been successfully received without error. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = No frame has been successfully received.<br/>1h (R) = A frame has been successfully received.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>   |
| 5   | BUF_OVERRUN   | R    | 0h    | <p>Receive Buffer Overrun Flag</p> <p>This bit indicates that a buffer overrun condition has occurred in the receive buffer. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Receive buffer overrun has not occurred.<br/>1h (R) = Receive buffer overrun has occurred.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>   |

**Table 31-48. RX\_EVT\_STS Register Field Descriptions (continued)**

| Bit | Field       | Type | Reset | Description   |
|-----|-------------|------|-------|---|
| 4   | EOF_ERR     | R    | 0h    | <p>End-of-Frame Error Flag</p> <p>This bit indicates that an invalid end-of-frame bit pattern has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Invalid end-of-frame has not been received.<br/>1h (R) = Invalid end-of-frame has been received</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>                                    |
| 3   | TYPE_ERR    | R    | 0h    | <p>Frame Type Error Flag</p> <p>This bit indicates that an invalid frame type has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Invalid frame type has not been received.<br/>1h (R) = Invalid frame type has been received</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>  |
| 2   | CRC_ERR     | R    | 0h    | <p>CRC Error Flag</p> <p>This bit indicates that a CRC error has occurred. A CRC error will be generated on a data frame where the received CRC and the computed CRC do not match. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = CRC error has not occurred.<br/>1h (R) = CRC error has occurred.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p> |
| 1   | FRAME_WD_TO | R    | 0h    | <p>Frame Watchdog Timeout Flag</p> <p>This bit indicates that the frame watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Frame watchdog timeout has not occurred.<br/>1h (R) = Frame watchdog timeout has occurred.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>  |
| 0   | PING_WD_TO  | R    | 0h    | <p>Ping Watchdog Timeout Flag</p> <p>This bit indicates that the ping watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register.</p> <p>0h (R) = Ping watchdog timeout has not occurred.<br/>1h (R) = Ping watchdog timeout has occurred.</p> <p>To clear this bit, write to the corresponding bit in the RX_EVT_CLR register.</p> <p>Reset type: SYSRSn</p>  |

### 31.6.3.7 RX\_CRC\_INFO Register (Offset = Bh) [Reset = 0h]

RX\_CRC\_INFO is shown in [Figure 31-49](#) and described in [Table 31-49](#).

Return to the [Summary Table](#).

Receive CRC info of received and computed CRC

## 32.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware\_2\_00\_00\_03 and higher):

**C2000WARE\_INSTALL\_LOCATION\utilities\clb\_tool\clb\_syscfg\doc**

## 32.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices may contain more or fewer tiles. Tiles are numbered 1 to 'N', where 'N' is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. [Figure 32-1](#) shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. [Figure 32-2](#) shows the connections between the tile, the CPU interface, and the device.

## 32.3 CLB Input/Output Connection

### 32.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

### 32.3.2 CLB Input Selection

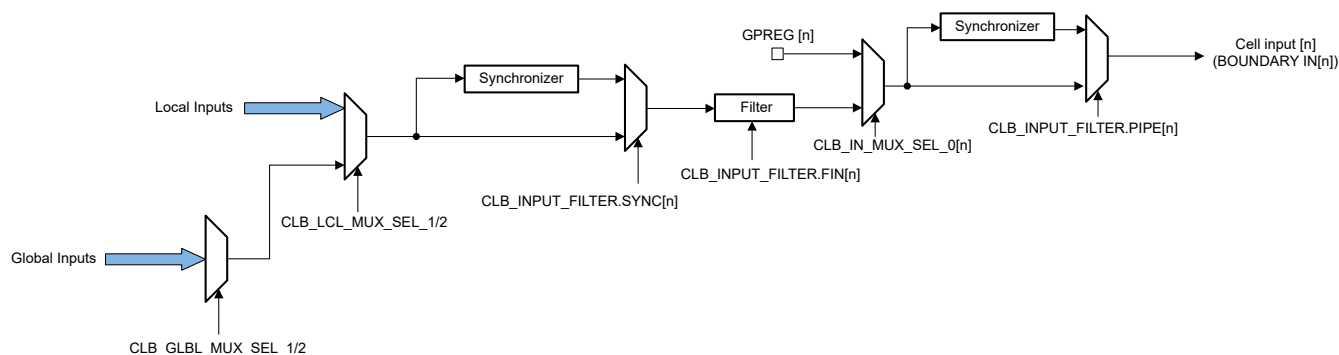

Each CLB module has eight inputs that feed into the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

A set of signals is common to all the CLB instances. These are referred to as global inputs in [Figure 32-3](#). A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in [Figure 32-3](#).

Registers `CLB_LCL_MUX_SEL_1` and `CLB_LCL_MUX_SEL_2` control the local mux selection for each of the eight inputs. The mux control registers `CLB_GLBL_MUX_SEL_1` and `CLB_GLBL_MUX_SEL_2` control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting `CLB_LCL_MUX_SEL_IN_0 = 0` and `CLB_GLBL_MUX_SEL_IN_0 = 8` causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global and local input mux settings are shown in [Table 32-1](#) and [Table 32-2](#).

**Figure 32-3. CLB Input Mux and Filter**

**Table 32-1. Global Signals and Mux Selection**

| Global Input Mux Bit Position | SYNC/ASYNC | Signal Name | Instance Name |
|-------------------------------|------------|-------------|---------------|
| <b>CLB1 to CLB4</b>           |            |             |               |
| 0                             | ASYNC      | ePWMxA      | EPWM1         |

---

**Note**

For the signals marked as ASYNC, the input filter synchronizer must be enabled.

---

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1's GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

In order to connect multiple tiles to each other, you can either use the CLBx OUT4/5 and connect it to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect it to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

In order to use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. [Figure 32-4](#) shows how GPIOs can be used as inputs to the CLB tiles.

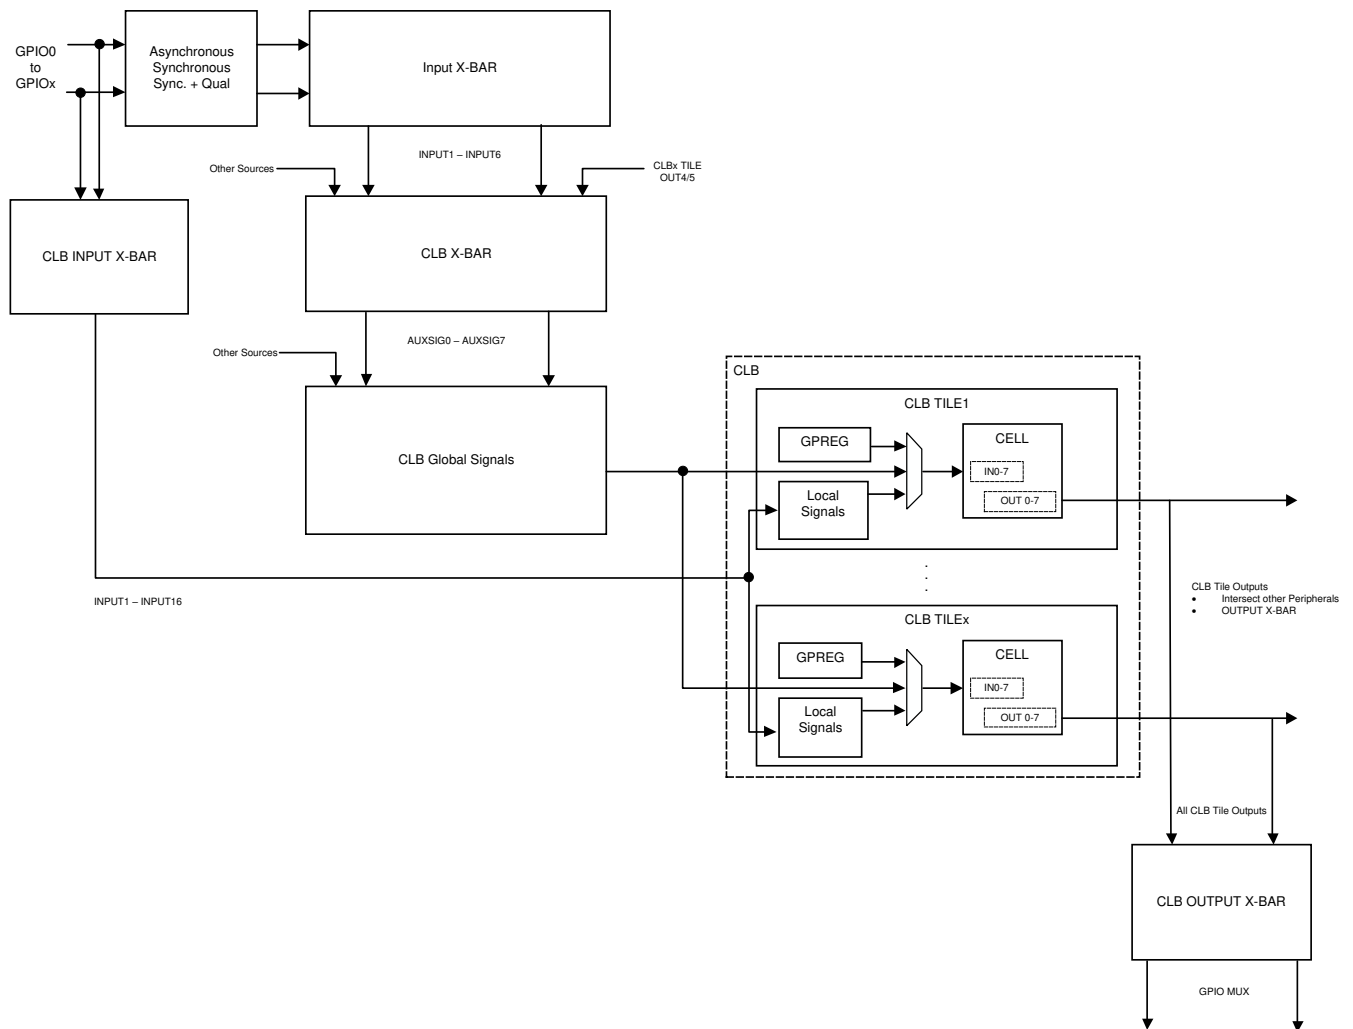

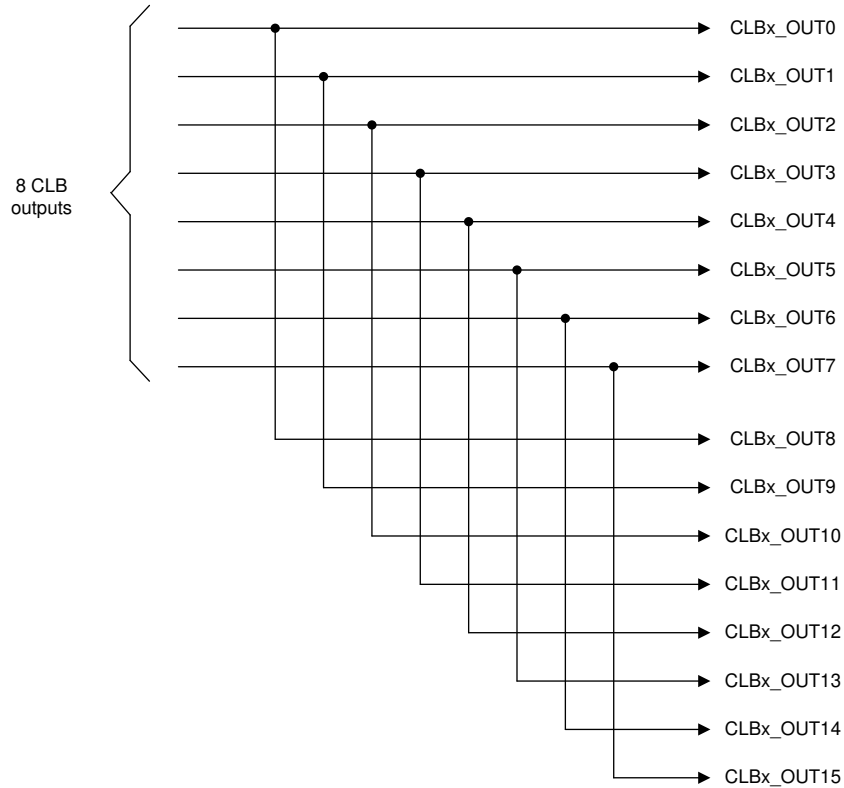

Figure 32-4. GPIO to CLB Tile Connections

### 32.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 16 output signals. Each of these 16 outputs has a separate enable bit defined in the CLB output enable register, CLB\_OUT\_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. Figure 32-5 shows the CLB outputs.

**Figure 32-5. CLB Outputs**

**Note**

CLBx\_OUT0\_1, CLBx\_OUT1\_1, CLBx\_OUT2\_1, ... CLBx\_OUT7\_1 is the same as CLBx\_OUT8, CLBx\_OUT9, CLBx\_OUT10, ... CLBx\_OUT15.

### 32.3.4 Peripheral Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see [Figure 32-6](#). The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by a bit in the CLB output enable register `CLB_OUT_EN`.

**Figure 32-6. Peripheral Signal Multiplexer**

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPUT ENABLE bit for OUT0 must be set to 1.

[Table 32-3](#) shows the allocation of peripheral signals and the CLB outputs that they are multiplexed.

**Table 32-3. Peripheral Signal Multiplexer Table**

| CLB Instance | CLB Output Signal | Peripheral Signal                                       | Peripheral Name                  |
|--------------|-------------------|---|----------------------------------|
| <b>CLB1</b>  |                   |   |                                  |

### 32.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured either as an adder, a counter, or a shifter. When functioning as an adder, it can either add or subtract. When functioning as a counter, it can count up or count down. When functioning as a shifter, it can shift left or shift right. The counter event inputs, as well as the reset input, may be freely connected to any of the other submodules in the same tile. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) which can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Configurable Switch Block:** The configurable switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the sole restriction that they must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in [Figure 32-7](#).

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at its output. The register field would therefore be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

**Figure 32-7. CLB Tile Submodules**

### 32.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

**Table 32-4. Output Table**

| Bit Position | Signal Connection | Comment  |
|--------------|-------------------|--|
| 0            | Always '0'        | This select value will be used to tie an input to '0'. |
| 1            | COUNTER_0 MATCH2  |  |
| 2            | COUNTER_0 ZERO    |  |
| 3            | COUNTER_0 MATCH1  |  |
| 4            | FSM_0 STATE_BIT_0 |  |
| 5            | FSM_0 STATE_BIT_1 |  |
| 6            | FSM_0 LUT output  |  |
| 7            | LUT4_0 output     |  |
| 8            | Always '1'        | This select value will be used to tie an input to '1'. |
| 9            | COUNTER_1 MATCH2  |  |
| 10           | COUNTER_1 ZERO    |  |
| 11           | COUNTER_1 MATCH1  |  |
| 12           | FSM_1 STATE_BIT_0 |  |
| 13           | FSM_1 STATE_BIT_1 |  |
| 14           | FSM_1 LUT output  |  |
| 15           | LUT4_1 output     |  |
| 16           | Always '0'        |  |
| 17           | COUNTER_2 MATCH2  |  |
| 18           | COUNTER_2 ZERO    |  |
| 19           | COUNTER_2 MATCH1  |  |
| 20           | FSM_2 STATE_BIT_0 |  |
| 21           | FSM_2 STATE_BIT_1 |  |
| 22           | FSM_2 LUT output  |  |
| 23           | LUT4_2 output     |  |
| 24           | External Input 0  |  |
| 25           | External Input 1  |  |
| 26           | External Input 2  |  |
| 27           | External Input 3  |  |
| 28           | External Input 4  |  |
| 29           | External Input 5  |  |
| 30           | External Input 6  |  |
| 31           | External Input 7  |  |

**Table 32-5. Input Table**

| Module Name   | Port Name     | Description  |
|---------------|---------------|--|
| Counter Block | RESET         | Acts as an active high reset when used as a counter  |
|               | MODE_0        | Acts as a enable when used as a counter. The counter will count only when this input is '1'.                               |
|               | MODE_1        | Acts as a direction control when used as a counter. If this input is '1', then the counter counts up else, it counts down. |
| LUT           | IN0           | Input 0 of the 4-input LUT.  |
|               | IN1           | Input 1 of the 4-input LUT.  |
|               | IN2           | Input 2 of the 4-input LUT.  |
|               | IN3           | Input 3 of the 4-input LUT.  |
| FSM           | EXT_IN0       | Input 0 of the FSM block.  |
|               | EXT_IN1       | Input 1 of the FSM block.  |
|               | EXTRA_EXT_IN0 | Extra external Input 0 of the FSM block. This input matters only if it is configured in the LUT mode.                      |
|               | EXTRA_EXT_IN1 | Extra external Input 1 of the FSM block. This input matters only if it is configured in the LUT mode.                      |

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in [Table 32-4](#). It is therefore easy to create a combinatorial loop. In order to prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to '0', as shown in [Table 32-6](#).

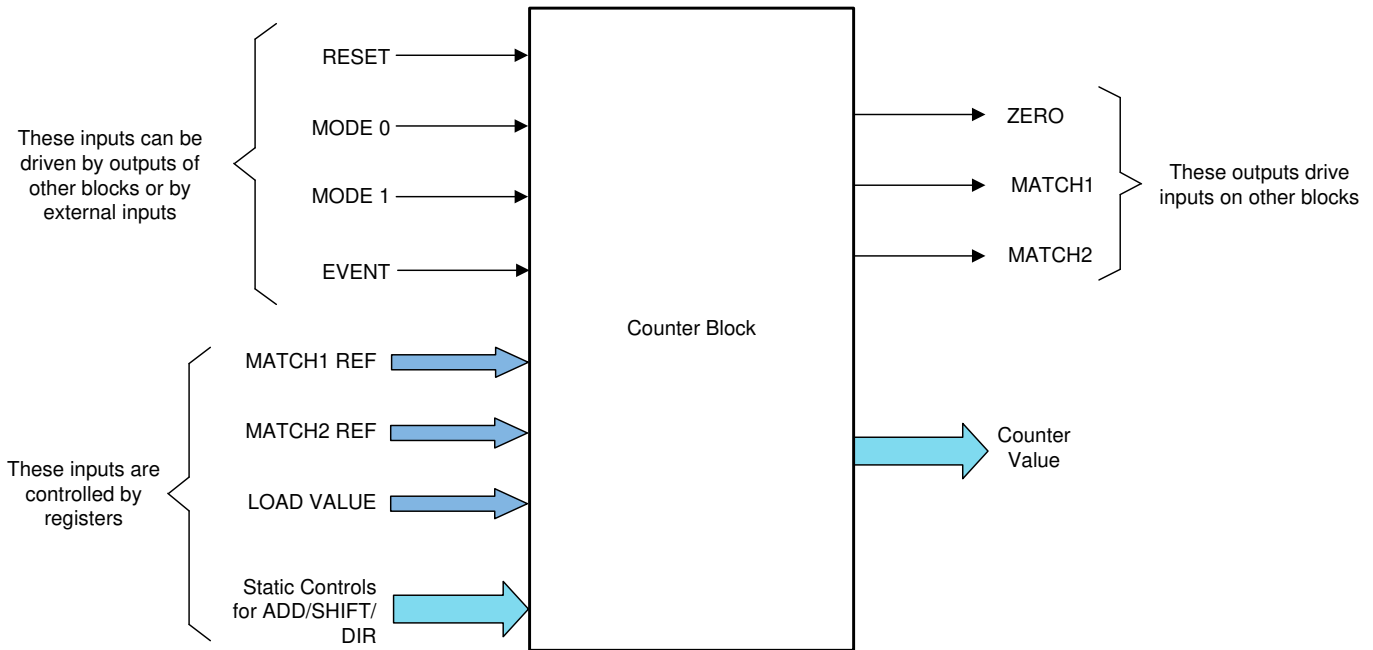

**Table 32-6. Ports Tied Off to Prevent Combinatorial Loops**

| Module Name | Ports of Input MUX Tied Off to '0' to Prevent Combinatorial Loops |
|-------------|---|
| LUT_0       | LUT_0 , LUT_1 and LUT_2 output, FSM_0, FSM_1 and FSM_2 output.    |
| FSM_0       | LUT_1 and LUT_2 output, FSM_0, FSM_1 and FSM_2 output.            |
| LUT_1       | LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.                   |
| FSM_1       | LUT_2 output, FSM_1 and FSM_2 output.                             |
| LUT_2       | LUT_2 output, FSM_2 output.                                       |
| FSM_2       | FSM_2 output.   |

### 32.4.2 Counter Block

#### 32.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in [Figure 32-8](#).

**Figure 32-8. Counter Block**

#### 32.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the configurable switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as it remains high, the counter will reset to 0 on the next clock cycle.
- **MODE\_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE\_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE\_1:** This input is the direction control for the counter. If this input is high, then the counter will increment on every clock cycle where it sees MODE\_0 to be high. If this input is low, then the counter decrements for every clock cycle it sees MODE\_0 high. The counter wraps around to 0x00000000 after 0xFFFFFFFF when counting up. The counter wraps around to 0xFFFFFFFF after 0x00000000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.

- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event itself can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation will continue based on the MODE\_0, MODE\_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see [Section 32.5.2](#).

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG\_MISC\_CTRL register. The following three bits of this register are relevant for each counter. The “x” below refers to the counter instance; 0, 1, or 2. For more information, see the CLB\_MISC\_CONTROL register description located in [Section 32.8](#).

- COUNT\_EVENT\_CTRL\_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter will just load the static value; 1 means an add/shift operation will be performed.
- COUNT\_ADD\_SHIFT\_x. 1 means add, 0 means shift.
- COUNT\_DIR\_x. 1 means left shift or add. 0 means right shift or subtract.

[Table 32-7](#) shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load:  $CNTVAL = EVENT\_LOAD\_VAL$

Shift right:  $CNTVAL = CNTVAL \gg EVENT\_LOAD\_VAL$

Shift left:  $CNTVAL = CNTVAL \ll EVENT\_LOAD\_VAL$

Subtract:  $CNTVAL = CNTVAL - EVENT\_LOAD\_VAL$

Add:  $CNTVAL = CNTVAL + EVENT\_LOAD\_VAL$

**Table 32-7. Counter Block Operating Modes**

| EVENT | MODE_0 | MODE_1 | COUNT_EVENT_CTRL_x | COUNT_ADD_SHIFT_x | COUNT_DIR_x | Action on CNTVAL |
|-------|--------|--------|--------------------|-------------------|-------------|------------------|
| 0     | 0      | 0      | X                  | X                 | X           | None             |
| 0     | 0      | 1      | X                  | X                 | X           | None             |
| 0     | 1      | 0      | X                  | X                 | X           | Count down       |
| 0     | 1      | 1      | X                  | X                 | X           | Count up         |
| 1     | X      | X      | 0                  | X                 | X           | Load             |
| 1     | X      | X      | 1                  | 0                 | 0           | Shift right      |
| 1     | X      | X      | 1                  | 0                 | 1           | Shift left       |
| 1     | X      | X      | 1                  | 1                 | 0           | Subtract         |
| 1     | X      | X      | 1                  | 1                 | 1           | Add              |

### 32.4.2.3 Serializer Mode

Starting with CLB Type 2, the Counter module can operate as a serializer. In this mode of operation, this module acts as a shift register (also referred to as a serializer). In serializer mode of operation, the EVENT input is used to shift one bit of data into the serializer. Either of MATCH1 and MATCH2 can be configured to send out the shift register data. Using the MATCH1/2\_TAP\_SEL bit of CLB\_COUNT\_MATCH\_TAP\_SEL, any bit position of the counter can be brought out on the MATCH1/MATCH2 outputs. The shifting and direction of the counter in this mode is controlled by MODE\_0(enable) and MODE\_1(direction).

To enable the Serializer mode, CLB\_MISC\_CONTROL.COUNT\_SERIALIZER\_0 (for Counter 0) must be set.

### 32.4.2.4 Linear Feedback Shift Register (LFSR) Mode

Starting with CLB Type 2, the Counter module operates as a linear feedback shift register. By configuring the characteristics of the LFSR, the counter module is used to compute the CRC on a serial bit stream. The polynomial for LFSR is in the MATCH2 reference register. The feedback bit position is in the MATCH1 reference register.

To enable the LFSR mode, CLB\_MISC\_CONTROL.COUNT\_SERIALIZER\_0 (for Counter 0) must be set along with COUNT0\_LFSR\_EN.

There are two types of LSFR that can be selected by changing the MODE1 value (0 or 1), as shown in [Figure 32-9](#).

Structure for LFSR Type 1 (MODE\_1 = 0)

CNT\_VAL is the 32-bit counter's active register  
 CNT\_VAL\_next is the 32-bit value to be written into CNT\_VAL on the next active cycle  
 (clock edge when MODE\_0 == 1)  
 LFSR\_MSB = CNT\_VAL[MATCH1\_REF[4:0]]  
 Poly[31:0] is MATCH2\_REF which acts as the CRC polynomial

Structure for LFSR Type 2 (MODE\_1 = 1)

CNT\_VAL is the 32-bit counter register  
 CNT\_VAL\_next is the 32-bit value to be written into CNT\_VAL on the next active cycle  
 (clock edge when MODE\_0 == 1)  
 LFSR\_MSB = CNT\_VAL[MATCH1\_REF[4:0]]  
 Poly[31:0] is MATCH2\_REF which acts as the CRC polynomial

Figure 32-9. LFSR Modes

### 32.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. It has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machines. For additional flexibility, there are two auxiliary inputs (EXTRA\_EXT\_IN0 and EXTRA\_EXT\_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 32-10.

Figure 32-10. FSM Block

The signals and functionality of the FSM block are:

- **EXT\_IN0 and EXT\_IN1:** These are the two external inputs that can be used to control the output FSM\_LUT\_OUT or either of the states S0 and S1.
- **S0 and S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM\_LUT\_OUT. An additional level of configurability is provided such that FSM\_LUT\_OUT can use extra inputs in case the states S0 and S1 are unused.

One extra bit is used to select EXTRA\_EXT\_IN0 instead of S0. One extra bit is used to select EXTRA\_EXT\_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM\_LUT\_OUT by giving up one or two state bits, respectively.

The CFG\_MISC\_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM\_EXTRA\_EXT\_INx. '0' means use the state bit, and '1' means use the FSM\_EXTRA\_EXT\_IN0 / FSM\_EXTRA\_EXT\_IN1 signal.

Figure 32-11. FSM LUT Block

### 32.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see [Figure 32-12](#)). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in [Section 32.8](#).

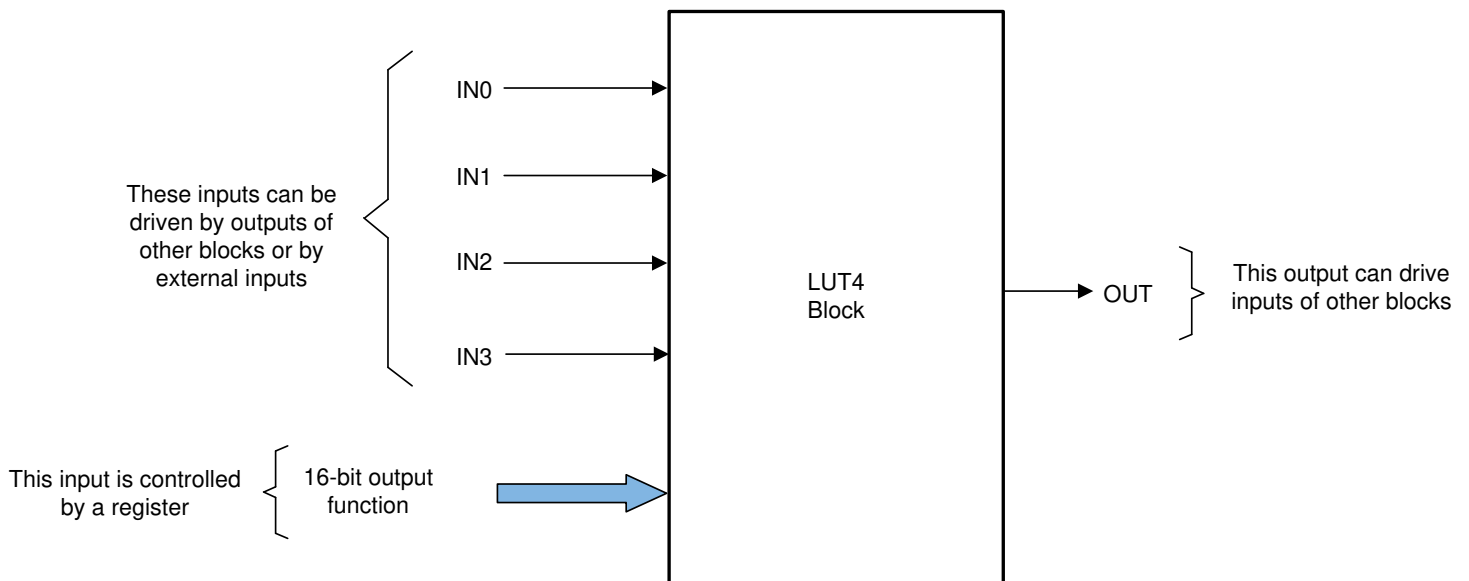

Figure 32-12. LUT4 Block

### 32.4.5 Output LUT Block

The output LUT block (Figure 32-13) is very similar in functionality to the LUT4 block, except that it has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence they cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in Section 32.8.

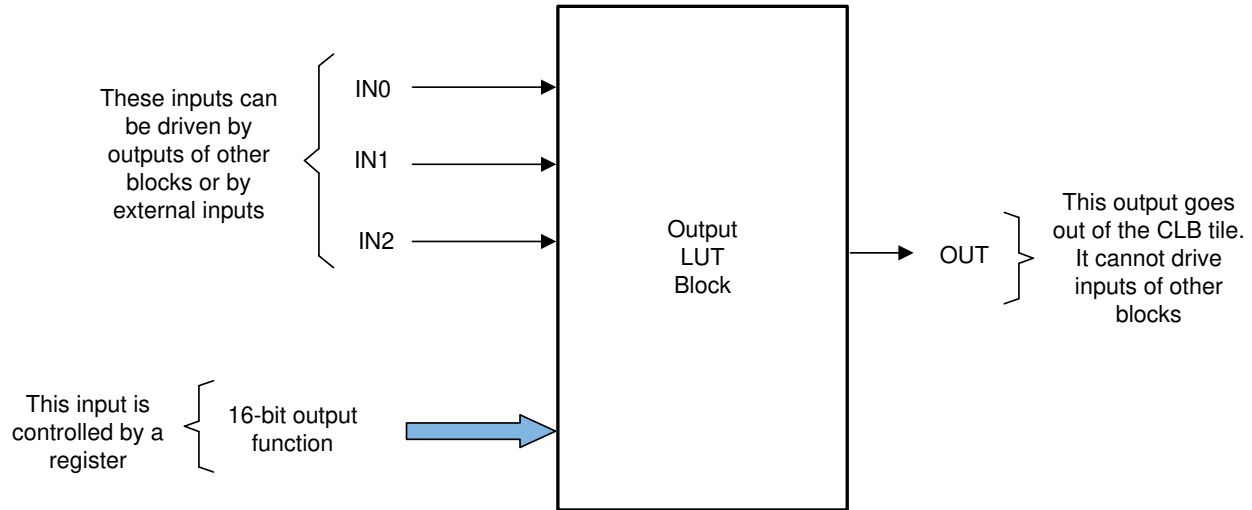

Figure 32-13. Output LUT Block

### 32.4.6 Asynchronous Output Conditioning (AOC) Block

The logic in the AOC block is organized into three stages with the inputs passing through different types of logic modification at each stage before proceeding to the next level. This is shown in Figure 32-14.

There are 8 inputs to this block. Each of these 8 inputs can pick the corresponding BOUNDARY input to the CLB or the CLB TILE output (for example the INPUT 0 of the AOC block can choose between CLB BOUNDARY INPUT0 and CLB TILE OUTPUT 0). If the CLB TILE OUTPUT 0 is selected, it is always registered before being sent to the subsequent asynchronous signal conditioning stages. In each of the three stages, there is always an option to do nothing and just send the signal as is to the next stage (bypass).

**Stage 1** : The input signal can be inverted before sending it to the next stage.

**Stage 2** : The signal coming from Stage 1 can be GATED with a gating control signal. The gating control signal can either be from a software register or can be any of the CLB TILE outputs. The GATING function can be a logical AND, OR or XOR.

**Stage 3** : The input signal can be used to either set or clear the output on the rising edge of the signal. This is a purely asynchronous set/clear that occurs without needing any clocks. The release control signal, when high, will restore the output to it's default state (HIGH if asynchronous clear is selected and LOW if asynchronous set is selected). The release control signal can be either from a software register or can be any of the CLB TILE outputs. Optionally, instead of any of the asynchronous set/clear operation, the input signal can just be delayed by a clock cycle.

The interaction of the CLB TILE and the AOC block is shown in Figure 32-15.

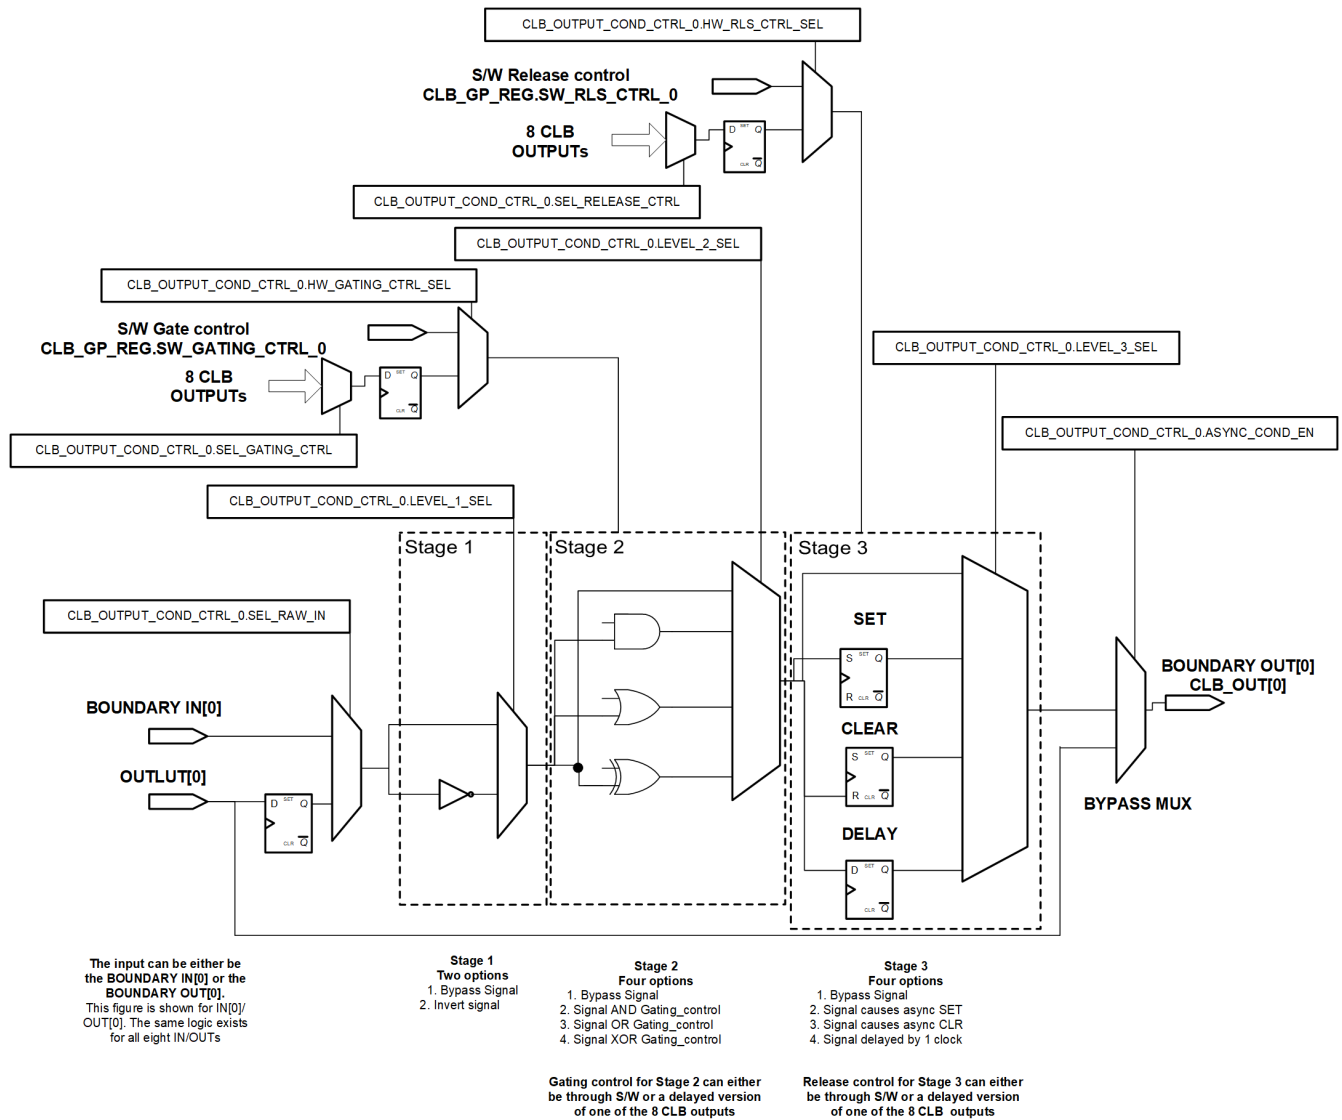

Figure 32-14. AOC Block

Figure 32-15. AOC Block and The CLB TILE

**Note**

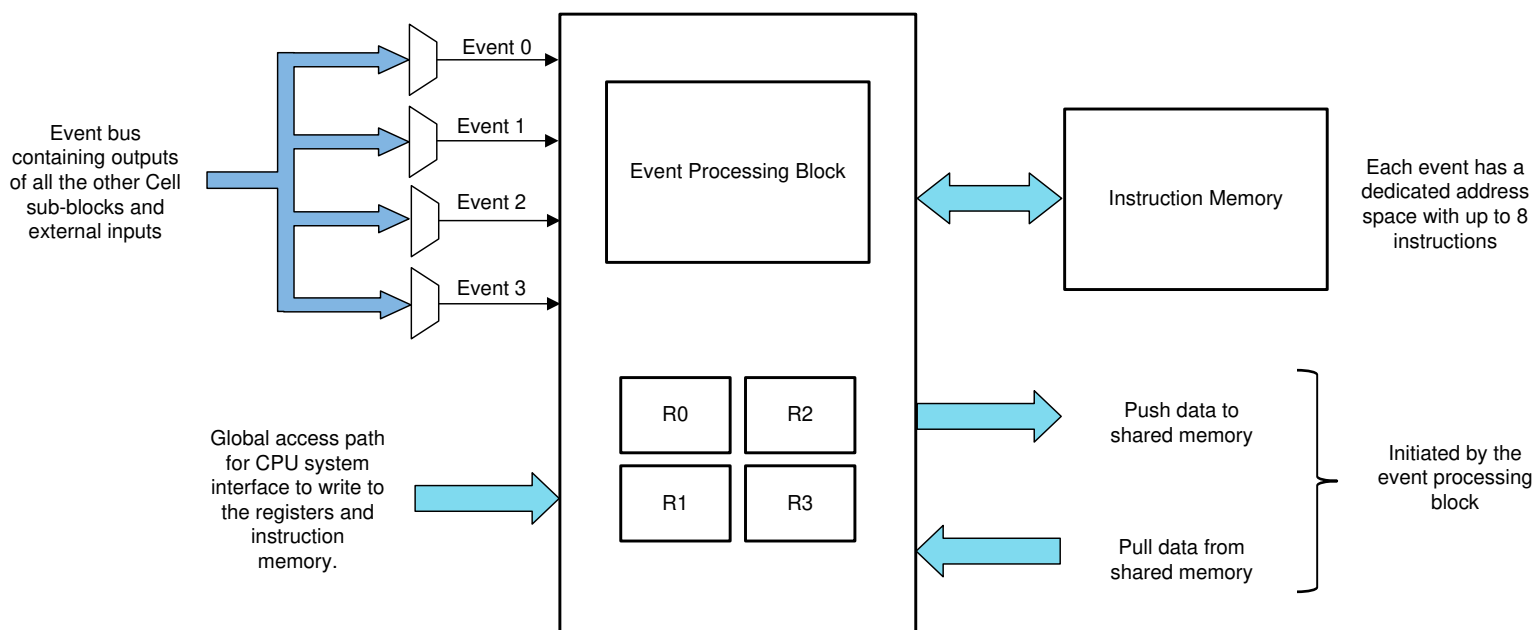

Only CLB\_OUT12 to CLB\_OUT15 can be used as ASYNC outputs. This is the same as CLB\_OUT4\_1 to CLB\_OUT7\_1. GPIO Output XBAR can be used to OUT4\_1 and OUT5\_1 ASYNC outputs to GPIOs.

### 32.4.7 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. It performs two main functions:

- Provides a means of communication and data exchange with the rest of the device.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in [Figure 32-16](#). It is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

**Figure 32-16. High Level Controller Block**

### 32.4.7.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in [Table 32-8](#). The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

**Table 32-8. HLC Event List**

| Index | HLC Event Mux     |
|-------|-------------------|
| 0     | Always '0'        |
| 1     | COUNTER_0 MATCH2  |
| 2     | COUNTER_0 ZERO    |
| 3     | COUNTER_0 MATCH1  |
| 4     | FSM_0 STATE_BIT_0 |
| 5     | FSM_0 STATE_BIT_1 |
| 6     | FSM_0 LUT output  |
| 7     | LUT4_0 output     |
| 8     | Always '1'        |
| 9     | COUNTER_1 MATCH2  |
| 10    | COUNTER_1 ZERO    |
| 11    | COUNTER_1 MATCH1  |
| 12    | FSM_1 STATE_BIT_0 |
| 13    | FSM_1 STATE_BIT_1 |
| 14    | FSM_1 LUT output  |
| 15    | LUT4_1 output     |
| 16    | Always '0'        |
| 17    | COUNTER_2 MATCH2  |
| 18    | COUNTER_2 ZERO    |
| 19    | COUNTER_2 MATCH1  |
| 20    | FSM_2 STATE_BIT_0 |
| 21    | FSM_2 STATE_BIT_1 |
| 22    | FSM_2 LUT output  |
| 23    | LUT4_2 output     |
| 24    | External Input 0  |
| 25    | External Input 1  |
| 26    | External Input 2  |
| 27    | External Input 3  |
| 28    | External Input 4  |
| 29    | External Input 5  |
| 30    | External Input 6  |
| 31    | External Input 7  |

### 32.4.7.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in [Table 32-9](#). An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences will each be executed sequentially in priority order.

**Table 32-9. HLC Instruction Address Ranges**

| Address        | Instructions for |
|----------------|------------------|
| 00000 to 00111 | Event 0          |
| 01000 to 01111 | Event 1          |
| 10000 to 10111 | Event 2          |
| 11000 to 11111 | Event 3          |

The HLC instruction format is shown in [Table 32-10](#).

**Table 32-10. HLC Instruction Format**

| Last Instruction Bit  | 5-Bit Opcode | 3-Bit Source  | 3-Bit Destination                              |
|---|--------------|---|--|
| This bit when set to 1 will stop execution after the current instruction. | MOV 00000    | Source can be R0, R1, R2, R3, C0, C1, C2.                                 | Destination can be R0, R1, R2, R3, C0, C1, C2. |
|   | MOV_T1 00001 |   |  |
|   | MOV_T2 00010 | Note that for ADD/SUB instructions, only R0 to R3 can be the destination. |  |
|   | PUSH 00011   |   |  |
|   | PULL 00100   |   |  |
|   | ADD 00101    |   |  |
|   | SUB 00110    |   |  |
| INTR 00111  |              |   |  |

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. [Table 32-11](#) describes the HLC instructions.

**Table 32-11. HLC Instruction Description**

| Instruction           | Description  |
|-----------------------|--|
| ADD <Src> <Dest>      | This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0 or R3.   |
| INTR <6-bit constant> | This instruction will flag an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG.   |
| MOV <Src> <Dest>      | This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2.   |
| MOV_T1 <Src> <Dest>   | This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are: <ul style="list-style-type: none"> <li>This instruction moves the count value in C1 into register R0:<br/>MOV_T1 C1 R0</li> <li>This instruction moves the value in R2 into the Match1 register of counter C0:<br/>MOV_T1 R2 C0</li> </ul> |
| MOV_T2 <Src> <Dest>   | This instruction is similar to MOV_T1. It moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2.   |

**Table 32-11. HLC Instruction Description (continued)**

| Instruction      | Description  |
|------------------|--|
| PULL <Dest>      | This instruction transfers data from to the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO. |
| PUSH <Src>       | This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.                            |
| SUB <Src> <Dest> | This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0 or R3.  |

### 32.4.7.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in [Table 32-12](#).

**Table 32-12. HLC Register Encoding**

| Bits | Register |
|------|----------|
| 000  | R0       |
| 001  | R1       |
| 010  | R2       |
| 011  | R3       |
| 100  | C0       |
| 101  | C1       |
| 110  | C2       |

### 32.4.7.4 Operation of the PUSH and PULL Instructions (overflow and underflow detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations will write to successive locations in a linearly mapped memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the registers section.

The CPU can read from and write to the PUSH and PULL buffers respectively, in order to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC will be written by the CPU to the PULL buffer and will be read by the HLC using the PULL instruction.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine their value. They are also writable and can be reset by the CPU can at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

## 32.5 CPU Interface

### 32.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses will be different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000 – 0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100 – 0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200 – 0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. They are accessible by normal memory mapped access and no EALLOW or LOCK protection exists.

---

#### Note

EALLOW protection means that the write access to the register will be enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see .

---

### 32.5.2 Non-Memory Mapped Registers

The memory mapped CLB registers are described later in this document; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory mapped. These registers are accessible through the two memory-mapped registers CLB\_LOAD\_DATA and CLB\_LOAD\_ADDR.

You load the data to be written into the CLB\_LOAD\_DATA register, then load the appropriate address into CLB\_LOAD\_ADDR to determine where this data is written. Writing a '1' to bit position 0 in the CLB\_LOAD\_EN register then causes an internal write operation to be triggered. The address allocation for the CLB\_LOAD\_ADDR register is shown in [Table 32-13](#).

**Table 32-13. Non-Memory Mapped Register Addresses**

| Address (Binary) | Resource                          |
|------------------|-----------------------------------|
| 000000 to 000010 | Counter 0 to 2 load value         |
| 000100 to 000110 | Counter 0 to 2 Match1 value       |
| 001000 to 001010 | Counter 0 to 2 Match2 value       |
| 001100 to 001111 | R0 to R3 of High Level controller |
| 100000 to 100111 | Instructions for Event 0          |
| 101000 to 101111 | Instructions for Event 1          |
| 110000 to 110111 | Instructions for Event 2          |
| 111000 to 111111 | Instructions for Event 3          |

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB\_LOAD\_DATA.
2. Write 0xc to CLB\_LOAD\_ADDR.
3. Write 0x1 to CLB\_LOAD\_EN.

#### Note

Even though HLC registers are accessible by the CPU, your application code needs to ensure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

## 32.6 CLB Data Export Through SPI RX Buffer

For a continuous export of data from the CLB peripherals, SPI RX buffers can be used. CLB data can be exported through the SPI RX buffers without CPU/CLA interventions.

For F28002x, CLB1 and CLB2 have access to SPIA and SPIB.

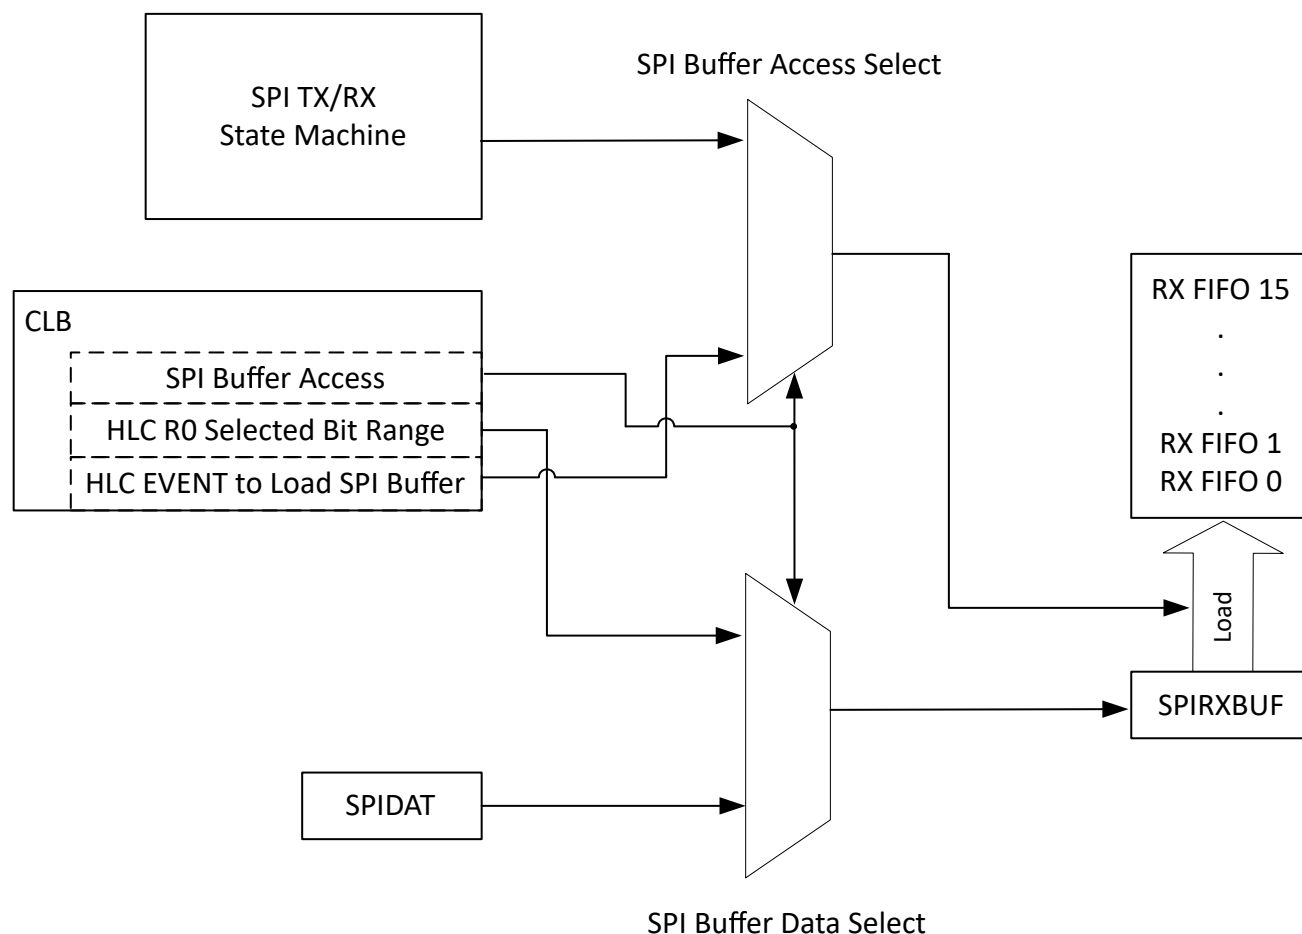

**Table 32-14. CLB to SPI RX Access**

| CLB Instance | SPI Instance |
|--------------|--------------|
| CLB1         | SPIA         |
| CLB2         | SPIB         |

When the CLB to SPI data exporting is enabled, 16-bit data can be exported from CLB to SPI RX buffers. The 32-bit HLC R0 register is the data which is exported to the SPI RX buffers. The user can select which 16-bit range of the HLC R0 is exported by configuring the **CLB\_SPI\_DATA\_CTRL\_HI.SHIFT**. The CLB also controls when HLC R0 data must be transferred to the SPI RX buffer through **CLB\_SPI\_DATA\_CTRL\_HI.STRB** that selects one of the HLC event signals from the static switch block.

When CLB to SPI data exporting is required, it is important to note:

- The selected SPI transmit functionality is not affected.
- Even though the data is being pushed into the SPI RX buffers by the CLB, the SPI RX interrupt and the DMA trigger for SPI RX in the respective peripherals must be configured.
- The SPI can resume normal operation when the CLB to SPI data exporting is disabled.

**Figure 32-17. CLB Control of SPI RX Buffer**

## 32.7 Software

### 32.7.1 CLB Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/clb

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 32.7.1.1 CLB Timer Two States

FILE: clb\_ex10\_timer\_two\_states.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.2 CLB Interrupt Tag

FILE: clb\_ex11\_interrupt\_tag.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.3 CLB Output Intersect

FILE: clb\_ex12\_output\_intersect.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.4 CLB PUSH PULL

FILE: clb\_ex13\_push\_pull.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.5 CLB Multi Tile

FILE: clb\_ex14\_multi\_tile.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.6 CLB Glue Logic

FILE: clb\_ex16\_glue\_logic.c

For the detailed description of this example, please refer to :  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.7 CLB based One-shot PWM

FILE: clb\_ex17\_one\_shot\_pwm.c

For the detailed description of this example, please refer to :  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 32.7.1.8 CLB AOC Control

FILE: clb\_ex18\_aoc.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.9 CLB AOC Release Control**

FILE: clb\_ex19\_aoc\_release\_control.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.10 CLB Combinational Logic**

FILE: clb\_ex1\_combinatorial\_logic.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.11 CLB XBARs**

FILE: clb\_ex20\_clxbars.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.12 CLB AOC Control**

FILE: clb\_ex21\_clockprescalar\_nmi.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.13 CLB Serializer**

FILE: clb\_ex22\_serializer.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.14 CLB LFSR**

FILE: clb\_ex23\_lfsr.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.15 CLB Lock Output Mask**

FILE: clb\_ex24\_lock\_output\_mask.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.16 CLB INPUT Pipeline Mode**

FILE: clb\_ex25\_input\_pipeline.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.17 CLB Clocking and PIPELINE Mode**

FILE: clb\_ex26\_clocking\_pipeline.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

**32.7.1.18 CLB SPI Data Export**

FILE: clb\_ex27\_spi\_data\_export.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.19 CLB SPI Data Export DMA

FILE: clb\_ex28\_spi\_data\_export\_dma.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.20 CLB Trip Zone Timestamp

FILE: clb\_ex29\_timestamp.c

This example displays how to timestamp interrupts generated by the CLB. An interrupt is generated when ePWM1 is tripped.

ePWM1 is configured to be interrupted by TZ1 and TZ2, both one shot trip sources.

The CLB is configured as follows:

- COUNTER0 and COUNTER1 continually count when the program begins.
- COUNTER0 timestamps TZ1 and COUNTER1 timestamps TZ2.
- COUNTER2 increments once when COUNTER0/COUNTER1 overflows using LUT2.
- FSM0/1 are configured to sync counters and stop COUNTER0/1 when an interrupt is received.
- TZ1 (GPIO12) and TZ2 (GPIO13) are routed as inputs through CLBXBAR.
- BOUNDARY.in0 denotes TZ1. On rising edge, HLC issues an interrupt with tag 12.
- BOUNDARY.in1 denotes TZ2. On rising edge, HLC issues an interrupt with tag 13.
- BOUNDARY.in7 serves as a simultaneous enable for COUNTER0/1 to begin counting.

TZ1 is tripped when GPIO12 is connected to GND. TZ2 is tripped when GPIO13 is connected to GND. When an interrupt occurs, the interrupt handler determines the initial trip source and stores this value in a variable 'initialTripZone'.

View these variables in Debug Expressions tab:

initialTripZone: stores the first TZ to have been tripped  
tz1Counter64bit: stores the counter value at the instant that TZ1 is tripped.  
tz2Counter64bit: stores the counter value at the instant that TZ2 is tripped.

### 32.7.1.21 CLB GPIO Input Filter

FILE: clb\_ex2\_gpio\_input\_filter.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.22 CLB Auxiliary PWM

FILE: clb\_ex3\_auxiliary\_pwm.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.23 CLB PWM Protection

FILE: clb\_ex4\_pwm\_protection.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.24 CLB Event Window

FILE: clb\_ex5\_event\_window.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.25 CLB Signal Generator

FILE: clb\_ex6\_siggen.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.26 CLB State Machine

FILE: clb\_ex7\_state\_machine.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.27 CLB External Signal AND Gate

FILE: clb\_ex8\_external\_signal\_AND\_gate.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.28 CLB Timer

FILE: clb\_ex9\_timer.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

### 32.7.1.29 CLB Empty Project

FILE: empty.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

## 32.8 CLB Registers

This section describes the Configurable Logic Block Registers.

### 32.8.1 CLB Base Address Table

**Table 32-15. CLB Base Address Table**

| Bit Field Name    |                        | DriverLib Name      | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|-------------------|------------------------|---------------------|--------------|------|-----|-----|-----|--------------------|
| Instance          | Structure              |                     |              |      |     |     |     |                    |

**Table 32-16. CLB\_LOGIC\_CONFIG\_REGS Registers (continued)**

| Offset | Acronym              | Register Name                  | Write Protection | Section            |
|--------|----------------------|--------------------------------|------------------|--------------------|
| 51h    | CLB_SPI_DATA_CTRL_HI | CLB to SPI buffer control High | EALLOW, LOCK     | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. [Table 32-17](#) shows the codes that are used for access types in this section.

**Table 32-17. CLB\_LOGIC\_CONFIG\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| R-0                      | R-0  | Read<br>Returns 0s   |
| Write Type               |      |  |
| W                        | W    | Write  |
| W1C                      | W1C  | Write<br>1 to clear  |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 32.8.2.1 CLB\_COUNT\_RESET Register (Offset = 2h) [Reset = 0h]

CLB\_COUNT\_RESET is shown in [Figure 32-18](#) and described in [Table 32-18](#).

Return to the [Summary Table](#).

Counter Block RESET

**Figure 32-18. CLB\_COUNT\_RESET Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |        |    |    |        |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|--------|----|----|--------|---|---|---|---|---|---|---|---|---|---|

### 32.8.3 CLB\_LOGIC\_CONTROL\_REGS Registers

Table 32-58 lists the memory-mapped registers for the CLB\_LOGIC\_CONTROL\_REGS registers. All register offset addresses not listed in Table 32-58 should be considered as reserved locations and the register contents should not be modified.

**Table 32-58. CLB\_LOGIC\_CONTROL\_REGS Registers**

| Offset | Acronym                | Register Name  | Write Protection   | Section            |
|--------|------------------------|--|--|--------------------|
| 0h     | CLB_LOAD_EN            | Global enable & indirect load enable control                     | EALLOW, LOCK<br>(only Global Enable Bit is LOCK protected) | <a href="#">Go</a> |
| 2h     | CLB_LOAD_ADDR          | Indirect address   |  | <a href="#">Go</a> |
| 4h     | CLB_LOAD_DATA          | Data for indirect loads  |  | <a href="#">Go</a> |
| 6h     | CLB_INPUT_FILTER       | Input filter selection for both edge detection and synchronizers | LOCK   | <a href="#">Go</a> |
| 8h     | CLB_IN_MUX_SEL_0       | Input selection to decide between Signals and GP register        | LOCK   | <a href="#">Go</a> |
| Ah     | CLB_LCL_MUX_SEL_1      | Input Mux selection for local mux                                | LOCK   | <a href="#">Go</a> |
| Ch     | CLB_LCL_MUX_SEL_2      | Input Mux selection for local mux                                | LOCK   | <a href="#">Go</a> |
| Eh     | CLB_BUF_PTR            | PUSH and PULL pointers   |  | <a href="#">Go</a> |
| 10h    | CLB_GP_REG             | General purpose register for CELL inputs                         |  | <a href="#">Go</a> |
| 12h    | CLB_OUT_EN             | CELL output enable register                                      |  | <a href="#">Go</a> |
| 14h    | CLB_GLBL_MUX_SEL_1     | Global Mux select for CELL inputs                                | LOCK   | <a href="#">Go</a> |
| 16h    | CLB_GLBL_MUX_SEL_2     | Global Mux select for CELL inputs                                | LOCK   | <a href="#">Go</a> |
| 18h    | CLB_PRESCALE_CTRL      | Prescaler register control                                       | LOCK   | <a href="#">Go</a> |
| 20h    | CLB_INTR_TAG_REG       | Interrupt Tag register   |  | <a href="#">Go</a> |
| 22h    | CLB_LOCK               | Lock control register  | EALLOW   | <a href="#">Go</a> |
| 24h    | CLB_HLC_INSTR_READ_PTR | HLC instruction read pointer                                     |  | <a href="#">Go</a> |
| 26h    | CLB_HLC_INSTR_VALUE    | HLC instruction read value                                       |  | <a href="#">Go</a> |
| 2Eh    | CLB_DBG_OUT_2          | Visibility for CLB inputs and final asynchronous outputs         |  | <a href="#">Go</a> |
| 30h    | CLB_DBG_R0             | R0 of High level Controller                                      |  | <a href="#">Go</a> |
| 32h    | CLB_DBG_R1             | R1 of High level Controller                                      |  | <a href="#">Go</a> |
| 34h    | CLB_DBG_R2             | R2 of High level Controller                                      |  | <a href="#">Go</a> |
| 36h    | CLB_DBG_R3             | R3 of High level Controller                                      |  | <a href="#">Go</a> |
| 38h    | CLB_DBG_C0             | Count of Unit 0  |  | <a href="#">Go</a> |
| 3Ah    | CLB_DBG_C1             | Count of Unit 1  |  | <a href="#">Go</a> |
| 3Ch    | CLB_DBG_C2             | Count of Unit 2  |  | <a href="#">Go</a> |
| 3Eh    | CLB_DBG_OUT            | Outputs of various units in the Cell                             |  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 32-59 shows the codes that are used for access types in this section.

**Table 32-59. CLB\_LOGIC\_CONTROL\_REGS Access Type Codes**

| Access Type | Code | Description        |
|-------------|------|--------------------|
| Read Type   |      |                    |
| R           | R    | Read               |
| R-0         | R-0  | Read<br>Returns 0s |

**Table 32-59. CLB\_LOGIC\_CONTROL\_REGS Access Type Codes (continued)**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| R-1                      | R<br>-1    | Read<br>Returns 1s   |
| Write Type               |            |  |
| W                        | W          | Write  |
| W1C                      | W<br>1C    | Write<br>1 to clear  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 32.8.3.1 CLB\_LOAD\_EN Register (Offset = 0h) [Reset = 0h]

CLB\_LOAD\_EN is shown in [Figure 32-58](#) and described in [Table 32-60](#).

Return to the [Summary Table](#).

Global enable & indirect load enable control

**Figure 32-58. CLB\_LOAD\_EN Register**

|          |    |    |             |        |        |           |         |
|----------|----|----|-------------|--------|--------|-----------|---------|
| 15       | 14 | 13 | 12          | 11     | 10     | 9         | 8       |
| RESERVED |    |    |             |        |        |           |         |
| R-0h     |    |    |             |        |        |           |         |
| 7        | 6  | 5  | 4           | 3      | 2      | 1         | 0       |
| RESERVED |    |    | PIPELINE_EN | NMI_EN | STOP   | GLOBAL_EN | LOAD_EN |
| R-0h     |    |    | R/W-0h      | R/W-0h | R/W-0h | R/W-0h    | R/W-0h  |

**Table 32-60. CLB\_LOAD\_EN Register Field Descriptions**

| Bit  | Field       | Type | Reset | Description   |
|------|-------------|------|-------|---|
| 15-5 | RESERVED    | R    | 0h    | Reserved  |
| 4    | PIPELINE_EN | R/W  | 0h    | This bit controls pipelining of all the CLB operations in HLC and Counter blocks. Pipelined operation is enabled when this bit is set to 1.<br>Reset type: SYSRSn   |
| 3    | NMI_EN      | R/W  | 0h    | This bit controls the generation of NMI along with the interrupt whenever a INTR operation is executed by the HLC. NMI generation is disabled by default. It will be enabled when this bit is set to 1.<br>Reset type: SYSRSn                         |
| 2    | STOP        | R/W  | 0h    | This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored.<br>Reset type: SYSRSn  |
| 1    | GLOBAL_EN   | R/W  | 0h    | This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected.<br>Reset type: SYSRSn |
| 0    | LOAD_EN     | R/W  | 0h    | A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL.<br>Reset type: SYSRSn   |

### 32.8.3.2 CLB\_LOAD\_ADDR Register (Offset = 2h) [Reset = 0h]

CLB\_LOAD\_ADDR is shown in [Figure 32-59](#) and described in [Table 32-61](#).

Return to the [Summary Table](#).

Indirect address

**Figure 32-59. CLB\_LOAD\_ADDR Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| Bit   | Field    | Type | Reset | Description  |
|-------|----------|------|-------|--|
| 31-16 | PRESCALE | R/W  | 0h    | 16-bit Value of prescaler to be used for the counter as reference to reset when reaching this value.<br>The counter is a simple incrementing counter which will count up to the reference value and reset to 0 and this cycle will continue as long as the counter is enabled.<br>This 16-bit register value is used as a reference for the 16-bit counter to reset to zero whenever count reaches this value.<br>Reset type: SYSRSn |
| 15-6  | RESERVED | R    | 0h    | Reserved   |
| 5-2   | TAP      | R/W  | 0h    | TAP Select value. These 4 bits will be used as a select to tap one of the 16 register bit position of the counter as the output.<br>0000 selects Counter Bit position 0<br>0001 selects Counter Bit position 1<br>....<br>1111 selects Counter Bit position 15<br>Reset type: SYSRSn   |
| 1     | STRB     | R/W  | 0h    | When set to 0, a strobe output will be sent out whenever the counter value matches the PRESCALE_VALUE.<br>When set to 1, the output of the counter register bit position as selected by TAP_SELECT_VALUE will be sent out.<br>Reset type: SYSRSn   |
| 0     | CLKEN    | R/W  | 0h    | Enable the prescale clock/strobe generator.<br>A 16-bit counter is used to either generate a strobe or send out a selected counter bit position to the CLB CELL. This is meant to be a general purpose strobe/prescaled clock which can be used by the CELL logic if needed. This will be sent to the CELL through one of the LCL_IN MUX ports.<br>Reset type: SYSRSn  |

### 32.8.3.14 CLB\_INTR\_TAG\_REG Register (Offset = 20h) [Reset = 0h]

CLB\_INTR\_TAG\_REG is shown in [Figure 32-71](#) and described in [Table 32-73](#).

Return to the [Summary Table](#).

Interrupt Tag register

**Figure 32-71. CLB\_INTR\_TAG\_REG Register**

|          |    |    |    |        |    |   |   |
|----------|----|----|----|--------|----|---|---|
| 15       | 14 | 13 | 12 | 11     | 10 | 9 | 8 |
| RESERVED |    |    |    |        |    |   |   |
| R-0h     |    |    |    |        |    |   |   |
| 7        | 6  | 5  | 4  | 3      | 2  | 1 | 0 |
| RESERVED |    |    |    | TAG    |    |   |   |
| R-0h     |    |    |    | R/W-0h |    |   |   |

**Table 32-73. CLB\_INTR\_TAG\_REG Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 15-6 | RESERVED | R    | 0h    | Reserved   |
| 5-0  | TAG      | R/W  | 0h    | 6 bits which are used by the High Level Controller to set a tag value on flagging interrupts. . This can be cleared through the VBUS interface since it is writeable through the VBUS.<br>Reset type: SYSRSn |

### 32.8.3.15 CLB\_LOCK Register (Offset = 22h) [Reset = 0h]

CLB\_LOCK is shown in [Figure 32-72](#) and described in [Table 32-74](#).

Return to the [Summary Table](#).

Lock control register

**Figure 32-72. CLB\_LOCK Register**

|           |    |    |    |    |    |    |        |
|-----------|----|----|----|----|----|----|--------|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24     |
| KEY       |    |    |    |    |    |    |        |
| WSonce-0h |    |    |    |    |    |    |        |
| 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16     |
| KEY       |    |    |    |    |    |    |        |
| WSonce-0h |    |    |    |    |    |    |        |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8      |

### 32.8.4 CLB\_DATA\_EXCHANGE\_REGS Registers

Table 32-86 lists the memory-mapped registers for the CLB\_DATA\_EXCHANGE\_REGS registers. All register offset addresses not listed in Table 32-86 should be considered as reserved locations and the register contents should not be modified.

**Table 32-86. CLB\_DATA\_EXCHANGE\_REGS Registers**

| Offset           | Acronym    | Register Name                      | Write Protection | Section            |
|------------------|------------|------------------------------------|------------------|--------------------|
| 0h +<br>formula  | CLB_PUSH_y | CLB_PUSH FIFO Registers (from HLC) |                  | <a href="#">Go</a> |
| 40h +<br>formula | CLB_PULL_y | CLB_PULL FIFO Registers (TO HLC)   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 32-87 shows the codes that are used for access types in this section.

**Table 32-87. CLB\_DATA\_EXCHANGE\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Write Type               |      |  |
| W                        | W    | Write  |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 32.8.4.1 CLB\_PUSH\_y Register (Offset = 0h + formula) [Reset = 0h]

CLB\_PUSH\_y is shown in [Figure 32-84](#) and described in [Table 32-88](#).

Return to the [Summary Table](#).

CLB\_PUSH FIFO Registers (from HLC)

Offset = 0h + (y \* 2h); where y = 0h to 3h

**Figure 32-84. CLB\_PUSH\_y Register**

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14   | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | PUSH |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | R-0h |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 33.1 Introduction

This section introduces the advanced encryption standard (AES) and describes the AES main functions and connections in the device.

The AES module provides hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-, 192-, or 256-bit key in hardware for encryption and decryption. The AES module is based on a symmetric algorithm, which means that the encryption and decryption keys are identical. To encrypt data means to convert it from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data to its original plain text form. The main features of the AES accelerator are:

AES encrypt and decrypt operations are supported by:

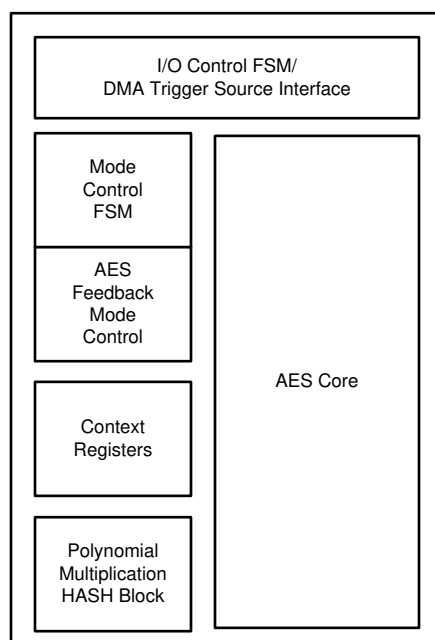

- Galois/Counter mode (GCM), with basic GHASH operation
- Counter mode with CBC-MAC (CCM)
- XTS mode

The following feedback operating modes are available:

- Electronic code book mode (ECB)
- Cipher block chaining mode (CBC)
- Counter mode (CTR)
- Cipher feedback mode (CFB), 128-bit
- F8 mode
- Key sizes: 128, 192, and 256 bits
- Support for CBC\_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for  $\mu$ DMA transfers
- Fully synchronous design

#### 33.1.1 AES Block Diagram

Figure 33-1 shows the AES block diagram. A single-core or dual-interface architecture is used.

**Figure 33-1. AES Block Diagram**

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, according to the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string: {0 120}||10000111. The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers, so that it can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O control FSM/ $\mu$ DMA request interface.

AES comprises the following major functional blocks:

- Global control FSM and  $\mu$ DMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption or decryption operation
- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2<sup>8</sup>) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32, 38, and 44 clock cycles, respectively, because {number of clock cycles} = 2 + 3 × {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds, and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one ECB core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128, 192, or 256 bits), this core requires 32, 38, or 44 clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, when the pipeline is full, sequential data blocks can be passed every 32, 38, or 44 clock cycles.

### 33.1.1.1 Interfaces

The interface signals to the AES module can be grouped into the following categories:

- Clock enable
- DMA and interrupt interface, used to request new context and packet data or to indicate available result data (encrypted or decrypted data, or authentication result)
- Functional register interface

### 33.1.1.2 AES Subsystem

The AES subsystem interfaces with the DMA module as shown in [Table 33-1](#). Input/output context and data ports from the AES directly feed to the DMA trigger source. Two interrupt registers are included, AES\_GLB\_INT\_FLG and AES\_GLB\_INT\_CLR. AES\_GLB\_INT\_FLG, that provide the status of the secure interrupt generated by the AES while AES\_GLB\_INT\_CLR clears the flag. AES only allows word access. Non-word access (not 32-bit) generates an interrupt and is aggregated in SYS\_ERR.

**Table 33-1. AES Subsystem DMA Interface**

| Request        | DMA Trigger Source |
|----------------|--------------------|
| Context Output | AES_ContextIn      |
| Context Input  | AES_ContextOut     |
| Data Output    | AES_DataOut        |
| Data Input     | AES_DataIn         |

### 33.1.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core follows:

#### AES Key Scheduler

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated arbitrarily and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so it can generate the subkeys in reverse order.

#### AES Encryption Core

The AES encryption core implements the Rijndael algorithm as specified in [FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

#### AES Decryption Core

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

#### AES Feedback Mode Block

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the NIST-SP800-38A specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with  $m$  set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly  $j$ , but  $\alpha^j$ , where  $\alpha = x^2$  in the  $GF(2^{128})$  domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

## GHASH Block

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve optimal performance.

### 33.1.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES keys can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits. The block length is represented by  $N_b = 4$ , which reflects the number of 32-bit words.
- The length of the cipher key ( $K$ ) is 128, 192, or 256 bits. The key length is represented by  $N_k = 4, 6, \text{ or } 8$ , which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm depends on the key size. The number of rounds is represented by  $N_r$ , where  $N_r = 10$  when  $N_k = 4$  (128-bit key);  $N_r = 12$  when  $N_k = 6$  (192-bit key); and  $N_r = 14$  when  $N_k = 8$  (256-bit key).

Table 33-2 lists the combinations of keys, blocks, and rounds.

**Table 33-2. Key-Block-Round Combinations**

| Key      | Key Length ( $N_k$ ) | Block Size ( $N_b$ ) | Number of Rounds ( $N_r$ ) |
|----------|----------------------|----------------------|----------------------------|
| 128 bits | 4                    | 4                    | 10                         |
| 192 bits | 6                    | 4                    | 12                         |
| 256 bits | 8                    | 4                    | 14                         |

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box): This transformation is a nonlinear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of  $[4 \times N_k]$  bytes) using an S-Box. This S-Box transformation is reversible.
- Shifting rows of the state array by different offsets: In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ( $\textcircled{0}$ ) is not shifted.
- Mixing the data within each column of the state array: This transformation operates on the state column-by-column, treating each column as a 4-term polynomial. The columns are considered polynomials over  $GF(2^8)$  and multiplied modulo  $x^4 + 1$  with a fixed polynomial  $a(x)$ .
- Adding a round key to the state: In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of  $N_b$  words from the key schedule.

The AES algorithm takes the cipher key ( $K$ ) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of  $N_b \times (N_r + 1)$  words: The algorithm requires an initial set of  $N_b$  words, and each  $N_r$  round requires  $N_b$  words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted  $[w_i]$ , with  $i$  in the range  $0 \leq i \leq N_b \times (N_r + 1)$ .

## 33.2 AES Operating Modes

### 33.2.1 GCM Operation

Figure 33-2 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see [Section 33.3.1](#).

**Figure 33-2. AES - GCM Operation**

### 33.2.2 CCM Operation

Figure 33-3 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

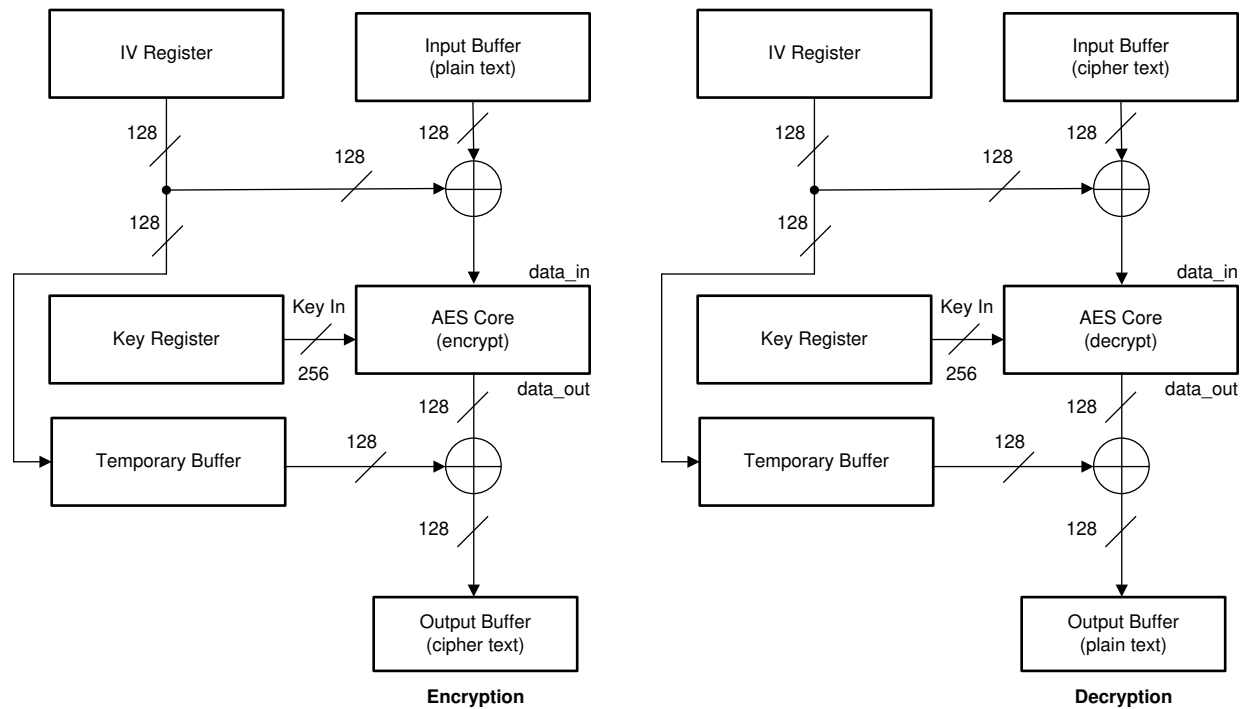

Figure 33-3. AES - CCM Operation

### 33.2.3 XTS Operation

Figure 33-4 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

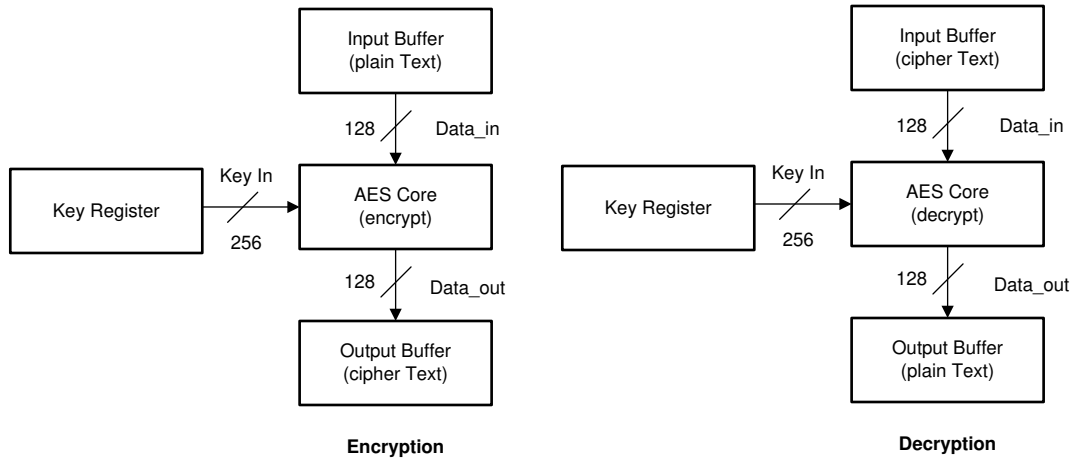

**Figure 33-4. AES - XTS Operation**

#### Note

The IV is created with an initial encryption, followed by an LFSR operation for each new block.

### 33.2.4 ECB Feedback Mode

Figure 33-5 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer. For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

**Figure 33-5. AES - ECB Feedback Mode**

### 33.2.5 CBC Feedback Mode

Figure 33-6 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

Figure 33-6. AES - CBC Feedback Mode

### 33.2.6 CTR and ICM Feedback Modes

Figure 33-7 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

**Figure 33-7. AES Encryption With CTR/ICM Mode**

#### Note

The value for n can be 1, 2, 3, or 4 for CTR mode and is ½ for ICM mode.

### 33.2.7 CFB Mode

Figure 33-8 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

**Figure 33-8. AES - CFB Feedback Mode**

### 33.2.8 F8 Mode

Figure 33-9 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

**Figure 33-9. AES - F8 Mode**

### 33.2.9 F9 Operation

Figure 33-10 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

**Figure 33-10. AES - F9 Operation**

### 33.2.10 CBC-MAC Operation

Figure 33-11 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

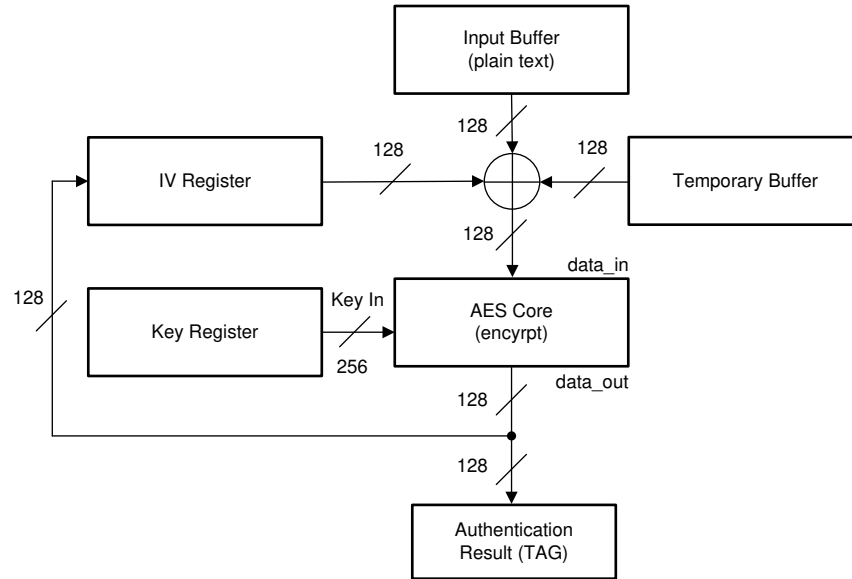

Figure 33-11. AES - CBC-MAC Authentication Mode

### 33.3 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

#### 33.3.1 GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted or decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption, decryption, and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit-long vector and finally encrypt the authentication result.

#### 33.3.2 CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. The authentication and encryption or decryption operations use the cryptographic core; these operations are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption or decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

## 33.4 AES Module Programming Guide

### 33.4.1 AES Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES module.

#### 33.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and associated modules.

1. Configure the DMA Trigger Source corresponding to AES. For more information, refer to the DMA chapter.
2. Specify the size of the keys by programming the KEY\_SIZE bit field in the AES\_CTRL register.
3. Load the AES Key 1 (AES\_KEY1\_n) register.
4. Load the AES Key 2 (AES\_KEY2\_n) register if it is used by the configuration mode.
5. Configure the AES for the appropriate encryption or decryption mode (see [Section 33.4.1.2](#)).
6. Select encryption or decryption by programming the DIRECTION bit in the AES Control (AES\_CTRL) register.

#### 33.4.1.2 AES Operating Modes Configuration

The following sections list the initialization subsequences for the available encryption and decryption modes:

##### Subsequence: Initialize CCM AES Core Mode

The steps to initialize CCM mode follow:

1. Define the width of the length field and the length of the authentication field by programming the CCM\_L and CCM\_M bit fields in the AES\_CTRL register.
2. Enable counter mode by setting the CTR bit in the AES\_CTRL register.
3. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES\_AUTH\_LENGTH) register.
4. Select the IV counter by programming the CTR\_WIDTH field in the AES\_CTRL register.
5. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

##### Subsequence: Initialize GCM AES Core Mode

The steps to enable GCM mode follow:

1. Enable counter mode by setting the CTR bit in the AES\_CTRL register.
2. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES\_AUTH\_LENGTH) register.
3. Select the IV counter by programming the CTR\_WIDTH field in the AES\_CTRL register.
4. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CBC-MAC AES Core Mode**

The steps to initialize CBC-MAC mode follow:

1. Enable CBC-MAC mode by setting the CBCMAC bit in the AES\_CTRL register.
2. Select encryption mode by setting the DIRECTION bit in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize F9 AES Core Mode**

The steps to configure the AES for F9 mode follow:

1. Enable F9 mode by setting the F9 bit in the AES\_CTRL register.
2. Set the key size to 128 bits by programming the KEY\_SIZE field to 0x1 in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize F8 AES Core Mode**

The steps to configure the AES for F8 mode follow:

1. Enable F8 mode by setting the F8 bit in the AES\_CTRL register.
2. Select the counter width by programming the CTR\_WIDTH field in the AES\_CTRL register.
3. Set the key size to 128 bits by setting the KEY\_SIZE field to 0x1 in the AES\_CTRL register.
4. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize XTS AES Core Mode**

The steps to configure XTS mode follow:

1. Enable XTS mode by configuring the XTS field in the AES\_CTRL register.
2. If the XTS field in the AES\_CTRL register indicates that the AAD length is required, load the AAD length in the AES\_AUTH\_LENGTH register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CFB AES Core Mode**

The steps to initialize the AES code for CFB mode follow:

1. Enable CFB mode by setting the CFB bit in the AES\_CTRL register.
2. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize ICM AES Core Mode**

The steps to initialize the AES code for ICM mode follow:

1. Enable ICM mode by setting the ICM bit in the AES\_CTRL register.
2. Configure for a 16-bit counter by programming the CTR\_WIDTH field to 0x0 in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CTR AES Core Mode**

The steps to initialize CTR mode follow:

1. Enable CTR mode by setting the CTR bit in the AES\_CTRL register.
2. Select counter width by programming the CTR\_WIDTH in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CBC AES Core Mode**

The steps to configure CBC mode follow:

1. Enable CBC mode by setting the MODE bit in the AES\_CTRL register.
2. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

### 33.4.1.3 AES Mode Configurations

#### AES Polling Mode

Main Sequence: AES Polling Mode – Figure 33-12 shows AES polling mode. The registers used in AES polling mode follow:

- AES Data RW Plaintext/Ciphertext 0 (AES\_DATA\_IN\_OUT\_0) registers
- AES Control (AES\_CTRL) register
- AES Hash Tag Out 0 (AES\_TAG\_OUT\_0) register

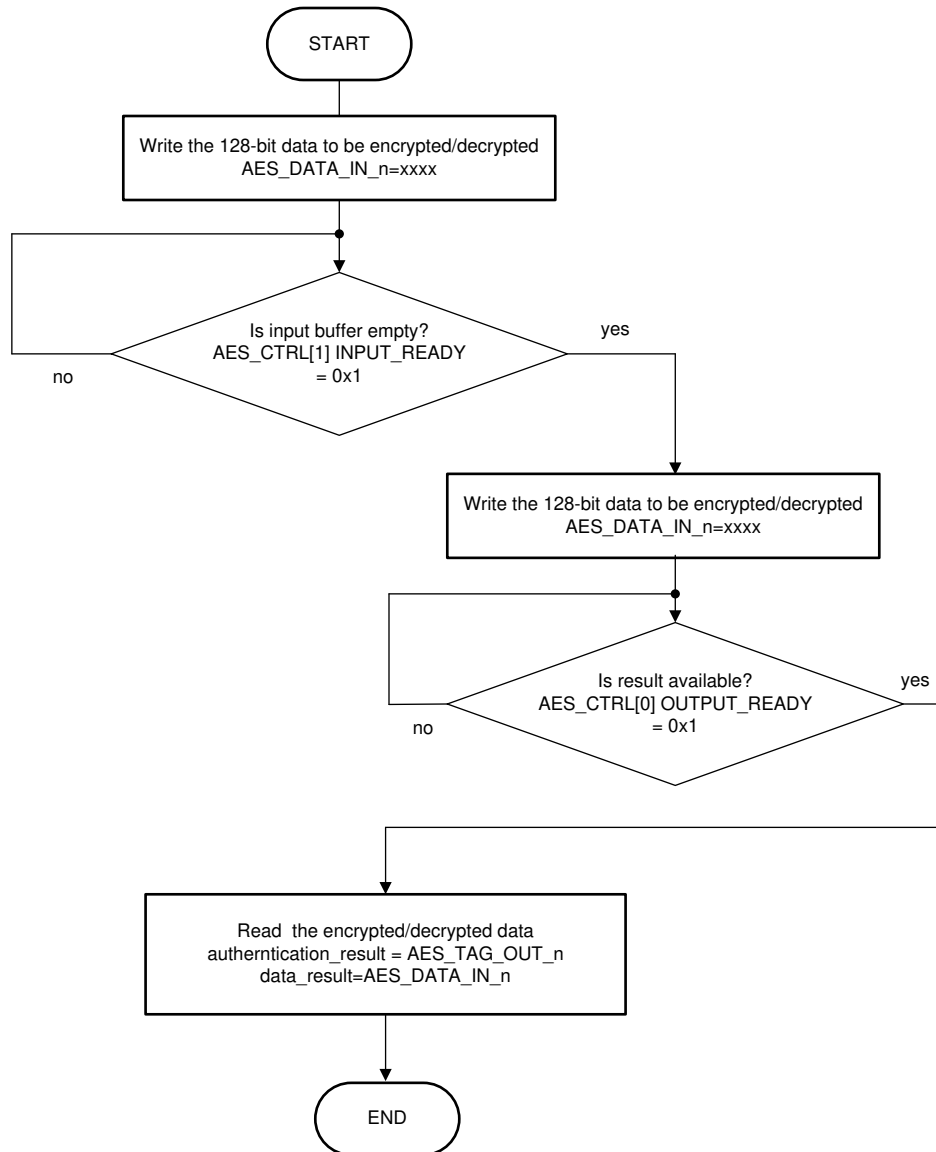

Figure 33-12. AES Polling Mode

## AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts

1. First, initialize the device by following the initialization sequences described in [Section 33.4.1.1](#) and [Section 33.4.1.2](#).
2. When the device has been initialized, the application can enable the AES module interrupts through the AES Interrupt Enable (AES\_IRQENABLE) register.
3. Load the input buffers, AES\_DATA\_IN\_OUT\_n, with data.

---

### Note

If the application uses interrupt mode, an interrupt is generated for each block of processed data. To support larger data flow, DMA access mode should be used and the bits in the AES\_IRQENABLE register should be cleared.

---

## AES DMA Mode

When AES DMA mode is enabled, the AES\_IRQENABLE register should be cleared. To enable the DMA to transfer data, follow these steps:

1. When the AES module is initialized, configure DMA sources and channels. Refer to the DMA chapter for the associated AES sources.
2. Configure the corresponding DMA enable and request bits in the AES System Configuration (AES\_SYSCONFIG) register.

The input buffer registers, AES\_DATA\_IN\_OUT\_n, are now loaded.

### 33.4.1.4 AES Events Servicing

#### Interrupt Servicing

This section describes the event servicing of the module. Figure 33-13 shows the AES interrupt service. The registers used during event servicing follow:

- AES\_IRQSTATUS
- AES\_KEY1\_n
- AES\_KEY2\_n
- AES\_IV\_IN\_n
- AES\_DATA\_IN\_OUT\_n
- AES\_TAG\_OUT\_n
- AES\_IRQENABLE

Figure 33-13. AES Interrupt Service

## 33.5 Software

### 33.5.1 AES Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/f28003x/examples/aes

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 33.5.1.1 AES ECB Encryption Example (CM)

FILE: aes\_ex1\_ecb\_encrypt.c

This example encrypts block cipher-text using AES128 in ECB mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

##### External Connections

- None

##### Watch Variables

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

#### 33.5.1.2 AES ECB De-cryption Example (CM)

FILE: aes\_ex2\_ecb\_decrypt.c

This example de-crypts block cipher-text using AES128 in ECB mode. It does the de-cryption first without uDMA and then with uDMA. The results are checked after each operation.

##### External Connections

- None

##### Watch Variables

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

#### 33.5.1.3 AES GCM Encryption Example (CM)

FILE: aes\_ex3\_gcm\_encrypt.c

This example encrypts block cipher-text using AES128 in GCM mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

##### External Connections

- None

##### Watch Variables

- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

#### 33.5.1.4 AES GCM Decryption Example (CM)

FILE: aes\_ex4\_gcm\_decrypt.c

This example decrypts block cipher-text using AES128 in GCM mode. It does the decryption first without uDMA and then with uDMA. The results are checked after each operation.

##### External Connections

- None

##### Watch Variables

- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

## 33.6 AES Registers

The following sections are register descriptions for the AES Subsystem and AES Peripheral Core.

### 33.6.1 AES Base Address Table

**Table 33-3. AES Base Address Table**

| Bit Field Name |                  | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|------------------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure        |                |              |      |     |     |     |                    |
| AesaRegs       | AES_IP_REGS      | AESA_BASE      | 0x0004_2000  | YES  | YES | -   | -   | -                  |
| AesaSsRegs     | AES_WRAPPER_REGS | AESA_SS_BASE   | 0x0004_2C00  | YES  | YES | -   | -   | -                  |

### 33.6.2 AES\_REGS Registers

Table 33-4 lists the memory-mapped registers for the AES\_REGS registers. All register offset addresses not listed in Table 33-4 should be considered as reserved locations and the register contents should not be modified.

**Table 33-4. AES\_REGS Registers**

| Offset | Acronym           | Register Name                                  | Write Protection | Section            |
|--------|-------------------|--|------------------|--------------------|
| 0h     | AES_KEY2_6        | XTS Second Key or CBC-MAC Third Key            |                  | <a href="#">Go</a> |
| 4h     | AES_KEY2_7        | XTS Second Key or CBC-MAC Third Key            |                  | <a href="#">Go</a> |
| 8h     | AES_KEY2_4        | XTS/CCM Second Key or CBC-MAC Third Key        |                  | <a href="#">Go</a> |
| Ch     | AES_KEY2_5        | XTS Second Key or CBC-MAC Third Key            |                  | <a href="#">Go</a> |
| 10h    | AES_KEY2_2        | XTS/CCM/CBC-MAC Second Key or Hash Key Input   |                  | <a href="#">Go</a> |
| 14h    | AES_KEY2_3        | XTS/CCM/CBC-MAC Second Key or Hash Key Input   |                  | <a href="#">Go</a> |
| 18h    | AES_KEY2_0        | XTS/CCM/CBC-MAC Second Key or Hash Key Input   |                  | <a href="#">Go</a> |
| 1Ch    | AES_KEY2_1        | XTS/CCM/CBC-MAC Second Key or Hash Key Input   |                  | <a href="#">Go</a> |
| 20h    | AES_KEY1_6        | Key  |                  | <a href="#">Go</a> |
| 24h    | AES_KEY1_7        | Key  |                  | <a href="#">Go</a> |
| 28h    | AES_KEY1_4        | Key  |                  | <a href="#">Go</a> |
| 2Ch    | AES_KEY1_5        | Key  |                  | <a href="#">Go</a> |
| 30h    | AES_KEY1_2        | Key  |                  | <a href="#">Go</a> |
| 34h    | AES_KEY1_3        | Key  |                  | <a href="#">Go</a> |
| 38h    | AES_KEY1_0        | Key  |                  | <a href="#">Go</a> |
| 3Ch    | AES_KEY1_1        | Key  |                  | <a href="#">Go</a> |
| 40h    | AES_IV_IN_OUT_0   | Initialization Vector 0                        |                  | <a href="#">Go</a> |
| 44h    | AES_IV_IN_OUT_1   | Initialization Vector 1                        |                  | <a href="#">Go</a> |
| 48h    | AES_IV_IN_OUT_2   | Initialization Vector 2                        |                  | <a href="#">Go</a> |
| 4Ch    | AES_IV_IN_OUT_3   | Initialization Vector 3                        |                  | <a href="#">Go</a> |
| 50h    | AES_CTRL          | Input/Output Buffer Control and Mode Selection |                  | <a href="#">Go</a> |
| 54h    | AES_C_LENGTH_0    | Crypto Data Length 0                           |                  | <a href="#">Go</a> |
| 58h    | AES_C_LENGTH_1    | Crypto Data Length 1                           |                  | <a href="#">Go</a> |
| 5Ch    | AES_AUTH_LENGTH   | AAD Data Length                                |                  | <a href="#">Go</a> |
| 60h    | AES_DATA_IN_OUT_0 | Data Word 0                                    |                  | <a href="#">Go</a> |
| 64h    | AES_DATA_IN_OUT_1 | Data Word 1                                    |                  | <a href="#">Go</a> |
| 68h    | AES_DATA_IN_OUT_2 | Data Word 2                                    |                  | <a href="#">Go</a> |
| 6Ch    | AES_DATA_IN_OUT_3 | Data Word 3                                    |                  | <a href="#">Go</a> |
| 70h    | AES_TAG_OUT_0     | Hash Result 0                                  |                  | <a href="#">Go</a> |
| 74h    | AES_TAG_OUT_1     | Hash Result 1                                  |                  | <a href="#">Go</a> |
| 78h    | AES_TAG_OUT_2     | Hash Result 2                                  |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. [Table 33-5](#) shows the codes that are used for access types in this section.

**Table 33-5. AES\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 33.6.2.1 AES\_KEY2\_6 Register (Offset = 0h) [Reset = 0h]

AES\_KEY2\_6 is shown in [Figure 33-14](#) and described in [Table 33-6](#).

Return to the [Summary Table](#).

Secure Host Interface Bank

**Table 33-13. AES\_KEY2\_1 Register Field Descriptions**

| Bit  | Field | Type  | Reset | Description   |
|------|-------|-------|-------|---|
| 31-0 | KEY   | R-0/W | 0h    | <p>Key Data</p> <p>This register contains the 32-bit key data for the AES module.</p> <p>Initial key for XTS operations</p> <p>For a Host write operation, these registers must be written with the 128, 192 or 256-bit key for a subsequent AES operation. The key size equals the AES_KEY1 size.</p> <p>For a Host write operation, these registers must be written with the new values to be subsequently transferred to the AES Engine.</p> <p>OR</p> <p>Pre-calculated CBC-MAC second key (K2), used to perform a final XOR operation on the last input data block.</p> <p>OR</p> <p>Hash key, can be calculated internal or written via these registers. Only used for GHASH (GCM) modes.</p> <p>For a Host write operation, these registers must be written with the new values to be subsequently transferred to the AES Engine.</p> <p>OR</p> <p>These 128-bits are used to store the CKKM / IKKM value for f8</p> <p>OR</p> <p>These 128-bits are used to store the CKKM / IKKM value for f9</p> <p>Reset type: PER.RESET</p> |

### 33.6.2.9 AES\_KEY1\_6 Register (Offset = 20h) [Reset = 0h]

AES\_KEY1\_6 is shown in [Figure 33-22](#) and described in [Table 33-14](#).

Return to the [Summary Table](#).

Secure Host Interface Bank

**Figure 33-22. AES\_KEY1\_6 Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 33-27. AES\_C\_LENGTH\_0 Register Field Descriptions**

| Bit  | Field  | Type  | Reset | Description   |
|------|--------|-------|-------|---|
| 31-0 | LENGTH | R-0/W | 0h    | <p>Bits [60:0] of the crypto length registers (LSW and MSW) store the cryptographic data length in bytes for all modes. Once processing with this context is started, this length decrements to zero. Data lengths up to <math>(2^{61} - 1)</math> bytes are allowed.</p> <p>For GCM, any value up to <math>2^{36} - 32</math> bytes can be used. This is because a 32-bit counter mode is used the maximum number of 128-bit blocks is <math>2^{32} - 2</math>, resulting in a maximum number of bytes of <math>2^{36} - 32</math>.</p> <p>A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM.</p> <p>Note that for the combined modes, this length does not include the authentication only data the authentication length is specified in the AES_AUTH_LENGTH register below.</p> <p>All modes must have a length <math>&gt; 0</math>. For the combined modes, it is allowed to have one of the lengths equal to zero.</p> <p>For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is allowed to program zero to the length field in that case the length is assumed infinite.</p> <p>All data must be byte (8-bit) aligned for stream cipher modes bit aligned data streams are not supported by the AES Engine.</p> <p>For block cipher modes, the data length must be programmed in multiples of the block cipher size, 16 bytes.</p> <p>For a Host read operation, these registers return all-zeroes.</p> <p>Reset type: PER.RESET</p> |

### 33.6.2.23 AES\_C\_LENGTH\_1 Register (Offset = 58h) [Reset = 0h]

AES\_C\_LENGTH\_1 is shown in [Figure 33-36](#) and described in [Table 33-28](#).

Return to the [Summary Table](#).

Secure Host Interface Bank MSW

| R-0/W-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 33-29. AES\_AUTH\_LENGTH Register Field Descriptions**

| Bit  | Field | Type  | Reset | Description  |
|------|-------|-------|-------|--|
| 31-0 | AUTH  | R-0/W | 0h    | Bits [31:0] of the authentication length register store the authentication data length in bytes for combined modes only (GCM or CCM)<br>Supported AAD-lengths for CCM are from 0 to $(2^{16} - 2^8)$ bytes. For GCM any value up to $(2^{32} - 1)$ bytes can be used. Once processing with this context is started, this length decrements to zero.<br>A write to this register triggers the engine to start using this context for GCM and CCM.<br>For XTS this register is optionally used to load "j". Loading of "j" is only required if "j" != 0. "j" is a 28-bit value and must be written to bits [31-4] of this register. "j" represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a "j" for each new data block within a unit. Note that it is possible to start with a "j" unequal to zero<br>refer to Table 4 for more details.<br>For a Host read operation, these registers return all-zeroes.<br>Reset type: PER.RESET |

### 33.6.2.25 AES\_DATA\_IN\_OUT\_0 Register (Offset = 60h) [Reset = 0h]

AES\_DATA\_IN\_OUT\_0 is shown in [Figure 33-38](#) and described in [Table 33-30](#).

Return to the [Summary Table](#).

|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DATA   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R/W-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 33-30. AES\_DATA\_IN\_OUT\_0 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 31-0 | DATA  | R/W  | 0h    | <p>The Data Input/Output Registers buffer the input/output data blocks to/from the AES Engine. Notice that the data input buffer (AES_DATA_IN_n) and data output buffer (AES_DATA_OUT_n) are mapped to the same address locations. Writes to these addresses load the Input Buffer while reads pull from the Output Buffer. Therefore, for write access, the data input buffer is written for read access, the data output buffer is read. The data input buffer must be written prior to starting an operation. The data output buffer contains valid data on completion of an operation. All writes from, and reads to, these registers are tracked independently per direction and HIB. Therefore, any 128-bit data block can be split over multiple 32-bit word transfers, which can be mixed with other transfers over the external interface.</p> <p>Reset type: PER.RESET</p> |

### 33.6.2.26 AES\_DATA\_IN\_OUT\_1 Register (Offset = 64h) [Reset = 0h]

**Table 33-35. AES\_TAG\_OUT\_1 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 31-0 | HASH  | R    | 0h    | Bits [31:0] of the AES TAG registers store the authentication value for the combined and authentication only modes.<br>For a Host read operation, these registers contain the last 128-bit TAG output of the AES Engine<br>the TAG is available until the next context is written.<br>This register will only contain valid data if the TAG is available, when the "store_ready" bit from AES_CTRL register is set. During processing or for operations/modes that do not return a TAG, reads from this register returns data from the IV register. For operations that do return a TAG in the IV register (e.g. XTS), the IV register must be accessed directly.<br>Reset type: PER.RESET |

### 33.6.2.31 AES\_TAG\_OUT\_2 Register (Offset = 78h) [Reset = 0h]

AES\_TAG\_OUT\_2 is shown in [Figure 33-44](#) and described in [Table 33-36](#).

Return to the [Summary Table](#).

| 10    | RESERVED                    | R/W  | 0h    | Reserved  |
| 9     | MAP_CONTEXT_OUT_ON_DATA_OUT | R/W  | 0h    | If set to '1' the two context out requests (dma_req_context_out_en, Bit [8] above, and context_out interrupt enable, Bit [3] of AES_IRQENABLE register) are mapped on the corresponding data output request bit. In this case, the original "context out" bit values are ignored.<br>Therefore, when this bit is enabled and the dma_req_data_out_en (Bit [6]) is enabled, this DMA request is used for the context output and data output. Similarly if the data_out interrupt enable (Bit [2] of AES_IRQENABLE register) is enabled, this interrupt is used for context output and data output. Note that when context and data output request or interrupt are mapped on each other, the context output is always requested after the last data output.<br>Reset type: PER.RESET |
| 8     | DMA_REQ_CONTEXT_OUT_EN      | R/W  | 0h    | DMA Request Context Out Enable<br>If set to 1, the DMA context output request is enabled (for context data out, for example, TAG for authentication modes).<br>Value Description<br>0 DMA disabled for context output request.<br>1 DMA enabled for context output request.<br>Reset type: PER.RESET  |

### 33.6.3 AES\_SS\_REGS Registers

Table 33-44 lists the memory-mapped registers for the AES\_SS\_REGS registers. All register offset addresses not listed in Table 33-44 should be considered as reserved locations and the register contents should not be modified.

**Table 33-44. AES\_SS\_REGS Registers**

| Offset | Acronym         | Register Name                       | Write Protection | Section            |
|--------|-----------------|-------------------------------------|------------------|--------------------|
| 4h     | AES_GLB_INT_FLG | AES Global Interrupt Flag Register  |                  | <a href="#">Go</a> |
| 8h     | AES_GLB_INT_CLR | AES Global Interrupt Clear Register |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 33-45 shows the codes that are used for access types in this section.

**Table 33-45. AES\_SS\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 33.6.3.1 AES\_GLB\_INT\_FLG Register (Offset = 4h) [Reset = 0h]

AES\_GLB\_INT\_FLG is shown in [Figure 33-52](#) and described in [Table 33-46](#).

Return to the [Summary Table](#).

The AES\_GLB\_INT\_FLG register contains the current status of the AES interrupt

**Figure 33-52. AES\_GLB\_INT\_FLG Register**

|          |    |    |    |    |    |    |         |

### 33.6.3.2 AES\_GLB\_INT\_CLR Register (Offset = 8h) [Reset = 0h]

AES\_GLB\_INT\_CLR is shown in [Figure 33-53](#) and described in [Table 33-47](#).

Return to the [Summary Table](#).

The AES\_GLB\_INT\_CLR register is used to clear the interrupt flags in AES\_GLB\_INT\_FLG register.

**Figure 33-53. AES\_GLB\_INT\_CLR Register**

## 34.1 Introduction

The Embedded Pattern Generator (EPG) module is a customizable pattern and clock generator that could serve many test and application scenarios that require a simple pattern generator or a periodic clock generator. The EPG module can also be used to capture an incoming serial stream of data.

### 34.1.1 Features

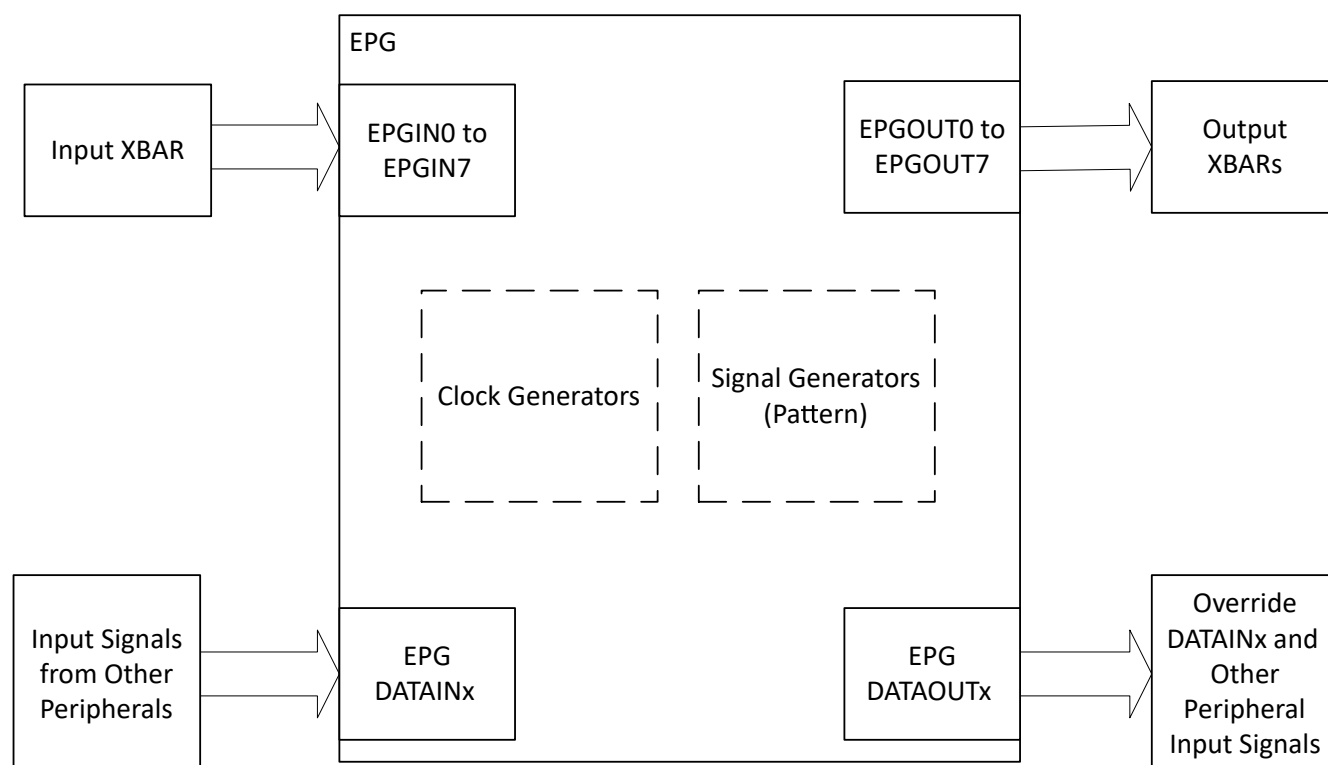

Features of the EPG module are:

- Clock generation:
  - Independent clock generation and clock division
  - Synchronous clock generation with programmable offsets
- Pattern generation:
  - Independent serial data stream generation
  - Serial data stream and the associated clock generation
  - Ability to skew clock with respect to serial data
  - Synchronous data stream with programmable offset with respect to one another

The EPG output signals are connected to GPIOs or other peripherals inside the device. The EPG inputs act as shift register inputs to capture incoming serial data streams. This allows the EPG to be configured as a custom serial module. The EPG is also capable of generating interrupts that are used to supply the pattern generators with new data or signal the completion of a generated pattern.

### 34.1.2 EPG Block Diagram

Figure 34-1 shows the EPG overview block diagram.

**Figure 34-1. EPG Overview Block Diagram**

Figure 34-2 shows the EPG block diagram.

Figure 34-2. EPG Detailed Block Diagram

**Note**

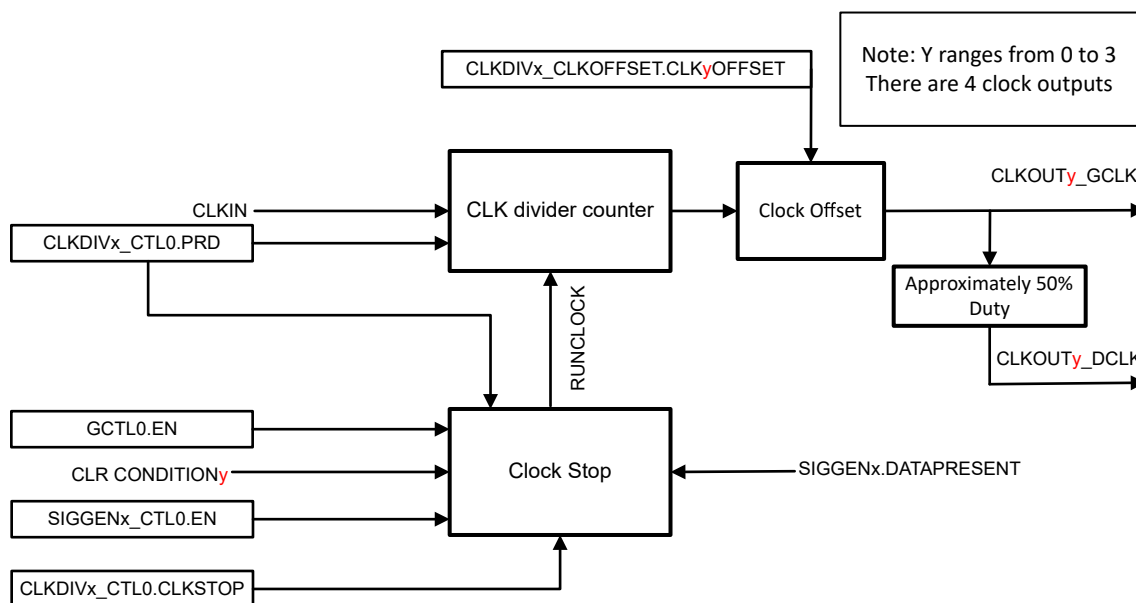

The number of available EPGx SIGGEN modules for each device can be different. This diagram shows an EPG with 2 SIGGEN modules (SIGGEN0 and SIGGEN1). Refer to the EPG\_REGS register description to see how many SIGGEN modules are available for a specific device.

**Note**

The EPG input clock (EPGCLK) is sourced from PERx.SYSCLK.

## 34.2 Clock Generator Modules

The clock generator modules use the EPG input clock and generate four output clocks, see [Figure 34-3](#). Each of the four output clocks (CLKOUT0 to CLKOUT3) has a DCLK and a GCLK version. The EPG clock division results in a gated, GCLK, version of the EPG input clock which are named CLKOUT0\_GCLK to CLKOUT3\_GCLK. The other version, DCLK (CLKOUT0\_DCLK to CLKOUT3\_DCLK), have the same period but with an approximately 50% duty cycle. The clock generation takes place using the divider settings CLKDIVx\_CTL0.PRD, and clock offset settings CLKDIVx\_CLK.CLK<sub>y</sub>OFFSET. The RUNCLOCK signal generated by the clock stop logic determines when the clock generation is started and stopped.

**Figure 34-3. EPG Clock Generator**

The clock divider counter is a simple up counter, which has a period determined by CLKDIVx\_CTL0.PRD. This divider counter begins counting when RUNCLOCK is set. The CLKOUT0 to CLKOUT4 GCLKs are gated versions of the CLKIN (EPG input clock). The clock gates are enabled when the counter value matches the corresponding clock offsets. In the case where RUNCLOCK is cleared, the clock gates are disabled and the counter is set to zero.

### Note

The CLKDIVx\_CTL0.PRD register should only be written when GCTL0.EN is 0.

### 34.2.1 DCLK (50% duty cycle clock)

The CLKOUT<sub>y</sub>\_DCLK is generated by setting the clock output for half the clock divider period. When CLKDIVx\_CTL0.PRD is set to zero, CLKOUT<sub>y</sub>\_DCLK is the same as the input clock.

### 34.2.2 Clock Stop

[Figure 34-4](#) shows how the Clock Stop module sets and clears the RUNCLOCK signal.

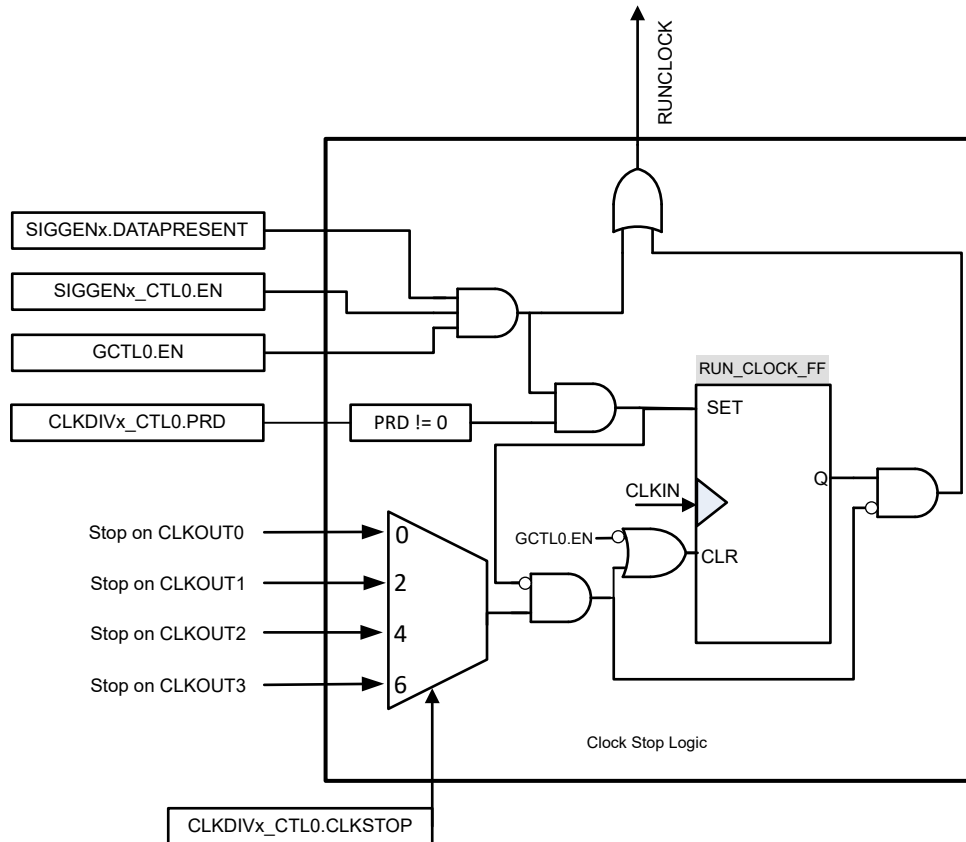

Figure 34-4. EPG Clock Stop

In signal generator modes, SIGGENx\_CTL0.EN bit is cleared when BIT\_LENGTH shifts (or rotates) is completed. This ensures that data is not shifted out. In addition, clock generation (generation of CLKOUT0 to CLKOUT3) also have to be stopped to ensure that sampling of input data does not continue after BIT\_LENGTH shifts when SIGGENx\_CTL0.EN is cleared to 0.

The RUNCLOCK signal has to be HIGH for the clock generation circuitry to be active. When SIGGENx\_CTL0.EN is cleared, the clock generation can be selected to stop on the falling edge of CLKOUT0 to CLKOUT3.

The clock stop module operates as follow:

- RUNCLOCK is asserted as soon as both SIGGENx\_CTL0.EN and GCTL0.EN are set.
- RUN\_CLOCK\_FF is set when both SIGGENx\_CTL0.EN and GCTL0.EN are set and CLKDIVx\_CTL0.PRD is not zero.
- When SIGGENx\_CTL0.EN is cleared, RUN\_CLOCK\_FF is not cleared immediately. This ensures that RUNCLOCK remains set and the clock generation circuitry remains enabled.
- When SIGGENx.DATA0 and SIGGENx.DATA1 are not filled with data before the next shift sequence (repeat shift modes) and signal generator is waiting for data to be written, clocks will be stopped.
- The RUN\_CLOCK\_FF can be cleared on the falling edge of CLKOUT0 to CLKOUT3 based on the configuration of CLKSTOP field.
- Clearing GCTL0.EN clears RUN\_CLOCK\_FF unconditionally.

### 34.3 Signal Generator Module

The signal generator module is the main component of the EPG. It generates the data stream that follows custom patterns. [Figure 34-5](#) shows the main components. This module has 8 output ports DATATRANOUT0 to DATATRANOUT7. The two registers SIGGENx\_DATA1 and SIGGENx\_DATA0 constitute a 64-bit bus named DATA[63:0]. DATATRANIN[63:0], which is used for all the data transform operations, could be DATA[63:0] or bit reversed DATA (when SIGGENx\_CTL0.BRIN bit is set). The DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0 to DATATRANIN7 when the signal generator is **not** in BIT\_BANG mode. In BIT\_BANG mode, DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0, DATATRANIN8, and DATATRANIN16 to DATATRANIN56.

In addition to generating data outputs, one of the 8 EPGIN inputs can act as data input to SIGGENx\_DATAy registers. In [Figure 34-5](#), the EPGIN\_MUX block illustrates the mechanism used to capture the input data stream. This enables one to capture a data input stream using EPG module.

Data transformation is done on the DATATRANIN bus, and is determined by the configured mode (SIGGENx\_CTL0.MODE), provided GCTL0.EN and SIGGENx\_CTL0.EN are both set. If either of these enable bits are 0, then the data output of the transform block is the same as the input. The transformed output is bit reversed when SIGGENx\_CTL0.BROUT bit is set. Conditions under which the DATA active register (SIGGENx\_DATA0\_ACTIVE and SIGGENx\_DATA1\_ACTIVE) are:

- Loaded from SIGGENx\_DATA1 and SIGGENx\_DATA0
- Directly updated on a memory mapped write to SIGGENx\_DATA1 and SIGGENx\_DATA0
- Holds the current data

Figure 34-5. EPG Signal Generator Detailed Overview

**Table 34-1. SIGGENx Active Register Loading**

| Condition  | SIGGENx_DATA1_ACTIVE<br>DATA ACTIVE Register [63:32]     | SIGGENx_DATA0_ACTIVE<br>DATA ACTIVE Register [31:0]      |
|--|--|--|
| Memory mapped write to SIGGENx_DATA0 register and SIGGENx_CTL0.EN is 0   | No updates   | Updated with the value written to SIGGENx_DATA0 register |
| Memory mapped write to SIGGENx_DATA1 register and SIGGENx_CTL0.EN is 0.  | Updated with the value written to SIGGENx_DATA1 register | No updates   |
| “BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Either SIGGENx_DATA0 or SIGGENx_DATA1 has been updated        | Copy SIGGENx_DATA1 register content                      | Copy SIGGENx_DATA0 register content                      |
| “BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Both SIGGENx_DATA0 and SIGGENx_DATA1 have been updated        | Copy SIGGENx_DATA1 register contents                     | Copy SIGGENx_DATA0 register contents                     |
| “BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has been updated     | Hold the current value, no shifts                        | Hold the current value, no shifts                        |
| “BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has not been updated | Hold the current value, no shifts                        | Hold the current value, no shifts                        |
| All other conditions   | Updates based on current mode of operation               | Updates based on current mode of operation               |

Following are the possible data transformations:

**Bit-bang mode:** In this mode, DATATRAN[63:0] is the same as DATATRANIN[63:0].

**Shift right once mode:** In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx\_CTL0.BITLENGTH shifts, SIGENx\_CTL0.EN is cleared.

**Shift right repeat mode:** In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx\_CTL0.BITLENGTH shifts, load the data as per [Table 34-1](#).

**Rotate right once mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[0],DATATRANIN[63:1]}. After SIGENx\_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx\_CTL0.EN is cleared.

**Rotate right repeat:** This mode is same as rotate right once, except that SIGENx\_CTL0.EN is not cleared upon SIGENx\_CTL0.BITLENGTH rotates.

**Shift left once mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx\_CTL0.BITLENGTH shifts, SIGENx\_CTL0.EN is cleared.

**Shift left repeat mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx\_CTL0.BITLENGTH shifts, load the data as per [Table 34-1](#).

**Rotate left once mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],DATATRANIN[63]}. After SIGENx\_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx\_CTL0.EN is cleared.

**Rotate left repeat:** This mode is same as rotate left once, except that SIGENx\_CTL0.EN is not cleared upon SIGENx\_CTL0.BITLENGTH rotates.

---

**Note**

SIGGENx\_CTL0.MODE and SIGGENx\_CTL.BITWIDTH should only be updated when SIGGENx\_CTL0.EN is 0.

---

### 34.4 EPG Peripheral Signal Mux Selection

EPG DATAINx signals are connected to input signal sources from other peripherals. The EPG DATAINx signal sources are listed in [Table 34-2](#).

**Table 34-2. EPG Data Input Connections**

| EPG1 Data Connection (DATAINx) | Peripheral Input Signal Name |
|--------------------------------|------------------------------|
| 0                              | CANA RX                      |
| 1                              | MCAN RX                      |
| 2 to 18                        | Reserved                     |
| 19                             | SD1 C1                       |
| 20                             | SD1 C2                       |
| 21                             | SD1 C3                       |
| 22                             | SD1 C4                       |
| 23                             | SD2 C1                       |
| 24                             | SD2 C2                       |
| 25                             | SD2 C3                       |
| 26                             | SD2 C4                       |
| 27 to 63                       | Reserved                     |

EPGOUT0 to EPGOUT7 can override peripheral input signals connected to DATAINx. For example, the peripheral CAN RX input signal can be overwritten by EPGOUTx. DATAINx can be passed to DATAOUTx untouched, if EPG is not required, or the DATAINx can be replaced with EPGOUTy ( $y = x\%8$ ). The EPGMXSEL0 and EPGMXSEL1 registers must be configured to select the source of the DATAOUTx signals. Also, EPGOUTx signals can be connected to GPIOs through Output XBARs.

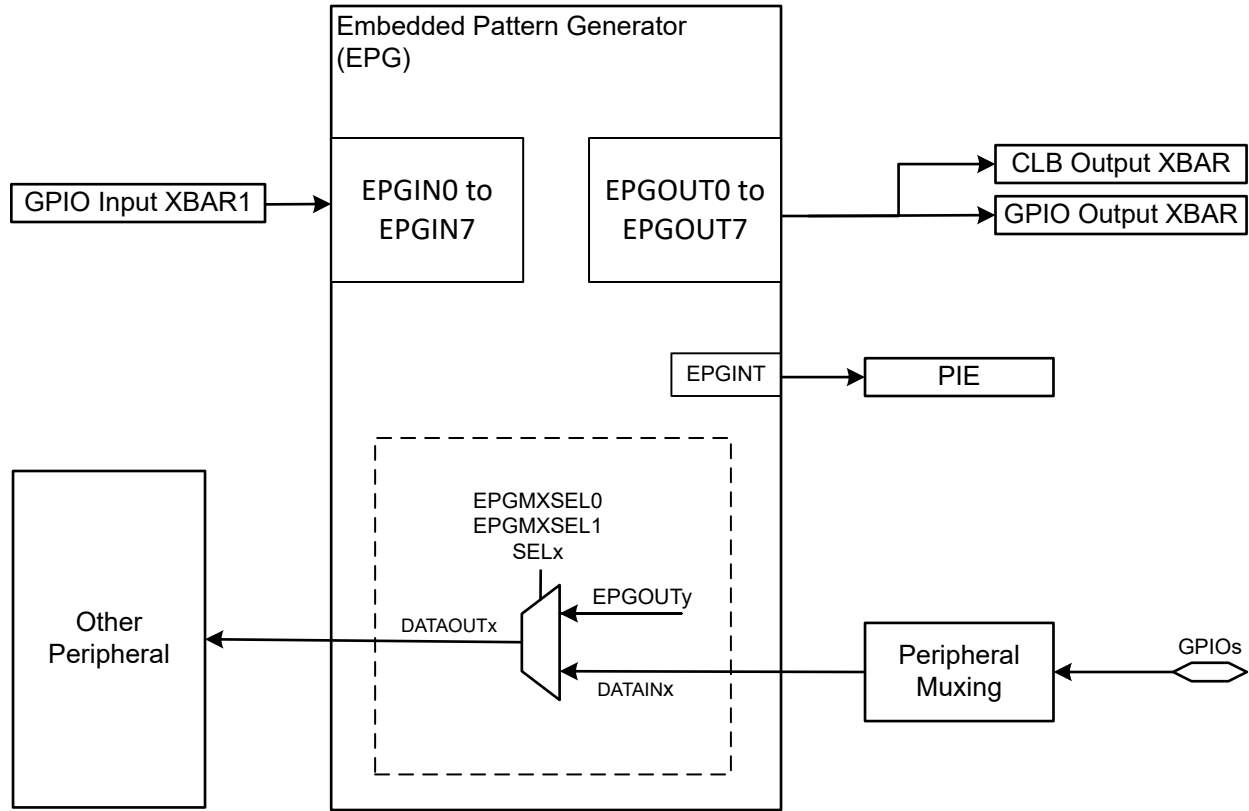

Figure 34-6. EPG Peripheral Signal Muxing

## 34.5 EPG Example Use Cases

This section provides example register configurations for different EPG use cases.

### Note

Some examples may require more than one SIGGEN modules. Check the device registers or datasheet for the number available SIGGEN modules.

### 34.5.1 EPG Example 1: Synchronous Clocks with Offset

The [Example 34-1](#) register configuration generates 4 clocks, all synchronous to one another with edges offset by 2 clock cycles. In [Example 34-1](#), a clock divide value of 12 is used.

#### Example 34-1. Register Configuration

| Register   | Value          | Selected Mode   |
|--|----------------|---|
| <b>Epg1MuxRegs</b>                               |                |   |
| EPGMXSEL0.SEL0                                   | 0x1            | Select EPGOUT0 to drive DATAOUT[0]  |
| EPGMXSEL0.SEL1                                   | 0x1            | Select EPGOUT1 to drive DATAOUT[1]  |
| EPGMXSEL0.SEL2                                   | 0x1            | Select EPGOUT2 to drive DATAOUT[2]  |
| EPGMXSEL0.SEL3                                   | 0x1            | Select EPGOUT3 to drive DATAOUT[3]  |
| <b>Epg1Regs</b>                                  |                |   |
| <b>Global Settings</b>                           |                |   |
| GCTL0.EPGOUT0SEL                                 | 0x0            | Selects signal mux output on EPGOUT0  |
| GCTL0.EPGOUT1SEL                                 | 0x0            | Selects signal mux output on EPGOUT1  |
| GCTL0.EPGOUT2SEL                                 | 0x0            | Selects signal mux output on EPGOUT2  |
| GCTL0.EPGOUT3SEL                                 | 0x0            | Selects signal mux output on EPGOUT3  |
| GCTL3.EPGOUT0_SIGOUTSEL                          | 0x0            | Select SIGGEN0.OUT[0] on EPGOUT0  |
| GCTL3.EPGOUT1_SIGOUTSEL                          | 0x1            | Select SIGGEN0.OUT[1] on EPGOUT1  |
| GCTL3.EPGOUT2_SIGOUTSEL                          | 0x2            | Select SIGGEN0.OUT[2] on EPGOUT2  |
| GCTL3.EPGOUT3_SIGOUTSEL                          | 0x3            | Select SIGGEN0.OUT[3] on EPGOUT3  |
| GCTL1.SIGGEN0_CLKSEL                             | 0x0            | Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0  |
| <b>CLKGEN0 Setting</b>                           |                |   |
| CLKDIV0_CTL0.PRD                                 | 0x0            | Divide by 1   |
| CLKDIV0_CLKOFFSET.CLK0OFFSET                     | 0x0            | No offset   |
| <b>SIGGEN0 Mode and Bit length configuration</b> |                |   |
| SIGGEN0_CTL0.BITLENGTH                           | 0xC            | Configure bit length to 12 to get a divide by 12 clock.   |
| SIGGEN0_CTL0.MODE                                | 0x3            | Configure the mode to rotate right repeat mode to generate a periodic waveform.                   |
| SIGGEN0_DATA0[11:0]                              | "000001111110" | Initialize the 12 bits to 6 ones and 6 zeroes, which ensures that we get a 50 % duty cycle clock. |
| SIGGEN0_DATA0[27:16]                             | "000111111000" | Create a 2 cycle offset with respect to first clock.  |
| SIGGEN0_DATA1[11:0]                              | "011111100000" | Create a 4 cycle offset with respect to first clock.  |
| SIGGEN0_DATA1[27:16]                             | "111110000001" | Create a 6 cycle offset with respect to first clock.  |

### 34.5.2 EPG Example 2: Serial Data Bit Stream (LSB first)

The [Example 34-2](#) register configuration shifts out a data word, the data rate is set to divide by 8 and LSB is shifted out first. After 32 shifts are completed, an interrupt is generated for further sequencing.

#### Example 34-2. Register Configuration

| Register   | Value  | Selected Mode  |
|--|--------|--|
| <b>Epg1MuxRegs</b>                               |        |  |
| EPGMXSEL0.SEL0                                   | 0x1    | Select EPGOUT0 to drive DATAOUT[0]   |
| <b>Epg1Regs</b>                                  |        |  |
| <b>Global Settings</b>                           |        |  |
| GCTL1.SIGGEN0_CLKSEL                             | 0x0    | Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0                             |
| <b>CLKGEN0 Setting</b>                           |        |  |
| CLKDIV0_CTL0.PRD                                 | 0x7    | Divide by 8  |
| CLKDIV0_CLKOFFSET.CLK0OFFSET                     | 0x0    | No offset  |
| <b>SIGGEN0 Mode and Bit length configuration</b> |        |  |
| SIGGEN0_CTL0.BITLENGTH                           | 0x20   | Do 32 shifts.  |
| SIGGEN0_CTL0.MODE                                | 0x1    | Configure the mode to shift right once mode. Generates an interrupt after 32 shifts. |
| SIGGEN0_DATA0[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA0[31:16]                             | 0xcccc | Data to be shifted out   |
| SIGGEN0_DATA1[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA1[31:16]                             | 0x55aa | Data to be shifted out   |

### 34.5.3 EPG Example 3: Serial Data Bit Stream (MSB first)

The [Example 34-3](#) register configuration shifts out a data word, the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

#### Example 34-3. Register Configuration

| Register   | Value  | Selected Mode  |
|--|--------|--|
| <b>Epg1MuxRegs</b>                               |        |  |
| EPGMXSEL0.SEL0                                   | 0x1    | Select EPGOUT0 to drive DATAOUT[0]   |
| <b>Epg1Regs</b>                                  |        |  |
| <b>Global Settings</b>                           |        |  |
| GCTL0.EPGOUT0SEL                                 | 0x0    | Selects signal mux output on EPGOUT0   |
| GCTL3.EPGOUT0_SIGOUTSEL                          | 0x4    | Select SIGGEN0.OUT[4] on EPGOUT0, on 64 bit reversal, 31 bit will appear on 32 bit (hence configuring to 4). |
| GCTL1.SIGGEN0_CLKSEL                             | 0x0    | Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0   |
| <b>CLKGEN0 Setting</b>                           |        |  |
| CLKDIV0_CTL0.PRD                                 | 0x7    | Divide by 8  |
| CLKDIV0_CLKOFFSET.CLK0OFFSET                     | 0x0    | No offset  |
| <b>SIGGEN0 Mode and Bit length configuration</b> |        |  |
| SIGGEN0_CTL0.BITLENGTH                           | 0x20   | Do 32 shifts.  |
| SIGGEN0_CTL0.MODE                                | 0x1    | Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.                         |
| SIGGEN0_CTL0.BRIN                                | 0x1    | Reverse the bits to the data transform block. This to ensure that MSB is transmitted first.                  |
| SIGGEN0_CTL0.BROUT                               | 0x1    | Reverse the data back and store in the register  |
| SIGGEN0_DATA0[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA0[31:16]                             | 0xcccc | Data to be shifted out   |
| SIGGEN0_DATA1[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA1[31:16]                             | 0x55aa | Data to be shifted out   |

### 34.5.4 EPG Example 4: Clock and Data Pair

The [Example 34-4](#) register configuration shifts out a data word, also an associated clock is generated to latch the data (EPGOUT1), the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

#### Example 34-4. Register Configuration

| Register   | Value  | Selected Mode  |
|--|--------|--|
| <b>Epg1MuxRegs</b>                               |        |  |
| EPGMXSEL0.SEL0                                   | 0x1    | Select EPGOUT0 to drive DATAOUT[0]   |
| EPGMXSEL0.SEL1                                   | 0x1    | Select EPGOUT1 to drive DATAOUT[1]   |
| <b>Epg1Regs</b>                                  |        |  |
| <b>Global Settings</b>                           |        |  |
| GCTL0.EPGOUT0SEL                                 | 0x0    | Selects signal mux output on EPGOUT0   |
| GCTL3.EPGOUT0_SIGOUTSEL                          | 0x4    | Select SIGGEN0.OUT[4] on EPGOUT0, on 64 bit reversal, 31 bit will appear on 32 bit (hence configuring to 4). |
| GCTL0.EPGOUT1SEL                                 | 0x0    | Selects signal mux output on EPGOUT1   |
| GCTL3.EPGOUT1_SIGOUTSEL                          | 0x8    | Select SIGGEN1.OUT[0] on EPGOUT1.  |
| GCTL1.SIGGEN0_CLKSEL                             | 0x0    | Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0   |
| GCTL1.SIGGEN1_CLKSEL                             | 0x4    | Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1   |
| <b>CLKGEN0 Setting</b>                           |        |  |
| CLKDIV0_CTL0.PRD                                 | 0x7    | Divide by 8  |
| CLKDIV0_CLKOFFSET.CLK0OFFSET                     | 0x0    | No offset  |
| CLKDIV1_CTL0.PRD                                 | 0x3    | Divide by 4  |
| <b>SIGGEN0 Mode and Bit length configuration</b> |        |  |
| SIGGEN0_CTL0.BITLENGTH                           | 0x20   | Do 32 shifts.  |
| SIGGEN0_CTL0.MODE                                | 0x1    | Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.                         |
| SIGGEN0_CTL0.BRIN                                | 0x1    | Reverse the bits to the data transform block. This to ensure that MSB is transmitted first.                  |
| SIGGEN0_CTL0.BROUT                               | 0x1    | Reverse the data back and store in the register  |
| SIGGEN0_DATA0[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA0[31:16]                             | 0xcccc | Data to be shifted out   |
| SIGGEN0_DATA1[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA1[31:16]                             | 0x55aa | Data to be shifted out   |
| <b>SIGGEN1 Mode and Bit length configuration</b> |        |  |
| SIGGEN1_CTL0.BITLENGTH                           | 0x2    | Set bit length to 2 to generate a 50% duty clock.  |
| SIGGEN1_CTL0.MODE                                | 0x3    | Configure the mode to rotate right repeat mode. Generates a 50 % duty cycle clock.                           |
| SIGGEN1_DATA0[15:0]                              | 0x2    | Data to be shifted out   |

### 34.5.5 EPG Example 5: Clock and Skewed Data Pair

Example 34-5 is similar to Example 34-4; however, the data shifted out is skewed by few EPG input clock cycles.

#### Example 34-5. Register Configuration

| Register   | Value  | Selected Mode  |
|--|--------|--|
| <b>Epg1MuxRegs</b>                               |        |  |
| EPGMXSEL0.SEL0                                   | 0x1    | Select EPGOUT0 to drive DATAOUT[0]   |
| EPGMXSEL0.SEL1                                   | 0x1    | Select EPGOUT1 to drive DATAOUT[1]   |
| <b>Epg1Regs</b>                                  |        |  |
| <b>Global Settings</b>                           |        |  |
| GCTL0.EPGOUT0SEL                                 | 0x0    | Selects signal mux output on EPGOUT0   |
| GCTL3.EPGOUT0_SIGOUTSEL                          | 0x4    | Select SIGGEN0.OUT[4] on EPGOUT0, on 64 bit reversal, 31 bit will appear on 32 bit (hence configuring to 4). |
| GCTL0.EPGOUT1SEL                                 | 0x0    | Selects signal mux output on EPGOUT1   |
| GCTL3.EPGOUT1_SIGOUTSEL                          | 0x8    | Select SIGGEN1.OUT[0] on EPGOUT1.  |
| GCTL1.SIGGEN0_CLKSEL                             | 0x0    | Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0   |
| GCTL1.SIGGEN1_CLKSEL                             | 0x4    | Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1   |
| <b>CLKGEN0 Setting</b>                           |        |  |
| CLKDIV0_CTL0.PRD                                 | 0x7    | Divide by 8  |
| CLKDIV0_CLKOFFSET.CLK0OFFSET                     | 0x2    | Offset of 2 cycles.  |
| CLKDIV1_CTL0.PRD                                 | 0x3    | Divide by 4  |
| <b>SIGGEN0 Mode and Bit length configuration</b> |        |  |
| SIGGEN0_CTL0.BITLENGTH                           | 0x20   | Do 32 shifts.  |
| SIGGEN0_CTL0.MODE                                | 0x1    | Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.                         |
| SIGGEN0_CTL0.BRIN                                | 0x1    | Reverse the bits to the data transform block. This to ensure that MSB is transmitted first.                  |
| SIGGEN0_CTL0.BROUT                               | 0x1    | Reverse the data back and store in the register  |
| SIGGEN0_DATA0[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA0[31:16]                             | 0xcccc | Data to be shifted out   |
| SIGGEN0_DATA1[15:0]                              | 0xaa55 | Data to be shifted out   |
| SIGGEN0_DATA1[31:16]                             | 0x55aa | Data to be shifted out   |
| <b>SIGGEN1 Mode and Bit length configuration</b> |        |  |
| SIGGEN1_DATA0[15:0]                              | 0x2    | Data to be shifted out   |
| SIGGEN1_CTL0.BITLENGTH                           | 0x2    | Set bit length to 2 to generate a 50% duty clock.  |
| SIGGEN1_CTL0.MODE                                | 0x3    | Configure the mode to rotate right repeat mode. Generates a 50 % duty cycle clock.                           |

### 34.5.6 EPG Example 6: Capturing Serial Data with a Known Baud Rate

The [Example 34-6](#) register configuration captures a 32-bit data stream. The data is generated from SIGGEN0 and captured in SIGGEN1 (EPGOUT0 looped back as EPGIN0). The clock to SIGEN1 is offset by a few cycles to reliably capture the data.

#### Example 34-6. Register Configuration

| Register   | Value  | Selected Mode  |
|--|--------|--|
| <b>Epg1MuxRegs</b>                               |        |  |
| EPGMXSEL0.SEL0                                   | 0x1    | Select EPGOUT0 to drive DATAOUT[0]   |
| EPGMXSEL0.SEL1                                   | 0x1    | Select EPGOUT1 to drive DATAOUT[1]   |
| <b>Epg1Regs</b>                                  |        |  |
| <b>Global Settings</b>                           |        |  |
| GCTL0.EPGOUT0SEL                                 | 0x0    | Selects signal mux output on EPGOUT0   |
| GCTL3.EPGOUT0_SIGOUTSEL                          | 0x4    | Select SIGGEN0.OUT[4] on EPGOUT0, on 64 bit reversal, 31 bit will appear on 32 bit (hence configuring to 4). |
| GCTL0.EPGOUT1SEL                                 | 0x0    | Selects signal mux output on EPGOUT1   |
| GCTL3.EPGOUT1_SIGOUTSEL                          | 0x8    | Select SIGGEN1.OUT[0] on EPGOUT1.  |
| GCTL1.SIGGEN0_CLKSEL                             | 0x0    | Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0   |
| GCTL1.SIGGEN1_CLKSEL                             | 0x4    | Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1   |
| <b>CLKGEN0 Setting</b>                           |        |  |
| CLKDIV0_CTL0.PRD                                 | 0x7    | Divide by 8  |
| CLKDIV0_CLKOFFSET.CLK0OFFSET                     | 0x0    | No offset  |
| CLKDIV1_CTL0.PRD                                 | 0x7    | Divide by 8  |
| CLKDIV1_CLKOFFSET.CLK0OFFSET                     | 0x2    | Offset the capture clock by a few cycles to capture the data reliably.                                       |
| <b>SIGGEN0 Mode and Bit length configuration</b> |        |  |
| SIGGEN0_CTL0.BITLENGTH                           | 0x20   | Do 32 shifts, data out looped back to EPGIN[0] to demonstrate the data capture function.                     |
| SIGGEN0_CTL0.MODE                                | 0x1    | Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.                         |
| SIGGEN0_CTL0.BRIN                                | 0x0    | Reverse the bits to the data transform block. This to ensure that MSB is transmitted first.                  |
| SIGGEN0_CTL0.BROUT                               | 0x0    | Reverse the data back and store in the register  |
| SIGGEN_DATA0[15:0]                               | 0xaa55 | Data to be shifted out   |
| SIGGEN_DATA0[31:16]                              | 0xcccc | Data to be shifted out   |
| SIGGEN_DATA1[15:0]                               | 0xaa55 | Data to be shifted out   |
| SIGGEN_DATA1[31:16]                              | 0x55aa | Data to be shifted out   |
| <b>SIGGEN1 Mode and Bit length configuration</b> |        |  |
| SIGGEN1_CTL0.BITLENGTH                           | 0x32   | Set bit length to 2 to generate a 50% duty clock.  |
| SIGGEN1_CTL0.MODE                                | 0x4    | Configure the mode to shift left once mode. To capture the data pattern on EPGIN[0].                         |
| SIGGEN1_CTL1.DATA0_INSEL                         | 0x1    | Select EPGIN[0] as the data input of 0'th bit.   |
| SIGGEN1_DATA0                                    | 0x0    | Clear the data contents. Will hold 0xAA553333 at the end of 32 shifts.                                       |

### 34.6 EPG Interrupt

EPG interrupt can be generated on “BIT\_LENGTH” shifts or rotates, or “BIT\_LENGTH/2” shifts or rotates. Interrupts can be generated in any of the signal generator modes.

The GINTSTS, GINTEN, GINTCLR, and GINTFRC registers are used to configure the EPG interrupt, as shown in Figure 34-7.

Figure 34-7. EPG Interrupt

## 34.7 Software

### 34.7.1 EPG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/epg

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 34.7.1.1 EPG Generate Serial Data Shift Mode

FILE: epg\_ex10\_generate\_serial\_data\_shift\_mode.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module in SHIFT mode. For more information on this example, visit: <https://www.ti.com/lit/spracy7>

##### External Connections

- None. Signal is generated on GPIO 58, 54. Can be visualized through oscilloscope.

#### 34.7.1.2 EPG Generating Synchronous Clocks

FILE: epg\_ex1\_generate\_clocks.c

This example shows how to generate 2 synchronous clocks with edges being offset by 2 clock cycles. It configures Signal Generator to shift a periodic data. Generated Clock has period EPG CLOCK/6.

##### External Connections

- None. Clock output is generated on GPIO 58, 54. Can be visualized through oscilloscope.

##### Watch Variables

- sigGenActiveData - Active Data of signal generator transform output

#### 34.7.1.3 EPG Generating Two Offset Clocks

FILE: epg\_ex7\_generate\_two\_offset\_clocks.c

This example generates two offset clocks using the CLKGEN (CLKDIV) modules. For more information on this example, visit: <https://www.ti.com/lit/spracy7>

##### External Connections

- None. Signal is generated on GPIO 58, 54. Can be visualized through oscilloscope.

#### 34.7.1.4 EPG Generating Two Offset Clocks With SIGGEN

FILE: epg\_ex8\_generate\_two\_offset\_clocks\_with\_siggen.c

This example generates two offset clocks using the SIGGEN module. For more information on this example, visit: <https://www.ti.com/lit/spracy7>

##### External Connections

- None. Signal is generated on GPIO 58, 54. Can be visualized through oscilloscope.

#### 34.7.1.5 EPG Generate Serial Data

FILE: epg\_ex9\_generate\_serial\_data.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module. For more information on this example, visit: <https://www.ti.com/lit/spracy7>

##### External Connections

- None. Signal is generated on GPIO 58, 54. Can be visualized through oscilloscope.

## 34.8 EPG Registers

The following sections are register descriptions for the EPG.

### 34.8.1 EPG Base Address Table

**Table 34-3. EPG Base Address Table**

| Bit Field Name |              | DriverLib Name | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|--------------|----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure    |                |              |      |     |     |     |                    |
| Epg1Regs       | EPG_REGS     | EPG1_BASE      | 0x0005_EC00  | YES  | -   | -   | -   | YES                |
| Epg1MuxRegs    | EPG_MUX_REGS | EPG1MUX_BASE   | 0x0005_ECD0  | YES  | -   | -   | -   | YES                |

### 34.8.2 EPG\_REGS Registers

Table 34-4 lists the memory-mapped registers for the EPG\_REGS registers. All register offset addresses not listed in Table 34-4 should be considered as reserved locations and the register contents should not be modified.

**Table 34-4. EPG\_REGS Registers**

| Offset | Acronym              | Register Name                               | Write Protection | Section            |
|--------|----------------------|---|------------------|--------------------|
| 0h     | GCTL0                | EPG Global control register 0               |                  | <a href="#">Go</a> |
| 2h     | GCTL1                | EPG Global control register 1               |                  | <a href="#">Go</a> |
| 4h     | GCTL2                | EPG Global control register 2               |                  | <a href="#">Go</a> |
| 6h     | GCTL3                | EPG Global control register 3               |                  | <a href="#">Go</a> |
| 8h     | EPGLOCK              | EPG LOCK Register                           |                  | <a href="#">Go</a> |
| Ah     | EPGCOMMIT            | EPG COMMIT register                         |                  | <a href="#">Go</a> |
| Ch     | GINTSTS              | EPG Global interrupt status register.       |                  | <a href="#">Go</a> |
| Eh     | GINTEN               | EPG Global interrupt enable register.       |                  | <a href="#">Go</a> |
| 10h    | GINTCLR              | EPG Global interrupt clear register.        |                  | <a href="#">Go</a> |
| 12h    | GINTFRC              | EPG Global interrupt force register.        |                  | <a href="#">Go</a> |
| 18h    | CLKDIV0_CTL0         | Clock divider 0's control register 0        |                  | <a href="#">Go</a> |
| 1Eh    | CLKDIV0_CLKOFFSET    | Clock divider 0's clock offset value        |                  | <a href="#">Go</a> |
| 24h    | CLKDIV1_CTL0         | Clock divider 1's control register 0        |                  | <a href="#">Go</a> |
| 2Ah    | CLKDIV1_CLKOFFSET    | Clock divider 1's clock offset value        |                  | <a href="#">Go</a> |
| 30h    | SIGGEN0_CTL0         | Signal generator 0's control register 0     |                  | <a href="#">Go</a> |
| 32h    | SIGGEN0_CTL1         | Signal generator 0's control register 1     |                  | <a href="#">Go</a> |
| 38h    | SIGGEN0_DATA0        | Signal generator 0's data register 0        |                  | <a href="#">Go</a> |
| 3Ah    | SIGGEN0_DATA1        | Signal generator 0's data register 1        |                  | <a href="#">Go</a> |
| 3Ch    | SIGGEN0_DATA0_ACTIVE | Signal generator 0's data active register 0 |                  | <a href="#">Go</a> |
| 3Eh    | SIGGEN0_DATA1_ACTIVE | Signal generator 0's data active register 1 |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 34-5 shows the codes that are used for access types in this section.

**Table 34-5. EPG\_REGS Access Type Codes**

| Access Type              | Code   | Description                            |
|--------------------------|--------|--|
| Read Type                |        |  |
| R                        | R      | Read                                   |
| R-0                      | R-0    | Read Returns 0s                        |
| Write Type               |        |  |
| W                        | W      | Write                                  |
| W1C                      | W1C    | Write 1 to clear                       |
| W1S                      | W1S    | Write 1 to set                         |
| WSonce                   | WSonce | Write Set once                         |
| Reset or Default Value   |        |  |
| -n                       |        | Value after reset or the default value |
| Register Array Variables |        |  |

**Table 34-5. EPG\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description  |
|-------------|------|--|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 34.8.2.1 GCTL0 Register (Offset = 0h) [Reset = 0h]

GCTL0 is shown in [Figure 34-8](#) and described in [Table 34-6](#).

Return to the [Summary Table](#).

**Table 34-25. SIGGEN0\_DATA1\_ACTIVE Register Field Descriptions**

| Bit  | Field        | Type | Reset | Description   |
|------|--------------|------|-------|---|
| 31-0 | SIGGEN_DATA1 | R    | 0h    | This is the upper 32 bits of the 64 bit active register (used in data transformation)<br>Reset type: SYSRSn |

### 34.8.3 EPG\_MUX\_REGS Registers

Table 34-26 lists the memory-mapped registers for the EPG\_MUX\_REGS registers. All register offset addresses not listed in Table 34-26 should be considered as reserved locations and the register contents should not be modified.

**Table 34-26. EPG\_MUX\_REGS Registers**

| Offset | Acronym        | Register Name                  | Write Protection | Section            |
|--------|----------------|--------------------------------|------------------|--------------------|
| 0h     | EPGMXSEL0      | EPG Mux select register 0      |                  | <a href="#">Go</a> |
| Ch     | EPGMXSELLOCK   | EPG Mux select register lock   |                  | <a href="#">Go</a> |
| Eh     | EPGMXSELCOMMIT | EPG Mux select register commit |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 34-27 shows the codes that are used for access types in this section.

**Table 34-27. EPG\_MUX\_REGS Access Type Codes**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| Read Type                |            |  |
| R                        | R          | Read   |
| Write Type               |            |  |
| W                        | W          | Write  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 34.8.3.1 EPGMXSEL0 Register (Offset = 0h) [Reset = 0h]

EPGMXSEL0 is shown in [Figure 34-28](#) and described in [Table 34-28](#).

Return to the [Summary Table](#).

EPG Mux select register 0
