| 3.1 Introduction.....   | 96  |
| 3.1.1 SYSCTL Related Collateral.....                                    | 96  |
| 3.1.2 LOCK Protection on System Configuration Registers.....            | 96  |
| 3.1.3 EALLOW Protection.....  | 96  |
| 3.2 Power Management.....   | 97  |
| 3.3 Device Identification and Configuration Registers.....              | 97  |
| 3.4 Resets.....   | 97  |
| 3.4.1 Reset Sources.....  | 97  |
| 3.4.2 External Reset (XRS).....   | 98  |
| 3.4.3 Simulate External Reset (SIMRESET. XRS).....                      | 98  |
| 3.4.4 Power-On Reset (POR).....   | 98  |
| 3.4.5 Brown-Out-Reset (BOR).....  | 98  |
| 3.4.6 Debugger Reset (SYSRS).....                                       | 99  |
| 3.4.7 Simulate CPU Reset (SIMRESET. CPU1RS).....                        | 99  |
| 3.4.8 Watchdog Reset (WDRS).....  | 99  |
| 3.4.9 Hardware BIST Reset (HWBISTR).....                                | 99  |
| 3.4.10 NMI Watchdog Reset (NMIWDRS).....                                | 99  |
| 3.4.11 DCSM Safe Code Copy Reset (SCCRESET).....                        | 99  |
| 3.5 Peripheral Interrupts.....  | 100 |
| 3.5.1 Interrupt Concepts.....   | 100 |
| 3.5.2 Interrupt Architecture.....                                       | 100 |
| 3.5.3 Interrupt Entry Sequence.....                                     | 101 |
| 3.5.4 Configuring and Using Interrupts.....                             | 102 |
| 3.5.5 PIE Channel Mapping.....  | 104 |
| 3.5.6 Vector Tables.....  | 106 |
| 3.6 Exceptions and Non-Maskable Interrupts.....                         | 112 |
| 3.6.1 Configuring and Using NMIs.....                                   | 112 |

|   |     |
|---|-----|
| 3.6.2 Emulation Considerations.....                                   | 112 |
| 3.6.3 NMI Sources.....  | 112 |
| 3.6.4 CRC Fail.....   | 113 |
| 3.6.5 ERAD NMI.....   | 113 |
| 3.6.6 Illegal Instruction Trap (ITRAP).....                           | 113 |
| 3.6.7 Error Pin.....  | 113 |
| 3.7 Clocking.....   | 114 |
| 3.7.1 Clock Sources.....  | 115 |
| 3.7.2 Derived Clocks.....   | 118 |
| 3.7.3 Device Clock Domains.....                                       | 118 |
| 3.7.4 XCLKOUT.....  | 119 |
| 3.7.5 Clock Connectivity.....   | 120 |
| 3.7.6 Clock Source and PLL Setup.....                                 | 121 |
| 3.7.7 Using an External Crystal or Resonator.....                     | 121 |
| 3.7.8 Using an External Oscillator.....                               | 121 |
| 3.7.9 Choosing PLL Settings.....                                      | 122 |
| 3.7.10 System Clock Setup.....  | 122 |
| 3.7.11 SYS PLL Bypass.....  | 123 |
| 3.7.12 Clock (OSCCLK) Failure Detection.....                          | 123 |
| 3.8 32-Bit CPU Timers 0/1/2.....                                      | 127 |
| 3.9 Watchdog Timer.....   | 128 |
| 3.9.1 Servicing the Watchdog Timer.....                               | 129 |
| 3.9.2 Minimum Window Check.....                                       | 129 |
| 3.9.3 Watchdog Reset or Watchdog Interrupt Mode.....                  | 130 |
| 3.9.4 Watchdog Operation in Low Power Modes.....                      | 130 |
| 3.9.5 Emulation Considerations.....                                   | 130 |
| 3.10 Low Power Modes.....   | 131 |
| 3.10.1 Clock-Gating Low-Power Modes.....                              | 131 |
| 3.10.2 IDLE.....  | 131 |
| 3.10.3 STANDBY.....   | 132 |
| 3.10.4 HALT.....  | 132 |
| 3.10.5 Flash Power-down Considerations.....                           | 133 |
| 3.11 Memory Controller Module.....                                    | 134 |
| 3.11.1 Dedicated RAM (Mx RAM).....                                    | 134 |
| 3.11.2 Local Shared RAM (LSx RAM).....                                | 134 |
| 3.11.3 Global Shared RAM (GSx RAM).....                               | 135 |
| 3.11.4 CLA-CPU Message RAM.....                                       | 135 |
| 3.11.5 CLA-DMA Message RAM.....                                       | 135 |
| 3.11.6 Access Arbitration.....  | 135 |
| 3.11.7 Access Protection.....   | 137 |
| 3.11.8 Memory Error Detection and Correction, and Error Handling..... | 138 |
| 3.11.9 Application Test Hooks for Error Detection and Correction..... | 140 |
| 3.11.10 RAM Initialization.....                                       | 140 |
| 3.12 JTAG.....  | 141 |
| 3.13 Live Firmware Update.....  | 141 |
| 3.13.1 LFU Background.....  | 141 |
| 3.13.2 LFU Switchover Steps.....                                      | 141 |
| 3.13.3 Device Features Supporting LFU.....                            | 142 |
| 3.13.4 LFU Switchover.....  | 145 |
| 3.13.5 LFU Resources.....   | 145 |
| 3.14 Software.....  | 146 |
| 3.14.1 INTERRUPT Examples.....  | 146 |
| 3.14.2 SYSCTL Examples.....   | 148 |
| 3.14.3 TIMER Examples.....  | 149 |
| 3.14.4 LPM Examples.....  | 149 |
| 3.14.5 MEMCFG Examples.....   | 151 |
| 3.14.6 WATCHDOG Examples.....   | 152 |
| 3.15 System Control Registers.....                                    | 153 |
| 3.15.1 SYSCTRL Base Address Table.....                                | 153 |
| 3.15.2 ACCESS_PROTECTION_REGS Registers.....                          | 154 |
| 3.15.3 CLK_CFG_REGS Registers.....                                    | 182 |

| 3.15.6 DEV_CFG_REGS Registers.....                   | 256        |
| 3.15.7 DMA_CLA_SRC_SEL_REGS Registers.....           | 286        |
| 3.15.8 MEM_CFG_REGS Registers.....                   | 293        |
| 3.15.9 MEMORY_ERROR_REGS Registers.....              | 345        |
| 3.15.10 NMI_INTRUPT_REGS Registers.....              | 367        |
| 3.15.11 PERIPH_AC_REGS Registers.....                | 384        |
| 3.15.12 PIE_CTRL_REGS Registers.....                 | 431        |
| 3.15.13 SYNC_SOC_REGS Registers.....                 | 471        |
| 3.15.14 SYS_STATUS_REGS Registers.....               | 477        |
| 3.15.15 TEST_ERROR_REGS Registers.....               | 484        |
| 3.15.16 UID_REGS Registers.....                      | 488        |
| 3.15.17 WD_REGS Registers.....                       | 497        |
| 3.15.18 XINT_REGS Registers.....                     | 504        |
| 3.15.19 LFU_REGS Registers.....                      | 513        |
| 3.15.20 Register to Driverlib Function Mapping.....  | 525        |
| <b>4 ROM Code and Peripheral Booting.....</b>        | <b>545</b> |
| 4.1 Introduction.....                                | 546        |
| 4.2 ROM Related Collateral.....                      | 546        |
| 4.3 Device Boot Sequence.....                        | 547        |
| 4.4 Device Boot Modes.....                           | 547        |
| 4.4.1 Default Boot Modes.....                        | 547        |
| 4.4.2 Custom Boot Modes.....                         | 548        |
| 4.5 Device Boot Configurations.....                  | 548        |
| 4.5.1 Configuring Boot Mode Pins.....                | 549        |
| 4.5.2 Configuring Boot Mode Table Options.....       | 551        |
| 4.5.3 Boot Mode Example Use Cases.....               | 552        |
| 4.6 Device Boot Flow Diagrams.....                   | 553        |
| 4.6.1 Boot Flow.....                                 | 553        |
| 4.6.2 Emulation Boot Flow.....                       | 555        |
| 4.6.3 Standalone Boot Flow.....                      | 556        |
| 4.7 Device Reset and Exception Handling.....         | 557        |
| 4.7.1 Reset Causes and Handling.....                 | 557        |
| 4.7.2 Exceptions and Interrupts Handling.....        | 557        |
| 4.8 Boot ROM Description.....                        | 558        |
| 4.8.1 Boot ROM Configuration Registers.....          | 558        |
| 4.8.2 Entry Points.....                              | 559        |
| 4.8.3 Wait Points.....                               | 560        |
| 4.8.4 Secure Flash Boot.....                         | 560        |
| 4.8.5 Live Firmware Update (LFU) Flash Boot.....     | 563        |
| 4.8.6 Secure LFU Flash Boot.....                     | 563        |
| 4.8.7 Memory Maps.....                               | 565        |
| 4.8.8 ROM Tables.....                                | 566        |
| 4.8.9 Boot Modes and Loaders.....                    | 566        |
| 4.8.10 GPIO Assignments.....                         | 582        |
| 4.8.11 Secure ROM Function APIs.....                 | 584        |
| 4.8.12 Clock Initializations.....                    | 585        |
| 4.8.13 Boot Status Information.....                  | 585        |
| 4.8.14 ROM Version.....                              | 587        |
| 4.9 Application Notes for Using the Bootloaders..... | 587        |
| 4.9.1 Bootloader Data Stream Structure.....          | 587        |
| Example 4-2. Data Stream Structure 8-bit.....        | 589        |
| 4.9.2 The C2000 Hex Utility.....                     | 589        |
| Example 4-3. HEX2000.exe Command Syntax.....         | 590        |
| <b>5 Dual Code Security Module (DCSM).....</b>       | <b>591</b> |
| 5.1 Introduction.....                                | 592        |
| 5.1.1 DCSM Related Collateral.....                   | 592        |
| 5.2 Functional Description.....                      | 592        |
| 5.2.1 CSM Passwords.....                             | 593        |
| 5.2.2 Emulation Code Security Logic (ECSL).....      | 595        |

|   |            |
|---|------------|
| 5.2.3 CPU Secure Logic.....                                       | 595        |
| 5.2.4 Password Lock.....  | 595        |
| 5.2.5 JTAGLOCK.....   | 596        |
| 5.2.6 Link Pointer and Zone Select.....                           | 596        |
| 5.2.7 C Code Example to Get Zone Select Block Addr for Zone1..... | 599        |
| 5.3 Flash and OTP Erase/Program.....                              | 599        |
| 5.4 Secure Copy Code.....   | 599        |
| 5.5 SecureCRC.....  | 600        |
| 5.6 CSM Impact on Other On-Chip Resources.....                    | 601        |
| 5.7 Incorporating Code Security in User Applications.....         | 602        |
| 5.7.1 Environments That Require Security Unlocking.....           | 602        |
| 5.7.2 CSM Password Match Flow.....                                | 602        |
| 5.7.3 C Code Example to Unsecure C28x Zone1.....                  | 604        |
| 5.7.4 C Code Example to Resecure C28x Zone1.....                  | 604        |
| 5.7.5 Environments That Require ECSL Unlocking.....               | 604        |
| 5.7.6 ECSL Password Match Flow.....                               | 604        |
| 5.7.7 ECSL Disable Considerations for any Zone.....               | 606        |
| 5.7.8 Device Unique ID.....                                       | 606        |
| 5.8 DCSM Registers.....   | 606        |
| 5.8.1 DCSM Base Address Table.....                                | 606        |
| 5.8.2 DCSM_Z1_REGS Registers.....                                 | 607        |
| 5.8.3 DCSM_Z2_REGS Registers.....                                 | 652        |
| 5.8.4 DCSM_COMMON_REGS Registers.....                             | 688        |
| 5.8.5 DCSM_Z1_OTP Registers.....                                  | 704        |
| 5.8.6 DCSM_Z2_OTP Registers.....                                  | 721        |
| <b>6 Flash Module.....</b>  | <b>731</b> |
| 6.1 Introduction to Flash and OTP Memory.....                     | 732        |
| 6.1.1 FLASH Related Collateral.....                               | 732        |
| 6.1.2 Features.....   | 732        |
| 6.1.3 Flash Tools.....  | 732        |
| 6.1.4 Default Flash Configuration.....                            | 733        |
| 6.2 Flash Bank, OTP, and Pump.....                                | 733        |
| 6.3 Flash Module Controller (FMC).....                            | 734        |

| 20.3 ePWM Modules Overview.....  | 2153        |
| 20.4 Time-Base (TB) Submodule.....   | 2155        |
| 20.4.1 Purpose of the Time-Base Submodule.....                                   | 2155        |
| 20.4.2 Controlling and Monitoring the Time-Base Submodule.....                   | 2156        |
| 20.4.3 Calculating PWM Period and Frequency.....                                 | 2158        |
| 20.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules.....          | 2163        |
| 20.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules..... | 2163        |
| 20.4.6 Time-Base Counter Modes and Timing Waveforms.....                         | 2164        |
| 20.4.7 Global Load.....  | 2167        |
| 20.5 Counter-Compare (CC) Submodule.....   | 2169        |
| 20.5.1 Purpose of the Counter-Compare Submodule.....                             | 2169        |
| 20.5.2 Controlling and Monitoring the Counter-Compare Submodule.....             | 2170        |
| 20.5.3 Operational Highlights for the Counter-Compare Submodule.....             | 2171        |
| 20.5.4 Count Mode Timing Waveforms.....  | 2172        |
| 20.6 Action-Qualifier (AQ) Submodule.....  | 2175        |
| 20.6.1 Purpose of the Action-Qualifier Submodule.....                            | 2175        |
| 20.6.2 Action-Qualifier Submodule Control and Status Register Definitions.....   | 2176        |
| 20.6.3 Action-Qualifier Event Priority.....                                      | 2178        |
| 20.6.4 AQCTLA and AQCTLB Shadow Mode Operations.....                             | 2179        |
| 20.6.5 Waveforms for Common Configurations.....                                  | 2181        |
| 20.7 Dead-Band Generator (DB) Submodule.....                                     | 2190        |
| 20.7.1 Purpose of the Dead-Band Submodule.....                                   | 2190        |
| 20.7.2 Dead-band Submodule Additional Operating Modes.....                       | 2191        |
| 20.7.3 Operational Highlights for the Dead-Band Submodule.....                   | 2193        |
| 20.8 PWM Chopper (PC) Submodule.....   | 2197        |
| 20.8.1 Purpose of the PWM Chopper Submodule.....                                 | 2197        |
| 20.8.2 Operational Highlights for the PWM Chopper Submodule.....                 | 2197        |
| 20.8.3 Waveforms.....  | 2198        |
| 20.9 Trip-Zone (TZ) Submodule.....   | 2201        |
| 20.9.1 Purpose of the Trip-Zone Submodule.....                                   | 2201        |
| 20.9.2 Operational Highlights for the Trip-Zone Submodule.....                   | 2202        |
| 20.9.3 Generating Trip Event Interrupts.....                                     | 2205        |
| 20.10 Event-Trigger (ET) Submodule.....  | 2207        |
| 20.10.1 Operational Overview of the ePWM Event-Trigger Submodule.....            | 2207        |
| 20.11 Digital Compare (DC) Submodule.....  | 2212        |
| 20.11.1 Purpose of the Digital Compare Submodule.....                            | 2213        |
| 20.11.2 Enhanced Trip Action Using CMPSS.....                                    | 2214        |
| 20.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis.....              | 2214        |
| 20.11.4 Operation Highlights of the Digital Compare Submodule.....               | 2214        |
| 20.12 ePWM Crossbar (X-BAR).....   | 2220        |

|   |             |

| 25.1 Introduction.....  | 2592        |
| 25.1.1 SCI Related Collateral.....                            | 2592        |
| 25.1.2 Features.....  | 2592        |
| 25.1.3 Block Diagram.....                                     | 2593        |
| 25.2 Architecture.....  | 2593        |
| 25.3 SCI Module Signal Summary.....                           | 2594        |
| 25.4 Configuring Device Pins.....                             | 2594        |
| 25.5 Multiprocessor and Asynchronous Communication Modes..... | 2596        |
| 25.6 SCI Programmable Data Format.....                        | 2596        |
| 25.7 SCI Multiprocessor Communication.....                    | 2597        |
| 25.7.1 Recognizing the Address Byte.....                      | 2597        |
| 25.7.2 Controlling the SCI TX and RX Features.....            | 2597        |
| 25.7.3 Receipt Sequence.....                                  | 2597        |
| 25.8 Idle-Line Multiprocessor Mode.....                       | 2598        |
| 25.8.1 Idle-Line Mode Steps.....                              | 2598        |
| 25.8.2 Block Start Signal.....                                | 2598        |
| 25.8.3 Wake-UP Temporary (WUT) Flag.....                      | 2599        |
| 25.8.4 Receiver Operation.....                                | 2599        |
| 25.9 Address-Bit Multiprocessor Mode.....                     | 2600        |
| 25.9.1 Sending an Address.....                                | 2600        |
| 25.10 SCI Communication Format.....                           | 2601        |
| 25.10.1 Receiver Signals in Communication Modes.....          | 2601        |
| 25.10.2 Transmitter Signals in Communication Modes.....       | 2602        |
| 25.11 SCI Port Interrupts.....                                | 2603        |
| 25.12 SCI Baud Rate Calculations.....                         | 2603        |
| 25.13 SCI Enhanced Features.....                              | 2604        |
| 25.13.1 SCI FIFO Description.....                             | 2604        |
| 25.13.2 SCI Auto-Baud.....                                    | 2606        |
| 25.13.3 Autobaud-Detect Sequence.....                         | 2606        |
| 25.14 Software.....   | 2607        |
| 25.14.1 SCI Examples.....                                     | 2607        |
| 25.15 SCI Registers.....                                      | 2608        |
| 25.15.1 SCI Base Address Table.....                           | 2608        |
| 25.15.2 SCI_REGS Registers.....                               | 2609        |
| 25.15.3 SCI Registers to Driverlib Functions.....             | 2628        |
| <b>26 Inter-Integrated Circuit Module (I2C).....</b>          | <b>2631</b> |
| 26.1 Introduction.....  | 2632        |
| 26.1.1 I2C Related Collateral.....                            | 2632        |
| 26.1.2 Features.....  | 2633        |
| 26.1.3 Features Not Supported.....                            | 2633        |
| 26.1.4 Functional Overview.....                               | 2634        |
| 26.1.5 Clock Generation.....                                  | 2635        |
| 26.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)..... | 2636        |
| 26.2 Configuring Device Pins.....                             | 2637        |
| 26.3 I2C Module Operational Details.....                      | 2637        |
| 26.3.1 Input and Output Voltage Levels.....                   | 2637        |
| 26.3.2 Data Validity.....                                     | 2637        |
| 26.3.3 Operating Modes.....                                   | 2637        |

|   |             |
|---|-------------|
| 26.3.4 I2C Module START and STOP Conditions.....                      | 2641        |
| 26.3.5 Non-repeat Mode vs Repeat Mode.....                            | 2642        |
| 26.3.6 Serial Data Formats.....                                       | 2643        |
| 26.3.7 Clock Synchronization.....                                     | 2645        |
| 26.3.8 Arbitration.....   | 2646        |
| 26.3.9 Digital Loopback Mode.....                                     | 2647        |
| 26.3.10 NACK Bit Generation.....                                      | 2648        |
| 26.4 Interrupt Requests Generated by the I2C Module.....              | 2649        |
| 26.4.1 Basic I2C Interrupt Requests.....                              | 2649        |
| 26.4.2 I2C FIFO Interrupts.....                                       | 2652        |
| 26.5 Resetting or Disabling the I2C Module.....                       | 2652        |
| 26.6 Software.....  | 2653        |
| 26.6.1 I2C Examples.....  | 2653        |
| 26.7 I2C Registers.....   | 2656        |
| 26.7.1 I2C Base Address Table.....                                    | 2656        |
| 26.7.2 I2C_REGS Registers.....  | 2657        |
| 26.7.3 I2C Registers to Driverlib Functions.....                      | 2680        |
| <b>27 Power Management Bus Module (PMBus).....</b>                    | <b>2683</b> |
| 27.1 Introduction.....  | 2684        |
| 27.1.1 PMBUS Related Collateral.....                                  | 2684        |
| 27.1.2 Features.....  | 2684        |
| 27.1.3 Block Diagram.....   | 2684        |
| 27.2 Configuring Device Pins.....                                     | 2685        |
| 27.3 Slave Mode Operation.....  | 2685        |
| 27.3.1 Configuration.....   | 2685        |
| 27.3.2 Message Handling.....  | 2686        |
| 27.4 Master Mode Operation.....                                       | 2696        |
| 27.4.1 Configuration.....   | 2696        |
| 27.4.2 Message Handling.....  | 2696        |
| 27.5 PMBus Registers.....   | 2706        |
| 27.5.1 PMBUS Base Address Table.....                                  | 2706        |
| 27.5.2 PMBUS_REGS Registers.....                                      | 2707        |
| 27.5.3 PMBUS Registers to Driverlib Functions.....                    | 2726        |
| <b>28 Controller Area Network (CAN).....</b>                          | <b>2729</b> |
| 28.1 Introduction.....  | 2730        |
| 28.1.1 DCAN Related Collateral.....                                   | 2730        |
| 28.1.2 Features.....  | 2730        |
| 28.1.3 Block Diagram.....   | 2731        |
| 28.2 Functional Description.....                                      | 2732        |
| 28.2.1 Configuring Device Pins.....                                   | 2732        |
| 28.2.2 Address/Data Bus Bridge.....                                   | 2733        |
| 28.3 Operating Modes.....   | 2734        |
| 28.3.1 Initialization.....  | 2734        |
| 28.3.2 CAN Message Transfer (Normal Operation).....                   | 2735        |
| 28.3.3 Test Modes.....  | 2736        |
| 28.4 Multiple Clock Source.....                                       | 2740        |
| 28.5 Interrupt Functionality.....                                     | 2741        |
| 28.5.1 Message Object Interrupts.....                                 | 2741        |
| 28.5.2 Status Change Interrupts.....                                  | 2741        |
| 28.5.3 Error Interrupts.....  | 2741        |
| 28.5.4 PIE Nomenclature for DCAN Interrupts.....                      | 2741        |
| 28.5.5 Interrupt Topologies.....                                      | 2742        |
| 28.6 DMA Functionality.....   | 2743        |
| 28.7 Parity Check Mechanism.....                                      | 2743        |
| 28.7.1 Behavior on Parity Error.....                                  | 2743        |
| 28.8 Debug Mode.....  | 2744        |
| 28.9 Module Initialization.....                                       | 2744        |
| 28.10 Configuration of Message Objects.....                           | 2745        |
| 28.10.1 Configuration of a Transmit Object for Data Frames.....       | 2745        |
| 28.10.2 Configuration of a Transmit Object for Remote Frames.....     | 2745        |
| 28.10.3 Configuration of a Single Receive Object for Data Frames..... | 2745        |

|   |             |
|---|-------------|
| 28.10.4 Configuration of a Single Receive Object for Remote Frames..... | 2746        |
| 28.10.5 Configuration of a FIFO Buffer.....                             | 2746        |
| 28.11 Message Handling.....   | 2746        |
| 28.11.1 Message Handler Overview.....                                   | 2747        |
| 28.11.2 Receive/Transmit Priority.....                                  | 2747        |
| 28.11.3 Transmission of Messages in Event Driven CAN Communication..... | 2747        |
| 28.11.4 Updating a Transmit Object.....                                 | 2748        |
| 28.11.5 Changing a Transmit Object.....                                 | 2748        |
| 28.11.6 Acceptance Filtering of Received Messages.....                  | 2749        |
| 28.11.7 Reception of Data Frames.....                                   | 2749        |
| 28.11.8 Reception of Remote Frames.....                                 | 2749        |
| 28.11.9 Reading Received Messages.....                                  | 2749        |
| 28.11.10 Requesting New Data for a Receive Object.....                  | 2750        |
| 28.11.11 Storing Received Messages in FIFO Buffers.....                 | 2750        |
| 28.11.12 Reading from a FIFO Buffer.....                                | 2750        |
| 28.12 CAN Bit Timing.....   | 2752        |
| 28.12.1 Bit Time and Bit Rate.....                                      | 2752        |
| 28.12.2 Configuration of the CAN Bit Timing.....                        | 2757        |
| 28.13 Message Interface Register Sets.....                              | 2761        |
| 28.13.1 Message Interface Register Sets 1 and 2 (IF1 and IF2).....      | 2761        |
| 28.13.2 Message Interface Register Set 3 (IF3).....                     | 2762        |
| 28.14 Message RAM.....  | 2763        |
| 28.14.1 Structure of Message Objects.....                               | 2763        |
| 28.14.2 Addressing Message Objects in RAM.....                          | 2766        |
| 28.14.3 Message RAM Representation in Debug Mode.....                   | 2767        |
| 28.15 Software.....   | 2768        |
| 28.15.1 CAN Examples.....   | 2768        |
| 28.16 CAN Registers.....  | 2771        |
| 28.16.1 CAN Base Address Table.....                                     | 2771        |
| 28.16.2 CAN_REGS Registers.....   | 2772        |
| 28.16.3 CAN Registers to Driverlib Functions.....                       | 2828        |
| <b>29 Modular Controller Area Network (MCAN).....</b>                   | <b>2833</b> |
| 29.1 MCAN Overview.....   | 2834        |
| 29.1.1 MCAN Related Collateral.....                                     | 2834        |
| 29.1.2 MCAN Features.....   | 2835        |
| 29.2 MCAN Environment.....  | 2835        |
| 29.3 CAN Network Basics.....  | 2836        |
| 29.4 MCAN Integration.....  | 2837        |
| 29.5 MCAN Functional Description.....                                   | 2839        |
| 29.5.1 Module Clocking Requirements.....                                | 2840        |
| 29.5.2 Interrupt Requests.....  | 2840        |
| 29.5.3 Operating Modes.....   | 2841        |
| 29.5.4 Transmitter Delay Compensation.....                              | 2844        |
| 29.5.5 Restricted Operation Mode.....                                   | 2845        |
| 29.5.6 Bus Monitoring Mode.....   | 2845        |
| 29.5.7 Disabled Automatic Retransmission (DAR) Mode.....                | 2846        |
| 29.5.8 Clock Stop Mode.....   | 2846        |
| 29.5.9 Test Modes.....  | 2848        |
| 29.5.10 Timestamp Generation.....                                       | 2848        |
| 29.5.11 Timeout Counter.....  | 2850        |
| 29.5.12 Safety.....   | 2850        |
| 29.5.13 Rx Handling.....  | 2852        |
| 29.5.14 Tx Handling.....  | 2858        |
| 29.5.15 FIFO Acknowledge Handling.....                                  | 2862        |
| 29.5.16 Message RAM.....  | 2862        |
| 29.6 Software.....  | 2874        |
| 29.6.1 MCAN Examples.....   | 2874        |
| 29.7 MCAN Registers.....  | 2877        |
| 29.7.1 MCAN Base Address Table.....                                     | 2877        |
| 29.7.2 MCANSS_REGS Registers.....                                       | 2878        |
| 29.7.3 MCAN_REGS Registers.....   | 2891        |

|   |             |
|---|-------------|

## List of Tables

|  |     |
|--|-----|
| Table 1-1. C2000Ware Root Directories.....                             | 88  |
| Table 2-1. TMU Supported Instructions.....                             | 93  |
| Table 3-1. Access to EALLOW-Protected Registers.....                   | 97  |
| Table 3-2. Reset Signals.....  | 97  |
| Table 3-3. Pie Channel Mapping.....                                    | 104 |
| Table 3-4. CPU Interrupt Vectors.....                                  | 106 |
| Table 3-5. PIE Interrupt Vectors.....                                  | 107 |
| Table 3-6. ALT Modes.....  | 118 |
| Table 3-7. Clock Connections Sorted by Clock Domain.....               | 120 |
| Table 3-8. Clock Source (OSCCLK) Failure Detection.....                | 123 |
| Table 3-9. Example Watchdog Key Sequences.....                         | 129 |
| Table 3-10. Effect of Clock-Gating Low-Power Modes on the Device.....  | 131 |
| Table 3-11. Local Shared RAM.....                                      | 135 |
| Table 3-12. Global Shared RAM.....                                     | 135 |
| Table 3-13. Error Handling in Different Scenarios.....                 | 139 |
| Table 3-14. Mapping of ECC Bits in Read Data from ECC Address Map..... | 140 |
| Table 3-15. SYCTRL Base Address Table.....                             | 153 |
| Table 3-16. ACCESS_PROTECTION_REGS Registers.....                      | 154 |
| Table 3-17. ACCESS_PROTECTION_REGS Access Type Codes.....              | 154 |
| Table 3-18. NMAVFLG Register Field Descriptions.....                   | 156 |
| Table 3-19. NMAVSET Register Field Descriptions.....                   | 158 |
| Table 3-20. NMAVCLR Register Field Descriptions.....                   | 160 |
| Table 3-21. NMAVINTEN Register Field Descriptions.....                 | 162 |
| Table 3-22. NMCPURDAVADDR Register Field Descriptions.....             | 164 |
| Table 3-23. NMCPUWRAVADDR Register Field Descriptions.....             | 165 |
| Table 3-24. NMCPUFAVADDR Register Field Descriptions.....              | 166 |
| Table 3-25. NMDMAWRAVADDR Register Field Descriptions.....             | 167 |
| Table 3-26. NMCLA1RDAVADDR Register Field Descriptions.....            | 168 |

## About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

## Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

## Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at [www.ti.com](http://www.ti.com).

Additionally, the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#) and the [TMS320C28x Floating Point Unit and Instruction Set Reference Guide](#) must be used in conjunction with this TRM.

## Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

## 1.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: [www.ti.com/tool/C2000WARE](http://www.ti.com/tool/C2000WARE)

## 1.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in [Table 1-1](#).

**Table 1-1. C2000Ware Root Directories**

| Directory Name | Description   |
|----------------|---|
| boards         | Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS. |
| device_support | Contains all device-specific support files, bit field headers and device development user's guides.   |
| docs           | Contains the C2000Ware package user's guides and the HTML index page of all package documentation.    |
| driverlib      | Contains the device-specific driver library and driver-based peripheral examples.                     |
| libraries      | Contains the device-specific and core libraries.  |

## 1.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDS. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

## 1.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: [www.ti.com/c2000](http://www.ti.com/c2000).

## 1.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

## 1.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: [www.ti.com/ccstudio](http://www.ti.com/ccstudio)

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, it is easily obtainable in a variety of versions.

## 1.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: [dev.ti.com](https://dev.ti.com)

## 2.1 Introduction

The C28x CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing, reduced instruction set computing (RISC), microcontroller architectures, firmware, and tool sets.

For more information on CPU architecture and instruction set, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

## 2.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

## 2.4 Floating-Point Unit

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision and double-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

Fast Integer Division (FINTDIV) supports Truncated, Modulo and Euclidean division formats without cycle penalty and provides results in integer and remainder representation.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.5 Trigonometric Math Unit

The TMU extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 2-1](#).

**Table 2-1. TMU Supported Instructions**

| Instruction             | C Equivalent Operation                     | Pipeline Cycles |
|-------------------------|--|-----------------|
| MPY2PIF32 RaH,RbH       | $a = b * 2\pi$                             | 2/3             |
| DIV2PIF32 RaH,RbH       | $a = b / 2\pi$                             | 2/3             |
| DIVF32 RaH,RbH,RcH      | $a = b/c$                                  | 5               |
| SQRTF32 RaH,RbH         | $a = \text{sqrt}(b)$                       | 5               |
| SINPUF32 RaH,RbH        | $a = \sin(b*2\pi)$                         | 4               |
| COSPUF32 RaH,RbH        | $a = \cos(b*2\pi)$                         | 4               |
| ATANPUF32 RaH,RbH       | $a = \text{atan}(b)/2\pi$                  | 4               |
| QUADF32 RaH,RbH,RcH,RdH | Operation to assist in calculating ATANPU2 | 5               |

Exponent instruction IEXP2F32 and logarithmic instruction LOG2F32 have been added to support computation of floating-point power function for the non-linear proportional integral derivative control (NLPID) component of the C2000 Digital Control Library. These two added instructions reduce the power function calculations from a typical of 300 cycles using library emulation to less than 10 cycles.

No changes have been made to existing instructions, pipeline or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out their operations.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.6 VCRC Unit

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCRC can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. For example, the VCU can compute the CRC for a block length of 10 bytes in 10 cycles. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

The following are the CRC polynomials used by the CRC calculation logic of VCRC:

- CRC8 polynomial = 0x07
- CRC16 polynomial1 = 0x8005
- CRC16 polynomial2 = 0x1021
- CRC24 polynomial = 0x5d6dcb
- CRC32 polynomial1 = 0x04c11db7
- CRC32 polynomial2 = 0x1edc6f41

This module can calculate CRCs for a byte of data in a single cycle. The CRC calculation for CRC8, CRC16, CRC24 and CRC32 is done byte-wise (instead of computing on a complete 16-bit or 32-bit data read by the C28x core) to match the byte-wise computation requirement mandated by various standards.

The VCRC Unit also allows the user to provide the size (1b-32b) and value of any polynomial to fit custom CRC requirements. The CRC execution time increases to **three cycles** when using a custom polynomial.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

This page intentionally left blank.

The system-level functionality of this microcontroller configures the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

## 3.1 Introduction

System-level configuration is controlled by a group of submodules that are collectively referred to as the system control module. The system control module provides the following capabilities:

- System-level resets, including power-on and brownout resets
- Clock source selection and PLL configuration
- Missing clock detection
- Clock-gating low-power modes
- Peripheral interrupt handling
- Non-maskable interrupts for certain fault conditions
- Three 32-bit timers
- Windowed watchdog timer, which can generate an interrupt or a reset
- RAM initialization, write protection, and mastership control
- Flash memory ECC, wait state, and cache configuration
- Dual-zone code security module

### 3.1.2 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by “LOCK” registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

### 3.1.3 EALLOW Protection

Some registers in the system are protected from spurious CPU writes by the EALLOW protection mechanism. This uses the special CPU instructions EALLOW and EDIS to enable and disable access to protected registers. The current protection state is given by the EALLOW bit in the CPU ST1 register, as shown in [Table 3-1](#).

Register protection is enabled by default at startup. While protected, all writes to protected registers by the CPU are ignored. Only CPU reads, JTAG reads, and JTAG writes are allowed. If protection is disabled by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, they can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

Writes to the clock configuration and peripheral clock enable registers may be disabled until the next reset by writing to special lock registers.

**Table 3-1. Access to EALLOW-Protected Registers**

| EALLOW Bit | CPU Writes | CPU Reads              | JTAG Writes | JTAG Reads |
|------------|------------|------------------------|-------------|------------|
| 0          | Ignored    | Allowed <sup>(1)</sup> | Allowed     | Allowed    |
| 1          | Allowed    | Allowed                | Allowed     | Allowed    |

(1) The EALLOW bit is overridden by way of the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio™ interface.

### 3.2 Power Management

The TMS320F28003x MCU supports both internal and external VREG selectable using the VREGENZ pin to supply the 1.2v rail. However, not all packages support the external VREG option. For packages that do not support external VREG, the VREGENZ pin is replaced by GPIO39. For more details, see the TMS320F28003x data manual.

### 3.3 Device Identification and Configuration Registers

The device identification registers and configuration registers provide information on the part number, product family, revision, pin count, qualification status, and feature availability of the device.

All of the device information is part of the DEV\_CFG\_REGS space. The identification registers are PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID\_REGS. The 256 bits are separated into these registers:

- UID\_PSRAND0-5: 192 bits of pseudo-random data
- UID\_UNIQUE: 32-bit unique data; the value in this register will be unique across all devices in the same PARTIDH
- UID\_CHECKSUM: 32-bit Fletcher checksum of UID\_PSRAND0-5 and UID\_UNIQUE and calculated as either little- or big-endian during factory testing

### 3.4 Resets

This section explains the types and effects of the different resets on this device.

#### 3.4.1 Reset Sources

Table 3-2 summarizes the various reset signals and their effect on the device.

**Table 3-2. Reset Signals**

| Reset Source           | CPU Core Reset (C28x, FPU, VCU, TMU) | Peripherals Reset | JTAG / Debug Logic Reset | IOs  | XRS Output |
|------------------------|--------------------------------------|-------------------|--------------------------|------|------------|
| POR                    | Yes                                  | Yes               | Yes                      | Hi-Z | Yes        |
| BOR                    | Yes                                  | Yes               | Yes                      | Hi-Z | Yes        |
| XRS Pin                | Yes                                  | Yes               | No                       | Hi-Z | -          |
| WDRS                   | Yes                                  | Yes               | No                       | Hi-Z | Yes        |
| NMIWDRS                | Yes                                  | Yes               | No                       | Hi-Z | Yes        |
| SYSRS (Debugger Reset) | Yes                                  | Yes               | No                       | Hi-Z | No         |
| SCCRESET               | Yes                                  | Yes               | No                       | Hi-Z | No         |
| SIMRESET. XRS          | Yes                                  | Yes               | No                       | Hi-Z | Yes        |
| SIMRESET. CPU1RS       | Yes                                  | Yes               | No                       | Hi-Z | No         |
| HWBISTR                | Yes                                  | No                | No                       | No   | No         |

The resets can be divided into two groups:

- Chip-level resets ( $\overline{XRS}$ , POR, BOR,  $\overline{WDRS}$ , SIMRESET.  $\overline{XRS}$  and  $\overline{NMIWDRS}$ ), which reset all or almost all of the device.
- System resets ( $\overline{SYSRS}$ , SIMRESET.  $\overline{CPU1RS}$  and  $\overline{SCCRESET}$ ), which reset a large subset of the device but maintain some system-level configuration.

- Special resets ( $\overline{\text{HWBISTR}}$  and  $\overline{\text{TRST}}$ ), which enable specific device functions.

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain their state across multiple resets. They can only be cleared by a power-on reset (POR) or by writing ones to the RESCCLR register. Some are cleared by the boot ROM as part of its start-up routines.

Many peripheral modules have individual resets accessible through the SOFTPRESx registers. For information about a module's reset state, refer to the chapter for that module.

After any reset, the CPU begins execution from address 0x3FFFC0 (the reset vector), which is in the boot ROM. After running the boot ROM code, the CPU will typically branch to the start of the Flash memory at address 0x80000. For more information on controlling the boot process, see [ROM Code and Peripheral Booting](#).

---

#### Note

After a POR, the boot ROMs will clear the M0/M1, LSx, GSx, and message RAMs to ensure that they contain valid ECC.

---

### 3.4.2 External Reset ( $\overline{\text{XRS}}$ )

The external reset ( $\overline{\text{XRS}}$ ) is the main chip-level reset for the device. It resets the CPU, all peripherals and I/O pin configurations, and most of the system control registers. There is a dedicated open-drain pin for  $\overline{\text{XRS}}$ . This pin may be used to drive reset pins for other ICs in the application, and may itself be driven by an external source. The  $\overline{\text{XRS}}$  is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register will be set whenever  $\overline{\text{XRS}}$  is driven low for any reason. This bit is then cleared by the boot ROM.

### 3.4.3 Simulate External Reset (SIMRESET. $\overline{\text{XRS}}$ )

In some cases, a user may need to simulate an external reset ( $\overline{\text{XRS}}$ ) in software. This can be done by setting XRSn bit to '1' in SIMRESET register through software. This toggles the  $\overline{\text{XRS}}$  pin hence resets the full device (just like an external reset).

After this reset, SIMRESET\_XRSn and XRSn bits in the RESC register will be set. Software can read these bits to know the cause of reset and clear the status by writing '1' into corresponding bits in the RESCCLR register.

### 3.4.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The  $\overline{\text{XRS}}$  pin is held low for the duration of the POR. In most applications,  $\overline{\text{XRS}}$  is held low long enough to reset other system ICs, but some applications may require a longer pulse. In these cases, the  $\overline{\text{XRS}}$  pin can be driven low externally to provide the correct reset duration. A POR resets everything that  $\overline{\text{XRS}}$  does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG), and the X1 clock counter register (X1CNT). A POR also resets the debug logic used by the JTAG port.

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

### 3.4.5 Brown-Out-Reset (BOR)

The brown-out-reset (BOR) is an internal supply voltage supervisor (SVS) circuit which monitors the VDDIO supply for glitches or supply interruptions. If the VDDIO supply voltage drops below operational voltage range, this circuit forces the XRSn pin low until the fault is removed and the supply voltage returns to the minimum operational voltage. A BOR resets everything in the same manner as a POR reset.

The BOR circuit is enabled by default and therefore will always be active during power up or after any type of reset. To disable the BOR circuit, set the BORLVMONDIS bit in the VMONCTL register.

### 3.4.6 Debugger Reset ( $\overline{\text{SYSRS}}$ )

During development, it is sometimes necessary to reset the CPU and its peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, the CPU has its own subsystem reset, which can be triggered by a debugger using Code Composer Studio™ IDE. This reset ( $\overline{\text{SYSRS}}$ ) resets the CPU, its peripherals, many system control registers (including its clock gating and LPM configuration), and all I/O pin configurations.

The  $\overline{\text{SYSRS}}$  does not reset the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 3.4.4](#)).

### 3.4.7 Simulate CPU Reset ( $\text{SIMRESET}$ . $\overline{\text{CPU1RS}}$ )

In some cases, a user may need to simulate the CPU reset ( $\overline{\text{SYSRS}}$ ) in software. This can be done by setting CPU1RSn bit to '1' in the SIMRESET register through software. This toggles CPU1.SYSRS signals hence resetting the CPU (just like the debugger reset).

After this reset, SIMRESET\_CPU1RSn bit in the RESC register will be set. Software can read this bit to know the cause of reset and clear the status by writing '1' into corresponding bit in RESCCLR register.

### 3.4.8 Watchdog Reset ( $\overline{\text{WDRS}}$ )

The device has a watchdog timer that can optionally trigger a reset if it is not serviced by the CPU within a user-specified amount of time. This watchdog reset ( $\overline{\text{WDRS}}$ ) produces an  $\overline{\text{XRS}}$  that lasts for 512 INTOSC1 cycles.

After a watchdog reset, the WDRSn and XRSn bits in RESC are set.

### 3.4.9 Hardware BIST Reset ( $\overline{\text{HWBISTRS}}$ )

The Hardware Built-In Self-Test (HWBIST) module tests the functionality of the CPU. At the end of the test, it resets the CPU to return it to a working state. This reset ( $\overline{\text{HWBISTRS}}$ ) only affects the CPU itself. The peripherals and system control remain as previously configured. The CPU state is restored in software as part of a special boot ROM flow. For more information on the HWBIST flow, contact your local TI representative.

After a HWBIST reset, the HWBISTRn bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing '1' into corresponding bit in RESCCLR register.

### 3.4.10 NMI Watchdog Reset ( $\overline{\text{NMIWDRS}}$ )

The device has a non-maskable interrupt (NMI) module that detects hardware errors in the system. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This NMI watchdog reset ( $\overline{\text{NMIWDRS}}$ ) produces an  $\overline{\text{XRS}}$  that lasts for 512 INTOSC1 cycles.

After an NMI watchdog reset, the NMIWDRSn and XRSn bits in RESC are set.

### 3.4.11 DCSM Safe Code Copy Reset ( $\overline{\text{SCCRESET}}$ )

The device has a dual-zone code security module (DCSM) that blocks read access to certain areas of the Flash memory. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a safe copy or CRC function, the DCSM triggers a reset. This security reset ( $\overline{\text{SCCRESET}}$ ) is similar to a  $\overline{\text{SYSRS}}$ . However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set.

## 3.5 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 3.6](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

### 3.5.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause its current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

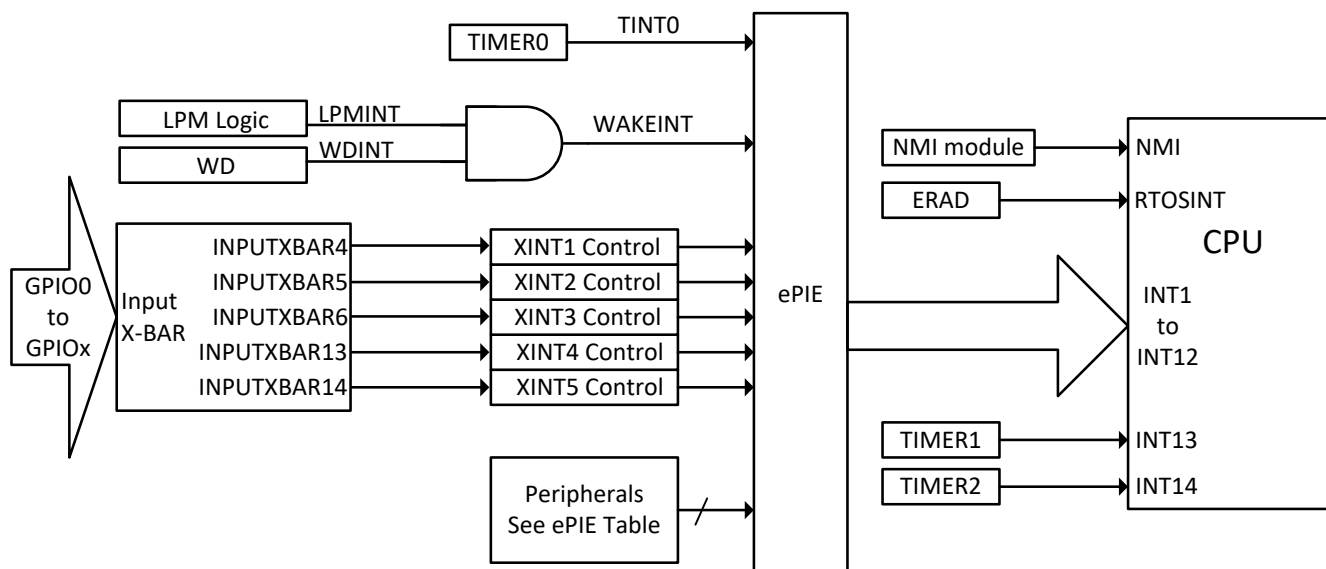

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until it is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

### 3.5.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line. It also expands the vector table to allow each interrupt to have its own ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has its own enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

[Figure 3-1](#) shows the interrupt architecture for this device.

**Figure 3-1. Device Interrupt Architecture**

### 3.5.2.1 Peripheral Stage

Each peripheral has its own unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral might use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt will be generated.

### 3.5.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to their associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, it fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition will not happen unless software changes the state of the PIE while an interrupt is propagating. Section 3.5.4 contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

### 3.5.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of its interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC and CLRC instructions. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is set, the next instruction in the pipeline will run with interrupts disabled. No software delays are needed.

### 3.5.3 Interrupt Entry Sequence

Figure 3-2 shows how peripheral interrupts propagate to the CPU.

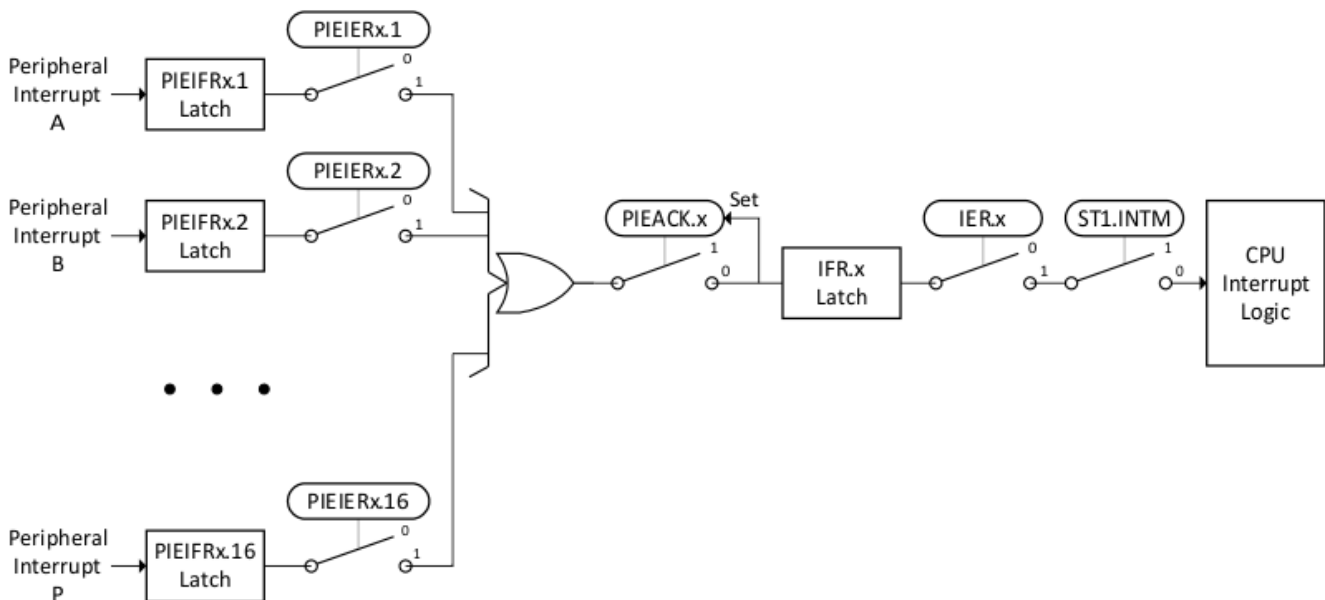

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group  $x$ , channel  $y$ ), it triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves its context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories will add to the latency. External interrupts add a minimum of two SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

### 3.5.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

#### 3.5.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which can be found in [Table 3-3](#). Note that the vector table is EALLOW-protected.
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments can be found in [Table 3-3](#).
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

#### 3.5.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the [TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide](#). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the [TMS320C28x CPU and Instruction Set Reference Guide](#).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU will not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

### 3.5.4.3 Disabling Interrupts

To disable all interrupts, set the CPU's global interrupt mask via DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction will execute with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, it may reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation may cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR will only contain a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to its original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

### 3.5.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts via software control of the IER and PIEIERx registers. Example code can be found in C2000Ware and documentation is available at .

### 3.5.4.5 Vector Address Validity Check

There are two copies of the ePIE vector table. The primary vector table is located at addresses 0xD00 - 0xEFF. The redundant vector table is located at addresses 0x0100D00 - 0x0100EFF. A write to a primary vector address writes to both tables, while a write to a redundant vector address only writes to the redundant table. Both tables are read independently.

During a vector fetch, the ePIE performs a hardware comparison of both vector table outputs. If there is a mismatch between the two vector tables, the CPU branches to the address in the PIEVERRADDR register and the ePIE sends trip signals to the PWMs. If the PIEVERRADDR register value has not been set, the default boot ROM handler at address 0x003FFFBE is used.

### 3.5.5 PIE Channel Mapping

Table 3-3 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel in the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

**Table 3-3. Pie Channel Mapping**

|                | INTx.1       | INTx.2        | INTx.3       | INTx.4        | INTx.5       | INTx.6       | INTx.7           | INTx.8                | INTx.9       | INTx.10              | INTx.11                | INTx.12               | INTx.13          | INTx.14        | INTx.15          | INTx.16               |

### 3.5.5.1 PIE Interrupt Priority

#### 3.5.5.1.1 Channel Priority

For every PIE group, the low number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 will be serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 will be serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, in order for channel 1.3 to be serviced, channel 1.1's ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1's ISR completes, channel 1.2 which is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU will service channel 1.2 and channel 1.3 will still be left pending. Using the steps from the Interrupt Entry Sequence ([Section 3.5.3](#)), channel 1.2 interrupt can happen as late as step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and it will still be serviced ahead of channel 1.3.

#### 3.5.5.1.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in their respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 will be serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence ([Section 3.5.3](#)).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence ([Section 3.5.3](#)).

1. As the CPU reaches step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 will be serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 will be serviced ahead of 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only guaranteed if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence ([Section 3.5.3](#)) is not executing.

### 3.5.6 Vector Tables

Table 3-4 shows the CPU interrupt vector table. The vectors for INT1 – INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table. All vectors are EALLOW-protected.

Table 3-5 shows the pie vector table.

**Table 3-4. CPU Interrupt Vectors**

| Name    | Vector ID | Address     | Size (x16) | Description   | Core Priority | ePIE Group Priority |
|---------|-----------|-------------|------------|---|---------------|---------------------|
| Reset   | 0         | 0x0000 0D00 | 2          | Reset is always fetched from location 0x003F_FFC0 in Boot ROM | 1 (Highest)   | -                   |
| INT1    | 1         | 0x0000 0D02 | 2          | Not used. See PIE Group 1                                     | 5             | -                   |
| INT2    | 2         | 0x0000 0D04 | 2          | Not used. See PIE Group 2                                     | 6             | -                   |
| INT3    | 3         | 0x0000 0D06 | 2          | Not used. See PIE Group 3                                     | 7             | -                   |
| INT4    | 4         | 0x0000 0D08 | 2          | Not used. See PIE Group 4                                     | 8             | -                   |

## 3.6 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

### 3.6.1 Configuring and Using NMIs

An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if it reaches the value in the NMIWDPRD register, it triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register may also be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

### 3.6.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

|                            |  |
|----------------------------|--|
| CPU Suspended              | When the CPU is suspended, the NMI watchdog counter will be suspended.   |
| Run-Free Mode              | When the CPU is placed in run-free mode, the NMI watchdog counter will resume operation as normal.   |
| Real-Time Single-Step Mode | When the CPU is in real-time single-step mode, the NMI watchdog counter will be suspended. The counter remains suspended even within real-time interrupts. |
| Real-Time Run-Free Mode    | When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.   |

### 3.6.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

#### 3.6.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and an NMI is fired to the CPU. For more information on missing clock detection, see [Section 3.7.12.1](#).

#### 3.6.3.2 RAM Uncorrectable Error

A double-bit ECC data error, or single-bit ECC address error in a RAM read will trigger an NMI. This applies to CPU and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 3.11.8](#).

#### 3.6.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read triggers an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on Flash error detection, see [Section 3.11.8](#).

#### 3.6.3.4 CPU HWBIST Error

If the Hardware Built-in self (HWBIST) module detects a fault in the CPU, an NMI is generated.

#### 3.6.3.5 Software-Forced Error

There is a special NMI source that can only be triggered by writing to the SWERR bit in the NMIFLGFRC register. Since the SWERR flag is never set by a real hardware fail, it can be used to implement a self-test mode for the NMI subsystem.

### 3.6.4 CRC Fail

A CRC fail result from the Background CRC (BGCRC) module can generate NMI. By default, this NMI is enabled. To disable this feature, the NMIDIS configuration field in the BGCRC\_CTRL1 register has to be written with "1010".

### 3.6.5 ERAD NMI

The ERAD module can generate NMI based on different events. This is configurable in the GLBL\_NMI\_CTL register.

### 3.6.6 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, it generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has its own vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#).

---

#### Note

A RAM fetch access violation will trigger an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU will handle the ITRAP first.

---

### 3.6.7 Error Pin

A signal called ERRORSTS can be output to GPIO24, GPIO28, GPIO29 or GPIO55. This signal goes low when any bit is set in the NMI shadow flag register (NMISHDFLG). It can be used to alert an external system to a problem in the microcontroller. Since the state of ERRORSTS is based on the shadow flags, ERRORSTS will remain low until the flags are cleared by the CPU or a power-on reset occurs.

All GPIO pins are inputs on power-up. If the state of the chosen ERRORSTS pin during power-up is important, an external pull-down should be connected to the pin.

### 3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 3-3 and Figure 3-4 provide an overview of the device's clocking system.

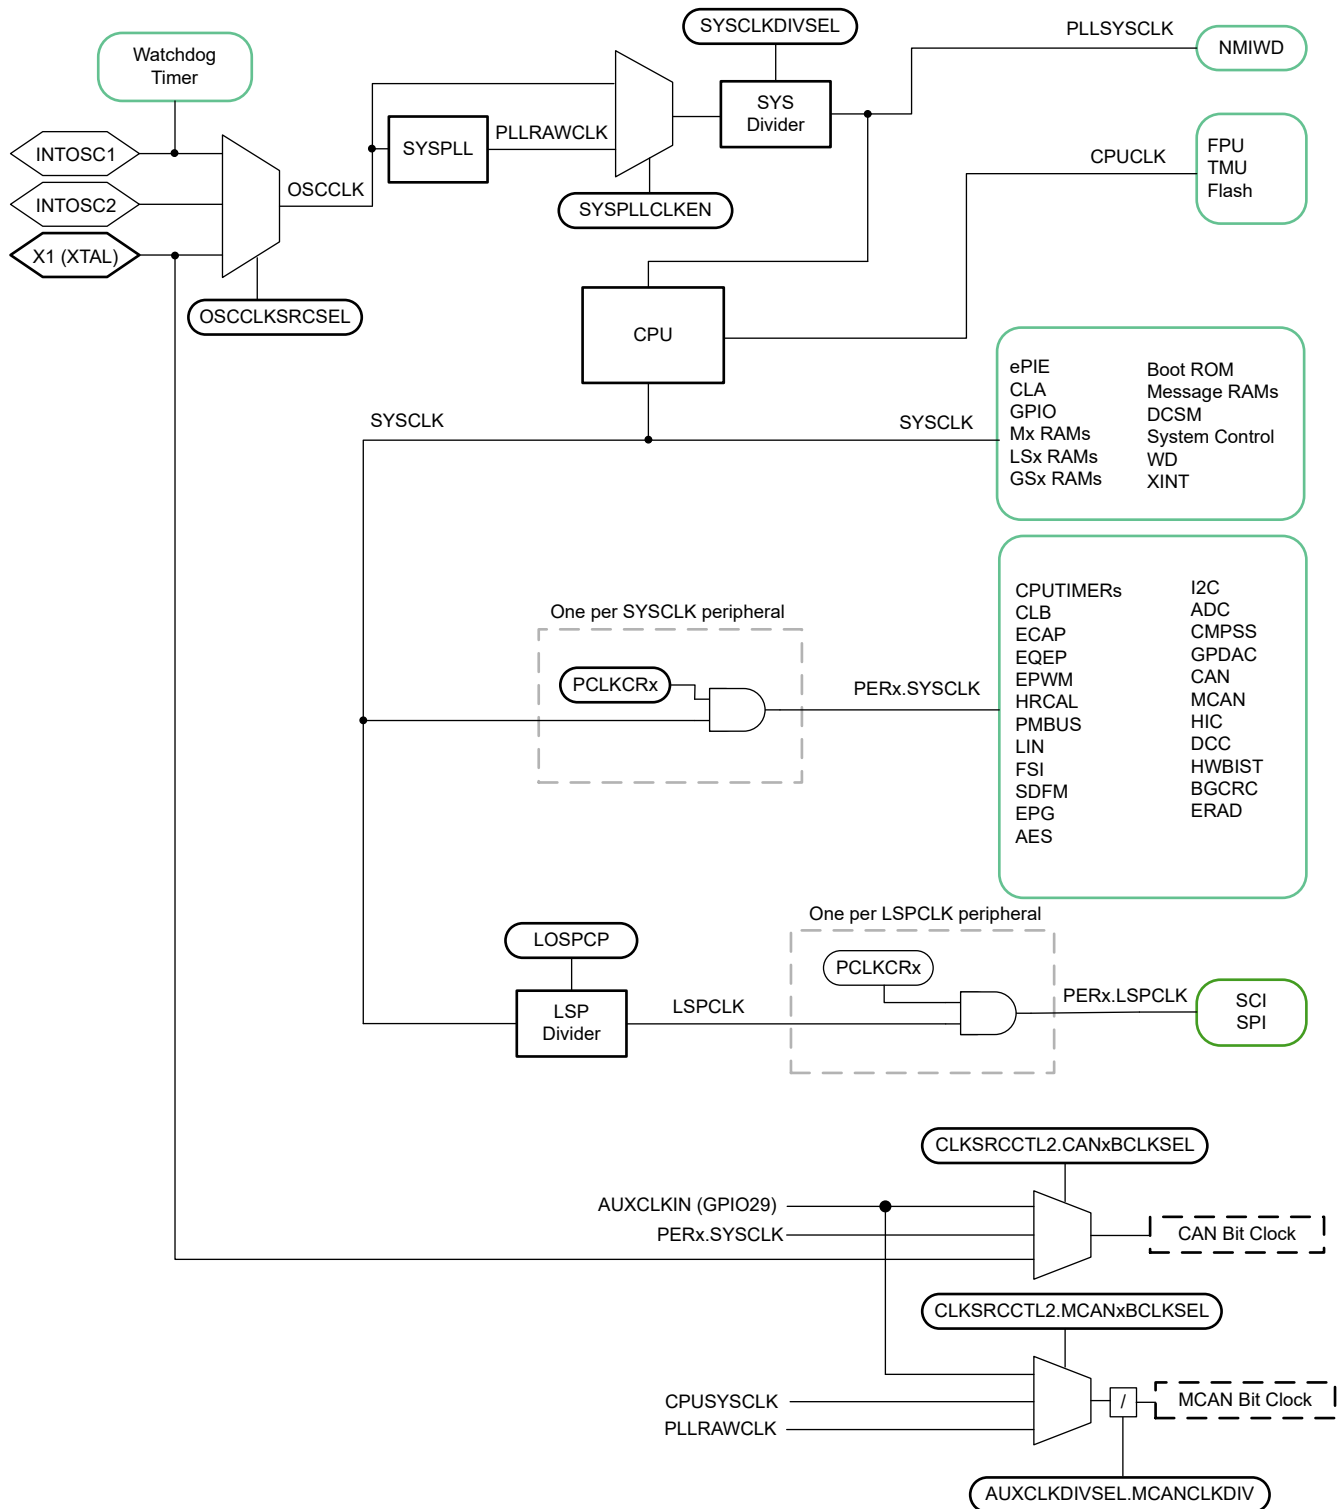

Figure 3-3. Clocking System

## SYSPLL

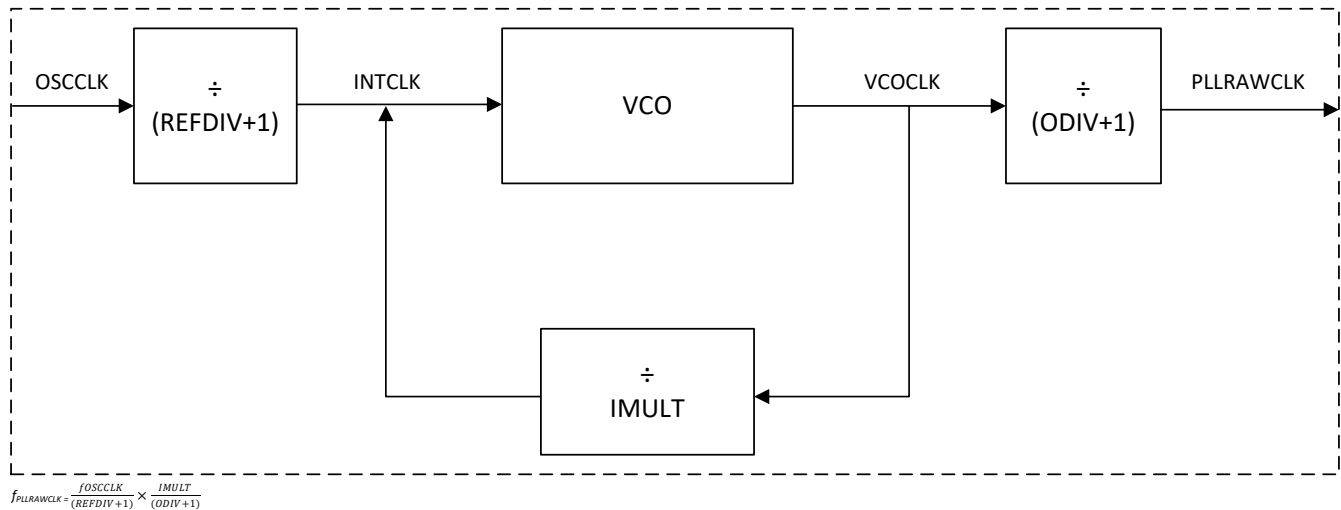

Figure 3-4. System PLL

### 3.7.1 Clock Sources

All of the clocks in the device are derived from one of four clock sources.

#### 3.7.1.1 Primary Internal Oscillator (INTOSC2)

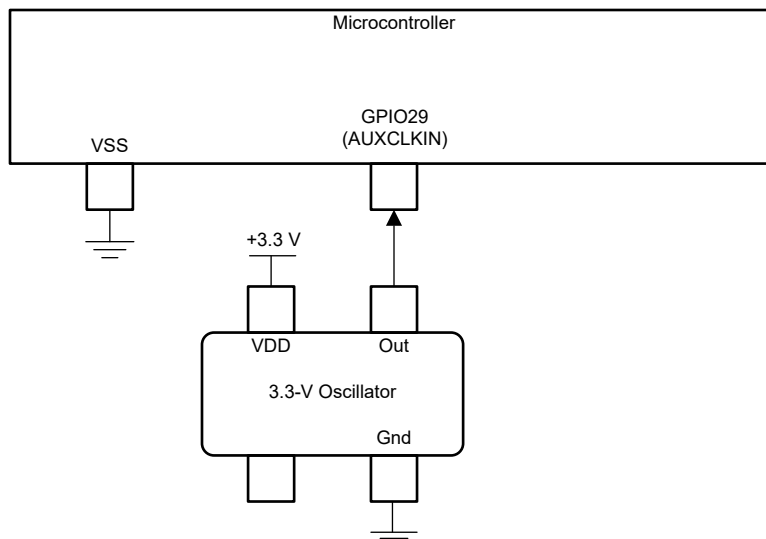

At power-up, the device is clocked from an on-chip 10-MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. It is used to run the boot ROM and can be used as the system clock source for the application. Note that the INTOSC2 frequency tolerance is too loose to meet the timing requirements for CAN. Use of the CAN modules requires an external oscillator. When INTOSC2 is used as the system clock source, GPIO19 (X1) and GPIO18 (X2) are available as GPIO pins.

#### 3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10 MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system clock source for debug purposes.

### 3.7.1.3 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO29 (AUXCLKIN). This must be a single-ended 3.3V external clock as shown in [Figure 3-5](#). It can be used as the clock source for DCAN and MCAN. Frequency limits and timing requirements are found in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#). The external clock should be connected directly to the GPIO29 pin.

**Figure 3-5. AUXCLKIN**

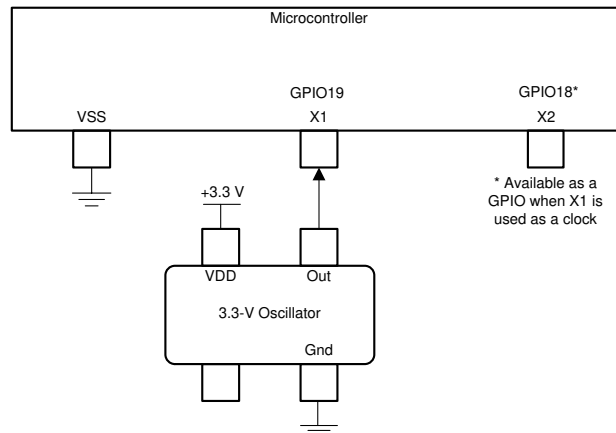

### 3.7.1.4 External Oscillator (XTAL)

The device supports an external clock source (XTAL), which can be used as the main system and CAN bit clock source. Frequency limits and timing requirements are found in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#). External clock sources use the X1/GPIO19 and X2/GPIO18 pins. After power-up, the X1 and X2 pin functionality can be enabled by following the procedure in [Section 3.7.6](#).

Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal should be connected to X1, as shown in [Figure 3-6](#).

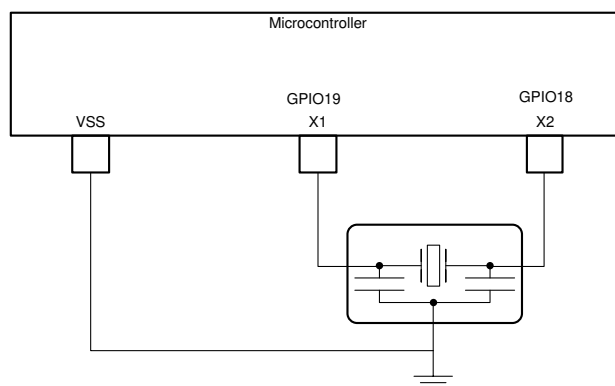

**Figure 3-6. Single-ended 3.3V External Clock**

- An external crystal. The crystal should be connected across X1 and X2 with its load capacitors connected to VSS as shown in [Figure 3-7](#).

**Figure 3-7. External Crystal**

- An external resonator. The resonator should be connected across X1 and X2 with its ground connected to VSS as shown in [Figure 3-8](#).

**Figure 3-8. External Resonator**
**Table 3-6. ALT Modes**

| XTALCR Bit <sup>(1)</sup> |    | Operating Mode                                  | GPIO19 Available on X1? | GPIO18 Available on X2? |
|---------------------------|----|---|-------------------------|-------------------------|
| OSCOFF                    | SE |   |                         |                         |
| 0                         | 0  | Crystal Mode: Quartz crystal connected to X1/X2 | No                      | No                      |
| 0                         | 1  | Single-Ended Mode: External clock on X1         | No                      | Yes                     |
| 1                         | 0  | Oscillator off                                  | Yes                     | Yes                     |
| 1                         | 1  | Single-Ended Mode: External clock on X1         | No                      | Yes                     |

(1) OSCOFF and SE determine the ALT mode of GPIO18 and GPIO19.

### 3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (via PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

#### 3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

#### 3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at its maximum rated operating frequency, and in most applications will generate the main system clock. This PLL uses OSCCLK as a reference. PLLRAWCLK is the output of the PLL's voltage-controlled oscillator (VCO). For configuration instructions, see [Section 3.7.6](#).

### 3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

#### 3.7.3.1 System Clock (PLLSYSCLK)

The NMI watchdog timer has its own clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK may be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured via the SYSCLKDIVSEL register. PLLSYSCLK is gated in HALT mode.

### 3.7.3.2 CPU Clock (CPUCLK)

The CPU has its own clock (CPUCLK) that is used to clock the CPU and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or HALT mode.

### 3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each peripheral clock has its own independent clock gating which is controlled by the PCLKCRx registers.

---

#### Note

Application needs to wait for 5 SYSCLK cycles after enabling clock to the peripherals when using PCLKCRx.

---

### 3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI and SPI modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed via the LOSPCP register. Each SCI and SPI module's clock (PERx.LSPCLK) can be gated independently via the PCLKCRx registers.

### 3.7.3.5 CAN Bit Clock

The required frequency tolerance for the DCAN and MCAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of SYSCLK) may not be precise enough, the bit clock can also be connected to XTAL, AUXCLKIN and PLLRAWCLK via the CLKSRCCTL2 register. There is an independent selection for each CAN module. See the CLKSRCCTL2 register for the valid options for the MCAN and DCAN.

To guarantee correct operation, the frequency of the CAN bit clock must be less than or equal to the SYSCLK frequency.

### 3.7.3.6 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but may also be connected to INTOSC1, INTOSC2, or XTAL via the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a non-SYSCLK source is used, it must be divided down to no more than half the SYSCLK frequency.

The main reason to use a non-SYSCLK source would be for internal frequency measurement. In most applications, timer 2 will run off of SYSCLK.

## 3.7.4 XCLKOUT

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, which can be GPIO16 or GPIO18. The available clock sources are PLLSYSCLK, PLLRAWCLK, SYSCLK, INTOSC1, INTOSC2, and XTAL.

To use XCLKOUT, first select the clock source via the CLKSRCCTL3 register. Next, select the desired output divider via the XCLKOUTDIVSEL register. Finally, connect GPIO16 or GPIO18 to mux channel 11 using the GPIO configuration registers.

### 3.7.5 Clock Connectivity

Table 3-7 shows the clock connections sorted by the clock domain.

**Table 3-7. Clock Connections Sorted by Clock Domain**

| Clock Domain    | Module Name  |
|-----------------|--|
| CPUCLK          | FPU<br>TMU<br>Flash  |
| SYSCLK          | CLA<br>ePIE<br>Mx RAMs<br>LSx RAMs<br>GSx RAMs<br>Message RAMs<br>Boot ROM<br>GPIO Input Sync and Qual<br>WD<br>XINT<br>DCSM   |
| PLLSYSCLK       | CPU<br>NMIWD   |
| PERx.SYSCLK     | AES<br>CLB<br>Timer0 - 2<br>DCC0 - 1<br>FSI<br>ePWM1 - 8<br>eCAP1 - 3<br>eQEP1 - 2<br>ADCA, B, C<br>GPDACA, B<br>CMPSS1 - 4<br>DCAN<br>MCAN<br>I2CA - B<br>PMBUSA<br>LINA - B<br>HICA<br>HWBIST<br>BGCRC<br>HRCAL<br>EPG<br>SDFM<br>ERAD |
| PERx.LSPCLK     | SCIA - B<br>SPIA - B   |
| CAN Bit Clock   | DCAN, MCAN   |
| WDCLK (INTOSC1) | Watchdog Timer   |

### 3.7.6 Clock Source and PLL Setup

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but they should provide answers to the following questions:

1. What is the desired CPU frequency?
2. Is CAN required?
3. What types of external oscillators or clock sources are available?

If CAN will be used in the application, it is recommended to use an external clock source with a precise frequency as the reference clock. Otherwise, it may be possible to use only INTOSC2 and avoid the need for more external components.

### 3.7.7 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO19 and GPIO18. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. 1ms is the typical wait time but this depends on the crystal that is being used.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7ff).
4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7ff).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCCR register. If it's set, the oscillator has not finished powering up, and more time is required:
  - a. Clear the missing clock status by writing a 1 to MCDCCR.MCLKCLR.
  - b. Repeat steps 2-7. Do not reset the device. Doing so will power down the oscillator, which requires the procedure to be restarted from step 1.
  - c. If the oscillator has not finished powering up in 10 milliseconds, there is a real clock failure.
8. If MCDCCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

#### 3.7.7.1 X1/X2 Precondition Circuit

The GPIO19/18 alternate functionality on X1/X2 can be used to speed up the start-up time of the crystal by as much as 30% if needed. This functionality is achieved by preconditioning the load capacitors CL1 and CL2 to a known state before the XTAL is turned on.

The steps below outline the procedure to precondition X1/X2 before turning on the XTAL:

1. ClkCfgRegs.XTALCR2.bit.XIF = 1; // Precondition X1 to High
2. ClkCfgRegs.XTALCR2.bit.XOF = 1; // Precondition X2 to High
3. ClkCfgRegs.XTALCR2.bit.FEN = 1; // Enable X1/X2 Precondition
4. DEVICE\_DELAY\_US(1);
5. ClkCfgRegs.XTALCR2.bit.OSCOFF = 0; // Removes Precondition and Turns on the XTAL
6. ClkCfgRegs.XTALCR2.bit.FEN = 0; // Disables X1/X2 Precondition

### 3.7.8 Using an External Oscillator

The procedure for using an external oscillator connected to the X1 pin is similar to the procedure for using a crystal or resonator:

1. Clear the XTALCR.OSCOFF bit.
2. Set the XTALCR.SE bit to enable single-ended mode.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7ff).

4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7ff).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCCR register. If it's set, either the external oscillator or the device has failed.
8. If MCLKSTS is clear, the switch to the external clock is a success. The system clock is now derived from XTAL.

### 3.7.9 Choosing PLL Settings

The equation shown in [Figure 3-4](#) should be used to configure the PLL.

IMULT is the integer value of the multiplier.

REFDIV is the reference divider for the OSCCLK.

ODIV is the output divider of the PLLRAWCLK.

PLLSYSCLKDIV is the system clock divider.

For the permissible values of the multipliers and dividers, see the documentation for their respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#).

---

#### Note

The system clock frequency (PLLSYSCLK) may not exceed the limit specified in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#). This limit does not allow for oscillator tolerance.

---

### 3.7.10 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure should be used to set up the desired application configuration:

Refer to your device SysCtl\_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN]. Allow at least 60 NOP instructions for this to take effect.
2. Power down the PLL by writing to SYSPLLCTL1.PPLEN=0 and allow at least 60 NOP instructions for this to take effect.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL. Allow at least 300 NOP instructions for this to take effect.
4. Set the system clock divider to "/1" to ensure the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing 32-bit value in SYSPLLMULT at once. This will automatically enable the PLL. Be sure the settings for the multiplier and dividers do not violate the frequency specifications defined in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#).
6. Wait for PLL to lock by polling for lock status bit to go high, that is, SYSPLLSTS.LOCKS=1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to DCC chapter for more information on its configuration and usage.
8. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN].

### Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least 60 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN=0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PLEN=0.
4. At least 300 CPU clock cycles delay is needed after OSSCLK source is changed.
5. PLL SLIP bit is not supported. DCC should be used to check the validity of the PLL clock. This feature is included as part of SysCtl\_setClock() function inside C2000Ware.

### 3.7.11 SYS PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then it needs to configure SYSPLLCTL1.PLLCLKEN=0. It takes up to 60 CPU clock cycles before the bypass is effective. In the meantime, if PLLSYSCLKDIV is reduced to a lower value (for example from /2 to /1 or /4 to /2) the device may be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 60 CPU clock cycles is required after bypassing the PLL from enable state, that is, going from PLLCLKEN=1 to PLLCLKEN=0.

### 3.7.12 Clock (OSCCLK) Failure Detection

In order to achieve safety diagnostic there are two circuits available, which can detect failure of PLL reference clock.

1. Missing Clock Detection (MCD)
2. PLL Reference Clock Detection

Table 3-8 lists the details of both circuits.

**Table 3-8. Clock Source (OSCCLK) Failure Detection**

| Clock Failure Detection Circuitry | Clocks Detected           | Time for Detection (in Cycles) | Limitations                          |
|-----------------------------------|---------------------------|--------------------------------|--------------------------------------|
| Missing Clock Detection (MCD)     | INTOSC2, XTAL/X1          | 8192 INTOSC1 cycles            | Cannot detect INTOSC1 clock failure. |
| PLL Reference Clock Detection     | INTOSC1, INTOSC2, XTAL/X1 | 10 OSCCLK cycles               | Requires PLL to be enabled.          |

#### 3.7.12.1 Missing Clock Detection

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and doesn't do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCCLK (primary clock) using the 10 MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as below:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT will never overflow.
4. If OSCCLK stops for some reason, or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT will overflow and a missing clock condition will be detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDPCR register (by making the MCLKOFF bit 1)

6. If the circuit ever detects a missing OSCCLK, the following occurs:
  - The MCDSTS flag is set
  - The MCDSCNT counter is frozen to prevent further missing clock detection
  - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWD.
  - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (New, System Clock Frequency = INTOSC1 Freq 10 MHz)/SYSDIV). In the meantime, when clock switches to INTOSC1 System runs on PLL limp Clock.
  - SYSPLLMULT.IMULT is zeroed out automatically in this case.
  - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
  - PLLRAWCLK going to the system is switched to INTOSC1 automatically
7. If the MCLKCLR bit is written (this is a W=1 bit), MCDSTS bit will be cleared and OSCCLK source will be decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR will also clear the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If user wants to lock the PLL after missing clock detection, he needs to first switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR and re-lock the PLL.
8. The MCD is enabled at power up.

Figure 3-9 shows the missing clock logic functional flow.

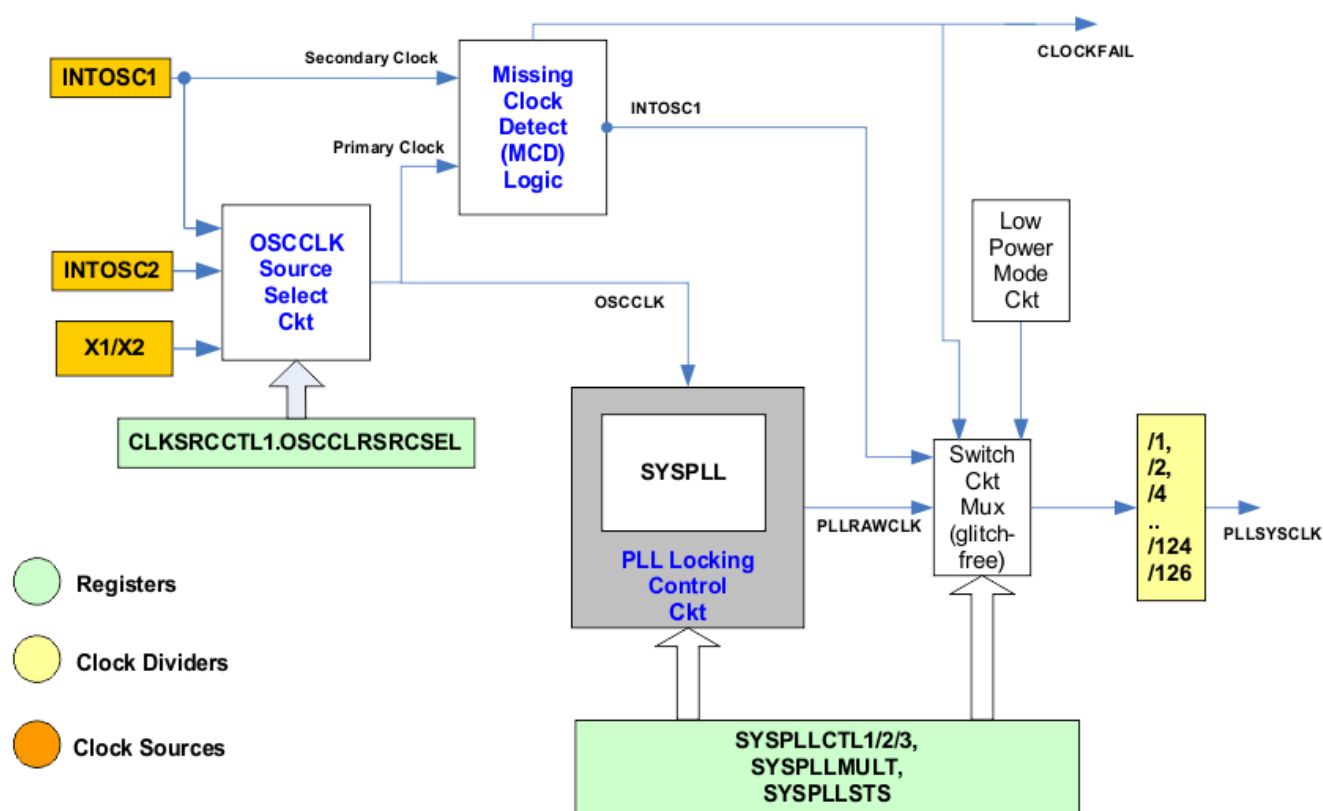

Figure 3-9. Missing Clock Detection Logic

---

**Note**

On a complete clock failure when OSCCLK is dead, it may take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192 ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated
  - OSCCLK is switched to INTOSC1
  - PWM Trip happens
- 

**3.7.12.2 PLL Reference Clock Lost Detection**

This circuit monitors reference clock to PLL (OSCCLK) and triggers Clock failure only on a complete loss of OSCCLK and not on OSCCLK frequency drift. Unlike MCD this circuit requires PLL to be configured and running. Features of PLL Reference Clock Lost Detection:

1. Response time for clock failure detection is much faster compared to MCD.
2. It can detect clock failure for any clock sources used, that is, INTOSC1, INTOSC2, and XTAL/X1. If INTOSC1 is used as OSCCLK, the steps for configuration are different and explained below in this section.

### 3.7.12.2.1 When OSCCLK = INTOSC2 or XTAL/X1

Recommended steps to configure PLL Reference Clock Lost Detection circuit:

1. Configure PLL as per the recommended sequence described in [Section 3.7.10](#).
2. Enable Reference Clock Lost to trigger a CLOCKFAIL event by configuring MCDCR.SYSREF\_LOST\_MCD\_EN=1.

When PLL Reference Clock Lost Detection subsystem detects that OSCCLK is missing:

- PLL is bypassed and OSCCLK is connected to INTOSC1 (after the PLLSYSCLK divider). In the meantime when clock switches to INTOSC1, system runs on PLL Limp Clock.
- SYSPLLMULT.IMULT is zeroed out automatically.
- The MCDCR.SYSREF\_LOSTS and SYSPLLSTS.REF\_LOSTS flag is set. While this flag is set, the OSCCLKSRCSEL bits have no effect.
- The CLOCKFAIL signal goes high, which generates trip events to the PWM modules and triggers an NMI.

To clear a Reference Clock Lost condition, write a 1 to the MCDCR.SYSREF\_LOSTSCLR bit, this will restore the functionality of the OSCCLKSRCSEL. To re-lock the PLL during the loss of Reference Clock Lost, switch the OSCCLK source to INTOSC1 using the OSCCLKSRCSEL bits, clear the missing clock condition, then write to the PLL registers.

### 3.7.12.2.2 When OSCCLK = INTOSC1

Recommended steps to configure PLL Reference Clock Lost Detection when OSCCLK= INTOSC1:

1. Configure PLL as per the recommended sequence described in [Section 3.7.10](#).
2. Disable MCD by configuring MCDCR.MCLKOFF=1.
3. Disable Reference Clock Lost to trigger a CLOCKFAIL event by configuring MCDCR.SYSREF\_LOST\_MCD\_EN=0.

When PLL Reference Clock Lost Detection subsystem detects that OSCCLK is missing:

- System runs on PLL Limp Clock.
- SYSPLLMULT.IMULT stays as it is and does not get zeroed out automatically.
- The SYSPLLSTS.REF\_LOSTS flag is set. While this flag is set, the OSCCLKSRCSEL bits have no effect.
- Since MCD is disabled it does not generate CLOCKFAIL signal, so it does not trigger NMI interrupt nor generate EPWM trip event. Application SW needs to monitor SYSPLLSTS.REF\_LOSTS flag to determine clock failure and then generate trip event for EPWM.

To clear a Reference Clock Lost condition, write a 1 to the MCDCR.SYSREF\_LOSTSCLR bit, this will restore the functionality of the OSCCLKSRCSEL. To re-lock the PLL during the loss of Reference Clock Lost, switch the OSCCLK source to INTOSC2 or XTAL/X1 using the OSCCLKSRCSEL bits, then write to the PLL registers.

---

#### Note

- It is recommended to use OSCCLK=INTOSC2 or XTAL/X1 and not INTOSC1. INTOSC1 should be treated as a fallback clock ONLY.
  - If clock failure happens when OSCCLK=INTOSC1 and MCD is not turned OFF then SYSCLK will be dead and system will hang up.
-

### 3.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU timers (TIMER0/1/2) shown in Figure 3-10.

Timer0 and Timer1 can be used in user applications. Timer2 is reserved for real-time operating system uses (for example, TI-RTOS). If the application is not using an operating system that utilizes this timer, then Timer2 can be used in the application. timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 3-11.

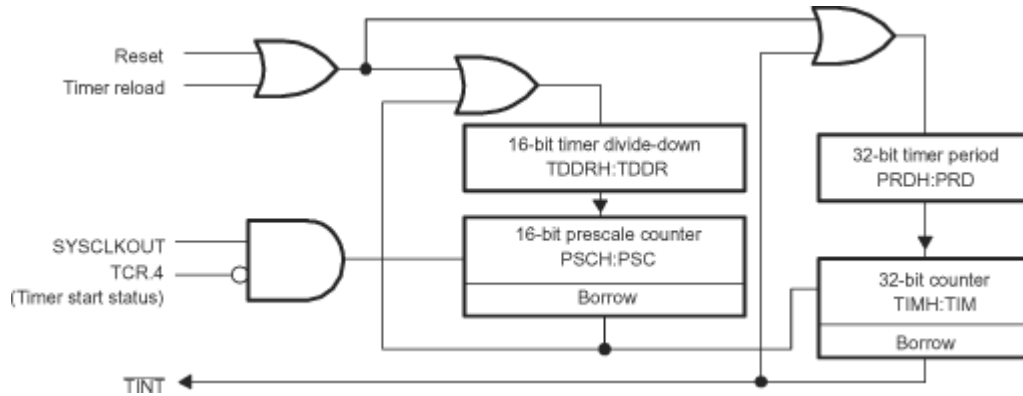

Figure 3-10. CPU Timers

- A. The timer registers are connected to the memory bus of the C28x processor.
- B. The CPU Timers are synchronized to SYSCLKOUT.

Figure 3-11. CPU Timer Interrupt Signals and Output Signal

The general operation of a CPU timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD
- The counter decrements once every  $(TPR[TDDR:H:TDDR]+1)$  SYSCLK cycles, where TDDR:H:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.15 are used to configure the timers.

### 3.9 Watchdog Timer

The watchdog module consists of an 8-bit counter fed by a prescaled clock (WDCLK, which is connected to INTOSC1). When the counter reaches its maximum value, the module generates an output pulse 512 WDCLKs wide. This pulse can generate an interrupt or a reset. The CPU must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled.

The counter's clock is divided down from WDCLK by two dividers. The prescaler is adjustable from /1 to /64 in powers of two. The pre-divider defaults to /512 for backwards compatibility, but is adjustable from /2 to /4096 in powers of two. This allows a wide range of timeout values for safety-critical applications.

Figure 3-12 shows the various functional blocks within the watchdog module.

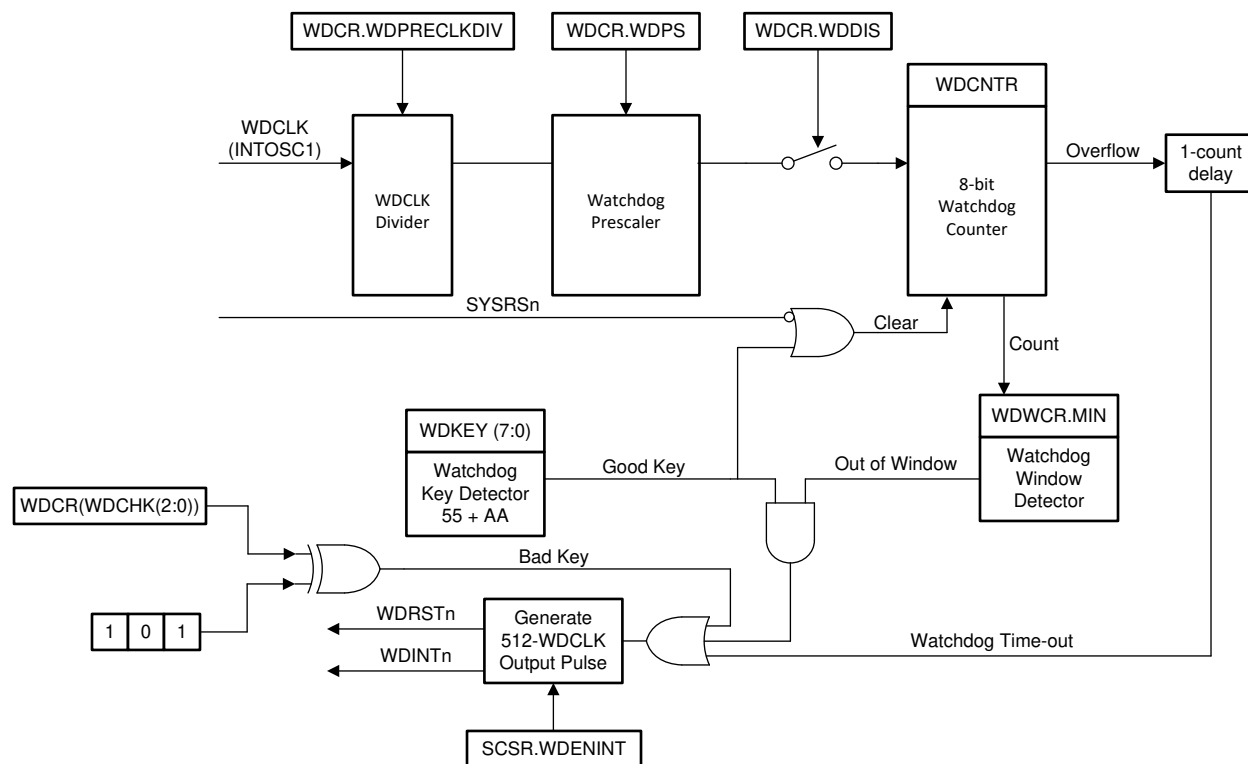

Figure 3-12. Watchdog Timer Module

### 3.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

The first action that enables the WDCNTR to be reset is shown in Step 3 in [Table 3-9](#). The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCR overflow or writing the incorrect value to the WDCR[WDCHK] bits will reset the device and set the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program should clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

**Table 3-9. Example Watchdog Key Sequences**

| Step | Value Written to WDKEY | Result  |
|------|------------------------|---|
| 1    | 0xAA                   | No action   |
| 2    | 0xAA                   | No action   |
| 3    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.  |
| 4    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.  |
| 5    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.  |
| 6    | 0xAA                   | WDCNTR is reset.  |
| 7    | 0xAA                   | No action   |
| 8    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.  |
| 9    | 0xAA                   | WDCNTR is reset.  |
| 10   | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.  |
| 11   | 0x32                   | Improper value written to WDKEY.<br>No action, WDCNTR no longer enabled to be reset by next 0xAA. |
| 12   | 0xAA                   | No action due to previous invalid value.  |
| 13   | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.  |
| 14   | 0xAA                   | WDCNTR is reset.  |

### 3.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value will take effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR will trigger a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

### 3.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ( $\overline{\text{WDRST}}$ ) or assert an interrupt ( $\overline{\text{WDINT}}$ ) if the watchdog counter reaches its maximum value. The behavior of each condition is:

- **Reset mode:**

If the watchdog is configured to reset the device, then the  $\overline{\text{WDRST}}$  signal will pull the device reset ( $\overline{\text{XRS}}$ ) pin low for 512 OSCCLK cycles when the watchdog counter reaches its maximum value.

- **Interrupt mode:**

When the watchdog counter expires, it will assert an interrupt by driving the  $\overline{\text{WDINT}}$  signal low for 512 OSCCLK cycles. The falling edge of  $\overline{\text{WDINT}}$  triggers a WAKEINT interrupt in the PIE if it is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while  $\overline{\text{WDINT}}$  is active will not produce a duplicate interrupt.

To avoid unexpected behavior, software should not change the configuration of the watchdog while  $\overline{\text{WDINT}}$  is active. For example, changing from interrupt mode to reset mode while  $\overline{\text{WDINT}}$  is active will immediately reset the device. Disabling the watchdog while  $\overline{\text{WDINT}}$  is active will cause a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while  $\overline{\text{WDINT}}$  is active, the reset cause register (RESC) will show a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of  $\overline{\text{WDINT}}$ .

### 3.9.4 Watchdog Operation in Low Power Modes

In IDLE mode, the watchdog interrupt ( $\overline{\text{WDINT}}$ ) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt will trigger a WAKE interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

**Note:** If the watchdog interrupt is used to wake-up from an IDLE low power mode condition, software must make sure that the  $\overline{\text{WDINT}}$  signal goes back high before attempting to reenter the IDLE mode. The  $\overline{\text{WDINT}}$  signal will be held low for 512 OSCCLK cycles when the watchdog interrupt is generated. The current state of  $\overline{\text{WDINT}}$  can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of  $\overline{\text{WDINT}}$  by two SYSCLKOUT cycles.

In HALT mode, the internal oscillators and watchdog timer are kept active if the user sets CLKSRCCTL1.WDHALTI = 1. A watchdog reset can wake the system from HALT mode, but a watchdog interrupt cannot.

### 3.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

|                            |  |
|----------------------------|--|
| CPU Suspended              | When the CPU is suspended, the watchdog clock (WDCLK) is suspended.  |
| Run-Free Mode              | When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.   |
| Real-Time Single-Step Mode | When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts. |
| Real-Time Run-Free Mode    | When the CPU is in real-time run-free mode, the watchdog operates as normal.   |

### 3.10 Low Power Modes

This device has HALT, IDLE, and STANDBY as clock-gating low-power modes.

All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [TMS320C28x CPU and Instruction Set Reference Guide](#).

Low-power modes should not be entered into while a Flash program or erase operation is ongoing. Entering HALT will stop all CPU and peripheral activities. This includes active transmissions and control algorithms. When preparing to enter HALT mode, the application should ensure that the system is prepared to enter a period of inactivity.

Before entering HALT mode, check the value of the GPIODAT register of the pin selected for HALT wake-up (GPIOLPMSEL0/1) prior to entering the low-power mode to ensure that the wake event has not already been asserted.

#### 3.10.1 Clock-Gating Low-Power Modes

IDLE and HALT modes on this device are similar to those on other C28x devices. [Table 3-10](#) describes the effect on the system when any of the clock-gating low-power modes are entered.

**Table 3-10. Effect of Clock-Gating Low-Power Modes on the Device**

| Modules/<br>Clock Domain                     | IDLE    | STANDBY | HALT   |
|--|---------|---------|--|
| SYSCLK                                       | Active  | Gated   | Gated  |
| CPUCLK                                       | Gated   | Gated   | Gated  |
| Clock to modules connected<br>to PERx.SYSCLK | Active  | Gated   | Gated  |
| WDCLK  | Active  | Active  | Gated if CLKSRCCTL1.WDHALTI = 0                    |
| PLL  | Powered | Powered | Software must power down PLL before entering HALT. |
| INTOSC1                                      | Powered | Powered | Powered down if CLKSRCCTL1.WDHALTI = 0             |
| INTOSC2                                      | Powered | Powered | Powered down if CLKSRCCTL1.WDHALTI = 0             |
| Flash <sup>(1)</sup>                         | Powered | Powered | Powered  |
| XTAL <sup>(2)</sup>                          | Powered | Powered | Powered  |

- (1) The Flash module is not powered down by hardware in any LPM. It may be powered down using software if required by the application. For more information, see the *Flash Module* chapter.
- (2) The XTAL is not powered down by hardware in any LPM. It may be powered down by software setting the XTALCR.OSCOFF bit to 1. This can be done at any time during the application if the XTAL is not required.

#### 3.10.2 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events.

Any enabled interrupt will wake the CPU up from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

The CPU will resume normal operations upon any enabled interrupt event.

### 3.10.3 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU's SYSCLK. The watchdog however, is left active. STANDBY is best suited for an application where the wake-up signal will come from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) a watchdog interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-60 can be configured to wake the CPU when they are driven active low. Upon wakeup, the CPU receives the WAKEINT interrupt if configured.

#### To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

#### To wake up from STANDBY mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; it must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block.

The CPU is now out of STANDBY mode and can resume normal execution.

### 3.10.4 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks.

Unlike on other C2000™ devices, HALT mode will not automatically power down the XTAL upon HALT entry. Additionally, if the XTAL is not powered on, waking up from HALT mode will not automatically power on the XTAL. The XTALCR.OSCOFF bit has been added to power on and off the XTAL circuitry when not needed through application software.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

GPIO0-60 can be configured to wake up the system from HALT. No other wakeup option is available. However, the watchdog timer may still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wakeup, the CPU receives a WAKEINT interrupt.

#### To enter HALT mode:

1. Enable the WAKEINT interrupt in the PIE .
2. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
3. Set CLKSRCCTL1.WDHALTI to 1 to keep the watchdog timer active and INTOSC1 and INTOSC2 powered up in HALT.
4. Set CLKSRCCTL1.WDHALTI to 0 to disable the watchdog timer and power down INTOSC1 and INTOSC2 in HALT.
5. Execute the IDLE instruction to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system will begin executing the WAKEINT ISR. After HALT wakeup, ISR execution will resume where it left off.

---

**Note**

Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), it must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device will never wake up.

---

**To wake up from HALT mode:**

1. Drive the selected GPIO low for a minimum 5us. This will activate the WAKEINT PIE interrupt.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL
3. Wait 16us plus 1024 OSCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

**3.10.5 Flash Power-down Considerations**

The Flash module on this device can be powered down at any time during an application. There are some considerations that must be made when powering down the Flash.

When the application software powers down the Flash, it must ensure that the function that puts the Flash to sleep is executed from RAM. Note that there should not be any access to Flash after the Flash is put to sleep to realize the power savings. If there is an access to Flash, Flash wakeup process (wakeup time depends on PSLEEP and RWAIT) gets initialized and the application will not realize Flash power savings. For example, if the application has to execute any code after putting the Flash to sleep and before putting the device in to low power mode, the application should execute that code from RAM and not from Flash.

PSLEEP and RWAIT can be optimized to reduce the Flash wakeup time for a given SYSCLK frequency. BootROM configures the best possible PSLEEP value for the 120 MHz operation. However, the application software can decrease the PSLEEP value to reduce the Flash wakeup time if the application SYSCLK is less than 120 MHz. This is applicable in the context of an application entering the Halt mode since PLL must be disabled before entering the Halt mode. In this case, the PSLEEP value can be decreased to get a faster Flash wakeup upon exit from LPM.

If the Wake ISR is in Flash, it is suggested to optimize the PSLEEP and RWAIT values before entering the LPM, and after the Flash is in sleep, since application does not get a chance to modify these before Flash is awake after exiting from LPM. However, after the LPM exit and once the Flash is awake, application should branch to RAM to restore RWAIT and PSLEEP (as per the application SYSCLK to which PLL will be locked for) and then proceed with Flash execution to lock the PLL.

If the Wake ISR is in RAM, application can optimize the PSLEEP and RWAIT values in the Wake ISR and then do a dummy Flash access to initiate the Flash wakeup process. While the Flash is waking up, application can initialize the PLL lock process. Once the Flash is awake, application can put the PLL in clock path. If the user does not want to lock the PLL from RAM, PLL can be locked from Flash (this means Flash wakeup and PLL lock are not done in parallel), but in any case make sure to restore the RWAIT and PSLEEP (as per the application SYSCLK to which PLL will be locked for) in Wake ISR before proceeding to Flash execution.

### 3.11 Memory Controller Module

On this device, the RAMs have different characteristics. These are:

- Dedicated to the CPU: M0, M1 RAMs
- Shared between the CPU and CLA: LSx RAMs
- Shared between the CPU, DMA and HIC: GSx RAMs
- Used to send and receive messages between processors: MSG RAMs

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. All the RAMs are enabled with the ECC feature (both data and address). Some of the memories are secure memory as well. Refer to the *Dual Code Security Module (DCSM)* chapter for more details. Each RAM has its own controller which takes care of the access protection/security related checks and ECC features for that RAM. [Figure 3-13](#) shows the configuration of these RAMs.

**Figure 3-13. Memory Architecture**

#### 3.11.1 Dedicated RAM (Mx RAM)

This device has two dedicated RAM blocks: M0 and M1. M0 and M1 memories are small blocks of memory which are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (CLA, DMA or HIC) have access to these memories.

All dedicated RAMs have ECC and access protection (CPU write protection/CPU fetch protection) feature. Each type of access protection for each RAM block can be enabled/disabled by configuring the specific bit in the access protection register, allocated to each subsystem (DxACCPROT).

#### 3.11.2 Local Shared RAM (LSx RAM)

Local shared RAMs (LSx RAMs) are secure memories and have ECC. These memories are shared between the CPU and CLA but are by default dedicated to the CPU only. CLA access can be enabled by configuring MSEL\_LSx bit field in the LSxMSEL register.

Further, when these memories are shared between the CPU and CLA, the user could choose to use these memories as CLA program memory by configuring the CLAPGM\_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write and CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. [Table 3-11](#) shows the LSx RAM features.

**Table 3-11. Local Shared RAM**

| MSEL_LSx | CLAPGM_LSx | CPUx<br>Allowed Access            | CPUx.CLA1<br>Allowed Access                     | Comment                                       |
|----------|------------|-----------------------------------|---|---|
| 00       | X          | All                               | -   | LSx memory is configured as CPU dedicated RAM |
| 01       | 0          | All                               | Data Read<br>Data Write                         | LSx memory is shared between CPU and CLA1     |
| 01       | 1          | Emulation Read<br>Emulation Write | Fetch Only<br>Emulation Read<br>Emulation Write | LSx memory is CLA1 program memory             |

### 3.11.3 Global Shared RAM (GSx RAM)

RAM blocks which are accessible from the CPU, DMA and HIC are called global shared RAMs (GSx RAMs).

[Table 3-12](#) shows the features of the GSx RAM.

**Table 3-12. Global Shared RAM**

| CPU (Fetch) | CPU (Read) | CPU (Write) | CPU.DMA<br>(Read) | CPU.DMA<br>(Write) | HIC (Read) | HIC (Write) |
|-------------|------------|-------------|-------------------|--------------------|------------|-------------|
| Yes         | Yes        | Yes         | Yes               | Yes                | Yes        | Yes         |

The shared RAM has different levels of access protection that can be enabled or disabled by configuring specific bits in the GSxACCPROT registers.

Access protection configuration for the GSx RAM block can be locked by the user to prevent further updates to this bit field. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once a configuration is committed for a particular GSx RAM block, it can not be changed further until CPU.SYSRS is issued.

### 3.11.4 CLA-CPU Message RAM

These RAM blocks can be used to share data between the CPU and CLA. The CLA has read and write access to the "CLA to CPU MSGRAM." The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

### 3.11.5 CLA-DMA Message RAM

These RAMs blocks can be used to share data between CLA and DMA. The CLA has read and write access to the "CLA to DMA MSGRAM." The DMA has read and write access to the "DMA to CLA MSGRAM." The CLA and DMA both have read access to both MSGRAMs.

### 3.11.6 Access Arbitration

For a shared RAM, multiple accesses can happen at any given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round-robin scheme is followed to arbitrate multiple access at any given time.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

Figure 3-14 represents the arbitration scheme on global shared memories.

Figure 3-15 represents the arbitration scheme on local shared memories.

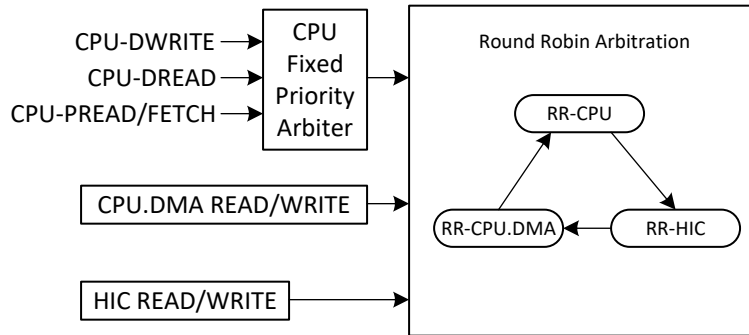

Figure 3-14. Arbitration Scheme on Global Shared Memories

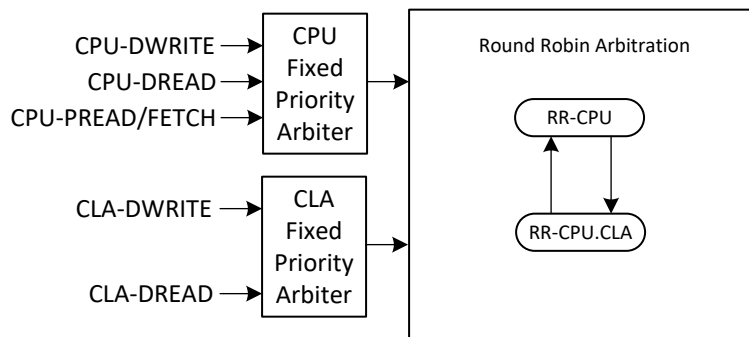

Figure 3-15. Arbitration Scheme on Local Shared Memories

### 3.11.7 Access Protection

The RAM blocks have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual masters. There is no protection for read accesses, hence reads are always allowed from all the masters which have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

---

#### Note

For debug accesses, all the protections are disabled.

---

**Note 1:** All access protections are ignored during debug accesses. Write access to a protected memory will go through when it is done via the debugger, irrespective of the write protection configuration for that memory.

#### 3.11.7.1 CPU Fetch Protection

Fetch accesses from the CPU can be protected by setting the FETCHPROTx bit of the specific register to '1.' If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

If a fetch protection violation occurs, it results in an ITRAP for CPU. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU fetch access violation address register.

#### 3.11.7.2 CPU Write Protection

Write accesses from the CPU can be protected by setting the CPUWRPROTx bit of the specific register to '1.' If write access is done by a CPU to memory where it is protected, a write protection violation occurs.

If a write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

#### 3.11.7.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and its CLA, the CPU will only have access if the memory is configured as data RAM for the CLA. If it is programmed as program RAM, all the access from the CPU, including a read, will be blocked and the violation will be considered as a non-master access violation.

If a read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CPU read access violation address register. Also, an access violation interrupt is generated, if enabled in the interrupt enable register.

#### 3.11.7.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, it results in a MSTOP, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

#### 3.11.7.5 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

#### **3.11.7.6 CLA Write Protection**

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation. Similarly any data write access from CLA to CPUTOCLA or DMATOCLA MSGRAM will result in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

#### **3.11.7.7 HIC Write Protection**

Write accesses from the HIC can be protected by setting the HICWRPROTx bit of a specific register to '1.' If a write access is done by the HIC to protected memory, a write protection violation occurs.

If a write access is made to GSx memory by a non-master HIC, it is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master HIC, and HICWRPROTx is set to '1' for that memory, it is called a master HIC write protection violation.

A flag gets set in the HIC access violation flag register, and the memory address where the violation happened gets latched in the HIC fetch access violation address register. These are dedicated registers for each subsystem.

#### **3.11.7.8 DMA Write Protection**

Write accesses from the DMA can be protected by setting the DMAWRPROTx bit of a specific register to '1.' If a write access is done by the DMA to protected memory, a write protection violation occurs.

If a write access is made to GSx memory by a non-master DMA, it is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to '1' for that memory, it is called a master DMA write protection violation.

A flag gets set in the DMA access violation flag register, and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

### **3.11.8 Memory Error Detection and Correction, and Error Handling**

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all RAMs support error correction code (ECC) protection. The ECC scheme used is Single Error Correction Double Error Detection (SECCDED). ECC will cover the data bits stored in memory as well as address.

ECC calculation is done inside the memory controller module and written into the memory along with the data. ECC is computed for 16-bit data; hence, for each 32-bit of data, there will be three 7-bit ECC codes, two of which are for data and a third one for the address.

#### **3.11.8.1 Error Detection and Correction**

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable and uncorrectable errors. The following are characteristics of these errors:

- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors

- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent a double-bit error due to another single-bit error at the same memory address.

### 3.11.8.2 Error Handling

For each correctable error, the count in the correctable error count register will increment by one. When the value in this count register becomes equal to the value configured in the correctable error threshold register, an interrupt is generated to the CPU, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into a register and a flag also gets set in a status register.

If there are uncorrectable errors, an NMI gets generated for the CPU. In this case also, the address for which the error occurred gets latched into a register, and a flag gets set in a status register.

[Table 3-13](#) summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

**Table 3-13. Error Handling in Different Scenarios**

| Access Type | Error Found In        | Error Type  | Status Indication  | Error Notification   |
|-------------|-----------------------|---|--|--|
| Reads       | Data read from memory | Uncorrectable Error (Double bit Error for ECC RAMs) | Yes -CPU/CPU.DMA/<br>CPU.CLA1/DMA/CLA Read Error<br>Address Register Data returned to CPU/<br>CPU.DMA/CPU.CLA1 is incorrect  | NMI for CPU access<br>NMI for CPU.DMA access<br>NMI to CPU for CPU.CLA1 access               |
| Reads       | Data read from memory | Single-bit error for ECC RAMs                       | Yes - CPU/CPU.DMA CPU/DMA Read Error<br>Address Register Increment single error counter                                      | Interrupt when error counter reaches the user programmable threshold for single errors       |
| Reads       | Address               | Address error                                       | Yes - CPU/CPU.DMA/<br>CPU.CLA1/DMA/CLA Read Address Error<br>Register Data returned to CPU/<br>CPU.DMA/CPU.CLA1 is incorrect | NMI to CPU for CPU access<br>NMI to CPU for CPU.DMA access<br>NMI to CPU for CPU.CLA1 access |

#### Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

### 3.11.9 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications may need to ensure that the logic is always working fine (during run time also). To enable this, a test mode is provided, in which a user can modify the data bits (without modifying the ECC bits) or ECC bits directly. Using this feature, an ECC error could be injected into data.

---

#### Note

The memory map for ECC bits and data bits are the same. The user must choose a different test mode to access ECC bits. In test mode, all access to memories (data as well as ECC) should be done as 32-bit access only.

---

Table 3-14 shows the bit mapping for the ECC bits when they are read in RAMTEST mode using their respective addresses.

**Table 3-14. Mapping of ECC Bits in Read Data from ECC Address Map**

| Data Bits Location in Read Data | Content (ECC Memory)               |
|---------------------------------|------------------------------------|
| 6:0                             | ECC Code for lower 16 bits of data |
| 7                               | Not Used                           |
| 14:8                            | ECC Code for upper 16 bits of data |
| 15                              | Not Used                           |
| 22:16                           | ECC Code for address               |
| 31:23                           | Not Used                           |

### 3.11.10 RAM Initialization

To ensure that read/fetch from uninitialized RAM locations do not cause ECC errors, the RAM\_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC bits accordingly. This can be initiated by setting the INIT bit to '1' for the specific RAM block in INIT registers. To check the status of RAM initialization, SW should poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access should be made to that RAM memory block.

---

#### Note

None of the masters should access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization will not happen correctly.

---

### 3.12 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected) the application may not work as expected, since there is no gel file to perform those initializations. For example, gel file disables watchdog. If user code does not service the watchdog in the application (or fails to disable it), there will be a difference in how the application behaves with the debugger and without.

Common tasks performed by the gel files (but not boot-ROM).

On Reset:

- Disable Flash ECC on some devices.
  - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
- Disable Watchdog
- Enable CLA clock
- Select real-time mode or C28x mode

On Restart:

- Select real-time mode or C28x mode
- Clear IER and IFR

On Target Connect:

- Select real-time mode or C28x mode

### 3.13 Live Firmware Update

This device includes hardware hooks to streamline firmware updates. These hardware hooks enable seamless switching from the old firmware to the new firmware without resetting the application.

This section discusses the Live Firmware Update (LFU) and the hardware features present on the device to support LFU.

#### 3.13.1 LFU Background

End equipment like Server Power Supply (PSU) are high availability systems that need to have minimum downtime, even during firmware upgrades. Firmware upgrades are essential to add additional functionality, enhance performance and fix software bugs/vulnerabilities. LFU helps update firmware while the application is running, thus eliminating downtime (with respect to critical real-time interrupts) and also providing a more cost-effective alternative compared to manually updating firmware.

LFU has traditionally been implemented in the C2000 family of MCUs using software-only techniques. This impacts LFU switchover time, which is the time to switchover to new firmware once the transition has begun. User application code initiates this transition, typically by jumping to an entry point in the new firmware. There, a compiler provided initialization routine specific to LFU is called. This initializes user-specified data variables. When execution arrives in `main()` of the new application, user application code performs minimal initialization to get the new application running.

#### 3.13.2 LFU Switchover Steps

A simplified representation of the LFU switchover is shown in [Figure 3-16](#), and is described in the following steps:

1. In typical systems, a host – typically a PC or another MCU, will initiate LFU (depicted as LFU Request) on the application MCU (in this case, the C2000 MCU) that is executing the real-time control application. This initiates the Flash Program sequence in the application MCU. This runs as a background process even as the application MCU continues executing firmware (depicted as Firmware - 1).
2. Since the compiler may move existing PIE vectors and function pointers to new locations between firmware versions, or PIE vectors or function pointers could get added or removed between firmware versions, user application code needs to manage these properly and efficiently during LFU. In the absence of Flash

remapping (where different Flash memory banks can be mapped to the same address), PIE vector table remapping, that is “swapping” and RAM memory block swapping are features supported on the device. Without swapping, user application code would need to individually update each PIE vector and each function pointer, adding valuable cycles to the LFU switchover time. With swapping, prior to LFU switchover, user application code can populate a different PIE vector table (depicted as PIE Swap Memory Update) and a different LS RAM region (depicted as LSx Swap Memory Update).

- When complete, at a suitable time (depicted as LFU Switchover – waiting for appropriate time), user application code initiates the transition to new firmware. Once the compiler LFU initialization routine completes and transfers execution to the new application (depicted as Firmware – 2), user application code needs to perform necessary initialization before the new application can begin running. Since PIE vectors and function pointers have already been populated in the “swap” locations, all that is required is a PIE vector table swap and LSx RAM Memory Swap (depicted as PIE Vector Swap, LSx Memory Swap).

**Figure 3-16. Simplified LFU Representation**

### 3.13.3 Device Features Supporting LFU

The new hardware capabilities implemented in the device to support LFU are:

- Multi-Bank Flash
- PIE Vector Table Swap
- LS0/LS1 RAM Memory Swap

#### 3.13.3.1 Multi-Bank Flash

The device has up to three Flash banks, each of size 128KB. With multiple banks, it is possible to Program/Erase a bank while other banks are in read mode.

#### 3.13.3.2 PIE Vector Table Swap

The device contains an additional PIE vector table, in addition to the typical PIE vector table that is present. This allows PIE vector addresses for the new firmware to be populated prior to the LFU switchover. During LFU switchover, a simple swap operation which activates the PIE vector swap table and deactivates the previously active PIE vector table is initiated by user application code, and this operation takes just 1 CPU clock cycle. To initiate the swap, user application code sets `LFUConfig.PieVectorSwap = 1`. The PIE vector table swap features are also implemented on a redundant PIE vector table implemented for safety. Therefore, to implement PIE vector table swap, the sizes of PIE vector memory and redundant PIE vector memory are both doubled.

The changes are summarized in [Figure 3-17](#). In previous devices, PIE vector RAM and redundant PIE vector RAM are present. In this device, these are duplicated. There are now four physical PIE vector RAM memories – Block A, Block B, Block C, and Block D. By default, Block A and Block B are *active*, and are mapped to addresses `0x0000_0D00-0x0000_0EFF` and `0x0100_0D00-0x0100_0EFF` respectively. Block C and Block D are *inactive*, and are mapped to addresses `0x0100_0900-0x0100_0AFF` and `0x0100_0B00-0x0100_0CFF` respectively.

When user application code initiates a PIE vector table swap by setting `LFUConfig.PieVectorSwap = 1`, Block C and Block D *become active*, and are mapped to addresses `0x0000_0D00-0x0000_0EFF` and `0x0100_0D00-0x0100_0EFF` respectively. Block A and Block B *become inactive*, and are mapped to addresses `0x0100_0900-0x0100_0AFF` and `0x0100_0B00-0x0100_0CFF` respectively.

Thus, note that the active addresses are always 0x0000\_0D00-0x0000\_0EFF, and 0x0100\_0D00-0x0100\_0EFF (for redundancy). The inactive addresses are always 0x0100\_0900-0x0100\_0AFF, and 0x0100\_0B00-0x0100\_0CFF (for redundancy). As mentioned above, prior to the LFU switchover, user application code will need to write to the inactive addresses with the PIE vector locations corresponding to the new firmware.

The register bit LFUStatus.PieVectorSwap provides the status of Pie Vector Swap.

Writes to addresses 0x0000\_0D00-0x0000\_0EFF will update both the currently active block and its redundant counterpart. Writes to addresses 0x0100\_0900-0x0100\_0AFF will update both the currently inactive block and its redundant counterpart.

Reads from addresses 0x0000\_0D00-0x0000\_0EFF will issue reads from both addresses 0x0000\_0D00-0x0000\_0EFF and the redundant counterpart 0x0100\_0D00-0x0100\_0EFF. The read values will be compared, and any data mismatches will generate the same error response as that of the existing PIE vector fetch mismatch (refer to PIEVERRADDR). On the other hand, a read from or write to the redundant PIE vector RAM (0x0100\_0D00-0x0100\_0EFF or 0x0100\_0B00-0x0100\_0CFF) will impact only the redundant PIE vector RAM.

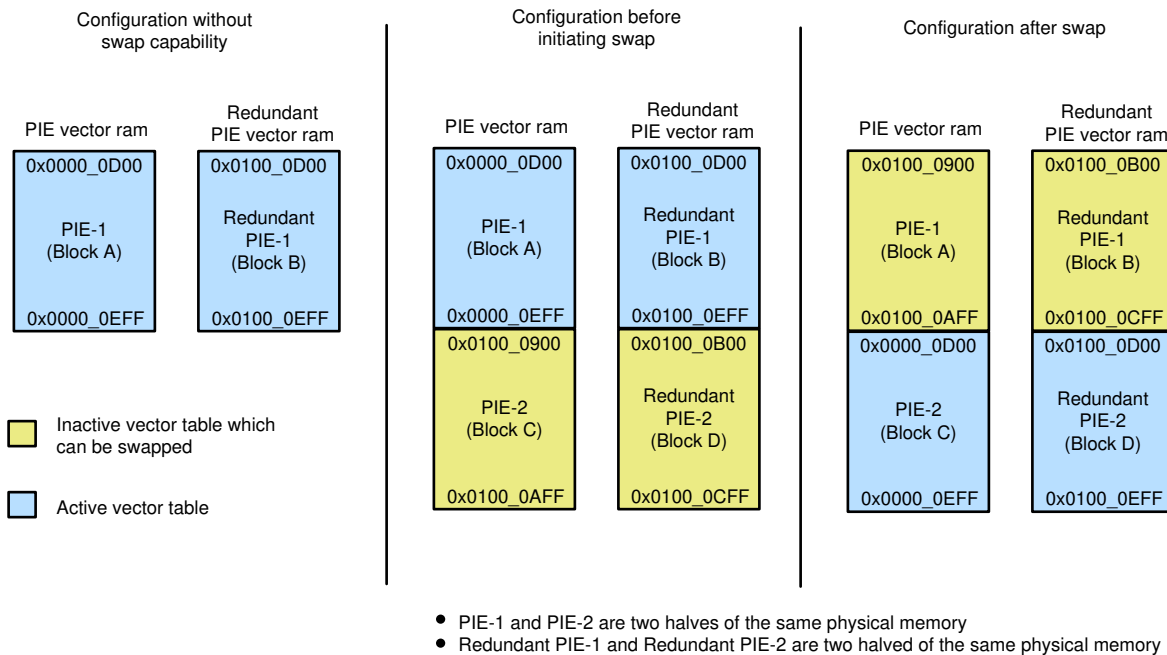

Figure 3-17. PIE Vector Table Swap

### 3.13.3.3 LS0/LS1 RAM Memory Swap

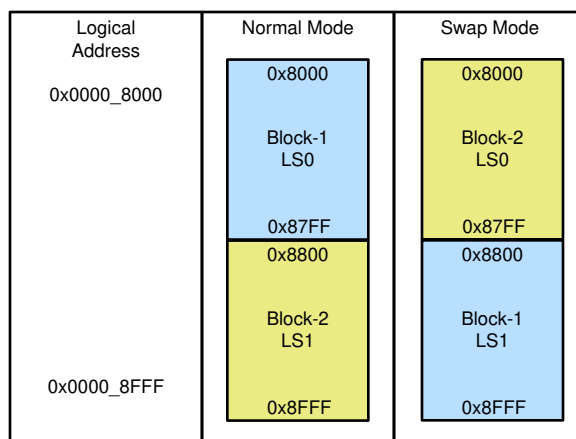

Similar to PIE Vector Table Swap, LS0 and LS1 physical RAM memory blocks can also be swapped. The memory architecture is similar to PIE vector table swap, and is shown in Figure 3-18. By default, physical Block 1 is assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical Block 2 is assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1). By configuring LFUConfig.LS01Swap = 1, user application code can execute a swap, where physical Block 2 is now assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical Block 1 is now assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1).

If physical memory Block 1 contains function pointers for the current firmware, the same relative locations in physical memory Block 2 can be populated with function pointers for the new firmware prior to LFU switchover. During LFU switchover, a simple swap operation is initiated by user application code, and this operation takes

just 1 CPU clock cycle. This allows user application code to always have function pointers in LS0, yet have two different physical blocks that can map to the LS0 address range.

For example, if current firmware contains 10 function pointers present at the start of Block 1 (LS0 address space). If the new firmware contains the same 10 function pointers that now need to be updated, user application code would place these at the start of Block 2 (LS1 address space) prior to LFU switchover. During LFU switchover, user application code would execute a LS0/LS1 RAM memory swap, where the physical RAM block previously mapped to the LS1 address space would *now* be mapped to the LS0 address space, and hence can be used seamlessly for function pointer addressing for the new firmware.

The register bit LFUStatus.LS01Swap provides the status of LS0/LS1 RAM memory swap.

**Figure 3-18. LS0/LS1 RAM Memory Swap**

Additional points pertaining to LS0/LS1 RAM memory swap are described below:

1. LFU registers can be accessed from both CPU and CLA.
2. Only LS0 and LS1 blocks can be swapped. LS2 to LS7 blocks cannot be swapped.
3. LS0 and LS1 blocks have ECC protection. Address ECC is computed based on the physical address and hence it will not change based on the memory swap.
4. A number of LSx RAM registers are available to the user application code to configure options such as master select (LSxMSEL.MSEL\_LS0, LSxMSEL.MSEL\_LS1), fetch protect (LSxACCPROT0.FETCHPROT\_LS0, LSxACCPROT0.FETCHPROT\_LS1), write protect (LSxACCPROT0.CPUWRPROT\_LS0, LSxACCPROT0.CPUWRPROT\_LS1), CLA program memory LSxCLAPGM.CLAPGM\_LS0, LSxCLAPGM.CLAPGM\_LS1). These register bits indicate the status of the memory block that is deemed as LS0 (CPU address 0x8000 to 0x87FF) and LS1 (CPU address 0x8800 to 0x8FFF) at any point of time. When a LS0/LS1 RAM memory swap occurs, the corresponding control/status bits will also automatically swap.
5. It is recommended to service all pending errors (access violation, ECC, parity) associated with memory before initiating a LS0/LS1 RAM memory swap.
6. LS0/LS1 RAM memory swap shall be initiated only after completion of RAM initialization for both LS0 and LS1 memories (LSxINITDONE.INITDONE\_LS0 = 1 and LSxINITDONE.INITDONE\_LS1 = 1).
7. LS0/LS1 RAM memory swap shall not be initiated when RAM-test (LSxTEST.TEST\_LS0 = 1 or LSxTEST.TEST\_LS1 = 1) is in progress for LS0 or LS1 blocks.
8. With DCSM security on the device, in general, LS0 and LS1 RAM blocks can be assigned to different security zones. However, with LS0/LS1 RAM memory swaps, different physical RAM blocks can get mapped to the same address space. Application software shall therefore ensure that both LS0 and LS1 have the same security settings (for example, zone, EXE protection), if there is a plan to implement LS0/LS1 RAM memory swap. Hardware logic is implemented on the device to prevent swap of LS0 and LS1 if the blocks have different security configurations.
9. In order to prevent security vulnerabilities, LS0/LS1 RAM memory swap will not be allowed if it is initiated by code from a different zone. For example, (i) If LS0 and LS1 are part of Zone1, swap will not be allowed if code that initiates the swap resides in Zone2 or unsecure zone; (ii) If LS0 and LS1 are part of Zone2, swap

will not be allowed if code that initiates the swap resides in Zone1 or unsecure zone; (iii) If LS0 and LS1 are part of the same zone which is unsecure, swap will be allowed in all cases irrespective of where the code that initiates the swap resides; (iv) if LS0 and LS1 are part of the same zone and it is unlocked, the swap can be initiated from code residing anywhere (including from the debugger).

10. Once swap is initiated, it will happen in the next cycle itself, subject to it meeting the security requirements mentioned above. After initiation of a swap, application software shall check if the swap was correctly configured by checking the LFUStatus.LS01Swap status register. Consistency between LFUStatus.LS01Swap and LFUConfig.LS01Swap helps determine if the swap was correctly configured. If LFUStatus.LS01Swap does not match LFUConfig.LS01Swap, LFUConfig.LS01Swap needs to be cleared by user application code.
11. Since the logical address accessed by BGCRC will change with LS0/LS1 RAM memory swap, the computed CRC values for these memories need to be updated after the LS0/LS1 RAM memory swap.

### 3.13.3.3.1 Applicability to CLA LFU

The device does not support a swap table for the CLA task vectors (MVECTs). CLA LFU is implemented typically on the CPU side, where the MVECTs are updated sequentially at an appropriate time. The techniques for when to update the MVECTs will be described in the LFU system reference design guide, but it should be noted here that the approach is different from the CPU PIE vector table case, where a simple single cycle swap achieves the switch to the new PIE vector table.

In order for the LS0/LS1 RAM memory swap feature to be useful for CLA LFU switchover, two conditions need to be satisfied:

- CLA code has to fit into a single LSx block. The MVECT table contains CLA task vectors, whose addresses correspond to locations in the LSx block. For example, if the current firmware CLA code is present in LS0, MVECTs will point to various locations in LS0. If the new firmware CLA code is present in LS1, MVECTs will point to various locations in LS1.
- When switching over from current to new firmware, the MVECTs will need to be updated, unless they reside at the same relative location in both LS0 and LS1. If that is the case, then simply swapping LS0/LS1 RAM memory blocks will effectively update the MVECT table, without the need to sequentially update the MVECTs.

### 3.13.4 LFU Switchover

After the new firmware has been programmed to Flash, user application code will need to determine when it is appropriate to switchover to the new firmware. The techniques to determine this differ between real-time critical firmware running on the CPU and CLA, and these techniques are beyond the scope of this document. They will be described in detail in the LFU system reference design guide.

The device supports two register bits that can be set or reset to indicate that LFU switchover is in progress on the CPU (LFUConfig.LFU\_CPU) and CLA (LFUConfig.LFU\_CLA1). These bits do not impact any hardware logic on the device. For example, LFUConfig.LFU\_CPU can be set by user application code at the start of switchover, and then tested in the initialization code in main(). This can enable only LFU switchover specific initialization to be performed (for example, PIE vector table swap, LS0/LS1 RAM memory swap), while bypassing all other initialization that typically happens after a device reset.

### 3.13.5 LFU Resources

The following are additional LFU resources available.

- [Live Firmware Update Without Device Reset on C2000™ MCUs User's Guide](#)
- [Live Firmware Update With Device Reset on C2000™ MCUs User's Guide](#)
- [Live Firmware Update Reference Design with C2000™ Real-Time MCUs](#)

## 3.14 Software

### 3.14.1 INTERRUPT Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/interrupt

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 3.14.1.1 External Interrupts (*ExternalInterrupt*)

FILE: interrupt\_ex1\_external.c

This program sets up GPIO0 as XINT1 and GPIO1 as XINT2. Two other GPIO signals are used to trigger the interrupt (GPIO10 triggers XINT1 and GPIO11 triggers XINT2). The user is required to externally connect these signals for the program to work properly.

XINT1 input is synced to SYSCLKOUT.

XINT2 has a long qualification - 6 samples at 510\*SYSCLKOUT each.

GPIO16 will go high outside of the interrupts and low within the interrupts. This signal can be monitored on a scope.

Each interrupt is fired in sequence - XINT1 first and then XINT2

##### *External Connections*

- Connect GPIO10 to GPIO0. GPIO0 will be assigned to XINT1
- Connect GPIO11 to GPIO1. GPIO1 will be assigned to XINT2

Monitor GPIO16 with an oscilloscope. GPIO16 will be high outside of the ISRs and low within each ISR.

##### *Watch Variables*

- xint1Count for the number of times through XINT1 interrupt
- xint2Count for the number of times through XINT2 interrupt
- loopCount for the number of times through the idle loop

#### 3.14.1.2 Multiple interrupt handling of I2C, SCI & SPI Digital Loopback

FILE: interrupt\_ex2\_with\_i2c\_sci\_spi\_loopback.c

This program is used to demonstrate how to handle multiple interrupts when using multiple communication peripherals like I2C, SCI & SPI Digital Loopback all in a single example. The data transfers would be done with FIFO Interrupts.

It uses the internal loopback test mode of these modules. Both the TX and RX FIFOs and their interrupts are used. Other than boot mode pin configuration, no other hardware configuration is required.

A stream of data is sent and then compared to the received stream. The sent data looks like this for I2C and SCI:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

The sent data looks like this for SPI:

```
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
```

FFFF 0000

etc..

This pattern is repeated forever.

#### External Connections

- None

#### Watch Variables

- *sDataI2cA* - Data to send through I2C
- *rDataI2cA* - Received I2C data
- *rDataPoint* - Used to keep track of the last position in the receive I2C stream for error checking
- *sDataSpiA* - Data to send through SPI
- *rDataSpiA* - Received SPI data
- *rDataPointSpiA* - Used to keep track of the last position in the receive SPI stream for error checking
- *sDataSciA* - SCI Data being sent
- *rDataSciA* - SCI Data received
- *rDataPointA* - Keep track of where we are in the SCI data stream. This is used to check the incoming data

### 3.14.1.3 CPU Timer Interrupt Software Prioritization

FILE: interrupt\_ex3\_sw\_prioritization.c

This examples demonstrates the software prioritization of interrupts through CPU Timer Interrupts. Software prioritization of interrupts is achieved by enabling interrupt nesting.

In this device, hardware priorities for CPU Timer 0, 1 and 2 are set as timer 0 being highest priority and timer 2 being lowest priority. This example configures CPU Timer0, 1, and 2 priority in software with timer 2 priority being highest and timer 0 being lowest in software and prints a trace for the order of execution.

For most applications, the hardware prioritizing of the interrupts is sufficient. For applications that need custom prioritizing, this example illustrates how this can be done through software. User specific priorities can be configured in `sw_prioritized_isr_level.h` header file.

To enable interrupt nesting, following sequence needs to be followed in ISRs. *Step 1:* Set the global priority: Modify the IER register to allow CPU interrupts with a higher user priority to be serviced. Note: at this time IER has already been saved on the stack. *Step 2:* Set the group priority: (optional) Modify the appropriate PIEIERx register to allow group interrupts with a higher user set priority to be serviced. Do NOT clear PIEIER register bits from another group other than that being serviced by this ISR. Doing so can cause erroneous interrupts to occur. *Step 3:* Enable interrupts: There are three steps to do this: a. Clear the PIEACK bits b. Wait at least one cycle c. Clear the INTM bit. *Step 4:* Run the main part of the ISR *Step 5:* Set INTM to disable interrupts. *Step 6:* Restore PIEIERx (optional depending on step 2) *Step 7:* Return from ISR

Refer to below link on more details on Interrupt nesting in C28x devices:

<C2000Ware>\docs\c28x\_interrupt\_nesting\html\index.html

#### External Connections

- None

#### Watch Variables

- `traceISR` - shows the order in which ISRs are executed.

### 3.14.1.4 EPWM Real-Time Interrupt

FILE: interrupt\_ex4\_epwm\_realtime\_interrupt.c

This example configures the ePWM1 Timer and increments a counter each time the ISR is executed. ePWM interrupt can be configured as time critical to demonstrate real-time mode functionality and real-time interrupt capability.

The example uses 2 LEDs - LED1 is toggled in the main loop and LED2 is toggled in the EPWM Timer Interrupt. `FREE_SOFT` bits and `DBGIER.INT3` bit must be set to enable ePWM1 interrupt to be time critical and operational in real time mode after halt command

How to run the example?

- Add the watch variables as mentioned below and enable Continuous Refresh.
- Enable real-time mode (Run->Advanced->Enable Silicon Real-time Mode)
- Initially, the DBGIER register is set to 0 and the EPWM emulation mode is set to EPWM\_EMULATION\_STOP\_AFTER\_NEXT\_TB (FREE\_SOFT = 0)
- When the application is running, you will find both LEDs toggling and the watch variables EPwm1TimerIntCount, EPwm1Regs.TBCTR getting updated.
- When the application is halted, both LEDs stop toggling and the watch variables remain constant. EPWM counter is stopped on debugger halt.
- To enable EPWM counter run during debugger halt, set emulation mode as EPWM\_EMULATION\_FREE\_RUN (FREE\_SOFT = 2). You will find EPwm1Regs.TBCTR is running, but EPwm1TimerIntCount remains constant. This means, the EPWM counter is running, but the ISRs are not getting serviced.
- To enable real-time interrupts, set DBGIER.INT3 = 1 (EPWM1 interrupt is part of PIE Group 3). You will find that the EPwm1TimerIntCount is incrementing and the LED starts toggling. The EPWM ISR is getting serviced even during a debugger halt.

For more details, watch this video : <https://training.ti.com/c2000-real-time-features>

#### External Connections

- None

#### Watch Variables

- EPwm1TimerIntCount - EPWM1 ISR counter
- EPwm1Regs.TBCTR.TBCTR - EPWM1 Time Base counter
- EPwm1Regs.TBCTL.FREE\_SOFT - Set this to 2 to enable free run
- DBGIER.INT3 - Set to 1 to enable real time interrupt

### 3.14.2 SYSCCTL Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/sysctl

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 3.14.2.1 Missing Clock Detection (MCD)

FILE: sysctl\_ex1\_missing\_clock\_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (120 MHz). Post MCD the frequency would move to 10 MHz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 120 MHz but using the INTOSC1 as clock source.

#### External Connections

- None.

#### Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd\_clkfail\_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd\_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

### 3.14.2.2 XCLKOUT (External Clock Output) Configuration

FILE: sysctl\_ex2\_xclkout\_config.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8. Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25 MHz

View the XCLKOUT on GPIO16 using an oscilloscope.

### 3.14.3 TIMER Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:

C2000Ware\_VERSION#/driverlib/f28003x/examples/timer

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 3.14.3.1 CPU Timers

FILE: timer\_ex1\_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

##### External Connections

- None

##### Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

### 3.14.4 LPM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:

C2000Ware\_VERSION#/driverlib/f28003x/examples/lpm

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 3.14.4.1 Low Power Modes: Device Idle Mode and Wakeup using GPIO

FILE: lpm\_ex1\_idlewake\_gpio.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using XINT1 which triggers on a falling edge of GPIO0.

The GPIO0 pin must be pulled from high to low by an external agent for wakeup. GPIO0 is configured as an XINT1 pin to trigger an XINT1 interrupt upon detection of a falling edge.

Initially, pull GPIO0 high externally. To wake device from IDLE mode by triggering an XINT1 interrupt, pull GPIO0 low (falling edge). The wakeup process begins as soon as GPIO0 is held low for the time indicated in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#).

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the external interrupt ISR.

##### External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking.

#### 3.14.4.2 Low Power Modes: Device Idle Mode and Wakeup using Watchdog

FILE: lpm\_ex2\_idlewake\_watchdog.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using watchdog timer.

The device wakes up from the IDLE mode when the watchdog timer overflows, triggering an interrupt. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the wakeup ISR.

#### *External Connections*

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

### **3.14.4.3 Low Power Modes: Device Standby Mode and Wakeup using GPIO**

FILE: lpm\_ex3\_standbywake\_gpio.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode and then wakes up the device from STANDBY using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. Initially, pull GPIO0 high externally. To wake device from STANDBY mode, pull GPIO0 low for at least (2+QUALSTDBY), OSCLKS, then pull it high again.

The example then wakes up the device from STANDBY using GPIO0. GPIO0 wakes the device from STANDBY mode when a low pulse (signal goes high->low->high) is detected on the pin. This pin must be pulsed by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

#### *External Connections*

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

### **3.14.4.4 Low Power Modes: Device Standby Mode and Wakeup using Watchdog**

FILE: lpm\_ex4\_standbywake\_watchdog.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode then wakes up the device from STANDBY using watchdog timer.

The device wakes up from the STANDBY mode when the watchdog timer overflows triggering an interrupt. In the ISR, the GPIO1 is pulled low. the GPIO1 is toggled to indicate the device is out of STANDBY mode. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

#### *External Connections*

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

### **3.14.4.5 Low Power Modes: Halt Mode and Wakeup using GPIO**

FILE: lpm\_ex5\_haltwake\_gpio.c

This example puts the device into HALT mode. If the lowest possible current consumption in HALT mode is desired, the JTAG connector must be removed from the device board while the device is in HALT mode.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT by setting the XTALCR.OSCOFF bit or by using the driverlib function SysCtl\_turnOffOsc(SYSCTL\_OSCSRC\_XTAL);. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

This example puts the device into HALT mode and then wakes up the device from HALT using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. The GPIO0 pin must be pulled from high to low by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

#### *External Connections*

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

#### **3.14.4.6 Low Power Modes: Halt Mode and Wakeup**

FILE: lpm\_ex6\_haltwake\_gpio\_watchdog.c

This example puts the device into HALT mode. If the lowest possible current consumption in HALT mode is desired, the JTAG connector must be removed from the device board while the device is in HALT mode.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT by setting the XTALCR.OSCOFF bit or by using the driverlib function SysCtl\_turnOffOsc(SYSCTL\_OSCSRC\_XTAL);. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

This example puts the device into HALT mode and then wakes up the device from HALT using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. The GPIO0 pin must be pulled from high to low by an external agent for wakeup.

In this example, the watchdog timer is clocked, and is configured to produce watchdog reset as a timeout mechanism.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

#### *External Connections*

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

#### **3.14.5 MEMCFG Examples**

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/f28003x/examples/memcfg

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

##### **3.14.5.1 Correctable and Uncorrectable Memory Error Handling**

FILE: memcfg\_ex1\_error\_handling.c

This example demonstrates error handling in case of various erroneous memory read/write operations. Error handling in case of CPU read/write violations, correctable and uncorrectable memory errors has been demonstrated.

Test functions used in this example:

- generateMasterCPUWrViolation -
  - This test configures Memconfig to block CPU writes to GS0 RAM. A write attempt to this memory location by CPU causes RAM\_ACC\_VIOL Interrupt
- generateECCMemCorrError
  - This test induces single bit ECC error in LS6 RAM. A read from the corrupted memory location causes INT\_RAM\_CORR\_ERR Interrupt
- generateECCMemUncorrError
  - This test induces double bit ECC error in LS7 RAM. A read from the corrupted memory location causes NMI

- `forceNonMasterDMAReadViolation`
  - This forces a DMA access violation using `MemCfg_forceViolationInterrupt` API. This casuses `RAM_ACC_VIOL` Interrupt

#### External Connections

- None

#### Watch Variables

- `testStatusGlobal` - Equivalent to `TEST_PASS` if test finished correctly, else the value is set to `TEST_FAIL`
- `errCountGlobal` - Error counter

### 3.14.6 WATCHDOG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
`C2000Ware_VERSION#/driverlib/f28003x/examples/watchdog`

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 3.14.6.1 Watchdog

FILE: `watchdog_ex1_service.c`

This example shows how to service the watchdog or generate a wakeup interrupt using the watchdog. By default the example will generate a Wake interrupt. To service the watchdog and not generate the interrupt, uncomment the `SysCtl_serviceWatchdog()` line in the main for loop.

#### External Connections

- None.

#### Watch Variables

- `wakeCount` - The number of times entered into the watchdog ISR
- `loopCount` - The number of loops performed while not in ISR

### 3.15 System Control Registers

#### 3.15.1 SYSCTRL Base Address Table

**Table 3-15. SYSCTRL Base Address Table**

| Bit Field Name       |                        | DriverLib Name        | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |

| 3Eh           | NMHICWRAVADDR  | Non-Master HIC Write Access Violation Address         |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-17 shows the codes that are used for access types in this section.

**Table 3-17. ACCESS\_PROTECTION\_REGS Access Type Codes**

| Access Type            | Code | Description                            |
|------------------------|------|--|
| Read Type              |      |  |
| R                      | R    | Read                                   |
| R-0                    | R-0  | Read Returns 0s                        |
| Write Type             |      |  |
| W                      | W    | Write                                  |
| W1S                    | W1S  | Write 1 to set                         |
| Reset or Default Value |      |  |
| -n                     |      | Value after reset or the default value |

**Table 3-17. ACCESS\_PROTECTION\_REGS Access Type Codes (continued)**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.2.1 NMAVFLG Register (Offset = 0h) [Reset = 0h]

NMAVFLG is shown in [Figure 3-19](#) and described in [Table 3-18](#).

Return to the [Summary Table](#).

Non-Master Access Violation Flag Register

**Figure 3-19. NMAVFLG Register**

| Register Array Variables |            |  |

**Table 3-41. CLK\_CFG\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description  |
|-------------|------|--|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.3.1 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 0h]

CLKCFGLOCK1 is shown in [Figure 3-41](#) and described in [Table 3-42](#).

Return to the [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

### 3.15.3.2 CLKSRCCTL1 Register (Offset = 8h) [Reset = 0h]

CLKSRCCTL1 is shown in [Figure 3-42](#) and described in [Table 3-43](#).

Return to the [Summary Table](#).

Clock Source Control register-1

This memory mapped register requires a delay of 45 SYSCCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 45 NOP instructions.

**Figure 3-42. CLKSRCCTL1 Register**

For example OSCCLKSRCSEL (SYSPLL), TMR2CLKSRCSEL (CPUTIMER2) and XCLOCKOUT (XCLKOUT).<br>Reset type: XRSn |
| 2    | RESERVED   | R    | 0h    | Reserved  |

**Table 3-43. CLKSRCCTL1 Register Field Descriptions (continued)**

| Bit | Field        | Type | Reset | Description  |
|-----|--------------|------|-------|--|
| 1-0 | OSCCLKSRCSEL | R/W  | 0h    | <p>Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK.</p> <p>00 = INTOSC2 (default on reset)<br/>           01 = External Oscillator (XTAL)<br/>           10 = INTOSC1<br/>           11 = reserved (default to INTOSC1)</p> <p>At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT[13:0] register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier.</p> <p>The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete..</p> <p>Notes:<br/>           [1] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL.</p> <p>Reset type: XRSn</p> |

### 3.15.3.3 CLKSRCCTL2 Register (Offset = Ah) [Reset = 0h]

CLKSRCCTL2 is shown in [Figure 3-43](#) and described in [Table 3-44](#).

Return to the [Summary Table](#).

Clock Source Control register-2

This memory mapped register requires a delay of 45 SYCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 45 NOP instructions.

| 16    | CLR      | R/W  | 0h    | X1 Counter clear:<br>A write of '1' to this bit field clears the X1CNT and makes it count from 0x0 again (provided X1 clock is ticking).<br>Writes of '0' are ignore to this bit field<br>Reset type: XRSn  |
| 15-11 | RESERVED | R    | 0h    | Reserved  |
| 10-0  | X1CNT    | R    | 0h    | X1 Counter:<br>- This counter increments on every X1 CLOCKS positive-edge.<br>- Once it reaches the values of 0x7ff, it freezes<br>- Before switching from INTOSC2 to X1, application must check this counter and make sure that it has saturated. This will ensure that the Crystal connected to X1/X2 is oscillating.<br>Reset type: XRSn |

### 3.15.3.14 XTALCR Register (Offset = 32h) [Reset = 5h]

XTALCR is shown in [Figure 3-54](#) and described in [Table 3-55](#).

Return to the [Summary Table](#).

#### XTAL Control Register

This memory mapped register requires a delay of 45 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 45 NOP instructions.

**Figure 3-54. XTALCR Register**

|          |    |    |    |          |    |        |        |

Complex bit access types are encoded to fit into small table cells. Table 3-59 shows the codes that are used for access types in this section.

**Table 3-59. CPU\_SYS\_REGS Access Type Codes**

| Access Type | Code | Description |
|-------------|------|-------------|
| Read Type   |      |             |

**Table 3-59. CPU\_SYS\_REGS Access Type Codes  
(continued)**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| R                        | R          | Read   |
| R-0                      | R<br>-0    | Read<br>Returns 0s   |
| Write Type               |            |  |
| W                        | W          | Write  |
| W1C                      | W<br>1C    | Write<br>1 to clear  |
| W1S                      | W<br>1S    | Write<br>1 to set  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.4.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 0h]

CPUSYSLOCK1 is shown in [Figure 3-57](#) and described in [Table 3-60](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

### 3.15.5 CPUTIMER\_REGS Registers

Table 3-94 lists the memory-mapped registers for the CPUTIMER\_REGS registers. All register offset addresses not listed in Table 3-94 should be considered as reserved locations and the register contents should not be modified.

**Table 3-94. CPUTIMER\_REGS Registers**

| Offset | Acronym | Register Name                     | Write Protection | Section            |
|--------|---------|-----------------------------------|------------------|--------------------|
| 0h     | TIM     | CPU-Timer, Counter Register       |                  | <a href="#">Go</a> |
| 2h     | PRD     | CPU-Timer, Period Register        |                  | <a href="#">Go</a> |
| 4h     | TCR     | CPU-Timer, Control Register       |                  | <a href="#">Go</a> |
| 6h     | TPR     | CPU-Timer, Prescale Register      |                  | <a href="#">Go</a> |
| 7h     | TPRH    | CPU-Timer, Prescale Register High |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-95 shows the codes that are used for access types in this section.

**Table 3-95. CPUTIMER\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| Write Type               |         |  |
| W                        | W       | Write  |
| W1C                      | W<br>1C | Write<br>1 to clear  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.5.1 TIM Register (Offset = 0h) [Reset = FFFFh]

TIM is shown in [Figure 3-91](#) and described in [Table 3-96](#).

Return to the [Summary Table](#).

CPU-Timer, Counter Register

**Figure 3-91. TIM Register**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 3.15.5.4 TPR Register (Offset = 6h) [Reset = 0h]

TPR is shown in [Figure 3-94](#) and described in [Table 3-99](#).

Return to the [Summary Table](#).

CPU-Timer, Prescale Register

**Figure 3-94. TPR Register**

|        |    |    |    |    |    |   |   |
|--------|----|----|----|----|----|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| PSC    |    |    |    |    |    |   |   |
| R-0h   |    |    |    |    |    |   |   |
| 7      | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| TDDR   |    |    |    |    |    |   |   |
| R/W-0h |    |    |    |    |    |   |   |

**Table 3-99. TPR Register Field Descriptions**

| Bit  | Field | Type | Reset | Description  |
|------|-------|------|-------|--|
| 15-8 | PSC   | R    | 0h    | <p>CPU-Timer Prescale Counter.</p> <p>These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0.</p> <p>Reset type: SYSRSn</p> |
| 7-0  | TDDR  | R/W  | 0h    | <p>CPU-Timer Divide-Down.</p> <p>Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software.</p> <p>Reset type: SYSRSn</p>   |

### 3.15.5.5 TPRH Register (Offset = 7h) [Reset = 0h]

TPRH is shown in [Figure 3-95](#) and described in [Table 3-100](#).

Return to the [Summary Table](#).

CPU-Timer, Prescale Register High

### 3.15.6 DEV\_CFG\_REGS Registers

Table 3-101 lists the memory-mapped registers for the DEV\_CFG\_REGS registers. All register offset addresses not listed in Table 3-101 should be considered as reserved locations and the register contents should not be modified.

**Table 3-101. DEV\_CFG\_REGS Registers**

| Offset | Acronym    | Register Name                                     | Write Protection | Section            |
|--------|------------|---|------------------|--------------------|
| 8h     | PARTIDL    | Lower 32-bit of Device PART Identification Number |                  | <a href="#">Go</a> |
| Ah     | PARTIDH    | Upper 32-bit of Device PART Identification Number |                  | <a href="#">Go</a> |
| Ch     | REVID      | Device Revision Number                            |                  | <a href="#">Go</a> |

| 130h   | TAP_STATUS | Status of JTAG State machine & Debugger Connect   |                  | <a href="#">Go</a> |
| 19Bh   | ECAPTYPE   | Configures ECAP Type for the device               | EALLOW           | <a href="#">Go</a> |
| 19Ch   | SDFMTYPE   | Configures SDFM Type for the device               | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-102 shows the codes that are used for access types in this section.

**Table 3-102. DEV\_CFG\_REGS Access Type Codes**

| Access Type | Code | Description     |
|-------------|------|-----------------|
| Read Type   |      |                 |
| R           | R    | Read            |
| R-0         | R-0  | Read Returns 0s |
| Write Type  |      |                 |
| W           | W    | Write           |

**Table 3-102. DEV\_CFG\_REGS Access Type Codes  
(continued)**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| W1C                      | W<br>1C    | Write<br>1 to clear  |
| W1S                      | W<br>1S    | Write<br>1 to set  |
| WOnce                    | W<br>Once  | Write<br>Write once  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default<br>value  |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in<br>a register name, an offset, or an<br>address, they refer to the value of<br>a register array where the register<br>is part of a group of repeating<br>registers. The register groups<br>form a hierarchical structure and<br>the array is represented with a<br>formula. |
| y                        |            | When this variable is used in a<br>register name, an offset, or an<br>address it refers to the value of<br>a register array.   |

### 3.15.6.1 PARTIDL Register (Offset = 8h) [Reset = X]

PARTIDL is shown in [Figure 3-96](#) and described in [Table 3-103](#).

Return to the [Summary Table](#).

Lower 32-bit of Device PART Identification Number

Data ready interrupts from individual filters are not generated.<br>"01" :<br>1. Data Ready conditions do not generate the SDFMINT.<br>2. Each filter generates a separate data ready interrupts.<br>Reset type: SYSRSn |

### 3.15.7 DMA\_CLA\_SRC\_SEL\_REGS Registers

Table 3-130 lists the memory-mapped registers for the DMA\_CLA\_SRC\_SEL\_REGS registers. All register offset addresses not listed in Table 3-130 should be considered as reserved locations and the register contents should not be modified.

**Table 3-130. DMA\_CLA\_SRC\_SEL\_REGS Registers**

| Offset | Acronym            | Register Name                                   | Write Protection | Section            |
|--------|--------------------|---|------------------|--------------------|
| 0h     | CLA1TASKSRCSELLOCK | CLA1 Task Trigger Source Select Lock Register   | EALLOW           | <a href="#">Go</a> |
| 4h     | DMACHSRCSELLOCK    | DMA Channel Trigger Source Select Lock Register | EALLOW           | <a href="#">Go</a> |
| 6h     | CLA1TASKSRCSEL1    | CLA1 Task Trigger Source Select Register-1      | EALLOW           | <a href="#">Go</a> |
| 8h     | CLA1TASKSRCSEL2    | CLA1 Task Trigger Source Select Register-2      | EALLOW           | <a href="#">Go</a> |
| 16h    | DMACHSRCSEL1       | DMA Channel Trigger Source Select Register-1    | EALLOW           | <a href="#">Go</a> |
| 18h    | DMACHSRCSEL2       | DMA Channel Trigger Source Select Register-2    | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-131 shows the codes that are used for access types in this section.

**Table 3-131. DMA\_CLA\_SRC\_SEL\_REGS Access Type Codes**

| Access Type              | Code  | Description  |
|--------------------------|-------|--|
| Read Type                |       |  |
| R                        | R     | Read   |
| R-0                      | R-0   | Read Returns 0s  |
| Write Type               |       |  |
| W                        | W     | Write  |
| WOnce                    | WOnce | Write Set once   |
| Reset or Default Value   |       |  |
| -n                       |       | Value after reset or the default value   |
| Register Array Variables |       |  |
| i,j,k,l,m,n              |       | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |       | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.7.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [Reset = 0h]

CLA1TASKSRCSELLOCK is shown in [Figure 3-123](#) and described in [Table 3-132](#).

Return to the [Summary Table](#).

CLA1 Task Trigger Source Select Lock Register

### 3.15.8 MEM\_CFG\_REGS Registers

Table 3-138 lists the memory-mapped registers for the MEM\_CFG\_REGS registers. All register offset addresses not listed in Table 3-138 should be considered as reserved locations and the register contents should not be modified.

**Table 3-138. MEM\_CFG\_REGS Registers**

| Offset | Acronym          | Register Name                                 | Write Protection | Section            |
|--------|------------------|---|------------------|--------------------|
| 0h     | DxLOCK           | Dedicated RAM Config Lock Register            | EALLOW           | <a href="#">Go</a> |
| 2h     | DxCOMMIT         | Dedicated RAM Config Lock Commit Register     | EALLOW           | <a href="#">Go</a> |
| 8h     | DxACCPROTO       | Dedicated RAM Config Register                 | EALLOW           | <a href="#">Go</a> |
| 10h    | DxTEST           | Dedicated RAM TEST Register                   |                  | <a href="#">Go</a> |
| 12h    | DxINIT           | Dedicated RAM Init Register                   | EALLOW           | <a href="#">Go</a> |
| 14h    | DxINITDONE       | Dedicated RAM InitDone Status Register        |                  | <a href="#">Go</a> |
| 16h    | DxRAMTEST_LOCK   | Lock register to Dx RAM TEST registers        |                  | <a href="#">Go</a> |

| 72h    | MSGxINIT         | Message RAM Init Register                     | EALLOW           | <a href="#">Go</a> |
| 74h    | MSGxINITDONE     | Message RAM InitDone Status Register          |                  | <a href="#">Go</a> |
| 76h    | MSGxRAMTEST_LOCK | Lock register for MSGx RAM TEST Register      |                  | <a href="#">Go</a> |
| A0h    | ROM_LOCK         | ROM Config Lock Register                      |                  | <a href="#">Go</a> |
| A2h    | ROM_TEST         | ROM TEST Register                             |                  | <a href="#">Go</a> |
| A4h    | ROM_FORCE_ERROR  | ROM Force Error register                      |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-139 shows the codes that are used for access types in this section.

**Table 3-139. MEM\_CFG\_REGS Access Type Codes**

| Access Type | Code | Description |
|-------------|------|-------------|
| Read Type   |      |             |
| R           | R    | Read        |

**Table 3-139. MEM\_CFG\_REGS Access Type Codes  
(continued)**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| R-0                      | R<br>-0    | Read<br>Returns 0s   |
| Write Type               |            |  |
| W                        | W          | Write  |
| W1S                      | W<br>1S    | Write<br>1 to set  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.8.1 DxLOCK Register (Offset = 0h) [Reset = 0h]

DxLOCK is shown in [Figure 3-129](#) and described in [Table 3-140](#).

Return to the [Summary Table](#).

Dedicated RAM Config Lock Register

### 3.15.9 MEMORY\_ERROR\_REGS Registers

Table 3-173 lists the memory-mapped registers for the MEMORY\_ERROR\_REGS registers. All register offset addresses not listed in Table 3-173 should be considered as reserved locations and the register contents should not be modified.

**Table 3-173. MEMORY\_ERROR\_REGS Registers**

| Offset | Acronym      | Register Name                                    | Write Protection | Section            |
|--------|--------------|--|------------------|--------------------|
| 0h     | UCERRFLG     | Uncorrectable Error Flag Register                |                  | <a href="#">Go</a> |
| 2h     | UCERRSET     | Uncorrectable Error Flag Set Register            | EALLOW           | <a href="#">Go</a> |
| 4h     | UCERRCLR     | Uncorrectable Error Flag Clear Register          | EALLOW           | <a href="#">Go</a> |
| 6h     | UCCPUREADDR  | Uncorrectable CPU Read Error Address             |                  | <a href="#">Go</a> |
| 8h     | UCDMAREADDR  | Uncorrectable DMA Read Error Address             |                  | <a href="#">Go</a> |
| Ah     | UCCLA1READDR | Uncorrectable CLA1 Read Error Address            |                  | <a href="#">Go</a> |
| 10h    | UCHICAREADDR | Uncorrectable HICA Read Error Address            |                  | <a href="#">Go</a> |
| 20h    | CERRFLG      | Correctable Error Flag Register                  |                  | <a href="#">Go</a> |
| 22h    | CERRSET      | Correctable Error Flag Set Register              | EALLOW           | <a href="#">Go</a> |
| 24h    | CERRCLR      | Correctable Error Flag Clear Register            | EALLOW           | <a href="#">Go</a> |
| 26h    | CCPUREADDR   | Correctable CPU Read Error Address               |                  | <a href="#">Go</a> |
| 28h    | CDMAREADDR   | Correctable DMA Read Error Address               |                  | <a href="#">Go</a> |
| 2Ah    | CCLA1READDR  | Correctable CLA1 Read Error Address              |                  | <a href="#">Go</a> |
| 2Eh    | CERRCNT      | Correctable Error Count Register                 |                  | <a href="#">Go</a> |
| 30h    | CERRTHRES    | Correctable Error Threshold Value Register       | EALLOW           | <a href="#">Go</a> |
| 32h    | CEINTFLG     | Correctable Error Interrupt Flag Status Register |                  | <a href="#">Go</a> |
| 34h    | CEINTCLR     | Correctable Error Interrupt Flag Clear Register  | EALLOW           | <a href="#">Go</a> |
| 36h    | CEINTSET     | Correctable Error Interrupt Flag Set Register    | EALLOW           | <a href="#">Go</a> |
| 38h    | CEINTEN      | Correctable Error Interrupt Enable Register      | EALLOW           | <a href="#">Go</a> |
| 3Ah    | CHICREADDR   | Correctable HIC Read Error Address               |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-174 shows the codes that are used for access types in this section.

**Table 3-174. MEMORY\_ERROR\_REGS Access Type Codes**

| Access Type              | Code    | Description                            |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read                                   |
| R-0                      | R<br>-0 | Read<br>Returns 0s                     |
| Write Type               |         |  |
| W                        | W       | Write                                  |
| W1S                      | W<br>1S | Write<br>1 to set                      |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value |
| Register Array Variables |         |  |

**Table 3-174. MEMORY\_ERROR\_REGS Access Type Codes (continued)**

| Access Type | Code | Description  |
|-------------|------|--|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.9.1 UCERRFLG Register (Offset = 0h) [Reset = 0h]

UCERRFLG is shown in [Figure 3-162](#) and described in [Table 3-175](#).

Return to the [Summary Table](#).

Uncorrectable Error Flag Register

**Table 3-194. CHICREADDR Register Field Descriptions**

| Bit  | Field      | Type | Reset | Description  |
|------|------------|------|-------|--|
| 31-0 | CHICREADDR | R    | 0h    | This register captures the address location for which HIC read access resulted in correctable ECC error.<br>Reset type: SYSRSn |

### 3.15.10 NMI\_INTRUPT\_REGS Registers

Table 3-195 lists the memory-mapped registers for the NMI\_INTRUPT\_REGS registers. All register offset addresses not listed in Table 3-195 should be considered as reserved locations and the register contents should not be modified.

**Table 3-195. NMI\_INTRUPT\_REGS Registers**

| Offset | Acronym     | Register Name                         | Write Protection | Section            |
|--------|-------------|---------------------------------------|------------------|--------------------|
| 0h     | NMICFG      | NMI Configuration Register            | EALLOW           | <a href="#">Go</a> |
| 1h     | NMIFLG      | NMI Flag Register (SYSRSn Clear)      |                  | <a href="#">Go</a> |
| 2h     | NMIFLGCLR   | NMI Flag Clear Register               | EALLOW           | <a href="#">Go</a> |
| 3h     | NMIFLGFRC   | NMI Flag Force Register               | EALLOW           | <a href="#">Go</a> |
| 4h     | NMIWDCNT    | NMI Watchdog Counter Register         |                  | <a href="#">Go</a> |
| 5h     | NMIWDPRD    | NMI Watchdog Period Register          | EALLOW           | <a href="#">Go</a> |
| 6h     | NMISHDFLG   | NMI Shadow Flag Register              |                  | <a href="#">Go</a> |
| 7h     | ERRORSTS    | Error pin status                      |                  | <a href="#">Go</a> |
| 8h     | ERRORSTSCLR | ERRORSTS clear register               | EALLOW           | <a href="#">Go</a> |
| 9h     | ERRORSTSFRC | ERRORSTS force register               | EALLOW           | <a href="#">Go</a> |
| Ah     | ERRORCTL    | Error pin control register            | EALLOW           | <a href="#">Go</a> |
| Bh     | ERRORLOCK   | Lock register to Error pin registers. | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-196 shows the codes that are used for access types in this section.

**Table 3-196. NMI\_INTRUPT\_REGS Access Type Codes**

| Access Type              | Code  | Description  |
|--------------------------|-------|--|
| Read Type                |       |  |
| R                        | R     | Read   |
| R-0                      | R-0   | Read<br>Returns 0s   |
| Write Type               |       |  |
| W                        | W     | Write  |
| W1S                      | W1S   | Write<br>1 to set  |
| WOnce                    | WOnce | Write<br>Set once  |
| Reset or Default Value   |       |  |
| -n                       |       | Value after reset or the default value   |
| Register Array Variables |       |  |
| i,j,k,l,m,n              |       | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |       | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.10.1 NMICFG Register (Offset = 0h) [Reset = 0h]

NMICFG is shown in [Figure 3-182](#) and described in [Table 3-197](#).

Return to the [Summary Table](#).

NMI Configuration Register

**Figure 3-182. NMICFG Register**

|          |    |    |    |    |    |   |          |

**Table 3-201. NMIWDCNT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description  |
|------|----------|------|-------|--|
| 15-0 | NMIWDCNT | R    | 0h    | <p>NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set.</p> <p>If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set.</p> <p>Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway.</p> <p>The counter is clocked at the SYSCLKOUT rate.</p> <p>Reset type: SYSRSn</p> |

### 3.15.10.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in [Figure 3-187](#) and described in [Table 3-202](#).

Return to the [Summary Table](#).

NMI Watchdog Period Register

**Figure 3-187. NMIWDPRD Register**

|           |    |    |    |    |    |   |   |
|-----------|----|----|----|----|----|---|---|
| 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

**Table 3-208. ERRORLOCK Register Field Descriptions**

| Bit  | Field    | Type    | Reset | Description   |
|------|----------|---------|-------|---|
| 15-1 | RESERVED | R       | 0h    | Reserved  |
| 0    | ERRORCTL | R/WOnce | 0h    | 0, Writes to ERRORCTL register allowed.<br>1, Writes to ERRORCTL register is blocked.<br>Writes of 0 to this bit has no effect. Write of 1 will set this bit, cleared only on a SYSRSn.<br>Reset type: SYSRSn |

### 3.15.11 PERIPH\_AC\_REGS Registers

Table 3-209 lists the memory-mapped registers for the PERIPH\_AC\_REGS registers. All register offset addresses not listed in Table 3-209 should be considered as reserved locations and the register contents should not be modified.

**Table 3-209. PERIPH\_AC\_REGS Registers**

| Offset | Acronym    | Register Name                         | Write Protection | Section            |
|--------|------------|---------------------------------------|------------------|--------------------|
| 0h     | ADCA_AC    | ADCA Master Access Control Register   | EALLOW           | <a href="#">Go</a> |
| 2h     | ADCB_AC    | ADCB Master Access Control Register   | EALLOW           | <a href="#">Go</a> |
| 4h     | ADCC_AC    | ADCC Master Access Control Register   | EALLOW           | <a href="#">Go</a> |
| 10h    | CMPSS1_AC  | CMPSS1 Master Access Control Register | EALLOW           | <a href="#">Go</a> |
| 12h    | CMPSS2_AC  | CMPSS2 Master Access Control Register | EALLOW           | <a href="#">Go</a> |
| 14h    | CMPSS3_AC  | CMPSS3 Master Access Control Register | EALLOW           | <a href="#">Go</a> |

**Table 3-209. PERIPH\_AC\_REGS Registers (continued)**

| Offset | Acronym        | Register Name   | Write Protection | Section            |
|--------|----------------|---|------------------|--------------------|
| 1AAh   | HRPWM_A_AC     | HRPWM Master Access Control Register                              | EALLOW           | <a href="#">Go</a> |
| 1ACh   | HIC_A_AC       | HIC Master Access Control Register                                | EALLOW           | <a href="#">Go</a> |
| 1AEh   | AESA_AC        | AES Master Access Control Register                                | EALLOW           | <a href="#">Go</a> |
| 1FEh   | PERIPH_AC_LOCK | Lock Register to stop Write access to peripheral Access register. | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. [Table 3-210](#) shows the codes that are used for access types in this section.

**Table 3-210. PERIPH\_AC\_REGS Access Type Codes**

| Access Type              | Code      | Description  |
|--------------------------|-----------|--|
| Read Type                |           |  |
| R                        | R         | Read   |
| R-0                      | R<br>-0   | Read<br>Returns 0s   |
| Write Type               |           |  |
| W                        | W         | Write  |
| WOnce                    | W<br>Once | Write<br>Set once  |
| Reset or Default Value   |           |  |
| -n                       |           | Value after reset or the default value   |
| Register Array Variables |           |  |
| i,j,k,l,m,n              |           | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |           | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.11.1 ADCA\_AC Register (Offset = 0h) [Reset = FFh]

ADCA\_AC is shown in [Figure 3-194](#) and described in [Table 3-211](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-194. ADCA\_AC Register**

### 3.15.11.5 CMPSS2\_AC Register (Offset = 12h) [Reset = FFh]

CMPSS2\_AC is shown in [Figure 3-198](#) and described in [Table 3-215](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

### 3.15.11.11 EPWM2\_AC Register (Offset = 4Ah) [Reset = FFh]

EPWM2\_AC is shown in [Figure 3-204](#) and described in [Table 3-221](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

### 3.15.11.17 EPWM8\_AC Register (Offset = 56h) [Reset = FFh]

EPWM8\_AC is shown in [Figure 3-210](#) and described in [Table 3-227](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

### 3.15.11.23 SDFM1\_AC Register (Offset = A8h) [Reset = FFh]

SDFM1\_AC is shown in [Figure 3-216](#) and described in [Table 3-233](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-216. SDFM1\_AC Register**

### 3.15.11.29 SCIA\_AC Register (Offset = 100h) [Reset = CFh]

SCIA\_AC is shown in [Figure 3-222](#) and described in [Table 3-239](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-222. SCIA\_AC Register**

| 1-0  | CPU1_ACC | R/W  | 3h    | Defines Access control definition for the CPU1 as:<br>11: Full Access for both read and Write<br>10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access<br>01: Reserved<br>00: No Read/Write Access to peripheral<br>Reset type: XRSn |

### 3.15.11.36 LIN\_A\_AC Register (Offset = 138h) [Reset = FFh]

LIN\_A\_AC is shown in [Figure 3-229](#) and described in [Table 3-246](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-229. LIN\_A\_AC Register**

### 3.15.11.42 HRPWM\_A\_AC Register (Offset = 1AAh) [Reset = FFh]

HRPWM\_A\_AC is shown in [Figure 3-235](#) and described in [Table 3-252](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-235. HRPWM\_A\_AC Register**

| 19h    | PIEIFR12 | Interrupt Group 12 Flag Register   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-257 shows the codes that are used for access types in this section.

**Table 3-257. PIE\_CTRL\_REGS Access Type Codes**

| Access Type            | Code    | Description        |
|------------------------|---------|--------------------|
| Read Type              |         |                    |
| R                      | R       | Read               |
| R-0                    | R<br>-0 | Read<br>Returns 0s |
| Write Type             |         |                    |
| W                      | W       | Write              |
| W1S                    | W<br>1S | Write<br>1 to set  |
| Reset or Default Value |         |                    |

**Table 3-257. PIE\_CTRL\_REGS Access Type Codes  
(continued)**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| <i>-n</i>                |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| <i>i,j,k,l,m,n</i>       |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| <i>y</i>                 |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.12.1 PIECTRL Register (Offset = 0h) [Reset = 0h]

PIECTRL is shown in [Figure 3-239](#) and described in [Table 3-258](#).

Return to the [Summary Table](#).

ePIE Control Register

**Figure 3-239. PIECTRL Register**

|         |    |    |    |    |    |   |        |
|---------|----|----|----|----|----|---|--------|
| 15      | 14 | 13 | 12 | 11 | 10 | 9 | 8      |
| PIEVECT |    |    |    |    |    |   |        |
| R-0h    |    |    |    |    |    |   |        |
| 7       | 6  | 5  | 4  | 3  | 2  | 1 | 0      |
| PIEVECT |    |    |    |    |    |   | ENPIE  |
| R-0h    |    |    |    |    |    |   | R/W-0h |

**Table 3-258. PIECTRL Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description  |
|------|---------|------|-------|--|
| 15-1 | PIEVECT | R    | 0h    | These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch.<br>Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts.<br>Reset type: SYSRSn |
| 0    | ENPIE   | R/W  | 0h    | Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled.<br>Reset type: SYSRSn   |

### 3.15.12.2 PIEACK Register (Offset = 1h) [Reset = 0h]

PIEACK is shown in [Figure 3-240](#) and described in [Table 3-259](#).

Return to the [Summary Table](#).

#### Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.

Writes of 0 are ignored.

**Figure 3-240. PIEACK Register**

### 3.15.12.3 PIEIER1 Register (Offset = 2h) [Reset = 0h]

PIEIER1 is shown in [Figure 3-241](#) and described in [Table 3-260](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-241. PIEIER1 Register**

|        |        |        |        |        |        |        |        |

### 3.15.12.4 PIEIFR1 Register (Offset = 3h) [Reset = 0h]

PIEIFR1 is shown in [Figure 3-242](#) and described in [Table 3-261](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-242. PIEIFR1 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.15.12.8 PIEIFR3 Register (Offset = 7h) [Reset = 0h]

PIEIFR3 is shown in [Figure 3-246](#) and described in [Table 3-265](#).

Return to the [Summary Table](#).

#### Interrupt Group 3 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-246. PIEIFR3 Register**

### 3.15.12.14 PIEIFR6 Register (Offset = Dh) [Reset = 0h]

PIEIFR6 is shown in [Figure 3-252](#) and described in [Table 3-271](#).

Return to the [Summary Table](#).

#### Interrupt Group 6 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-252. PIEIFR6 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.15.12.20 PIEIFR9 Register (Offset = 13h) [Reset = 0h]

PIEIFR9 is shown in [Figure 3-258](#) and described in [Table 3-277](#).

Return to the [Summary Table](#).

#### Interrupt Group 9 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-258. PIEIFR9 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.15.12.21 PIEIER10 Register (Offset = 14h) [Reset = 0h]

PIEIER10 is shown in [Figure 3-259](#) and described in [Table 3-278](#).

Return to the [Summary Table](#).

#### Interrupt Group 10 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-259. PIEIER10 Register**

|        |        |        |        |        |        |        |        |

### 3.15.12.25 PIEIER12 Register (Offset = 18h) [Reset = 0h]

PIEIER12 is shown in [Figure 3-263](#) and described in [Table 3-282](#).

Return to the [Summary Table](#).

#### Interrupt Group 12 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-263. PIEIER12 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.15.12.26 PIEIFR12 Register (Offset = 19h) [Reset = 0h]

PIEIFR12 is shown in [Figure 3-264](#) and described in [Table 3-283](#).

Return to the [Summary Table](#).

#### Interrupt Group 12 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-264. PIEIFR12 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.15.13 SYNC\_SOC\_REGS Registers

Table 3-284 lists the memory-mapped registers for the SYNC\_SOC\_REGS registers. All register offset addresses not listed in Table 3-284 should be considered as reserved locations and the register contents should not be modified.

**Table 3-284. SYNC\_SOC\_REGS Registers**

| Offset | Acronym         | Register Name                              | Write Protection | Section            |
|--------|-----------------|--|------------------|--------------------|
| 0h     | SYNCSELECT      | Sync Input and Output Select Register      | EALLOW           | <a href="#">Go</a> |
| 2h     | ADCSOCOUTSELECT | External ADCSOC Select Register            | EALLOW           | <a href="#">Go</a> |
| 4h     | SYNCSOCLOCK     | SYNCSEL and EXTADCSOC Select Lock register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-285 shows the codes that are used for access types in this section.

**Table 3-285. SYNC\_SOC\_REGS Access Type Codes**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| Read Type                |            |  |
| R                        | R          | Read   |
| R-0                      | R<br>-0    | Read<br>Returns 0s   |
| Write Type               |            |  |
| W                        | W          | Write  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.13.1 SYNCSELECT Register (Offset = 0h) [Reset = E003FFFFh]

SYNCSELECT is shown in [Figure 3-265](#) and described in [Table 3-286](#).

Return to the [Summary Table](#).

### 3.15.14 SYS\_STATUS\_REGS Registers

Table 3-289 lists the memory-mapped registers for the SYS\_STATUS\_REGS registers. All register offset addresses not listed in Table 3-289 should be considered as reserved locations and the register contents should not be modified.

**Table 3-289. SYS\_STATUS\_REGS Registers**

| Offset | Acronym         | Register Name  | Write Protection | Section            |
|--------|-----------------|--|------------------|--------------------|
| 10h    | SYS_ERR_INT_FLG | Status of interrupts due to multiple different errors in the system. |                  | <a href="#">Go</a> |
| 12h    | SYS_ERR_INT_CLR | SYS_ERR_INT_FLG clear register                                       |                  | <a href="#">Go</a> |
| 14h    | SYS_ERR_INT_SET | SYS_ERR_INT_FLG set register   | EALLOW           | <a href="#">Go</a> |
| 16h    | SYS_ERR_MASK    | SYS_ERR_MASK register  | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-290 shows the codes that are used for access types in this section.

**Table 3-290. SYS\_STATUS\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| R-0                      | R-0  | Read Returns 0s  |
| Write Type               |      |  |
| W                        | W    | Write  |
| W1S                      | W1S  | Write 1 to set   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.14.1 SYS\_ERR\_INT\_FLG Register (Offset = 10h) [Reset = 0h]

SYS\_ERR\_INT\_FLG is shown in [Figure 3-268](#) and described in [Table 3-291](#).

Return to the [Summary Table](#).

Status of interrupts due to multiple different errors in the system.

**Figure 3-268. SYS\_ERR\_INT\_FLG Register**

### 3.15.15 TEST\_ERROR\_REGS Registers

Table 3-295 lists the memory-mapped registers for the TEST\_ERROR\_REGS registers. All register offset addresses not listed in Table 3-295 should be considered as reserved locations and the register contents should not be modified.

**Table 3-295. TEST\_ERROR\_REGS Registers**

| Offset | Acronym                    | Register Name                         | Write Protection | Section            |
|--------|----------------------------|---------------------------------------|------------------|--------------------|
| 0h     | CPU_RAM_TEST_ERROR_STS     | Ram Test: Error Status Register       |                  | <a href="#">Go</a> |
| 2h     | CPU_RAM_TEST_ERROR_STS_CLR | Ram Test: Error Status Clear Register |                  | <a href="#">Go</a> |
| 4h     | CPU_RAM_TEST_ERROR_ADDR    | Ram Test: Error address register      |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-296 shows the codes that are used for access types in this section.

**Table 3-296. TEST\_ERROR\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W1S                      | W<br>1S | Write<br>1 to set  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.15.1 CPU\_RAM\_TEST\_ERROR\_STS Register (Offset = 0h) [Reset = 0h]

CPU\_RAM\_TEST\_ERROR\_STS is shown in [Figure 3-272](#) and described in [Table 3-297](#).

Return to the [Summary Table](#).

Ram Test: Error Status Register

**Figure 3-272. CPU\_RAM\_TEST\_ERROR\_STS Register**

|          |    |    |    |    |    |           |           |

| ADDR |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 3-299. CPU\_RAM\_TEST\_ERROR\_ADDR Register Field Descriptions**

| Bit  | Field | Type | Reset | Description   |
|------|-------|------|-------|---|
| 31-0 | ADDR  | R    | 0h    | Address of the location where error was detected in RAM/ROM test modes.<br>Reset type: SYSRSn |

### 3.15.16 UID\_REGS Registers

Table 3-300 lists the memory-mapped registers for the UID\_REGS registers. All register offset addresses not listed in Table 3-300 should be considered as reserved locations and the register contents should not be modified.

**Table 3-300. UID\_REGS Registers**

| Offset | Acronym      | Register Name                    | Write Protection | Section            |
|--------|--------------|----------------------------------|------------------|--------------------|
| 0h     | UID_PSRAND0  | UID Psuedo-random 192 bit number |                  | <a href="#">Go</a> |
| 2h     | UID_PSRAND1  | UID Psuedo-random 192 bit number |                  | <a href="#">Go</a> |
| 4h     | UID_PSRAND2  | UID Psuedo-random 192 bit number |                  | <a href="#">Go</a> |
| 6h     | UID_PSRAND3  | UID Psuedo-random 192 bit number |                  | <a href="#">Go</a> |
| 8h     | UID_PSRAND4  | UID Psuedo-random 192 bit number |                  | <a href="#">Go</a> |
| Ah     | UID_PSRAND5  | UID Psuedo-random 192 bit number |                  | <a href="#">Go</a> |
| Ch     | UID_UNIQUE   | UID Unique 32 bit number         |                  | <a href="#">Go</a> |
| Eh     | UID_CHECKSUM | UID Checksum                     |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-301 shows the codes that are used for access types in this section.

**Table 3-301. UID\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.16.1 UID\_PSRAND0 Register (Offset = 0h) [Reset = X]

UID\_PSRAND0 is shown in [Figure 3-275](#) and described in [Table 3-302](#).

Return to the [Summary Table](#).

UID Psuedo-random 192 bit number

**Figure 3-275. UID\_PSRAND0 Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RandomID |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-X      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| 31-0 | Checksum | R    | X     | Fletcher checksum of UID_PSRANDx and UID_UNIQUE<br>Reset type: N/A |

### 3.15.17 WD\_REGS Registers

Table 3-310 lists the memory-mapped registers for the WD\_REGS registers. All register offset addresses not listed in Table 3-310 should be considered as reserved locations and the register contents should not be modified.

**Table 3-310. WD\_REGS Registers**

| Offset | Acronym | Register Name                      | Write Protection | Section            |
|--------|---------|------------------------------------|------------------|--------------------|
| 22h    | SCSR    | System Control & Status Register   | EALLOW           | <a href="#">Go</a> |
| 23h    | WDCNTR  | Watchdog Counter Register          | EALLOW           | <a href="#">Go</a> |
| 25h    | WDKEY   | Watchdog Reset Key Register        | EALLOW           | <a href="#">Go</a> |
| 29h    | WDCR    | Watchdog Control Register          | EALLOW           | <a href="#">Go</a> |
| 2Ah    | WDWCR   | Watchdog Windowed Control Register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-311 shows the codes that are used for access types in this section.

**Table 3-311. WD\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| R-0                      | R-0  | Read Returns 0s  |
| Write Type               |      |  |
| W                        | W    | Write  |
| W1C                      | W1C  | Write 1 to clear   |
| W1S                      | W1S  | Write 1 to set   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.17.1 SCSR Register (Offset = 22h) [Reset = 5h]

SCSR is shown in [Figure 3-283](#) and described in [Table 3-312](#).

Return to the [Summary Table](#).

#### System Control & Status Register

It is recommended to only use 16 bit accesses to write to this register. Use a read-modify-write instruction may inadvertently clear other bits.

**Figure 3-283. SCSR Register**

|          |    |    |    |    |        |         |            |
|----------|----|----|----|----|--------|---------|------------|
| 15       | 14 | 13 | 12 | 11 | 10     | 9       | 8          |
| RESERVED |    |    |    |    |        |         |            |
| R-0h     |    |    |    |    |        |         |            |
| 7        | 6  | 5  | 4  | 3  | 2      | 1       | 0          |
| RESERVED |    |    |    |    | WDINTS | WDENINT | WDOVERRIDE |
| R-0h     |    |    |    |    | R-1h   | R/W-0h  | R/W1C-1h   |

**Table 3-312. SCSR Register Field Descriptions**

| Bit  | Field      | Type  | Reset | Description  |
|------|------------|-------|-------|--|
| 15-3 | RESERVED   | R     | 0h    | Reserved   |
| 2    | WDINTS     | R     | 1h    | <p>Watchdog Interrupt Status</p> <p>This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The watchdog interrupt signal is active.</p> <p>1h (R/W) = The watchdog interrupt signal is inactive.</p> |
| 1    | WDENINT    | R/W   | 0h    | <p>Watchdog Interrupt Enable/Reset Disable</p> <p>This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Counter expiration triggers a reset. This is the default state on power-up and after any system reset.</p> <p>1h (R/W) = Counter expiration triggers an interrupt.</p>  |
| 0    | WDOVERRIDE | R/W1C | 1h    | <p>If this bit is set to 1, the user is allowed to change the state of the Watchdog disable (WDDIS) bit in the Watchdog Control (WDCR) register. If the WDOVERRIDE bit is cleared, by writing a 1 the WDDIS bit cannot be modified by the user. Writing a 0 will have no effect. If this bit is cleared, then it will remain in this state until a reset occurs. The current state of this bit is readable by the user.</p> <p>Reset type: SYSRSn</p>  |

### 3.15.17.2 WDCNTR Register (Offset = 23h) [Reset = 0h]

WDCNTR is shown in [Figure 3-284](#) and described in [Table 3-313](#).

Return to the [Summary Table](#).

Watchdog Counter Register

**Figure 3-284. WDCNTR Register**

|          |    |    |    |    |    |   |   |

|------|----------|------|-------|---|
| 15-9 | RESERVED | R    | 0h    | Reserved  |
| 8    | FIRSTKEY | R    | 0h    | This bit indicates if the 1st valid WDKEY (0x55 + 0xAA) got detected after MIN was configured to a non-zero value<br>0: First Valid Key after non-zero MIN configuration has not happened yet<br>1: First Valid key after non-zero MIN configuration got detected<br>Notes:<br>[1] If MIN = 0, this bit is never set<br>[2] If MIN is changed back to 0x0 from a non-zero value, this bit is auto-cleared<br>[3] This bit is added for debug purposes only<br>Reset type: IORSn |
| 7-0  | MIN      | R/W  | 0h    | Watchdog Window Threshold<br>These bits specify the lower limit of the watchdog counter reset window. If the counter is reset via the WDKEY register before the counter value reaches the value in this register, the watchdog immediately triggers a reset or interrupt.<br>Reset type: IORSn  |

### 3.15.18 XINT\_REGS Registers

Table 3-317 lists the memory-mapped registers for the XINT\_REGS registers. All register offset addresses not listed in Table 3-317 should be considered as reserved locations and the register contents should not be modified.

**Table 3-317. XINT\_REGS Registers**

| Offset | Acronym  | Register Name                | Write Protection | Section            |
|--------|----------|------------------------------|------------------|--------------------|
| 0h     | XINT1CR  | XINT1 configuration register |                  | <a href="#">Go</a> |
| 1h     | XINT2CR  | XINT2 configuration register |                  | <a href="#">Go</a> |
| 2h     | XINT3CR  | XINT3 configuration register |                  | <a href="#">Go</a> |
| 3h     | XINT4CR  | XINT4 configuration register |                  | <a href="#">Go</a> |
| 4h     | XINT5CR  | XINT5 configuration register |                  | <a href="#">Go</a> |
| 8h     | XINT1CTR | XINT1 counter register       |                  | <a href="#">Go</a> |
| 9h     | XINT2CTR | XINT2 counter register       |                  | <a href="#">Go</a> |
| Ah     | XINT3CTR | XINT3 counter register       |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-318 shows the codes that are used for access types in this section.

**Table 3-318. XINT\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.18.1 XINT1CR Register (Offset = 0h) [Reset = 0h]

XINT1CR is shown in [Figure 3-288](#) and described in [Table 3-319](#).

Return to the [Summary Table](#).

XINT1 configuration register

### 3.15.18.6 XINT1CTR Register (Offset = 8h) [Reset = 0h]

XINT1CTR is shown in [Figure 3-293](#) and described in [Table 3-324](#).

Return to the [Summary Table](#).

XINT1 counter register

**Figure 3-293. XINT1CTR Register**

|        |    |    |    |    |    |   |   |
|--------|----|----|----|----|----|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
| INTCTR |    |    |    |    |    |   |   |
| R-0h   |    |    |    |    |    |   |   |
| 7      | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| INTCTR |    |    |    |    |    |   |   |
| R-0h   |    |    |    |    |    |   |   |

**Table 3-324. XINT1CTR Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description  |
|------|--------|------|-------|--|
| 15-0 | INTCTR | R    | 0h    | This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset.<br>Reset type: SYSRSn |

### 3.15.18.7 XINT2CTR Register (Offset = 9h) [Reset = 0h]

XINT2CTR is shown in [Figure 3-294](#) and described in [Table 3-325](#).

Return to the [Summary Table](#).

XINT2 counter register

**Figure 3-294. XINT2CTR Register**

|        |    |    |    |    |    |   |   |

**Table 3-326. XINT3CTR Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description  |
|------|--------|------|-------|--|
| 15-0 | INTCTR | R    | 0h    | This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset.<br>Reset type: SYSRSn |

### 3.15.19 LFU\_REGS Registers

Table 3-327 lists the memory-mapped registers for the LFU\_REGS registers. All register offset addresses not listed in Table 3-327 should be considered as reserved locations and the register contents should not be modified.

**Table 3-327. LFU\_REGS Registers**

| Offset | Acronym            | Register Name                     | Write Protection | Section            |
|--------|--------------------|-----------------------------------|------------------|--------------------|
| 0h     | LFUConfig          | LFU configuration Register        | EALLOW           | <a href="#">Go</a> |
| 2h     | LFUStatus          | LFU Configuration Status Register |                  | <a href="#">Go</a> |
| 10h    | SWConfig1_SYSRSn   | Spare registers reset by SYSRSn   | EALLOW           | <a href="#">Go</a> |
| 12h    | SWConfig2_SYSRSn   | Spare registers reset by SYSRSn   | EALLOW           | <a href="#">Go</a> |
| 14h    | SWConfig1_XRSn     | Spare registers reset by XRSn     | EALLOW           | <a href="#">Go</a> |
| 16h    | SWConfig2_XRSn     | Spare registers reset by XRSn     | EALLOW           | <a href="#">Go</a> |
| 18h    | SWConfig1_PORESETn | Spare registers reset by PORESETn | EALLOW           | <a href="#">Go</a> |
| 1Ah    | SWConfig2_PORESETn | Spare registers reset by PORESETn | EALLOW           | <a href="#">Go</a> |
| 1Ch    | LFU_LOCK           | LFU Lock Configuration            |                  | <a href="#">Go</a> |
| 1Eh    | LFU_COMMIT         | LFU Commit Configuration          |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-328 shows the codes that are used for access types in this section.

**Table 3-328. LFU\_REGS Access Type Codes**

| Access Type              | Code       | Description  |
|--------------------------|------------|--|
| Read Type                |            |  |
| R                        | R          | Read   |
| R-0                      | R<br>-0    | Read<br>Returns 0s   |
| Write Type               |            |  |
| W                        | W          | Write  |
| WSonce                   | W<br>Sonce | Write<br>Set once  |
| Reset or Default Value   |            |  |
| -n                       |            | Value after reset or the default value   |
| Register Array Variables |            |  |
| i,j,k,l,m,n              |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 3.15.19.1 LFUConfig Register (Offset = 0h) [Reset = 0h]

LFUConfig is shown in [Figure 3-296](#) and described in [Table 3-329](#).

Return to the [Summary Table](#).

LFU configuration Register

### 3.15.19.10 LFU\_COMMIT Register (Offset = 1Eh) [Reset = 0h]

LFU\_COMMIT is shown in [Figure 3-305](#) and described in [Table 3-338](#).

Return to the [Summary Table](#).

LFU Commit Configuration

**Figure 3-305. LFU\_COMMIT Register**

## 4.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for the CPU core, including the boot procedure. It also discusses the functions and features of the boot ROM code, and provides details about the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run the application code. For the CPU, the boot ROM also contains peripheral bootloaders that can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

See [Table 4-1](#) for details on available boot features for the C28x CPU. Additionally, [Table 4-2](#) shows the sizes of the various ROMs on the device.

For details on the security APIs provided, refer to [Section 4.8.11](#).

Various tables are provided in ROM for use in software library, refer to [Section 4.8.8](#) for more details.

**Table 4-1. Boot System Overview**

| Boot Feature                      | CPU   |
|-----------------------------------|---|
| Initial boot process              | Device reset  |
| Boot mode selection               | GPIOs   |
| Boot modes supported              | Flash boot<br>Secure Flash boot<br>RAM boot<br>Live firmware update (LFU) boot<br>Secure LFU boot |
| Peripheral boot loaders supported | Parallel IO<br>SCI / Wait<br>CAN<br>CAN-FD<br>I2C<br>SPI  |

**Table 4-2. ROM Memory**

| ROM               | CPU Size |
|-------------------|----------|
| Unsecure boot ROM | 64 KB    |
| Secure ROM        | 48 KB    |
| CLA data ROM      | 8 KB     |

## 4.2 ROM Related Collateral

### Foundational Materials

- [Bootloading 101](#) (Video)

### Expert Materials

- [C2000 Software Controlled Firmware Update Process Application Report](#)

### 4.3 Device Boot Sequence

Table 4-3 describes the general boot ROM procedure each time the CPU core is reset.

During boot, boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to Section 4.8.13 for more details.

**Table 4-3. Device Boot ROM Sequence**

| Step | CPU Action  |
|------|---|
| 1    | After reset, check for HWBIST reset. If it is a HWBIST reset, immediately branch and return to the user application. If it is not a HWBIST reset, then continue boot and check the FUSE error register for any errors and handle accordingly. |
| 2    | Clock configuration and Flash power-up  |
| 3    | Peripheral trimming and device configuration registers are loaded from OTP.   |
| 4    | On power-on reset (POR), all RAMs are initialized.  |
| 5    | Non-maskable interrupt (NMI) handling is enabled and DCSM initialization is performed.  |
| 6    | Device calibration is performed; trimming the specified peripherals with set OTP values.  |
| 7    | Determine if polling the GPIO pins are needed for determining the boot mode and, if so, read the boot mode GPIO pins to determine the boot mode to run.   |
| 8    | Based on the boot mode and options, the appropriate boot sequence is executed. Refer to Section 4.6.1 for a flow chart of the boot sequences.   |

### 4.4 Device Boot Modes

This section explains the default boot modes, as well as all the available boot modes supported on this device. The boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration.

#### 4.4.1 Default Boot Modes

Table 4-4 shows the boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used.

**Table 4-4. Device Default Boot Modes**

| Boot Mode                      | GPIO24<br>(Default boot mode select pin 1) | GPIO32<br>(Default boot mode select pin 0) |
|--------------------------------|--|--|
| Parallel IO                    | 0  | 0  |
| SCI / Wait Boot <sup>(1)</sup> | 0  | 1  |
| CAN                            | 1  | 0  |
| Flash                          | 1  | 1  |

(1) SCI boot mode is used as a wait boot mode as long as SCI continues to wait for an 'A' or 'a' during the SCI autobaud lock process.

Refer to Section 4.8.9.1 for functional details of the boot modes.

Refer to Section 4.8.10 for GPIOs used for selecting the boot modes.

Refer to Section 4.5 for details of boot configurations.

#### Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, it is actually referring to the first module instance, which means the SCI boot on the SCIA port. The same applies to the other peripheral boot modes.

#### 4.4.2 Custom Boot Modes

Once the user programs a custom boot table in user OTP, an entry in the custom table is used for booting. Users can customize the boot mode select pins in the end system design by programming the BOOTPIN\_CONFIG location in user OTP. This allows customers to use 0, 1, 2, or 3 boot mode select pins as needed. You can also customize the boot definition table and indicate which location to boot from by programming the boot mode definition table in the BOOTDEF location of user OTP. [Table 4-5](#) shows the options for various boot modes.

**Table 4-5. Custom Boot Modes**

| Boot Mode Number | Boot Modes   |
|------------------|--------------|
| 0                | Parallel     |
| 1                | SCI / Wait   |
| 2                | CAN          |
| 3                | Flash        |
| 4                | Wait         |
| 5                | RAM          |
| 6                | SPI          |
| 7                | I2C          |
| 10               | Secure Flash |

#### 4.5 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from **one** boot mode select pins up to **three** boot mode select pins as well as from **one** configured boot mode up to **eight** configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SCI boot for debugging, etc)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: **Two** BMSPs are required to select between **three** boot mode options)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO10, BMSP1 to GPIO51, and BMSP2 left as default which is disabled). Refer to [Section 4.5.1](#) for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0=Boot to Flash, BOOTDEF1=CAN Boot, BOOTDEF2=SCI Boot; all other BOOTDEFx are left as default/nothing). Refer to [Section 4.5.2](#) for all the details on setting up and configuring the custom boot mode table.

Additionally, [Section 4.5.3](#) provides some example use cases on how to configure the BMSPs and custom boot tables.

### 4.5.1 Configuring Boot Mode Pins

This section explains how the boot mode select pins ARE customized by the user, by programming the BOOTPIN-CONFIG location (refer to [Table 4-6](#)) in the user-configurable dual-zone security module (DCSM) OTP. The location in the DCSM OTP is Z1-OTP-BOOTPIN-CONFIG or Z2-OTP-BOOTPIN-CONFIG. When debugging, EMU-BOOTPIN-CONFIG is the emulation equivalent of Z1-OTP-BOOTPIN-CONFIG/Z2-OTP-BOOTPIN-CONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use **zero, one, two** or **three** boot mode select pins as needed.

---

#### Note

When using Z2-OTP-BOOTPIN-CONFIG, the configurations programmed in this location take priority over the configurations in Z1-OTP-BOOTPIN-CONFIG. It is **recommended** to use Z1-OTP-BOOTPIN-CONFIG first and then if OTP configurations need to be altered, switch to using Z2-OTP-BOOTPIN-CONFIG.

---

**Table 4-6. BOOTPIN-CONFIG Bit Fields**

| Bit   | Name                           | Description   |
|-------|--------------------------------|---|
| 31:24 | Key                            | Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.  |
| 23:16 | Boot Mode Select Pin 2 (BMSP2) | Refer to BMSP0 description.   |
| 15:8  | Boot Mode Select Pin 1 (BMSP1) | Refer to BMSP0 description.   |
| 7:0   | Boot Mode Select Pin 0 (BMSP0) | Set to the GPIO pin to be used during boot (up to 255).<br>0x0 = GPIO0, 0x01 = GPIO1, and so on.<br>Writing 0xFF disables this BMSP and this pin is no longer used to select the boot mode. |

---

#### Note

GPIO 20, 21, 224 to 253 are analog pins, but digital inputs are possible on these pins provided the software writes to the GPIOHAMSEL register bits.

The following GPIOs **cannot** be used as a BMSP. If selected for a particular BMSP, the boot ROM will automatically select the factory default GPIOs for BMSP0 and BMSP1. Factory default for BMSP2 is 0xFF, which disables the BMSP.

- GPIO 36 and GPIO 38 (Not available on any package)
  - GPIO 62 to GPIO 223 (Not available on any package)
  - GPIO 20 and GPIO 21 are analog pins on 80-pin package only
-

**Table 4-7. Standalone Boot Mode Select Pin Decoding**

| BOOTPIN_CONFIG Key | BMSP0        | BMSP1        | BMSP2  | Realized Boot Mode   |
|--------------------|--------------|--------------|--|--|
| != 0x5A            | Don't Care   | Don't Care   | Don't Care   | Boot as defined by the factory default BMSPs   |
| = 0x5A             | 0xFF         | 0xFF         | 0xFF   | Boot as defined in the boot table for boot mode 0 (All BMSPs disabled)                                       |
|                    | Valid GPIO   | 0xFF         | 0xFF   | Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)   |
|                    | 0xFF         | Valid GPIO   | 0xFF   | Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)   |
|                    | 0xFF         | 0xFF         | Valid GPIO   | Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)   |
|                    | Valid GPIO   | Valid GPIO   | 0xFF   | Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)  |
|                    | Valid GPIO   | 0xFF         | Valid GPIO   | Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)  |
|                    | 0xFF         | Valid GPIO   | Valid GPIO   | Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)  |
|                    | Valid GPIO   | Valid GPIO   | Valid GPIO   | Boot as defined by the values of BMSP0, BMSP1, and BMSP2   |
|                    | Invalid GPIO | Valid GPIO   | Valid GPIO   | BMSP0 is reset to the factory default BMSP0 GPIO<br>Boot as defined by the values of BMSP0, BMSP1, and BMSP2 |
|                    | Valid GPIO   | Invalid GPIO | Valid GPIO   | BMSP1 is reset to the factory default BMSP1 GPIO<br>Boot as defined by the values of BMSP0, BMSP1, and BMSP2 |
| Valid GPIO         | Valid GPIO   | Invalid GPIO | BMSP2 is reset to the factory default state, which is disabled<br>Boot as defined by the values of BMSP0 and BMSP1 |  |

#### Note

When decoding the boot mode, BMSP0 is the least-significant-bit and BMSP2 is the most-significant-bit of the boot table index value. It is **recommended** when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 will be selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

## 4.5.2 Configuring Boot Mode Table Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options. The 64-bit location is located in user-configurable DCSM OTP in the Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations. When debugging, EMU-BOOTDEF-LOW and EMU-BOOTDEF-HIGH are the emulation equivalents of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to [Section 4.5.3](#) for examples on how to setup the BOOTPIN\_CONFIG and BOOTDEF values.

### Note

The locations Z2-OTP-BOOTDEF-LOW and Z2-OTP-BOOTDEF-HIGH will be used instead of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations when Z2-OTP-BOOTPIN-CONFIG is configured. Refer to [Section 4.5.1](#) for more details on BOOTPIN\_CONFIG usage.

**Table 4-8. BOOTDEF Bit Fields**

| BOOTDEF Name | Byte Position | Name                    | Description  |
|--------------|---------------|-------------------------|--|
| BOOT_DEF0    | 7:0           | [3:0] BOOT_DEF0 Mode    | Set the boot mode number from <a href="#">Section 4.4.2</a> . Any unsupported boot mode will cause the device to either go to wait boot (debugger connected) or boot to Flash (standalone).  |
|              |               | [7:4] BOOT_DEF0 Options | Set alternate / additional boot options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Refer to <a href="#">Section 4.8.10</a> for valid BOOTDEF values to set in the table. |
| BOOT_DEF1    | 15:8          | BOOT_DEF1 Mode/Options  | Refer to BOOT_DEF0 description.  |
| BOOT_DEF2    | 23:16         | BOOT_DEF2 Mode/Options  |  |
| BOOT_DEF3    | 31:24         | BOOT_DEF3 Mode/Options  |  |
| BOOT_DEF4    | 39:32         | BOOT_DEF4 Mode/Options  |  |
| BOOT_DEF5    | 47:40         | BOOT_DEF5 Mode/Options  |  |
| BOOT_DEF6    | 55:48         | BOOT_DEF6 Mode/Options  |  |
| BOOT_DEF7    | 63:56         | BOOT_DEF7 Mode/Options  |  |

### 4.5.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

#### 4.5.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
- Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.8.10](#) for valid BOOTDEF values to set in the table.
  - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
  - Refer to [Section 4.8.2](#) for the available Flash entry points.

**Table 4-9. Zero Boot Pin Boot Table Result**

| Boot Mode Table Number | Boot Mode         |
|------------------------|-------------------|
| 0                      | Flash Boot (0x03) |

#### 4.5.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
- Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.8.10](#) for valid BOOTDEF values to set in the table.
  - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
  - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

**Table 4-10. One Boot Pin Boot Table Result**

| Boot Mode Table Number | Boot Mode         |
|------------------------|-------------------|
| 0                      | CAN Boot (0x02)   |
| 1                      | Flash Boot (0x03) |

### 4.5.3.3 Three Boot Mode Select Pins

This use case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
  - Set BOOTPIN\_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
  - Set BOOTPIN\_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.8.10](#) for valid BOOTDEF values to set in the table.
  - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
  - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.
  - Set BOOTDEF.BOOTDEF2 to 0x24 for booting to wait boot (alternate option). This sets wait boot to boot table index 2.
  - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
  - Set BOOTDEF.BOOTDEF4 to 0x43 for booting to Flash (entry address option 2). This sets Flash boot to boot table index 4.

**Table 4-11. Three Boot Pins Boot Table Result**

| Boot Mode Table Number | Boot Mode                |
|------------------------|--------------------------|
| 0                      | CAN Boot (0x02)          |
| 1                      | Flash Boot (0x03)        |
| 2                      | Wait Boot - Alt (0x24)   |
| 3                      | SPI - Alt3 (0x66)        |
| 4                      | Flash Boot - Alt2 (0x43) |
| 5, 6, 7                | Not used in this example |

## 4.6 Device Boot Flow Diagrams

This section details the boot flow diagrams for standalone and emulation boot flows.

### 4.6.1 Boot Flow

Upon reset, the CPU follows the boot flow shown in [Figure 4-1](#). Depending on whether a JTAG debugger is connected to the device, the CPU either continues booting following the emulation boot flow or the standalone boot flow.

---

#### Note

BOR follows same flow as POR.

---

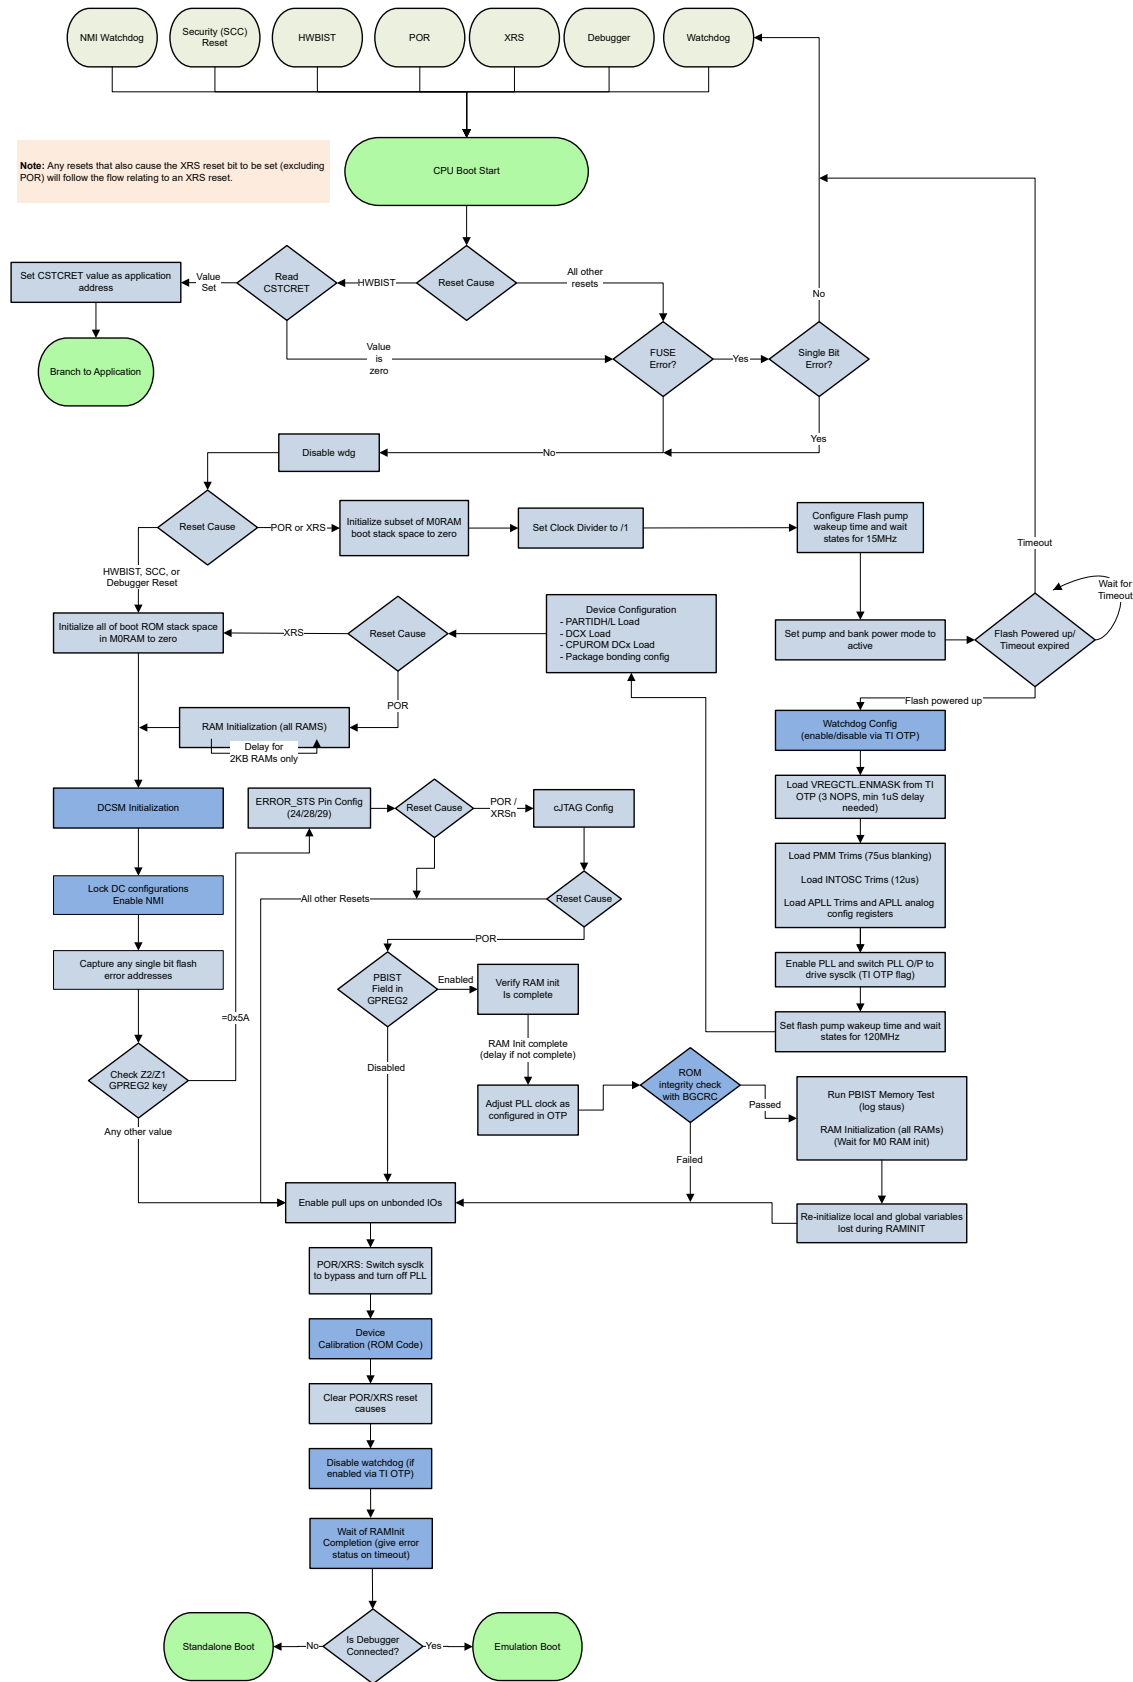

Figure 4-1. Device Boot Flow

### 4.6.2 Emulation Boot Flow

Figure 4-2 shows the emulation boot flow when JTAG debugger is connected.

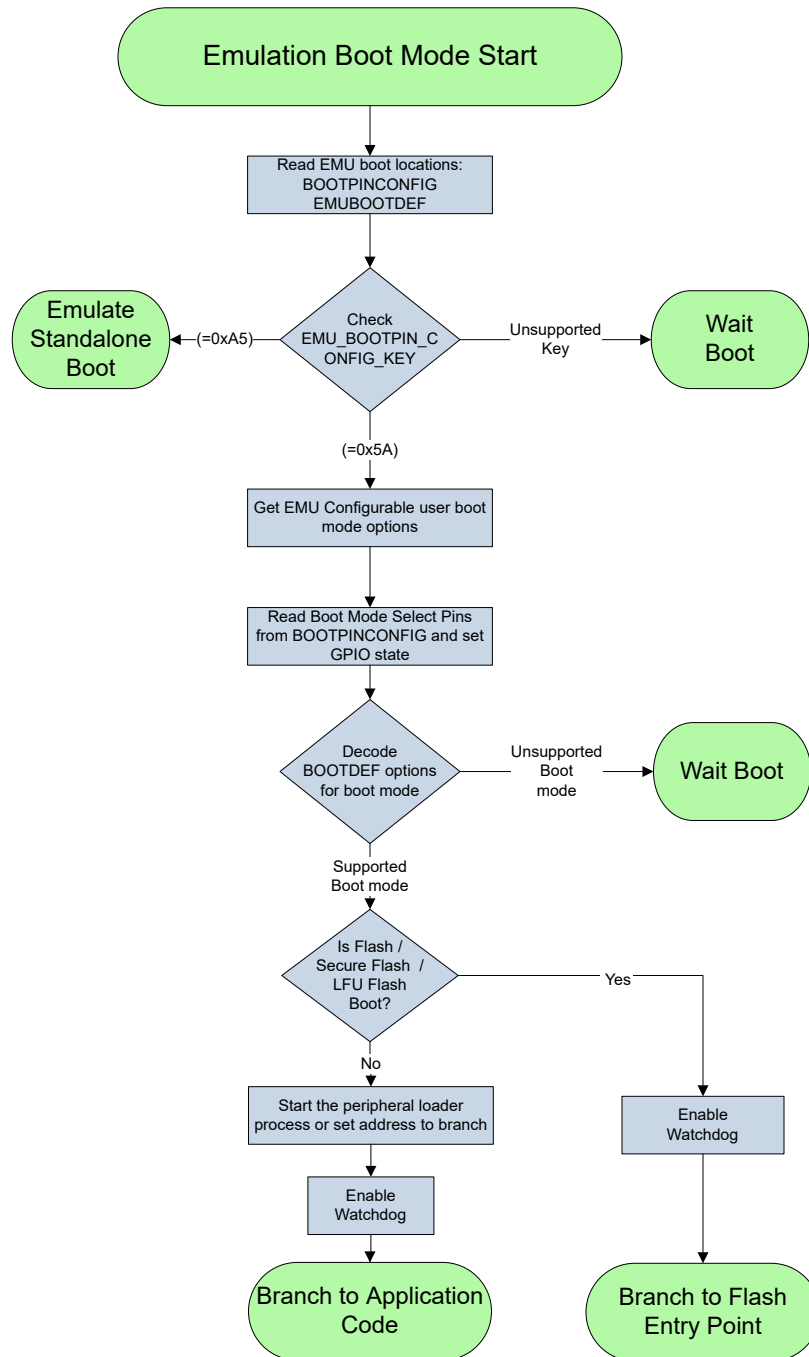

Figure 4-2. Emulation Boot Flow

### 4.6.3 Standalone Boot Flow

Figure 4-3 shows the standalone boot flow when no JTAG debugger is connected to the device.

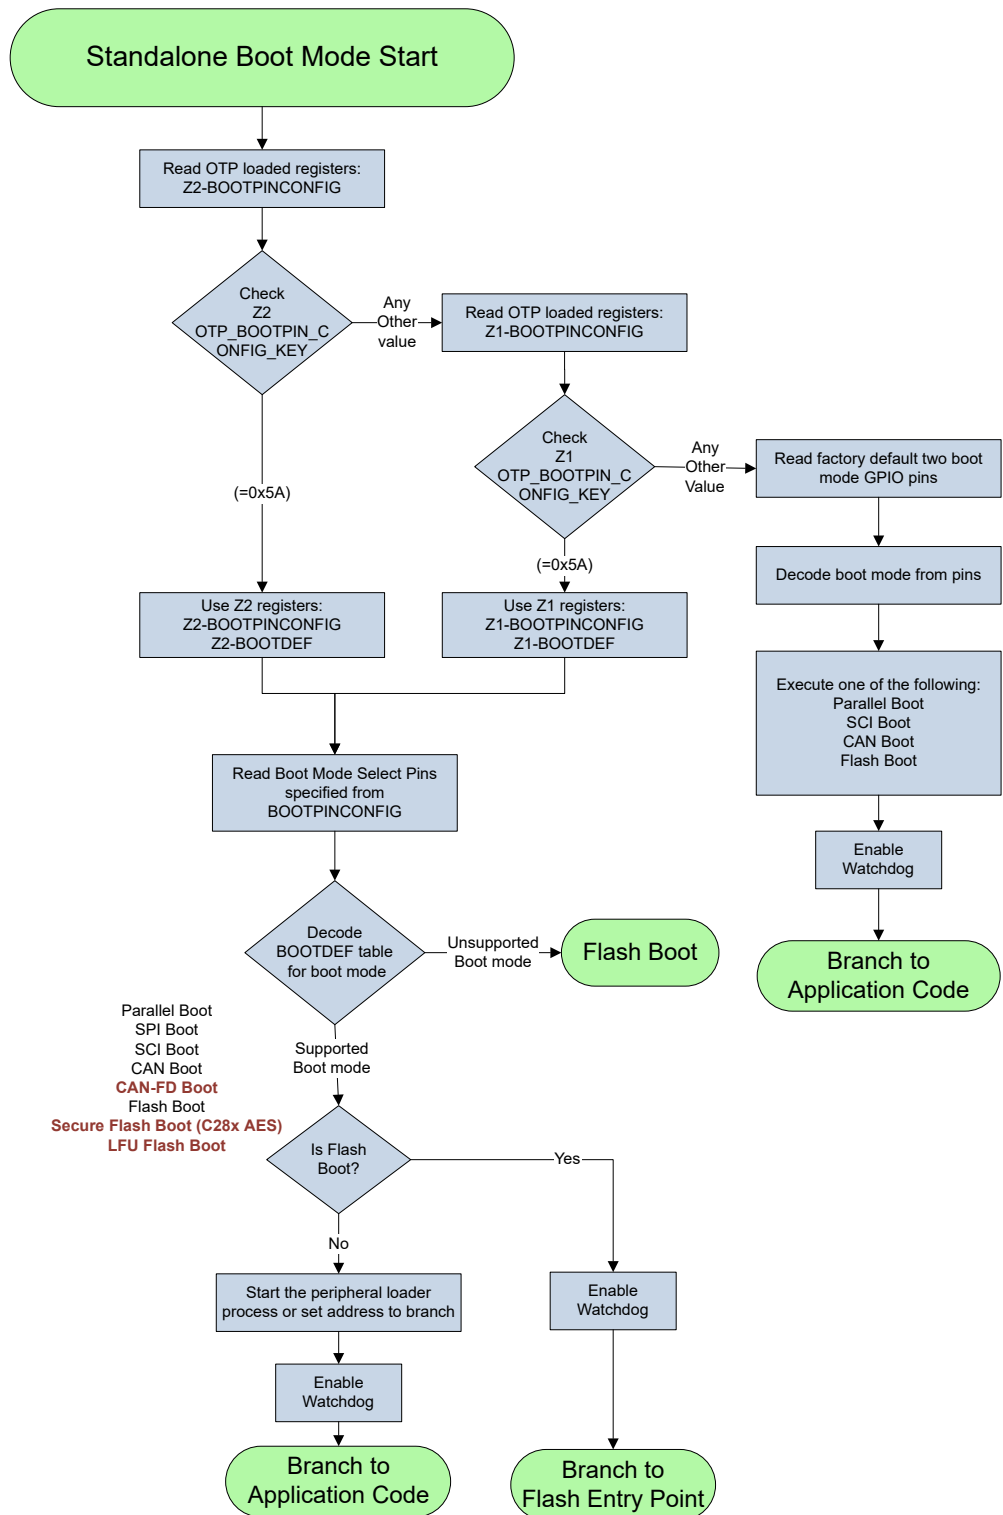

Figure 4-3. CPU Standalone Boot Flow

## 4.7 Device Reset and Exception Handling

### 4.7.1 Reset Causes and Handling

Table 4-12 explains the actions each boot ROM performs upon reset for a specific reset cause.

**Table 4-12. Boot ROM Reset Causes and Actions**

| Reset Source   | Boot ROM Action   |
|--|---|
| Power on Reset (POR)   | <ol style="list-style-type: none"> <li>1. Configure Clock Divider</li> <li>2. Flash Power Up</li> <li>3. Device configuration and trimming</li> <li>4. RAM Initialization</li> <li>5. Continue default boot flow</li> </ol>       |
| External Reset (XRS)<br>Includes: <ul style="list-style-type: none"> <li>• Watchdog Reset</li> <li>• NMI Watchdog Reset</li> <li>• SIMRESET XRS</li> </ul> | <ol style="list-style-type: none"> <li>1. Configure Clock Divider</li> <li>2. Flash Power Up</li> <li>3. Device configuration and trimming</li> <li>4. Clear RAM for boot stack</li> <li>5. Continue default boot flow</li> </ol> |
| Hardware Built-In Self Test (HWBIST)   | <ol style="list-style-type: none"> <li>1. Read HWBIST return address</li> <li>2. If set, branch to address</li> <li>3. If not set, continue boot following "Debugger" boot flow</li> </ol>  |
| Secure Copy Code (SCC) Reset   | <ol style="list-style-type: none"> <li>1. Clear RAM for boot stack</li> <li>2. Continue default boot flow</li> </ol>  |
| SIMRESET   | <ol style="list-style-type: none"> <li>1. Clear RAM for boot stack</li> <li>2. Continue default boot flow</li> </ol>  |
| Debugger Reset   | <ol style="list-style-type: none"> <li>1. Clear RAM for boot stack</li> <li>2. Continue default boot flow</li> </ol>  |

### 4.7.2 Exceptions and Interrupts Handling

Table 4-13 explains the actions boot ROM performs if any exceptions occur during boot. The exception handling philosophy in most cases, is to log the error and continue booting to reach the application.

**Table 4-13. Boot ROM Exceptions and Actions**

| Exception Event Source                                | Boot ROM Action  | Event Logged       |
|---|--|--------------------|
| Single-bit error in FUSEERR                           | Ignore and continue to boot  | No                 |
| Multi-bit error in FUSEERR                            | Reset the device   | No                 |
| Clock Fail  | Clear the NMI flag and continue to boot  | Yes                |
| RAM Uncorrectable Error<br>ROM Parity Error           | Perform RAM initialization and reset the device  | Yes <sup>(1)</sup> |
| Flash Uncorrectable Error                             | Reset the device   | Yes                |
| HWBIST Error  | Clear the NMI flag and continue to boot  | Yes                |
| Embedded Real-time Analysis and Diagnostic (ERAD) NMI | Clear the NMI flag and continue to boot  | Yes                |
| RL NMI (CLB)  | Clear the NMI flag and continue to boot  | Yes                |
| Software NMI error (Software self test error)         | Reset the device   | No                 |
| ITRAP Exception                                       | Record memory address of where the illegal instruction was executed and let device reset | Yes                |
| Unsupported PIE Interrupts                            | Ignore and continue to boot  | No                 |

(1) A RAM uncorrectable error or ROM parity error will clear the boot status information stored in RAM because a RAM initialization is performed to attempt to correct the error. Since the boot status information is erased, this exception can be identified in that a NMIWD reset occurred and all the RAMs are erased.

## 4.8 Boot ROM Description

This section explains the details regarding the device boot ROMs.

### 4.8.1 Boot ROM Configuration Registers

The boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in RAM emulate the OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. [Table 4-14](#) details these locations. For bit field configuration details for BOOTPIN-CONFIG and BOOTDEF, see [Section 4.5.1](#) and [Section 4.5.2](#).

Additionally, the boot ROM supports boot configurations from DCSM zone 1 and zone 2 registers. Zone 2 configurations will supercede zone 1 configurations, so it is recommended to use zone 1 configurations and use zone 2 as a secondary option.

**Table 4-14. Boot ROM Registers**

| Boot Flow                | Register Name | Boot ROM Name         | Register Address | User OTP Address |
|--------------------------|---------------|-----------------------|------------------|------------------|
| Emulation                | -             | EMU-BOOTPIN-CONFIG    | 0x0000 0D00      | -                |
|                          | -             | EMU-GPREG2            | 0x0000 0D02      | -                |
|                          | -             | EMU-BOOTDEF-LOW       | 0x0000 0D04      | -                |
|                          | -             | EMU-BOOTDEF-HIGH      | 0x0000 0D06      | -                |
| Standalone<br>(Using Z1) | Z1-GPREG1     | Z1-OTP-BOOTPIN-CONFIG | 0x0005 F008      | 0x0007 8008      |
|                          | Z1-GPREG2     | Z1-OTP-BOOT-GPREG2    | 0x0005 F00A      | 0x0007 800A      |
|                          | Z1-GPREG3     | Z1-OTP-BOOTDEF-LOW    | 0x0005 F00C      | 0x0007 800C      |
|                          | Z1-GPREG4     | Z1-OTP-BOOTDEF-HIGH   | 0x0005 F00E      | 0x0007 800E      |
| Standalone<br>(Using Z2) | Z2-GPREG1     | Z2-OTP-BOOTPIN-CONFIG | 0x0005 F088      | 0x0007 8208      |
|                          | Z2-GPREG2     | Z2-OTP-BOOT-GPREG2    | 0x0005 F08A      | 0x0007 820A      |
|                          | Z2-GPREG3     | Z2-OTP-BOOTDEF-LOW    | 0x0005 F08C      | 0x0007 820C      |
|                          | Z2-GPREG4     | Z2-OTP-BOOTDEF-HIGH   | 0x0005 F08E      | 0x0007 820E      |

#### 4.8.1.1 GPREG2 Usage and MPOST Configuration

Table 4-15 explains how the bit field values from the user configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2 or Z2-OTP-BOOT-GPREG2, are decoded by boot ROM.

**Table 4-15. DCSM Z1/Z2 GPREG2 Bit Fields**

| Bit   | Name                 | Description   | Boot ROM Action   |
|-------|----------------------|---|---|
| 31:24 | Key                  | Write 0x5A to indicate to the boot ROM code that the bits in this register are valid. | If user sets to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores values in this register.   |
| 23:8  | Reserved             | Reserved  | No Action   |
| 7:6   | MPOST                | 0x0 = Run MPOST with PLL disabled (10-MHz internal oscillator)                        | When configured to a valid value, MPOST POR memory self-test will be run on all device memories   |
|       |                      | 0x1 = Run MPOST with PLL enabled for 95 MHz   |   |
|       |                      | 0x2 = Run MPOST with PLL enabled for 47.5 MHz   |   |
|       |                      | 0x3 = Disable MPOST   |   |
| 5:4   | ERROR_STS_PIN config | 0x0 – GPIO24, MUX Option 13   | This indicates which GPIO pin is supposed to be used as ERROR_PIN and boot ROM configures the mux as such for the said pin. The ERROR_STS pin mux configuration is locked by the boot ROM, but not committed. |
|       |                      | 0x1 – GPIO28, MUX Option 13   |   |
|       |                      | 0x2 – GPIO29, MUX Option 13   |   |
|       |                      | 0x3 – ERROR_STS function disabled (default)   |   |
| 3:0   | CJTAGNODEID          | CJTAGNODEID[3:0]  | Boot ROM takes this values and programs the lower 4 bits of the CJTAGNODEID register.   |

#### 4.8.2 Entry Points

This sections gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

Table 4-16 gives details about the entry point addresses for Flash boot mode.

Table 4-17 gives details about the entry point addresses for RAM boot mode.

**Table 4-16. Flash Entry Point Addresses**

| Option | BOOTDEFx Value | Flash Sector                | Address     | Packages Supported |
|--------|----------------|-----------------------------|-------------|--------------------|
| 0      | 0x03           | CPU Bank 0 Sector 0         | 0x0008 0000 | All                |
| 1      | 0x23           | CPU Bank 0 Sector 8         | 0x0008 8000 | All                |
| 2      | 0x43           | CPU Bank 0 End of Sector 15 | 0x0008 FFF0 | All                |
| 3      | 0x63           | CPU Bank 1 Sector 0         | 0x0009 0000 | All                |
| 4      | 0x83           | CPU Bank 1 End of Sector 7  | 0x0009 7FF0 | All                |
| 5      | 0xA3           | CPU Bank 1 End of Sector 15 | 0x0009 FFF0 | All                |
| 6      | 0xC3           | CPU Bank 2 Sector 0         | 0x000A 0000 | All                |
| 7      | 0xE3           | CPU Bank 2 End of Sector 15 | 0x000A FFF0 | All                |

**Table 4-17. RAM Entry Point Address**

| Option | BOOTDEFx Value | RAM Entry Point | Package Supported |
|--------|----------------|-----------------|-------------------|
| 0      | 0x05           | 0x0000 0000     | All               |

### 4.8.3 Wait Points

The wait mode puts the CPU in a loop in the boot ROM code and won't branch to the user application code. The device can enter wait boot mode either through manually being set or because of some issue during boot up. Using wait boot mode is recommended when using a debugger to avoid any JTAG issues. There will an ESTOP provided for debugging during Wait boot.

**Table 4-18. Wait Boot Options**

| Option      | BOOTDEFx Value | Watchdog Status | Package Supported |
|-------------|----------------|-----------------|-------------------|
| 0 (default) | 0x04           | Enabled         | All               |
| 1           | 0x24           | Disabled        | All               |

During boot ROM execution, there are situations where the CPU may enter a wait loop in the code. This state can occur for a variety of reasons. details the address ranges that the CPU PC register value will fall between if it has entered one of these instances.

Following are the actions for entering wait boot mode:

- Wait boot is set by the user as the boot mode.
- Boot mode is unrecognizable and a debugger is connected to the device.
- The emulation BOOTPIN\_CONFIG key isn't equal to 0xA5 or 0x5A.
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode.

**Table 4-19. Wait Point Addresses**

| Address Range         | Description                                 |
|-----------------------|---|
| 0x3FB8B9 – 0x3FB8C0   | In Wait Boot Mode                           |
| 0x3FC7D0 – 0x3FC7D8   | In SCI Boot waiting on autobaud lock        |
| 0x3FEDFE – 0x3FEDEC   | In NMI Handler                              |
| 0x3FEDEC9 – 0x3FEEDF9 | In ITRAP ISR                                |
| 0x3FCB96 - 0x3FCB9A   | In Parallel boot waiting for control signal |

### 4.8.4 Secure Flash Boot

Secure Flash boot mode is similar to Flash boot mode in that the boot flow branches to the configured memory address in Flash except only after the Flash memory contents have been authenticated. The Flash authentication uses a Cipher-based Message Authentication Protocol (CMAC) to authenticate 16 KB of Flash starting from the configured Flash entry point address. The CMAC calculation requires a user-defined 128-bit key programmed in the CPU User OTP Zone 1 Header OTP CMACKEY bit field. Additionally, the user must calculate the golden CMAC tag based on the 16 KB Flash memory range and store it along with the user code at a hardcoded address in Flash. During secure Flash boot, the calculated CMAC tag is compared to the user golden CMAC tag in Flash to determine the pass/fail status of the CMAC authentication. When authentication passes, boot flow continues and branches to Flash to begin executing the application. When authentication fails, the device is reset.

For the available secure Flash boot entry address options, refer to [Section 4.8.2](#).

For generating the secure Flash golden CMAC tag for CPU, refer to the [TMS320C28x Assembly Language Tools User's Guide](#) within section "Using Secure Flash Boot on TMS320F2838x Devices" for instructions.

---

**Note**

Both the CMAC golden signature and CMAC key are stored in the most-significant double format, but each 32-bit section is in little-endian format.

Key: 2B7E1516 28AED2A6 ABF71588 09CF4F3C

(MSB is 2B and LSB is 3C)

CMACKEY0 = 0x2B7E1516

CMACKEY1 = 0x28AED2A6

CMACKEY2 = 0xABF71588

CMACKEY3 = 0x09CF4F3C

---

**Note**

User must ensure that the Flash sector that encompasses the configured Flash entry point and the first 16 KB of Flash is assigned to Zone 1 for the core setup for secure Flash boot.

Recommended to use device JTAGLOCK when using secure Flash boot.

---

APIs for CMAC calculation and authentication is provided as part of ROM. Details are available in [Section 4.8.11](#)

**Table 4-20. Secure Flash Boot Details**

| Details                                      | Location Address   |
|--|--|
| CMAC Signature Address                       | Flash Entry Point Address + 0x2  |
| CMAC Key Address (128-bit key)               | DCSM Z1 OTP CMACKEY0/1/2/3   |
| Flash Entry Point (Bank 0, Sector 0)         | 0x0008 0000  |
| Flash Entry Point (Bank 0, Sector 8)         | 0x0008 8000  |
| Flash Entry Point (Bank 0, End of Sector 15) | 0x0008 FFF0  |
| Flash Entry Point (Bank 1, Sector 0)         | 0x0009 0000  |
| Flash Entry Point (Bank 1, End of Sector 7)  | 0x0009 7FF0  |
| Flash Entry Point (Bank 1, End of Sector 15) | 0x0009 FFF0  |
| Flash Entry Point (Bank 2, Sector 0)         | 0x000A 0000  |
| Address Range for CMAC Calculation           | Start: Flash Entry Point Address<br>End: Flash Entry Point Address + 16 KB |

**Table 4-21. Secure Flash Tag and Key Details**

| Name                         | Address   | Details   |
|------------------------------|---|---|
| CMAC Golden Tag<br>(128-bit) | <b>CPU:</b><br><i>Flash Entry Point Address + 0x2</i> | <p>Located in Flash, offset from the entry point address, by 2 words (CPU).</p> <p>When CMAC calculations are performed, the golden tag location in memory is considered all 0xFs. Refer to <a href="#">Example 4-1</a> for an example regarding linker configuration on CPU.</p> <p>Lower memory contains the tag's MSW and higher memory contains the LSW.</p> <p><b>Example (on CPU):</b><br/>           Tag = 0x00112233 44556677 8899AABB CCDDEEFF<br/>           Address 0x0 = 0x00112233<br/>           Address 0x2 = 0x44556677<br/>           Address 0x4 = 0x8899AABB<br/>           Address 0x6 = 0xCCDDEEFF</p> |

**Table 4-21. Secure Flash Tag and Key Details (continued)**

| Name             | Address     | Details  |
|------------------|-------------|--|
| CMAC 128-Bit Key | 0x0007 8018 | Located in CPU Zone 1 User Header OTP (CMACKEY0, CMACKEY1, CMACKEY2, CMACKEY3)<br>CMACKEY0 contains the key's MSW and CMACKEY3 contains the LSW.<br><br><b>Example:</b><br>Key = 0x00112233 44556677 8899AABB CCDDEEFF<br>CMACKEY0 = 0x00112233<br>CMACKEY1 = 0x44556677<br>CMACKEY2 = 0x8899AABB<br>CMACKEY3 = 0xCCDDEEFF |

**Table 4-22. Secure Flash Authentication Failure Actions**

| CPU      | Action on Failed Authentication   |
|----------|---|
| C28x CPU | 1. Emulation only - Halt debugger (ESTOP)<br>2. Wait in endless loop (for device reset due to WD reset) |

**Table 4-23. Secure Flash on all CPUs Recommended Flow**

| Step | Action  |
|------|---|
| 1    | Secure Flash boot CPU   |
| 2    | Any Flash beyond the first 16 KB from the entry point that is planned for use should be authenticated by the user using a different CMAC golden tag embedded at an address somewhere within the already authenticated 16 KB of Flash. |

**Example 4-1. Secure Flash CPU1 Linker File Example**

```

MEMORY
{
    /* Code Start branch to _c_int00 */
    BEGIN : origin = 0x80000, length = 0x0002
    /* User calculated golden CMAC tag for Flash Sector 0 */
    GOLDEN_CM_TAG : origin = 0x80002, length = 0x0008
    /* Flash Sector 0 containing application code */
    FLASH_SECTOR_0 : origin = 0x8000A, length = 0x1FF6
    .
    .
    .
}
    
```

### 4.8.5 Live Firmware Update (LFU) Flash Boot

Live Firmware Update (LFU) boot mode is required to handle the Live Firmware Update feature. In this boot mode, the boot loader reads the version number from images present in multiple banks and identifies the latest image. The boot ROM then hands off the execution to the application with the latest version. To support LFU boot mode each Flash bank containing an application image needs a few fields as shown in [Table 4-24](#).

**Table 4-24. LFU Application Image Format**

| Image Address Offset | Content                                |
|----------------------|--|
| 0x0                  | Application entry point (32-bit)       |
| 0xA                  | Key (32-bit)<br>Valid Key = 0x5A5A5A5A |
| 0xC                  | Firmware version number (32-bit)       |

**Application entry point:** This is the code execution start address of the image stored in Flash.

**Key:** This 32-bit field determines if this image is valid. The image in a bank is considered valid only if the location contains the value 0x5A5A5A5A. In case all banks have invalid keys, an error is flagged in `boot_status` variable and program jumps to a while loop in standalone boot mode (ESTOP in emulation boot mode).

**Firmware version number:** This 32-bit field is the version number of the firmware or application. 0xFFFF FFFF is considered as the initial value and this needs to be decremented after every update. The image with lower version number is the latest application. If all valid images have same version number, then bank-0 (or the lowest numbered bank) is chosen.

For example, if bank-0 has invalid **Key** and bank-1 and bank-2 have valid keys, then the one having lowest **Firmware version number** will be selected for boot. If both are same, then bank-1 will be selected.

[Table 4-25](#) shows the entry points for LFU boot mode.

**Table 4-25. LFU Entry Point Addresses**

| Option | BOOTDEFx Value | Bank 0      | Bank 1      | Bank 2      |
|--------|----------------|-------------|-------------|-------------|
| 0      | 0x0B           | 0x0008 0000 | 0x0009 0000 | 0x000A 0000 |
| 1      | 0x2B           | 0x0008 8000 | 0x0009 8000 | 0x000A 8000 |
| 2      | 0x4B           | 0x0008 FFF0 | 0x0009 FFF0 | 0x000A FFF0 |
| 3      | 0x6B           | 0x0008 8000 | 0x0009 0000 | 0x000A 0000 |
| 4      | 0x8B           | 0x0008 EFF0 | 0x0009 7FF0 | 0x0008 7FF0 |

For example, if Option 0 with Bank 0 has the application image:

[0008 0000-0008 0001] = Application entry point

[0008 000A-0008 000B] = Key

[0008 000C-0008 000D] = Firmware version number

### 4.8.6 Secure LFU Flash Boot

Secure LFU Flash boot performs the same Flash bank selection as the non-secure LFU described in [Section 4.8.5](#). Once the bank entry address is determined, this address + 16 KB is authenticated using a CMAC algorithm. The CPUBROM\_verifySecureFlash and CMAC algorithms are reused from the [Section 4.8.4](#) to perform this authentication.

The flow is:

1. Secure LFU boot mode selected.
2. Perform LFU bank selection.
3. Perform CMAC on selected entry address + 16 KB.
4. Boot to Flash bank.

To support Secure LFU Flash boot mode, the application image has to have a few fields as shown in [Table 4-26](#).

**Table 4-26. Secure LFU Application Image Format**

| Image Address Offset | Content                                |
|----------------------|--|
| 0x0                  | Application entry point (32-bit)       |
| 0x2                  | Golden CMAC Tag (128-bits)             |
| 0xA                  | Key (32-bit)<br>Valid Key = 0x5A5A5A5A |
| 0xC                  | Firmware version number (32-bit)       |

**Application entry point:** This is the code execution start address of the image stored in Flash.

**Key:** This 32-bit field determines if this image is valid. The image in a bank is considered valid only if the location contains the value 0x5A5A5A5A. In case all banks have invalid keys, an error is flagged in boot\_status variable and program jumps to a while loop in standalone boot mode (ESTOP in emulation boot mode).

**Firmware version number:** This 32-bit field is the version number of the application. 0xFFFF FFFF is considered as the initial value and this needs to be decremented after every update. The image with lower version number is the latest application. If all valid images have same version number, then bank-0 (or the lowest numbered bank) is chosen.

**Golden CMAC Tag:** This 128-bit field stores the calculated golden CMAC tag that is used as part of the secure Flash CMAC authentication.

[Table 4-27](#) shows the entry points for LFU boot mode.

**Table 4-27. Secure LFU Entry Point Addresses**

| Option | BOOTDEFx Value | Bank 0      | Bank 1      | Bank 2      |
|--------|----------------|-------------|-------------|-------------|
| 0      | 0x0C           | 0x0008 0000 | 0x0009 0000 | 0x000A 0000 |
| 1      | 0x2C           | 0x0008 8000 | 0x0009 8000 | 0x000A 8000 |
| 3      | 0x6C           | 0x0008 8000 | 0x0009 0000 | 0x000A 0000 |
| 4      | 0x8C           | 0x0008 EFF0 | 0x0009 7FF0 | 0x0008 7FF0 |

#### Note

Secure LFU boot mode has the same bank addresses as non-secure LFU boot mode, except boot option 2 is not supported due to CMAC requirements.

For example, if Option 0 with Bank 0 has the application image:

[0008 0000-0008 0001] = Application entry point

[0008 0002-0008 0009] = Golden CMAC Tag

[0008 000A-0008 000B] = Key

[0008 000C-0008 000D] = Firmware version number

## 4.8.7 Memory Maps

### 4.8.7.1 Boot ROM Memory Maps

Table 4-28 details the ROM memory maps.

**Table 4-28. Boot ROM Memory Map**

| Memory                        | Origin Address | Length (Words) |
|-------------------------------|----------------|----------------|
| ROM Signature                 | 0x003F 0000    | 0x0002         |
| Golden CRC                    | 0x003F 0002    | 0x0002         |
| Full ROM Checksum             | 0x003F 0040    | 0x0042         |
| Version                       | 0x003F 0082    | 0x0004         |
| IQmath Tables                 | 0x003F 812C    | 0x1674         |

### 4.8.7.2 CLA Data ROM Memory Maps

#### Note

In Table 4-30, **Load** refers to the memory addresses where the C28x CPU can view the data. **Run** refers to the CLA memory addresses that the CLA uses to access the data.

**Table 4-30. CLA Data ROM Memory Map**

| Memory            | Origin Address | Length (Words) |
|-------------------|----------------|----------------|
| FFT Tables (Load) | 0x0100 1070    | 0x0800         |
| Data (Load)       | 0x0100 1870    | 0x078A         |
| Version (Load)    | 0x0100 1FFA    | 0x0006         |
| FFT Tables (Run)  | 0x0000 F070    | 0x0800         |
| Data (Run)        | 0x0000 F870    | 0x078A         |
| Version (Run)     | 0x0000 FFFA    | 0x0006         |

### 4.8.7.3 Reserved RAM Memory Maps

Table 4-31 details memory usage in RAM that is reserved for boot ROM to use. These memory sections should be reserved in the user application.

**Table 4-31. Reserved RAM Memory Map**

| Memory | Description                                      | Origin Address | Length (Words) |
|--------|--|----------------|----------------|
| RAM    | Boot Status, Boot Mode, MPOST Status, Boot Stack | 0x0000 0002    | 0x0126         |

### 4.8.8 ROM Tables

Table 4-32 details the boot ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

**Table 4-32. ROM Symbol Tables**

| ROM Symbols                   | Library Name                 | Location  |
|-------------------------------|------------------------------|---|
| ROM Bootloaders and Functions | F28003xCPU_BootROM_Symbols   | Under <code>/libraries/boot_rom</code> in <a href="#">C2000Ware</a> |
| FPU32 Tables                  | F28003xCPU_BootROM_Symbols   |   |
| IQmath                        | F28003xCPU_IQMathROM_Symbols |   |

### 4.8.9 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

#### 4.8.9.1 Boot Modes

This section details the available boot modes that do not involve a peripheral boot loader. Table 4-33 details the available boot modes that do not involve a peripheral boot loader.

**Table 4-33. Boot Mode Availability**

| Boot Mode             | CPU Support |
|-----------------------|-------------|
| Flash Boot            | C28x CPU    |
| RAM Boot              | C28x CPU    |
| Wait Boot             | C28x CPU    |
| Secure Flash Boot     | C28x CPU    |
| LFU Flash Boot        | C28x CPU    |
| Secure LFU Flash Boot | C28x CPU    |

#### 4.8.9.1.1 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to [Section 4.8.2](#) for all the available Flash address options.

#### 4.8.9.1.2 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to [Section 4.8.2](#) for all the available RAM address options.

#### 4.8.9.1.3 Wait Boot

Wait boot mode branches to the memory address as mentioned in [Section 4.8.3](#).

**Table 4-34. Wait Boot Options**

| Option      | BOOTDEFx Value | Watchdog Status | Package Supported |
|-------------|----------------|-----------------|-------------------|
| 0 (default) | 0x04           | Enabled         | All               |
| 1           | 0x24           | Disabled        | All               |

#### 4.8.9.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader. For more specific details on the supported data stream structure used by the following bootloaders, refer to [Section 4.9.1](#).

##### 4.8.9.2.1 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as shown in [Figure 4-4](#).

**Figure 4-4. Overview of SCI Bootloader Operation**

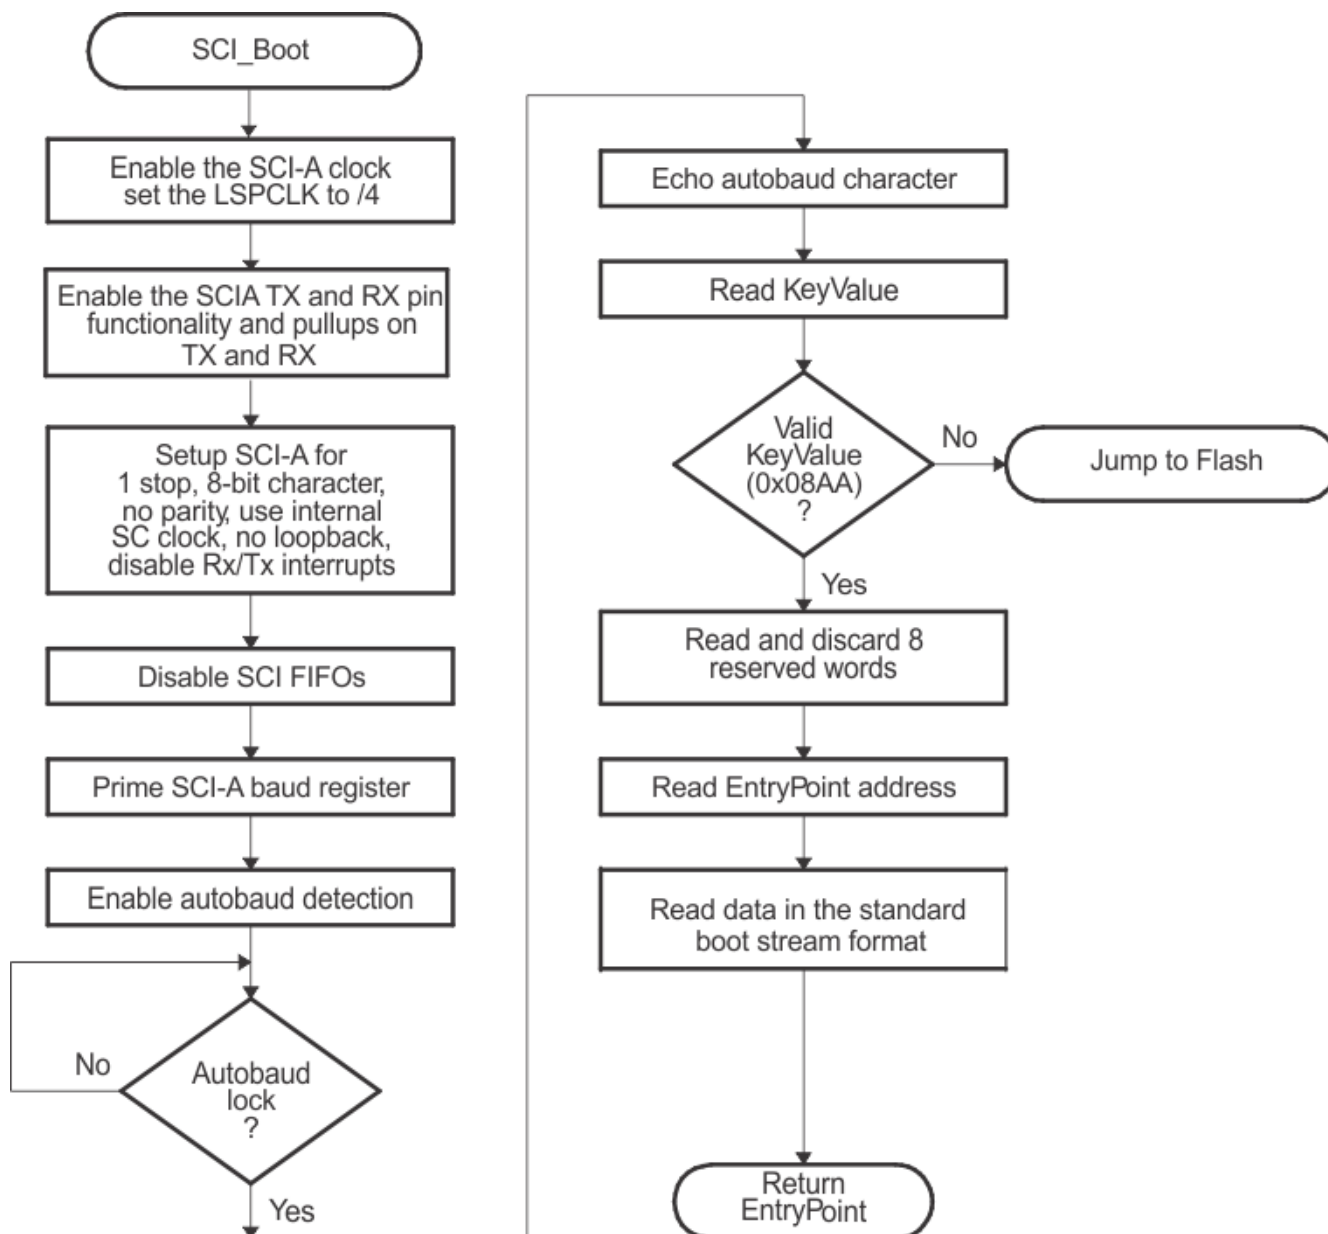

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader will echo back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications may work well, this slew rate may limit reliable auto-baud detection at higher baud rates (typically beyond 100kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host may then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

**Figure 4-5. Overview of SCI Boot Function**

4.8.9.2.2 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as shown in Figure 4-6. The SPI bootloader supports an 8-bit data stream. It does not support a 16-bit data stream.

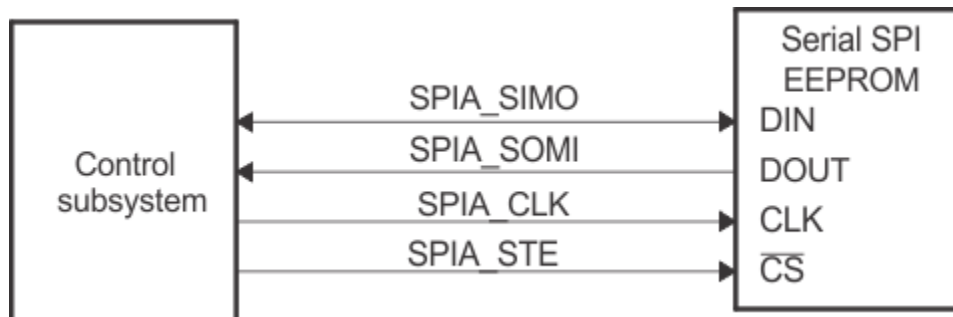

Figure 4-6. Overview of SPI Bootloader Operation

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI\_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, you could specify a change in baud rate or low speed peripheral clock. Table 4-35 shows the 8-bit data stream used by the SPI.

Table 4-35. SPI 8-Bit Data Stream

| Byte | Contents   |
|------|--|
| 1    | LSB: AA (KeyValue for memory width = 8-bits)   |
| 2    | MSB: 08h (KeyValue for memory width = 8-bits)  |
| 3    | LSB: LOSPCP  |
| 4    | MSB: SPIBRR  |
| 5    | LSB: reserved for future use   |
| 6    | MSB: reserved for future use   |
| ...  | Reserved   |
| 17   | LSB: reserved for future use   |
| 18   | MSB: reserved for future use   |
| 19   | LSB: Upper half (MSW) of Entry point PC[23:16]   |
| 20   | MSB: Upper half (MSW) of Entry point PC[31:24] (Note: Always 0x00)   |
| 21   | LSB: Lower half (LSW) of Entry point PC[7:0]   |
| 22   | MSB: Lower half (LSW) of Entry point PC[15:8]  |
| ...  | ....   |
| ...  | Data for this section.   |
| ...  | ....   |
| ...  | Blocks of data in the format size/destination address/data as shown in the generic data stream description |
| ...  | ....   |
| ...  | Data for this section.   |
| n    | LSB: 00h   |

**Table 4-35. SPI 8-Bit Data Stream (continued)**

| Byte | Contents                                   |
|------|--|
| n+1  | MSB: 00h - indicates the end of the source |

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence is:

1. The SPI-A port is initialized.
2. The GPIO pin, as defined by SPI option configured from [Table 4-45](#), is used as a chip-select for the serial SPI EEPROM or Flash.
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash.
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next two bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next seven words are reserved for future enhancements. The SPI bootloader reads these seven words and discards them.
7. The next two words makeup the 32-bit entry point address where execution will continue after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

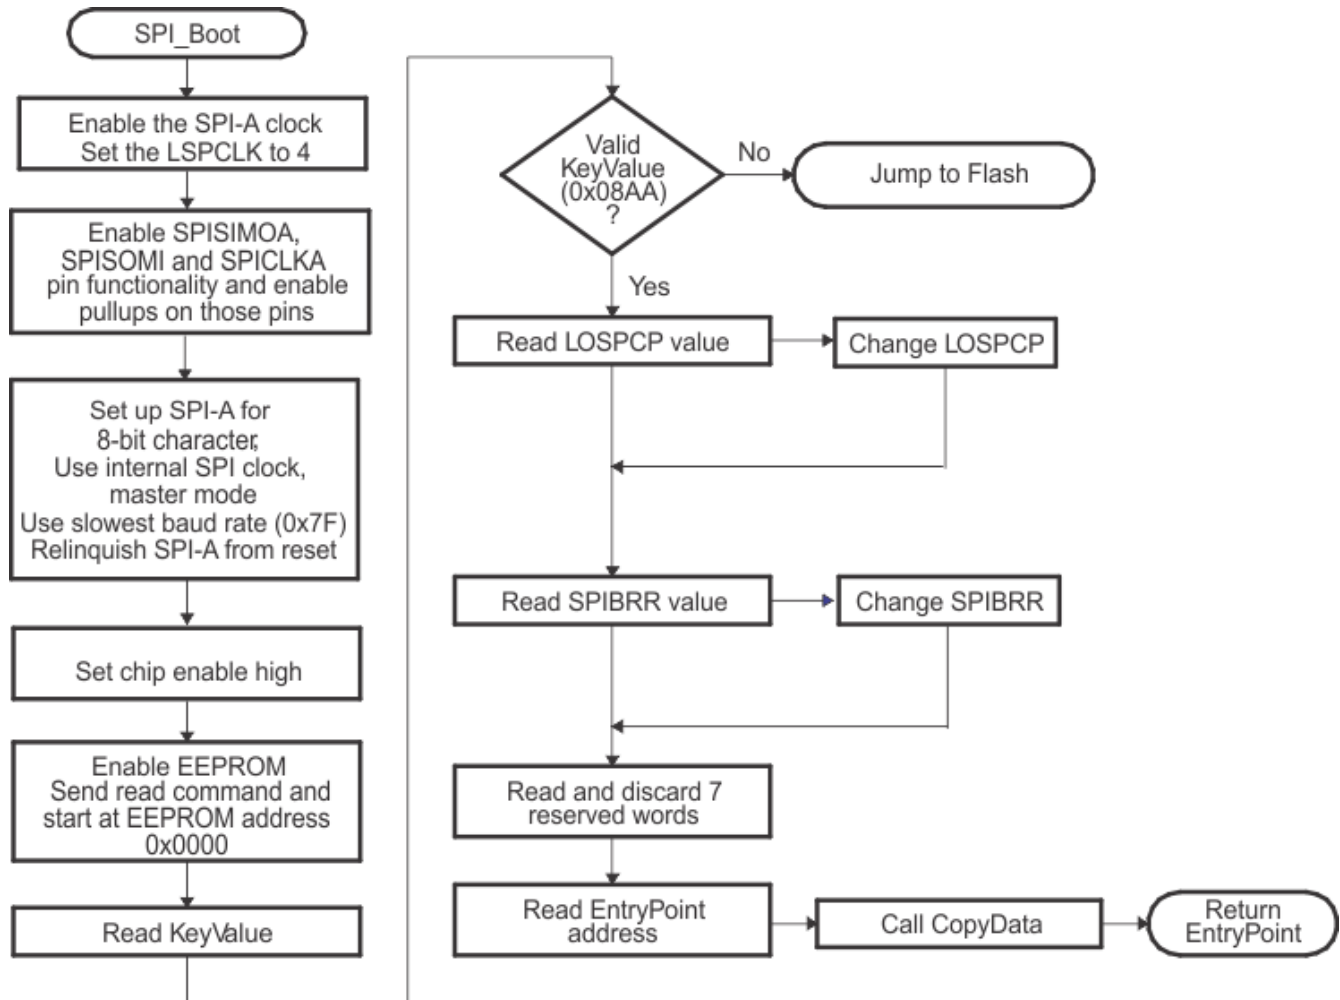

Figure 4-7. Data Transfer from EEPROM Flow

#### 4.8.9.2.3 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as shown in [Figure 4-8](#). The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

**Figure 4-8. EEPROM Device at Address 0x50**

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100-kHz bit rate (standard I2C mode) when the system clock is 10 MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400-kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that it is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C\_Get Word). If a non acknowledgment is received during the data read messages, the I2C bus will hang. [Table 4-36](#) shows the 8-bit data stream used by the I2C.

The I2C EEPROM protocol required by the I2C bootloader is shown in [Figure 4-10](#) and [Figure 4-11](#). The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA) from it, is shown in [Figure 4-10](#). All subsequent reads are shown in [Figure 4-11](#) and are read two bytes at a time.

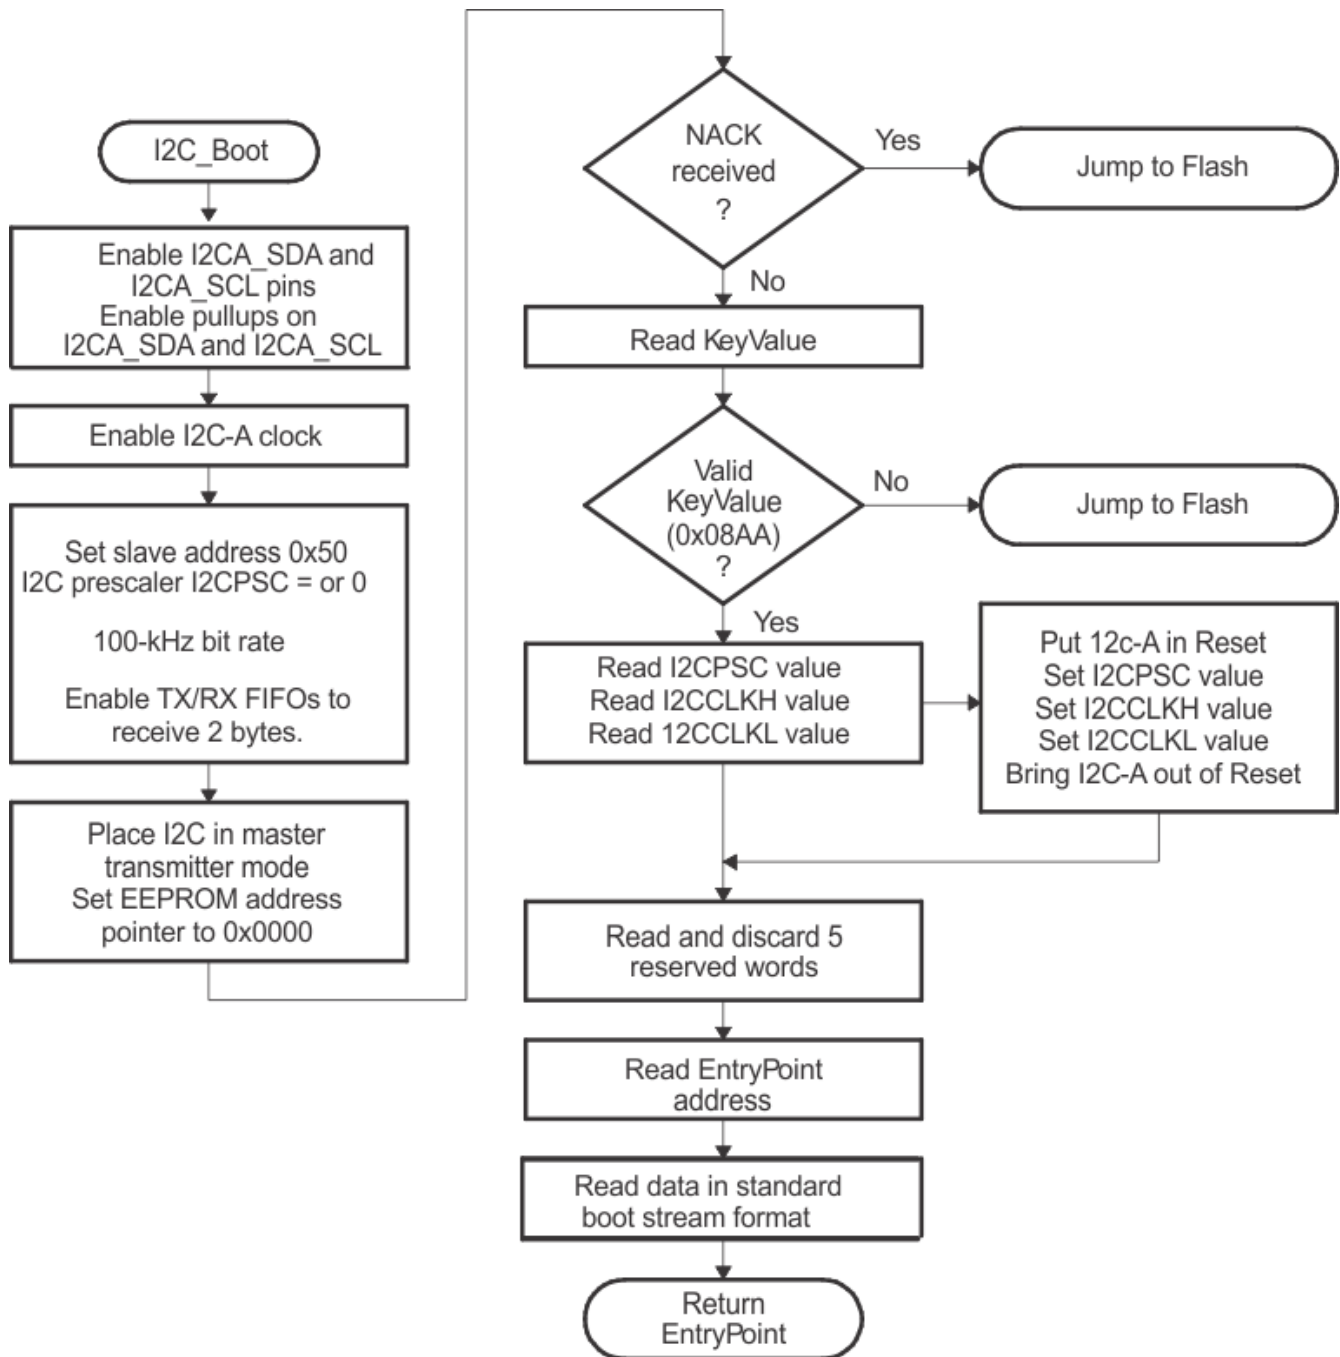

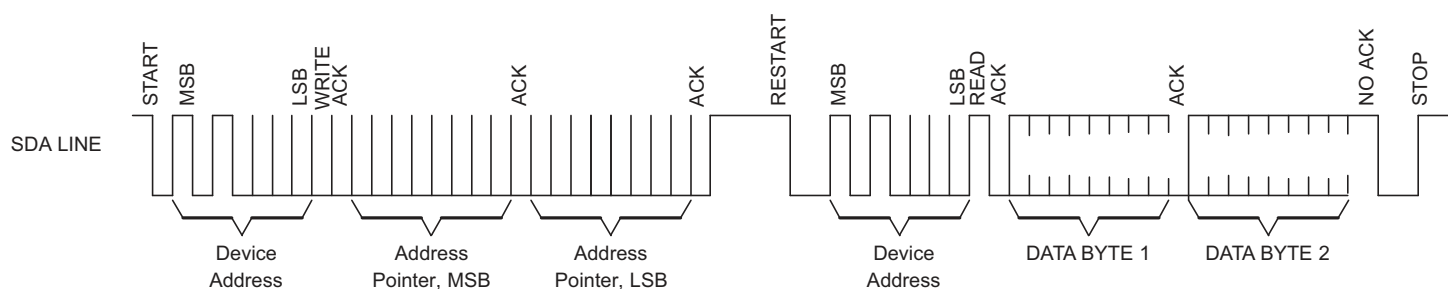

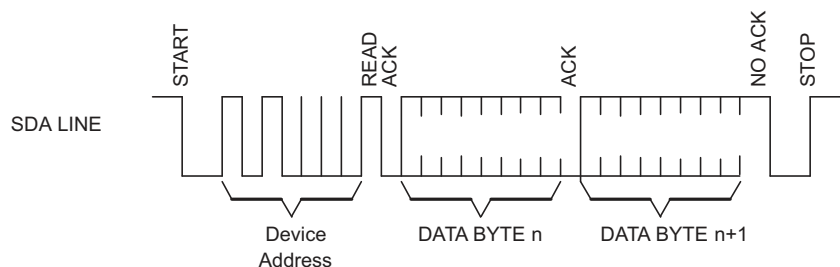

Figure 4-9. Overview of I2C Boot Function

**Table 4-36. I2C 8-Bit Data Stream**

| Byte | Contents  |

**Figure 4-10. Random Read**

**Figure 4-11. Sequential Read**

4.8.9.2.4 Parallel Boot Mode

The parallel general purpose I/O (GPIO) boot mode asynchronously transfers code from host to C28x's internal memory. Each value is eight bits long and follows the same data flow as outlined in Figure 4-12.

Figure 4-12. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the Host Control and 28x control lines. The handshake protocol shown in Figure 4-13 must be used to successfully transfer each word via GPIO [D0:D7]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least significant byte (LSB) is read first followed by the most significant byte (MSB). In this case, data is read from GPIO[D0:D7].

The 8-bit data stream is shown in Table 4-37.

Table 4-37. Parallel GPIO Boot 8-Bit Data Stream

| Bytes   | GPIO[D0:D7] (Byte 1 of 2) | GPIO[D0:D7] (Byte 2 of 2) | Description  |
|---------|---------------------------|---------------------------|--|
| 1 2     | AA                        | 08                        | 0x08AA (KeyValue for memory width = 16 bits)                                       |
| 3 4     | 00                        | 00                        | 8 reserved words (words 2 - 9)   |
| ...     | ...                       | ...                       | ...  |
| 17 18   | 00                        | 00                        | Last reserved word   |
| 19 20   | BB                        | 00                        | Entry point PC[22:16]  |
| 21 22   | DD                        | CC                        | Entry point PC[15:0] (PC = 0x00BBCCDD)   |
| 23 24   | NN                        | MM                        | Block size of the first block of data to load = 0xMMNN words                       |

The device first signals the host that it is ready to begin data transfer by pulling the 28x Control pin low. The host load then initiates the data transfer by pulling the DSP control pin low. The complete protocol is shown in [Figure 4-13](#).

**Figure 4-13. Parallel GPIO Bootloader Handshake Protocol**

1. The device indicates it is ready to start receiving data by pulling the 28x control pin low.
2. The bootloader waits until the host puts data on GPIO [D0:D7]. The host signals to the device that data is ready by pulling the host control pin low.
3. The device reads the data and signals the host that the read is complete by pulling 28x control high.
4. The bootloader waits until the host acknowledges the device by pulling host control high.
5. The device again indicates it is ready for more data by pulling the 28x control pin low.

This process is repeated for each data value to be sent.

[Figure 4-14](#) shows an overview of the Parallel GPIO bootloader flow.

**Figure 4-14. Overview of Parallel GPIO Boot Function**

Figure 4-15 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host will wait for the device and the device will in turn wait for the host. In this manner the protocol will work with both a host running faster and a host running slower than the device.

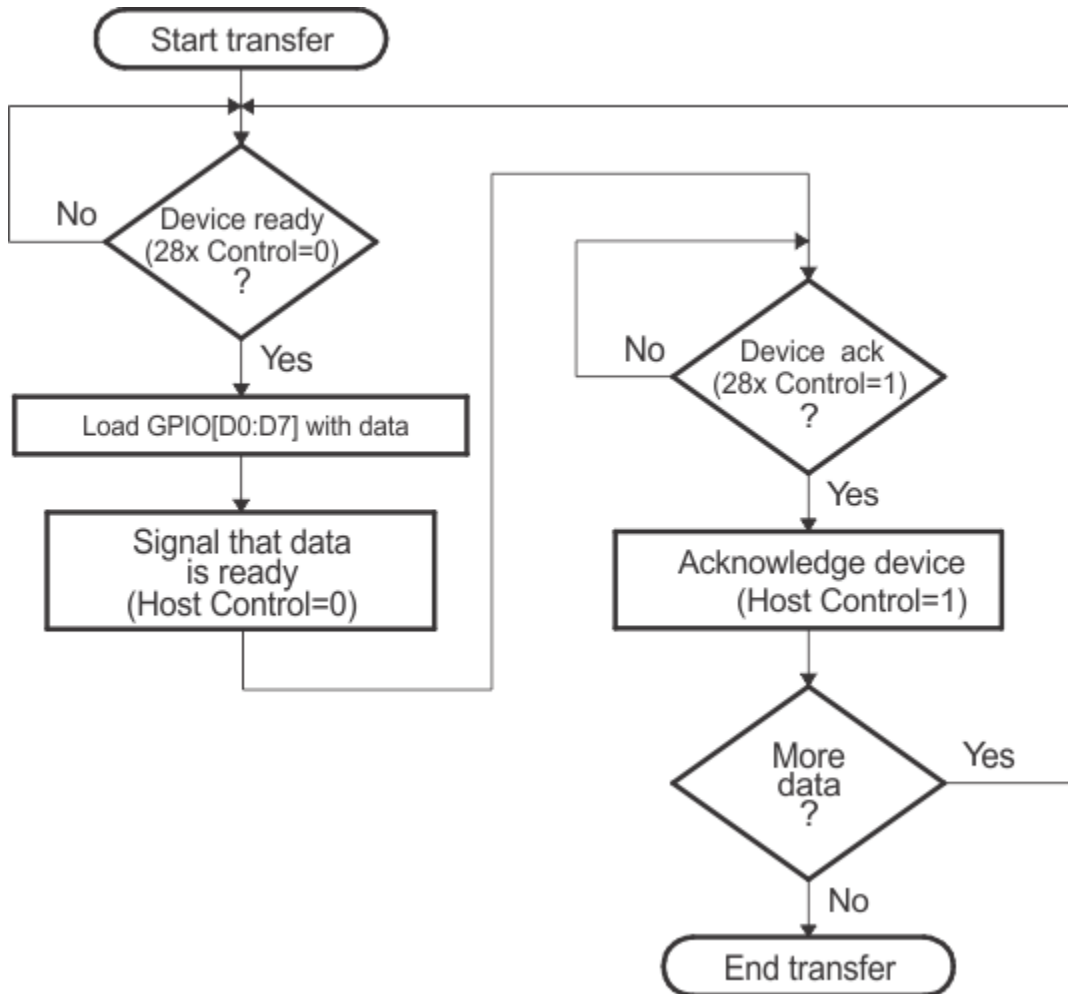

Figure 4-15. Parallel GPIO Mode - Host Transfer Flow

Figure 4-16 shows the flow used to read a single word of data from the parallel port.

- **8-bit data stream**

The 8-bit routine, shown in Figure 4-16, discards the upper eight bits of the first read from the port and treats the lower eight bits masked with D7 in bit position 7 and D6 in bit position six as the least significant byte (LSB) of the word to be fetched. The routine will then perform a second read to fetch the most significant byte (MSB). The routine will then perform a second read to fetch the most significant byte (MSB). It then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

Figure 4-16. 8-Bit Parallel GetWord Function

#### 4.8.9.2.5 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory as shown in [Figure 4-17](#). The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

**Figure 4-17. Overview of CAN-A Bootloader Operation**

The bit timing registers are programmed in such a way that a 100 kbps bit rate is achieved with a 20 MHz external oscillator, as shown in [Table 4-38](#).

**Table 4-38. Bit-Rate Value for Internal Oscillators**

| OSCCLK | SYSCLK | Bit Rate |
|--------|--------|----------|
| 20 MHz | 10 MHz | 100 kbps |

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

**Note**

The CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host should transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in [Table 4-39](#).

**Table 4-39. CAN 8-Bit Data Stream**

| Bytes | Byte 1 of 2 | Byte 2 of 2 | Description |   |
|-------|-------------|-------------|-------------|---|
| 1     | 2           | AA          | 08          | 0x08AA (KeyValue for memory width = 16 bits)  |

#### 4.8.9.2.6 CAN-FD Boot Mode

The CAN-FD bootloader asynchronously transfers code from CAN-FD to internal memory and follows same bootloader execution flow as [Section 4.8.9.2.5](#). The host can be any CAN-FD node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. It uses a fixed 64-byte payload size and default bit rate of 1-Mbps for nominal phase and 2-Mbps for data phase. Bit data timing can be optionally reconfigured after receiving first data segment. It supports same debug boot mode and GOIP option-0 as CAN bootloader.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN-FD host should transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN-FD bootloader is identical to the CAN bootloader. The data sequence for the CAN-FD bootloader is shown in [Table 4-40](#).

**Table 4-40. CAN-FD 8-Bit Data Stream**

| Bytes |     | Byte 1 of 2             | Byte 2 of 2             | Description   |
|-------|-----|-------------------------|-------------------------|---|
| 1     | 2   | AA                      | 08                      | 0x08AA (KeyValue for memory width = 16 bits)  |
| 3     | 4   | XX<br>(for example, BB) | XX<br>(for example, AA) | 0: Ignored<br>Nonzero: Custom nominal bit register timing [31:16]                       |

#### 4.8.10 GPIO Assignments

This section details the GPIOs and boot option values used for boot mode set in the BOOT\_DEF memory location located at Z1-OTP-BOOTDEF-LOW/ Z2-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH/ Z2-OTP-BOOTDEF-HIGH. Refer to [Section 4.5.2](#) on how to configure BOOT\_DEF. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

**Table 4-41. SCI Boot Options**

| Option      | BOOTDEF Value | SCITXDA GPIO | SCIRXDA GPIO |
|-------------|---------------|--------------|--------------|
| 0 (default) | 0x01          | GPIO29       | GPIO28       |
| 1           | 0x21          | GPIO16       | GPIO17       |
| 2           | 0x41          | GPIO8        | GPIO9        |
| 3           | 0x61          | GPIO2        | GPIO3        |
| 4           | 0x81          | GPIO16       | GPIO3        |

**Table 4-42. CAN Boot Options**

| Option      | BOOTDEF Value | CANTXA GPIO | CANRXA GPIO |
|-------------|---------------|-------------|-------------|
| 0 (default) | 0x02          | GPIO4       | GPIO5       |
| 1           | 0x22          | GPIO32      | GPIO33      |
| 2           | 0x42          | GPIO2       | GPIO3       |
| 3           | 0x62          | GPIO13      | GPIO12      |

**Table 4-43. CAN-FD Boot Options**

| Option | BOOTDEFx Value | CANTXA GPIO | CANRXA GPIO |
|--------|----------------|-------------|-------------|
| 0      | 0x08           | GPIO4       | GPIO5       |
| 1      | 0x28           | GPIO1       | GPIO0       |
| 2      | 0x48           | GPIO13      | GPIO12      |

| Option      | BOOTDEF Value | D0-D7 GPIO | C28x (DSP) Control GPIO | Host Control GPIO |
|-------------|---------------|------------|-------------------------|-------------------|
| 0 (default) | 0x00          | D0 - GPIO0 | GPIO16                  | GPIO29            |
|             |               | D1 - GPIO1 |                         |                   |
|             |               | D2 - GPIO2 |                         |                   |
|             |               | D3 - GPIO3 |                         |                   |
|             |               | D4 - GPIO4 |                         |                   |
|             |               | D5 - GPIO5 |                         |                   |
|             |               | D6 - GPIO6 |                         |                   |
|             |               | D7 - GPIO7 |                         |                   |
| 1           | 0x20          | D0 - GPIO0 | GPIO16                  | GPIO11            |
|             |               | D1 - GPIO1 |                         |                   |
|             |               | D2 - GPIO2 |                         |                   |
|             |               | D3 - GPIO3 |                         |                   |
|             |               | D4 - GPIO4 |                         |                   |
|             |               | D5 - GPIO5 |                         |                   |
|             |               | D6 - GPIO6 |                         |                   |
|             |               | D7 - GPIO7 |                         |                   |

### 4.8.11 Secure ROM Function APIs

There are a few functions that are available within Secure ROM to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

#### Note

The application should disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU (C28) while its program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset will fire (RSN if from C28). The consequence of this is if an NMI or ITRAP or Bus Fault occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP/Fault cannot be serviced because a reset will be fired to the subsystem.

The **secure copy code zone 1 and zone 2 functions** allow EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements will result in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

**Table 4-47. Secure Copy Code Function**

| CPU        | Function Prototype   | Function Parameters  | Function Return Value   |
|------------|--|--|---|
| CPU (C28x) | <code>uint16_t SecureCopyCodeZ1(uint32_t size, uint16_t *dst, uint16_t *src)</code><br><code>uint16_t SecureCopyCodeZ2(uint32_t size, uint16_t *dst, uint16_t *src)</code> | <p><i>size</i> : The number of 16-bit words to copy</p> <p><i>dst</i> : The destination memory address in EXEONLY RAM</p> <p><i>src</i> : The source memory address in EXEONLY Flash</p> | <p>0xFFFF : Returns the number of 16-bit words copied</p> <p>0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM don't belong to the same zone; Flash and/or RAM aren't set to EXEONLY; Error occurred during data copy</p> |

The **secure CRC calculation zone 1 and zone 2 functions** allow a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value will be stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. Any violations of these requirements will result in a failure status returned. Upon successful CRC, the number of 16-bit words CRC'd is returned.

**Table 4-48. Secure CRC Calculation Function**

| CPU        | Function Prototype   | Function Parameters  | Function Return Value  |
|------------|--|--|--|
| CPU (C28x) | <code>uint16_t SecureCRCCalcZ1(uint16_t len_id, uint16_t *dst, uint16_t *src)</code><br><code>uint16_t SecureCRCCalcZ2(uint16_t size, uint16_t *dst, uint16_t *src)</code> | <p><i>len_id</i> : A number from 1 to 8 which corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words</p> <p><i>dst</i> : The destination memory address for resulting CRC</p> <p><i>src</i> : The source memory address to begin CRC calculation</p> | <p>0xFFFF : Returns the number of 16-bit words CRC'd</p> <p>0x0000 : Indicates one of the following: Invalid length option; Source address isn't modulo of length value; Destination address isn't within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory don't belong to the same zone; On CM, CRCLOCK is enabled</p> |

The **CMAC calculate and compare function** allows to calculate CMAC signature of a Flash memory block and compare against a golden signature. This is used in the secure boot mode to authenticate the boot image.

**Table 4-49. Secure CRC Calculation Function**

| CPU        | Function Prototype  | Function Parameters   | Function Return Value   |
|------------|---|---|---|
| CPU (C28x) | <pre>uint32_t CPU1BROM_calculateCMAC(uint32_t startAddress, uint32_t endAddress, uint32_t signatureAddress)</pre> | <p><b>startAddress:</b> Starting address of memory for which CMAC has to be calculated</p> <p><b>endAddress:</b> Ending address of memory for which CMAC has to be calculated</p> <p><b>signatureAddress:</b> Address of location where golden CMAC signature is stored</p> | <p><b>0xFFFFFFFFU:</b> Calculated CMAC signature did not match golden signature (fail)</p> <p><b>0xA5A5A5A5U:</b> Memory range provided isn't aligned to 128-bit boundary or length is zero</p> <p><b>0xE1E1E1E1U:</b> AES Engine timed out</p> <p><b>0x00000000U:</b> No Error</p> |

#### 4.8.12 Clock Initializations

During boot-up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR and XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

#### Note

CPU performs clock configurations during boot up. If the PLL is used during the boot process, it will be bypassed by the boot ROM code before branching to the user application.

**Table 4-50. CPU Boot Clock Sources**

| Source  | Frequency         | Description  |
|---------|-------------------|--|
| INTOSC2 | 10 MHz            | Default clock source   |
| INTOSC1 | 10 MHz            | Set as clock source if missing clock is detected at power up or right after device reset.  |
| SYSPLL  | 115 MHz, 57.5 MHz | Enabled optionally as part of main boot flow or as part of MPOST POR memory test boot flow. PLL is bypassed and disabled after memory test has completed. See more details regarding enabling MPOST POR memory test in <a href="#">Section 4.8.1.1</a> . |

**Table 4-51. CPU Clock State After Boot**

| Reset Source     | Clock State   |
|------------------|---|
| POR/XRS          | <ol style="list-style-type: none"> <li>Using INTOSC2</li> <li>System clock divider set to /1</li> </ol> |
| All other Resets | Maintain clocks setup before device reset.  |

#### 4.8.13 Boot Status Information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

### 4.8.13.1 Booting Status

Boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, you should clear the status before performing a debugger device reset in order to view the latest boot ROM actions reflected in the status.

**Table 4-52. Boot Status Address**

| Description     | Address     |
|-----------------|-------------|
| Boot ROM Status | 0x0000 0002 |

**Table 4-53. Boot Status Bit Fields**

| Value       | Description                            |
|-------------|--|
| 0x8000 0000 | HWBIST reset is handled successfully   |
| 0x2000 0000 | EFuse Single Bit Error                 |
| 0x1000 0000 | LFU Flash Boot Error                   |
| 0x0800 0000 | Flash Verification Error               |
| 0x0400 0000 | DCSM initialization LP Error           |
| 0x0200 0000 | DCSM Initialization Invalid LP         |
| 0x0100 0000 | SYSPLL enabled successfully            |
| 0x0080 0000 | HWBIST NMI occurred                    |
| 0x0040 0000 | Missing clock NMI occurred             |
| 0x0020 0000 | RAM Uncorrectable Error NMI occurred   |
| 0x0010 0000 | Flash Uncorrectable Error NMI occurred |
| 0x0008 0000 | RL NMI occurred                        |
| 0x0004 0000 | ERAD NMI occurred                      |
| 0x0002 0000 | Boot ROM detected a PIE mismatch       |
| 0x0001 0000 | Boot ROM detected an ITRAP             |
| 0x0000 8000 | Boot ROM has completed running         |
| 0x0000 2000 | Boot ROM handled POR                   |
| 0x0000 1000 | Boot ROM handled XRS                   |
| 0x0000 0800 | Boot ROM handled all the resets        |
| 0x0000 0400 | POR memory test has completed          |
| 0x0000 0200 | DCSM initialization has completed      |
| 0x0000 0100 | RAM Initialization Complete            |
| 0x0000 000D | Secure LFU boot has started            |
| 0x0000 000C | LFU boot has started                   |
| 0x0000 000B | Wait boot has started                  |
| 0x0000 000A | CAN-FD boot has started                |
| 0x0000 0009 | CAN boot has started                   |
| 0x0000 0008 | I2C boot has started                   |
| 0x0000 0007 | SPI boot has started                   |
| 0x0000 0006 | SCI boot has started                   |
| 0x0000 0005 | RAM boot has started                   |
| 0x0000 0004 | Parallel boot has started              |
| 0x0000 0003 | Secure Flash boot has started          |
| 0x0000 0002 | Flash boot has started                 |
| 0x0000 0001 | Boot ROM has started running           |

#### 4.8.13.2 Boot Mode and MPOST (Memory Power On Self-Test) Status

Once the boot mode is decoded during the boot flow, the boot mode value is written to RAM. Additionally when running the MPOST POR memory test, the test result is written to RAM.

For more information, see the [C2000™ Memory Power-On Self-Test \(M-POST\) Application Report](#).

**Table 4-54. Boot Mode and MPOST Status Addresses**

| Description                  | Address     |
|------------------------------|-------------|
| Boot Mode                    | 0x0000 0004 |
| MPOST POR Memory Test Result | 0x0000 0006 |

#### 4.8.14 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in [Table 4-55](#). Reading a revision number value of “0x100” represents version “1.0”, “0x101” represents version “1.1”, and so on. Reading a revision date value of “0x0119” represents “01/19” or “January 2019”.

**Table 4-55. Boot ROM Version Information**

| Contents        | Address     |
|-----------------|-------------|
| Revision Number | 0x003F 8044 |
| Revision Date   | 0x003F 8045 |
| Build Number    | 0x003F 8046 |

### 4.9 Application Notes for Using the Bootloaders

#### 4.9.1 Bootloader Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on C2000 devices.

[Table 4-56](#) and [Example 4-2](#) show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex. Refer to for more details on using the C28x hex utility to convert a project to this format.

The first 16-bit word in the data stream is known as the key value. The key value is used to tell the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders will accept both 8 and 16-bit streams. Please refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA and for a 16-bit stream it is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to it. If a bootloader does not use these values then they are reserved for future use and the bootloader simply reads the value and then discards it. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size would be 0x000A to indicate 10 16-bit words.

The next two words tell the loader the destination address of the block of data. Following the size and address will be the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point, the loader returns the entry point address to the calling routine, which will clean up and exit. Execution then continues at the entry point address as determined by the input data stream contents.

**Table 4-56. LSB/MSB Loading Sequence in 8-Bit Data Stream**

|      |     | Contents  |  |
|------|-----|---|--|
| Byte |     | LSB (First Byte of 2)   | MSB (Second Byte of 2)                                 |
| 1    | 2   | LSB: AA (KeyValue for memory width = 8 bits)  | MSB: 08h (KeyValue for memory width = 8 bits)          |
| 3    | 4   | LSB: Register initialization value or reserved  | MSB: Register initialization value or reserved         |
| 5    | 6   | LSB: Register initialization value or reserved  | MSB: Register initialization value or reserved         |
| 7    | 8   | LSB: Register initialization value or reserved  | MSB: Register initialization value or reserved         |
| ...  | ... | ...   | ...  |
| 17   | 18  | LSB: Register initialization value or reserved  | MSB: Register initialization value or reserved         |
| 19   | 20  | LSB: Upper half of Entry point PC[23:16]  | MSB: Upper half of entry point PC[31:24] (Always 0x00) |
| 21   | 22  | LSB: Lower half of Entry point PC[7:0]  | MSB: Lower half of Entry point PC[15:8]                |
| 23   | 24  | LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program. Otherwise another block follows. For example, a block size of 0x000A would indicate 10 words or 20 bytes in the block. | MSB: block size  |
| 25   | 26  | LSB: MSW destination address, first block Addr[23:16]   | MSB: MSW destination address, first block Addr[31:24]  |
| 27   | 28  | LSB: LSW destination address, first block Addr[7:0]   | MSB: LSW destination address, first block Addr[15:8]   |
| 29   | 30  | LSB: First word of the first block being loaded   | MSB: First word of the first block being loaded        |
| ...  | ... | ...   | ...  |
| ...  | ... | ...   | ...  |
| .    | .   | LSB: Last word of the first block to load   | MSB: Last word of the first block to load              |
| .    | .   | LSB: Block size of the second block   | MSB: Block size of the second block                    |
| .    | .   | LSB: MSW destination address, second block Addr[23:16]  | MSB: MSW destination address, second block Addr[31:24] |
| .    | .   | LSB: LSW destination address, second block Addr[7:0]  | MSB: LSW destination address, second block Addr[15:8]  |
| .    | .   | LSB: First word of the second block being loaded  | MSB: First word of the second block being loaded       |
| ...  | ... | ...   | ...  |
| ...  | ... | ...   | ...  |
| .    | .   | LSB: Last word of the second block  | MSB: Last word of the second block                     |
| .    | .   | LSB: Block size of the last block   | MSB: Block size of the last block                      |
| .    | .   | LSB: MSW of destination address of last block Addr[23:16]   | MSB: MSW destination address, last block Addr[31:24]   |
| .    | .   | LSB: LSW destination address, last block Addr[7:0]  | MSB: LSW destination address, last block Addr[15:8]    |
| .    | .   | LSB: First word of the last block being loaded  | MSB: First word of the last block being loaded         |
| ...  | ... | ...   | ...  |
| ...  | ... | ...   | ...  |
| .    | .   | LSB: Last word of the last block  | MSB: Last word of the last block                       |
| n    | n+1 | LSB: 00h  | MSB: 00h - indicates the end of the source             |

### Example 4-2. Data Stream Structure 8-bit

```

AA 08      ; 0x08AA 8bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00      ; 0x0005 First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 First block will be loaded starting at 0x3F9010
01 00      ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00      ; 0x0002 - 2nd block consists of 2 16bit words
3F 00 00 80 ; 0x003F8000 2nd block will be loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 Size of 0 indicates end of data stream
After load has completed the following memory values will have been initialized as follows:
Location Value
0x3F9010 0x0001
0x3F9011 0x0002
0x3F9012 0x0003
0x3F9013 0x0004
0x3F9014 0x0005
0x3F8000 0x7700
0x3F8001 0x7625
PC Begins execution at 0x3F8000

```

## 4.9.2 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in [Section 4.9.1](#). The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in [Example 4-3](#).

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, and so on) will differ from one specific application to another and some additional conversion may be required.

To build the boot table, follow these steps:

- 1. Assemble or compile the code.**

This creates the object files that will then be used by the linker to create a single output file.

- 2. Link the file.**

The linker combines all of the object files into a single output file in common object file format (ELF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the ELF file. Uninitialized sections are not converted by the hex conversion utility. The following options may be useful:

- The linker `-m` option can be used to generate a map file. This map file will show all of the sections that were created, their location in memory, and their length. It can be useful to check this file to make sure that the initialized sections are where you expect them.
- The linker `-w` option configures the linker to show, if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called `.TI.ramfunc`.

### 3. Run the hex conversion utility.

Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the ELF file produced by the linker to a boot table.

See the [TMS320C28x Assembly Language Tools User's Guide](#) and the [TMS320C28x Optimizing C/C++ Compiler User's Guide](#) for more information on the compiling and linking process.

[Table 4-57](#) summarizes the hex conversion utility options available for the bootloader. See the [TMS320C28x Assembly Language Tools User's Guide](#) for a detailed description of the hex2000 operations used to generate a boot table. Updates will be made to support the I2C boot. See the Codegen release notes for the latest information.

**Table 4-57. Boot Loader Options**

| Option         | Description  |
|----------------|--|
| -boot          | Convert all sections into bootable form (use instead of a SECTIONS directive)  |
| -sci8          | Specify the source of the bootloader table as the SCI-A port, 8-bit mode   |
| -spi8          | Specify the source of the bootloader table as the SPI-A port, 8-bit mode   |
| -gpio8         | Specify the source of the bootloader table as the GPIO port, 8-bit mode  |
| -bootorg value | Specify the source address of the bootloader table   |
| -lospcp value  | Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.  |
| -spibrr value  | Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.  |
| -e value       | Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally _c_int00 unless defined otherwise by the -e linker option. |
| -i2c8          | Specify the source of the bootloader table as the I2C-A port, 8-bit  |
| -i2cpsc value  | Specify the value for the I2CPSC register. This value will be loaded and take effect after all I2C options are loaded, prior to reading data from the EEPROM. This value will be truncated to the least significant eight bits and should be set to maintain an I2C module clock of 7-12 MHz.  |
| -i2cclkh value | Specify the value for the I2CCLKH register. This value will be loaded and take effect after all I2C options are loaded, prior to reading data from the EEPROM.   |
| -i2cckl value  | Specify the value for the I2CCLKL register. This value will be loaded and take effect after all I2C options are loaded, prior to reading data from the EEPROM.   |

#### Example 4-3. HEX2000.exe Command Syntax

```
C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
Where:
- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN
        uses the same data format as the GPIO in 8bit mode.
- a     Select ASCII-Hex as the output format.
```

This chapter explains the dual code security module.

## 5.1 Introduction

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) by unauthorized persons. It also prevents duplication and reverse-engineering of proprietary code. The term “secure” means that access to on-chip secure memories and resources is blocked. The term “unsecure” means that access is allowed; that is, the contents of the memory could be read by any means (for example, through a debugging tool such as Code Composer Studio™ IDE).

The CSM has dual-zone security, Zone1 (Z1) and Zone2 (Z2).

### 5.1.1 DCSM Related Collateral

#### Getting Started Materials

- [C2000 DCSM Security Tool Application Report](#)
- [C2000 Unique Device Number Application Report](#)
- [Enhancing Device Security by Using JTAGLOCK Feature Application Report](#)

## 5.2 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone1 (Z1) and Zone2 (Z2). The security mechanism for both the zones is identical. Each zone has its own dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has its own dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, its USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **RAM:** All LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM locations in the USER OTP.
- **Flash Sectors:** Flash sectors of each CPU subsystems can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT locations in the bank's USER OTP.
- **Secure ROM:** This device also has secure ROM on each CPU subsystem which is EXEONLY-protected. These ROM contains specific function for the user, provided by TI.

[Table 5-1](#) shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

The security of each zone is ensured by its own 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in [Section 5.7.4](#).

There are three types of accesses: data/program reads, JTAG access, and instruction fetches (calls, jumps, code executions, ISRs). Instruction fetches are never blocked. JTAG accesses are always blocked when a memory is secure. Data reads to a secure memory are always blocked unless the program is executing from a memory which belongs to the same zone. Data reads to unsecure memory are always allowed. [Table 5-2](#) shows the levels of security.

**Table 5-1. RAM/Flash Status**

| Zone 1<br>GRABRAMx/GRABSECTx Bits | Zone 2<br>GRABRAMx/GRABSECTx Bits | Ownership and Accessibility  |
|-----------------------------------|-----------------------------------|--|
| 01                                | 10                                | RAM block/Flash Sector belongs to Zone1  |
| 01                                | 11 <sup>(2)</sup>                 | RAM block/Flash Sector belongs to Zone1  |
| 10                                | 01                                | RAM block/Flash Sector belongs to Zone2  |
| 11 <sup>(1)</sup>                 | 01                                | RAM block/Flash Sector belongs to Zone2  |
| 10                                | 10                                | RAM block/Flash Sector is unsecure   |
| 11 <sup>(1)</sup>                 | 11 <sup>(2)</sup>                 | RAM block/Flash Sector is unsecure   |
| 11                                | 11                                | RAM block/Flash Sector inaccessible if either of the zone is secure (CSM passwords are programmed). User should never leave these values default (11) if CSM passwords are programmed for even one zone. |

- (1) Zone1 must be unsecure. Assumption in this case is that user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user hence Zone1 will always be unsecure.
- (2) Zone2 must be unsecure. Assumption in this case is that user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user hence Zone2 will always be unsecure.

#### Note

You should never program any other values in these fields. Failing any of these conditions for a RAM block/Flash sector makes that RAM block/Flash sector inaccessible.

**Table 5-2. Security Levels**

| PMF Executed With Correct Password? | Operating Mode of the Zone | Program Fetch Location | Security Description  |
|-------------------------------------|----------------------------|------------------------|---|
| No                                  | Secure                     | Outside secure memory  | Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.     |
| No                                  | Secure                     | Inside secure memory   | CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents. |
| Yes                                 | Unsecure                   | Anywhere               | Full access for CPU and JTAG port to secure memory of that zone.  |

### 5.2.1 CSM Passwords

Unlike earlier C2000™ devices, on this device ALL\_1 value (0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF, 0xFFFFFFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL\_1 from USER OTP, the device will be in BLOCKED state. Due to this reason TI will program a few bits in the second 32-bit password value (ZxOTP\_CSMPSWD1) in every zone select block of each zone with value '0'. The default value for this password location is chosen in a manner that the respective ECC value remains ALL\_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See [Table 5-3](#) for ZxOTP\_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user will be able to change this value by flipping the bits which are '1' to '0' but leaving the ones which are already programmed by TI as '0'. BOOTROM code will write the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL\_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers which means the zone cannot be unlocked using PMF, the password match flow described in [Section 5.7.4](#). Therefore, the user should never

use ALL\_0 as password. A password of ALL\_0 will prevent debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

**Table 5-3. Default Value of ZxOTP (Programmed by TI)**

| Zone Select Block     | Zone1 USER OTP          |            | Zone2 USER OTP        |            |
|-----------------------|-------------------------|------------|-----------------------|------------|
|                       | Address                 | Value      | Address               | Value      |
| JLM_ENABLE (JTAGLOCK) | 0x00078006              | 0xffff000f | NA                    | NA         |

### 5.2.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected will trip the ECSL and break the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, you must write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This will disable the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU will start running and may execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL will trip and cause the emulator connection to be broken.

The solution to this problem is to use the Wait Boot Mode boot option. In this mode, the CPU will be in a loop and will not jump to the user application code. Using this BOOTMODE, you can connect to CCS and debug the code.

### 5.2.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

### 5.2.4 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone's PSWDLOCK field with any value other than "1111" (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations will not be secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a fresh device the value for password lock fields for all zones at the PSWDLOCK location in OTP will be "1111" which means the password for all zones will be unlocked.

---

#### Note

Password unlock only makes password locations non-secure. All other secure memories remains secure as per security settings. Since password locations are non-secure, anyone can read the password and make the zone un-secure by running through PMF, user must program PSWDLOCK locations to lock the password before sending the device in field.

---

### 5.2.5 JTAGLOCK

Sometimes you want to disable the JTAG access on a device to avoid any debug access to it. This can be done by using the JTAGLOCK feature on this device. You need to follow a two step process to enable the JTAGLOCK feature (both steps can be performed at the same time).

1. Program the JTAG passwords. This device has a 128-bit JTAG password that needs to be programmed in Z1 USER OTP. JTAG passwords are split into two parts, JTAGPSWDH and JTAGPSWDL. JTAGPSWDH is part of Z1 USER OTP header and JTAGPSWDL is part of Z1 Zone Select Block (ZSB). What this means is program JTAGPSWDH once and change the JTAGPSWDL multiple times, if needed. Code Composer Studio has an integrated tool that you need to use to unlock the JTAGLOCK on device.
2. After programming the JTAG passwords, you need to enable the JTAGLOCK module (JLM) by programming bit [3:0] of Z1OTP\_JLM\_ENABLE with any value other than 0xF. It is recommended to program all four bits with a value 0x0.

### 5.2.6 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists that holds the configuration related to zone's security. The following are user programmable configurations:

- |                      |                      |
|----------------------|----------------------|
| • ZxOTP_LINKPOINTER1 | • ZxOTP_CSMPSWD1     |
| • ZxOTP_LINKPOINTER2 | • ZxOTP_CSMPSWD2     |
| • ZxOTP_LINKPOINTER3 | • ZxOTP_CSMPSWD3     |
| • Z1OTP_JLM_ENABLE   | • ZxOTP_GRABSECT1    |
| • ZxOTP_GPREG1       | • ZxOTP_GRABSECT2    |
| • ZxOTP_GPREG2       | • ZxOTP_GRABSECT3    |
| • ZxOTP_GPREG3       | • ZxOTP_GRABRAM1     |
| • ZxOTP_GPREG4       | • ZxOTP_GRABRAM2     |
| • ZxOTP_PSWDLOCK     | • ZxOTP_GRABRAM3     |
| • ZxOTP_CRCLOCK      | • ZxOTP_EXEONLYSECT1 |
| • Z1OTP_JTAGPSWDH    | • ZxOTP_EXEONLYSECT2 |
| • Z1OTP_CMACKKEY     | • ZxOTP_EXEONLYRAM1  |
| • ZxOTP_CSMPSWD0     | • Z1OTP_JTAGPSWDL    |

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks:

- |                   |                      |
|-------------------|----------------------|
| • ZxOTP_CSMPSWD0  | • ZxOTP_GRABRAM1     |
| • ZxOTP_CSMPSWD1  | • ZxOTP_GRABRAM2     |
| • ZxOTP_CSMPSWD2  | • ZxOTP_GRABRAM3     |
| • ZxOTP_CSMPSWD3  | • ZxOTP_EXEONLYSECT1 |
| • ZxOTP_GRABSECT1 | • ZxOTP_EXEONLYSECT2 |
| • ZxOTP_GRABSECT2 | • ZxOTP_EXEONLYRAM1  |
| • ZxOTP_GRABSECT3 | • Z1OTP_JTAGPSWDL    |

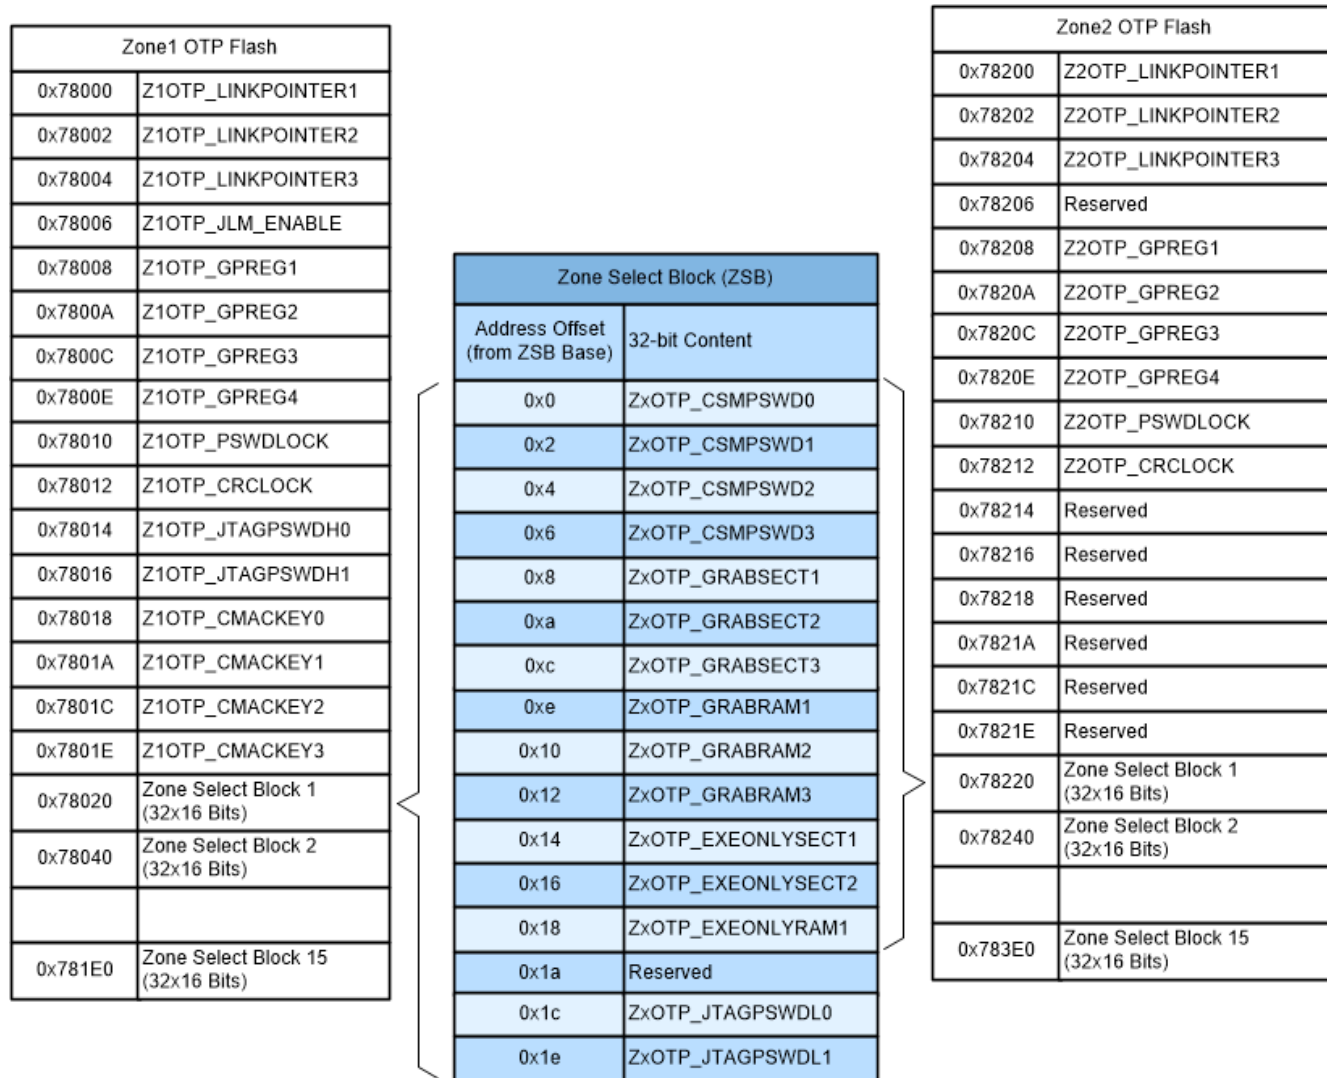

The location of the valid zone select block in OTP is decided based on the value of three 14-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointers and Z1OTP\_JLM\_ENABLE locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware, when a dummy read is done to all the link pointers, by comparing all the three values (bit-wise voting logic). Since in OTP, a '1' can be flipped by the user to '0' but '0' can not be flipped to '1' (no erase operation for OTP), the most significant bit position in the resolved link pointer which is '0', defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in [Figure 5-1](#), the final link pointer value becomes All\_1 (0xFFFF\_FFFF), which selects the Zone-Select-Block1 (also known as the default zone select block).

| Zx-LINKPOINTER                       | Selected ZSB | Zone1 ZSB Address | Zone2 ZSB Address |
|--------------------------------------|--------------|-------------------|-------------------|
| 32xxxxxxxxxxxxxxxxxxxx11111111111111 | ZSB1         | 0x78020           | 0x78220           |
| 32xxxxxxxxxxxxxxxxxxxx11111111111110 | ZSB2         | 0x78040           | 0x78240           |
| 32xxxxxxxxxxxxxxxxxxxx11111111111100 | ZSB3         | 0x78060           | 0x78260           |
| 32xxxxxxxxxxxxxxxxxxxx11111111111000 | ZSB4         | 0x78080           | 0x78280           |
| 32xxxxxxxxxxxxxxxxxxxx11111111110000 | ZSB5         | 0x780a0           | 0x782a0           |
| 32xxxxxxxxxxxxxxxxxxxx11111111100000 | ZSB6         | 0x780c0           | 0x782c0           |
| 32xxxxxxxxxxxxxxxxxxxx11111111000000 | ZSB7         | 0x780e0           | 0x782e0           |
| 32xxxxxxxxxxxxxxxxxxxx11111100000000 | ZSB8         | 0x78100           | 0x78300           |
| 32xxxxxxxxxxxxxxxxxxxx11111000000000 | ZSB9         | 0x78120           | 0x78320           |
| 32xxxxxxxxxxxxxxxxxxxx11110000000000 | ZSB10        | 0x78140           | 0x78340           |
| 32xxxxxxxxxxxxxxxxxxxx11100000000000 | ZSB11        | 0x78160           | 0x78360           |
| 32xxxxxxxxxxxxxxxxxxxx11000000000000 | ZSB12        | 0x78180           | 0x78380           |
| 32xxxxxxxxxxxxxxxxxxxx10000000000000 | ZSB13        | 0x781a0           | 0x783a0           |
| 32xxxxxxxxxxxxxxxxxxxx10000000000000 | ZSB14        | 0x781c0           | 0x783c0           |
| 32xxxxxxxxxxxxxxxxxxxx00000000000000 | ZSB15        | 0x781e0           | 0x783e0           |

**Figure 5-1. Storage of Zone-Select Bits in OTP**

**Note**

Address locations for other security settings that are not part of Zone Select blocks can be programmed only once; therefore, you should program them towards end of the development cycle.

**Figure 5-2. Location of Zone-Select Block Based on Link-Pointer**

### CAUTION

USER OTP is ECC protected. You must program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value causes the device to be blocked permanently and you will have to replace the device.

### 5.2.7 C Code Example to Get Zone Select Block Addr for Zone1

```

unsigned long LinkPointer;
unsigned long *ZoneSelBlockPtr;
int Bitpos = 13;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 to 15 as most-significant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 18;
while ((ZeroFound == 0) && (bitpos > -1))
{
if ((LinkPointer & 0x80000000) == 0)
{
ZeroFound = 1;
ZoneSelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 2)*32));
}
else
{
bitpos--;
LinkPointer = LinkPointer << 1;
}
}
if (ZeroFound == 0)
{
//Default in case there is no zero found.
ZoneSelBlockPtr = (unsigned long *)0x78020;
}

```

### 5.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has its own dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECTx location in OTP. Each zone has its own 128bit CSM passwords. Read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Z2 and vice versa. Before programming any secure Flash sector the user must either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory which belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

A semaphore mechanism is provided to avoid the program/erase conflict between Z1 and Z2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the secure Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

### 5.4 Secure Copy Code

In some applications, the user may want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Secure Copy Code” library functions for each zone to enable the user to copy content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the *ROM Code and Peripheral Booting* chapter.

## 5.5 SecureCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC on content in EXEONLY memories using the CRC engine available on this device (for example, VCUCRC, GCRC) or software. In some safety-critical applications, the user may have to calculate the CRC even on these memories. To enable this without compromising on security, TI provides specific “SecureCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address should be modulo the number of words (based on length\_id) for which the CRC needs to be calculated.
- The destination address should belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

---

### Note

The user must disable all the interrupts before calling the secure functions in ROM. If there is a vector fetch during secure function execution, the CPU gets reset immediately.

---

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

## 5.6 CSM Impact on Other On-Chip Resources

On this device, some of the memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP ) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT\_ROM and OTP is accessible to the user.

The following steps are required by CPU after reset (any type of reset) to initialize the security on device.

### Security Initialization

- Dummy Read to address location of SECD (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP\_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1OTP\_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1OTP\_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z2OTP\_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2OTP\_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2OTP\_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location Z1OTP\_JLM\_ENABLE in Z1 OTP
- Dummy Read to address location of Z1OTP\_GPREG1, Z1OTP\_GPREG2, Z1OTP\_GPREG3, Z1OTP\_GPREG4 in Z1 OTP
- Dummy Read to address location of Z1OTP\_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_CRCLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_JTAGPSWDH0, Z1OTP\_JTAGPSWDH1 in Z1 OTP
- Dummy Read to address location of Z2OTP\_GPREG1, Z2OTP\_GPREG2, Z2OTP\_GPREG3, Z2OTP\_GPREG4 in Z2 OTP
- Dummy Read to address location of Z2OTP\_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2OTP\_CRCLOCK in Z2 OTP
- Read to memory map register of Z1\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP\_GRABSECT1, Z1OTP\_GRABSECT2, Z1OTP\_GRABSECT3 in Z1 OTP
- Dummy read to address location of Z1OTP\_GRABRAM1, Z1OTP\_GRABRAM2, Z1OTP\_GRABRAM3 in Z1 OTP
- Dummy read to address location of Z1OTP\_EXEONLYSECT1, Z1OTP\_EXEONLYSECT2 in Z1 OTP
- Dummy read to address location of Z1OTP\_EXEONLYRAM1 in Z1 OTP
- Dummy Read to address location of Z1OTP\_JTAGPSWDL0, Z1OTP\_JTAGPSWDL1 in Z1 OTP
- Read to memory map register of Z2\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP\_GRABSECT1, Z2OTP\_GRABSECT2, Z2OTP\_GRABSECT3 in Z2 OTP
- Dummy read to address location of Z2OTP\_GRABRAM1, Z2OTP\_GRABRAM2, Z2OTP\_GRABRAM3 in Z2 OTP
- Dummy read to address location of Z2OTP\_EXEONLYSECT1, Z2OTP\_EXEONLYSECT2 in Z2 OTP
- Dummy read to address location of Z2OTP\_EXEONLYRAM1 in Z2 OTP

---

### Note

Security Initialization is done by BOOTROM code on all the resets (as part of device initialization) that assert SYSRSn. This will not be part of user application code.

The order of initialization matters; hence, if a memory watch window with the USER OTP address is opened in the debugger (CCS), the security initialization could occur in an incorrect order locking the device down. To avoid this, you should not keep a memory window with USER OTP address opened in the debugger (CCS) when performing a reset.

---

## 5.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password should be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx\_CR.31) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (via JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

### 5.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring the zone can be required:

- Code development using debuggers (such as Code Composer Studio™ IDE). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the Flash utilities disable the security logic before attempting to program the Flash. In custom programming solutions that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application
  - In addition to the above, access to secure memory contents can be required in situations such as:
    - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
    - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code could compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 5-3](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

### 5.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. [Figure 5-3](#) shows how PMF helps to initialize the security logic registers and disable security logic.

Figure 5-3. CSM Password Match Flow (PMF)

### 5.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)5F090; //CSM register file volatile
long int *CSMPWL = (volatile long int *)0x78020; //CSM Password location (assuming default Zone
select block)
volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL then the CSM will become unsecure. If it does not
// match, then the zone will remain secure.
// An example password of: // 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F094
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F096
```

### 5.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

### 5.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and may halt while main IP code is running. If ECSL is not unlocked, then Code Composer Studio connections will get disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to secure code but only avoids disconnection of CCS (JTAG).

### 5.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. [Figure 5-4](#) shows how the PMF helps to initialize the security logic registers and disable security logic.

Figure 5-4. ECSSL Password Match Flow (PMF)

### 5.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled should have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, it stays enabled.

#### 5.7.7.1 C Code Example to Disable ECSL for C28x Zone1

```
volatile long int *ECSL = (volatile int *)0x5F090; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)
volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL).
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL then ECSL will get disable. If it does not
// match, then the zone will remain secure.
// An example password of: // 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
```

### 5.7.8 Device Unique ID

TI OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x7020E. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

## 5.8 DCSM Registers

This section describes the various DCSM registers.

### 5.8.1 DCSM Base Address Table

**Table 5-4. DCSM Base Address Table**

| Bit Field Name |                  | DriverLib Name  | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|------------------|-----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure        |                 |              |      |     |     |     |                    |
| DcsmZ1Regs     | DCSM_Z1_REGS     | DCSM_Z1_BASE    | 0x0005_F000  | YES  | -   | -   | -   | YES                |
| DcsmZ2Regs     | DCSM_Z2_REGS     | DCSM_Z2_BASE    | 0x0005_F080  | YES  | -   | -   | -   | YES                |
| DcsmCommonRegs | DCSM_COMMON_REGS | DCSMCOMMON_BASE | 0x0005_F0C0  | YES  | -   | -   | -   | YES                |
| DcsmZ1OtpRegs  | DCSM_Z1_OTP      | DCSM_Z1OTP_BASE | 0x0007_8000  | YES  | -   | -   | -   | -                  |
| DcsmZ2OtpRegs  | DCSM_Z2_OTP      | DCSM_Z2OTP_BASE | 0x0007_8200  | YES  | -   | -   | -   | -                  |

## 5.8.2 DCSM\_Z1\_REGS Registers

Table 5-5 lists the memory-mapped registers for the DCSM\_Z1\_REGS registers. All register offset addresses not listed in Table 5-5 should be considered as reserved locations and the register contents should not be modified.

**Table 5-5. DCSM\_Z1\_REGS Registers**

| Offset | Acronym           | Register Name                               | Write Protection | Section            |
|--------|-------------------|---|------------------|--------------------|
| 0h     | Z1_LINKPOINTER    | Zone 1 Link Pointer                         |                  | <a href="#">Go</a> |
| 2h     | Z1_OTPSECLOCK     | Zone 1 OTP Secure Lock                      |                  | <a href="#">Go</a> |
| 4h     | Z1_JLM_ENABLE     | Zone 1 JTAGLOCK Enable Register             |                  | <a href="#">Go</a> |
| 6h     | Z1_LINKPOINTERERR | Link Pointer Error                          |                  | <a href="#">Go</a> |
| 8h     | Z1_GPREG1         | Zone 1 General Purpose Register-1           |                  | <a href="#">Go</a> |
| Ah     | Z1_GPREG2         | Zone 1 General Purpose Register-2           |                  | <a href="#">Go</a> |
| Ch     | Z1_GPREG3         | Zone 1 General Purpose Register-3           |                  | <a href="#">Go</a> |
| Eh     | Z1_GPREG4         | Zone 1 General Purpose Register-4           |                  | <a href="#">Go</a> |
| 10h    | Z1_CSMKEY0        | Zone 1 CSM Key 0                            |                  | <a href="#">Go</a> |
| 12h    | Z1_CSMKEY1        | Zone 1 CSM Key 1                            |                  | <a href="#">Go</a> |
| 14h    | Z1_CSMKEY2        | Zone 1 CSM Key 2                            |                  | <a href="#">Go</a> |
| 16h    | Z1_CSMKEY3        | Zone 1 CSM Key 3                            |                  | <a href="#">Go</a> |
| 18h    | Z1_CR             | Zone 1 CSM Control Register                 |                  | <a href="#">Go</a> |
| 1Ah    | Z1_GRABSECT1R     | Zone 1 Grab Flash Status Register 1         |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 5-6 shows the codes that are used for access types in this section.

**Table 5-6. DCSM\_Z1\_REGS Access Type Codes**

| Access Type            | Code    | Description                            |
|------------------------|---------|--|
| Read Type              |         |  |
| R                      | R       | Read                                   |
| R-0                    | R<br>-0 | Read<br>Returns 0s                     |
| Write Type             |         |  |
| W                      | W       | Write                                  |
| Reset or Default Value |         |  |
| -n                     |         | Value after reset or the default value |

**Table 5-6. DCSM\_Z1\_REGS Access Type Codes  
(continued)**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 5.8.2.1 Z1\_LINKPOINTER Register (Offset = 0h) [Reset = FFFFC000h]

Z1\_LINKPOINTER is shown in [Figure 5-5](#) and described in [Table 5-7](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer

**Figure 5-5. Z1\_LINKPOINTER Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17          | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED |    |    |    |    |    |    |    |    |    |    |    |    |    | LINKPOINTER |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    | R-0h        |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 5-7. Z1\_LINKPOINTER Register Field Descriptions**

| Bit   | Field       | Type | Reset | Description   |

Complex bit access types are encoded to fit into small table cells. Table 5-36 shows the codes that are used for access types in this section.

**Table 5-36. DCSM\_Z2\_REGS Access Type Codes**

| Access Type              | Code    | Description  |
|--------------------------|---------|--|
| Read Type                |         |  |
| R                        | R       | Read   |
| R-0                      | R<br>-0 | Read<br>Returns 0s   |
| Write Type               |         |  |
| W                        | W       | Write  |
| Reset or Default Value   |         |  |
| -n                       |         | Value after reset or the default value   |
| Register Array Variables |         |  |
| i,j,k,l,m,n              |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |

**Table 5-36. DCSM\_Z2\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description   |
|-------------|------|---|
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 5.8.3.1 Z2\_LINKPOINTER Register (Offset = 0h) [Reset = FFFFC000h]

Z2\_LINKPOINTER is shown in [Figure 5-33](#) and described in [Table 5-37](#).

Return to the [Summary Table](#).

Zone 2 Link Pointer

**Figure 5-33. Z2\_LINKPOINTER Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

### 5.8.4 DCSM\_COMMON\_REGS Registers

Table 5-56 lists the memory-mapped registers for the DCSM\_COMMON\_REGS registers. All register offset addresses not listed in Table 5-56 should be considered as reserved locations and the register contents should not be modified.

**Table 5-56. DCSM\_COMMON\_REGS Registers**

| Offset | Acronym    | Register Name                    | Write Protection | Section            |
|--------|------------|----------------------------------|------------------|--------------------|
| 0h     | FLSEM      | Flash Wrapper Semaphore Register | EALLOW           | <a href="#">Go</a> |
| 8h     | SECTSTAT1  | Flash Sectors Status Register 1  |                  | <a href="#">Go</a> |
| Ah     | SECTSTAT2  | Flash Sectors Status Register 2  |                  | <a href="#">Go</a> |
| Ch     | SECTSTAT3  | Flash Sectors Status Register 3  |                  | <a href="#">Go</a> |
| 10h    | RAMSTAT1   | RAM Status Register 1            |                  | <a href="#">Go</a> |
| 18h    | SECERRSTAT | Security Error Status Register   |                  | <a href="#">Go</a> |
| 1Ah    | SECERRCLR  | Security Error Clear Register    |                  | <a href="#">Go</a> |
| 1Ch    | SECERRFRC  | Security Error Force Register    |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 5-57 shows the codes that are used for access types in this section.

**Table 5-57. DCSM\_COMMON\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| R-0                      | R-0  | Read Returns 0s  |
| Write Type               |      |  |
| W                        | W    | Write  |
| W1S                      | W1S  | Write 1 to set   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 5.8.4.1 FLSEM Register (Offset = 0h) [Reset = 0h]

FLSEM is shown in [Figure 5-52](#) and described in [Table 5-58](#).

Return to the [Summary Table](#).

| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    |    | R-0/<br>W1S-0<br>h |

**Table 5-65. SECERRFRC Register Field Descriptions**

| Bit   | Field    | Type    | Reset | Description  |
|-------|----------|---------|-------|--|
| 31-16 | KEY      | R-0/W   | 0h    | In order to write to the ERR bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every write to ERR. Reads will return 0.<br>Reset type: N/A |
| 15-1  | RESERVED | R       | 0h    | Reserved   |
| 0     | ERR      | R-0/W1S | 0h    | A write of '1', along with the proper KEY, sets the SECERRSTST.ERR bit. Write of '0' is ignored. This bit always reads back '0'.<br>Reset type: N/A  |

### 5.8.5 DCSM\_Z1\_OTP Registers

Table 5-66 lists the memory-mapped registers for the DCSM\_Z1\_OTP registers. All register offset addresses not listed in Table 5-66 should be considered as reserved locations and the register contents should not be modified.

**Table 5-66. DCSM\_Z1\_OTP Registers**

| Offset | Acronym            | Register Name                     | Write Protection | Section            |
|--------|--------------------|-----------------------------------|------------------|--------------------|
| 0h     | Z1OTP_LINKPOINTER1 | Zone 1 Link Pointer1              |                  | <a href="#">Go</a> |
| 2h     | Z1OTP_LINKPOINTER2 | Zone 1 Link Pointer2              |                  | <a href="#">Go</a> |
| 4h     | Z1OTP_LINKPOINTER3 | Zone 1 Link Pointer3              |                  | <a href="#">Go</a> |
| 6h     | Z1OTP_JLM_ENABLE   | Zone 1 JTAGLOCK Enable Register   |                  | <a href="#">Go</a> |
| 8h     | Z1OTP_GPREG1       | Zone 1 General Purpose Register 1 |                  | <a href="#">Go</a> |
| Ah     | Z1OTP_GPREG2       | Zone 1 General Purpose Register 2 |                  | <a href="#">Go</a> |
| Ch     | Z1OTP_GPREG3       | Zone 1 General Purpose Register 3 |                  | <a href="#">Go</a> |
| Eh     | Z1OTP_GPREG4       | Zone 1 General Purpose Register 4 |                  | <a href="#">Go</a> |
| 10h    | Z1OTP_PSWDLOCK     | Secure Password Lock              |                  | <a href="#">Go</a> |
| 12h    | Z1OTP_CRCLOCK      | Secure CRC Lock                   |                  | <a href="#">Go</a> |
| 14h    | Z1OTP_JTAGPSWDH0   | JTAG Lock Permanent Password 0    |                  | <a href="#">Go</a> |
| 16h    | Z1OTP_JTAGPSWDH1   | JTAG Lock Permanent Password 1    |                  | <a href="#">Go</a> |
| 18h    | Z1OTP_CMACKKEY0    | Secure Boot CMAC Key 0            |                  | <a href="#">Go</a> |
| 1Ah    | Z1OTP_CMACKKEY1    | Secure Boot CMAC Key 1            |                  | <a href="#">Go</a> |
| 1Ch    | Z1OTP_CMACKKEY2    | Secure Boot CMAC Key 2            |                  | <a href="#">Go</a> |
| 1Eh    | Z1OTP_CMACKKEY3    | Secure Boot CMAC Key 3            |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 5-67 shows the codes that are used for access types in this section.

**Table 5-67. DCSM\_Z1\_OTP Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 5.8.5.1 Z1OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

Z1OTP\_LINKPOINTER1 is shown in [Figure 5-60](#) and described in [Table 5-68](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer1

**Figure 5-60. Z1OTP\_LINKPOINTER1 Register**

|                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Z1OTP_LINKPOINTER1 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-FFFFFFFh         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 5-68. Z1OTP\_LINKPOINTER1 Register Field Descriptions**

| Bit  | Field              | Type | Reset    | Description  |
|------|--------------------|------|----------|--|
| 31-0 | Z1OTP_LINKPOINTER1 | R    | FFFFFFFh | Zone1 Link Pointer 1 location in USER OTP.<br>Note:<br>[1] ECC comparison is disabled for this location<br>[2] When this value is loaded into DCSM, if the bits[31:14] !=0, device will remain in BLOCKED state. Before shipping parts to customers, TI would change the value of these bits to 0s.<br>Reset type: N/A |

### 5.8.5.2 Z1OTP\_LINKPOINTER2 Register (Offset = 2h) [Reset = FFFFFFFFh]

Z1OTP\_LINKPOINTER2 is shown in [Figure 5-61](#) and described in [Table 5-69](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer2

**Figure 5-61. Z1OTP\_LINKPOINTER2 Register**

|                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

**Table 5-70. Z1OTP\_LINKPOINTER3 Register Field Descriptions**

| Bit  | Field              | Type | Reset    | Description  |
|------|--------------------|------|----------|--|
| 31-0 | Z1OTP_LINKPOINTER3 | R    | FFFFFFFh | Zone1 Link Pointer 3 location in USER OTP.<br>Note:<br>[1] ECC comparison is disabled for this location<br>[2] When this value is loaded into DCSM, if the bits[31:14] !=0, device will remain in BLOCKED state. Before shipping parts to customers, TI would change the value of these bits to 0s.<br>Reset type: N/A |

#### 5.8.5.4 Z1OTP\_JLM\_ENABLE Register (Offset = 6h) [Reset = FFFFFFFFh]

Z1OTP\_JLM\_ENABLE is shown in [Figure 5-63](#) and described in [Table 5-71](#).

Return to the [Summary Table](#).

Zone 1 JTAGLOCK Enable Register

**Figure 5-63. Z1OTP\_JLM\_ENABLE Register**

|                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Z1OTP_JLM_ENABLE |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-FFFFFFFh       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 5-71. Z1OTP\_JLM\_ENABLE Register Field Descriptions**

| Bit  | Field            | Type | Reset    | Description  |
|------|------------------|------|----------|--|
| 31-0 | Z1OTP_JLM_ENABLE | R    | FFFFFFFh | Zone1 JLM_ENABLE register location in USER OTP.<br>Note: When this value is loaded into Z1_JLM_ENABLE, if the value is 32-bit all-1s, the JTAGLOCK will be enabled. Before shipping parts to customers, TI will program the default value to 0xFFFF_000F, which will disable the JTAGLOCK feature. Users should program 0xFFFF_0000 to enable the JTAGLOCK feature.<br>Reset type: N/A |

### 5.8.5.5 Z1OTP\_GPREG1 Register (Offset = 8h) [Reset = FFFFFFFFh]

Z1OTP\_GPREG1 is shown in [Figure 5-64](#) and described in [Table 5-72](#).

Return to the [Summary Table](#).

Zone 1 General Purpose Register 1

**Figure 5-64. Z1OTP\_GPREG1 Register**

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 5-83. Z1OTP\_CMACKKEY3 Register Field Descriptions**

| Bit  | Field     | Type | Reset    | Description   |
|------|-----------|------|----------|---|
| 31-0 | CMACKKEY3 | R    | FFFFFFFh | Secure Boot CMAC Key 3 (bits 127:96) location in User Z1 OTP. This value is dummy loaded into the CMACKKEY3 register. Reset type: N/A |

### 5.8.6 DCSM\_Z2\_OTP Registers

Table 5-84 lists the memory-mapped registers for the DCSM\_Z2\_OTP registers. All register offset addresses not listed in Table 5-84 should be considered as reserved locations and the register contents should not be modified.

**Table 5-84. DCSM\_Z2\_OTP Registers**

| Offset | Acronym            | Register Name                     | Write Protection | Section            |
|--------|--------------------|-----------------------------------|------------------|--------------------|
| 0h     | Z2OTP_LINKPOINTER1 | Zone 2 Link Pointer1              |                  | <a href="#">Go</a> |
| 2h     | Z2OTP_LINKPOINTER2 | Zone 2 Link Pointer2              |                  | <a href="#">Go</a> |
| 4h     | Z2OTP_LINKPOINTER3 | Zone 2 Link Pointer3              |                  | <a href="#">Go</a> |
| 8h     | Z2OTP_GPREG1       | Zone 2 General Purpose Register 1 |                  | <a href="#">Go</a> |
| Ah     | Z2OTP_GPREG2       | Zone 2 General Purpose Register 2 |                  | <a href="#">Go</a> |
| Ch     | Z2OTP_GPREG3       | Zone 2 General Purpose Register 3 |                  | <a href="#">Go</a> |
| Eh     | Z2OTP_GPREG4       | Zone 2 General Purpose Register 4 |                  | <a href="#">Go</a> |
| 10h    | Z2OTP_PSWDLOCK     | Secure Password Lock              |                  | <a href="#">Go</a> |
| 12h    | Z2OTP_CRCLOCK      | Secure CRC Lock                   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 5-85 shows the codes that are used for access types in this section.

**Table 5-85. DCSM\_Z2\_OTP Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 5.8.6.1 Z2OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

Z2OTP\_LINKPOINTER1 is shown in [Figure 5-76](#) and described in [Table 5-86](#).

Return to the [Summary Table](#).

Zone 2 Link Pointer1

## 6.1 Introduction to Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of Flash. It also includes information on Flash and OTP power modes, how to improve Flash performance by enabling the Flash prefetch/cache mode, and the SECDED safety feature.

### 6.1.2 Features

Features of Flash memory include:

- Three Flash banks (Bank0, 1,2) (refer to the device data manual for the size of the Flash bank)
- 128 bits (bank width) can be programmed at a time along with ECC
- Multiple sectors providing the option of leaving some sectors programmed and only erasing specific sectors
- User-programmable OTP locations (in user-configurable DCSM OTP, also called USER OTP) for configuring security, OTP boot-mode and boot-mode select pins (if the user is unable to use the factory-default boot-mode select pins)
- Flash pump shared by the two banks
- Enhanced performance using the code-prefetch mechanism and data cache in FMC
- Configurable wait states to give the best performance for a given execution speed
- Safety Features:
  - SECDED-single error correction and double error detection is supported in the FMC
  - Address bits are included in ECC
  - Test mode to check the health of ECC logic
- Supports low-power modes for Flash bank and pump for power savings
- Built-in power mode control logic
- Integrated Flash program/erase state machine (FSM) in the FMC
  - Simple Flash API algorithms
  - Fast erase and program times (refer to the device data manual for details)
- Dual Code Security Module (DCSM) to prevents access to the Flash by unauthorized persons (refer to DCSM chapter for details)

### 6.1.3 Flash Tools

Texas Instruments provides the following tools for Flash:

- Code Composer Studio™ (CCS) IDE - the development environment with integrated Flash plugin. TI recommends performing a debug reset and restart after programming the code into Flash using CCS.
- Flash API Library - a set of software peripheral functions to erase/program Flash
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS is required.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

### 6.1.4 Default Flash Configuration

The following are Flash module configuration settings at power-up:

- Dedicated Flash banks are in sleep mode (BNKPWR bit field in the FBFALLBAC register)
- Shared pump is in sleep mode (PMPPWR bit field in the FPAC1 register)
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled in all three FMCs
- Bank and pump active grace periods are set to 0x0 (refer to the BAGP field in the FBAC register and PAGP bit field in the FPAC2 register)

Note that boot ROM changes the BNKPWR and PMPPWR bit fields to active mode.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the FRD\_INTF\_CTRL register, to achieve optimum system performance. Software that configures Flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from Flash memory.

---

#### Note

Before initializing wait-states, turn off the pre-fetch and data caching in the FRD\_INTF\_CTRL register.

---

## 6.2 Flash Bank, OTP, and Pump

There is a dedicated Flash bank for CPU subsystem. Also, there is a one-time programmable (OTP) memory called USER OTP, which the user can program only once and cannot erase. Flash and OTP are uniformly mapped in both program and data memory space.

CPU subsystem have a TI-OTP that contains manufacturing information like settings used by the Flash state machine for erase and program operations, and so on. Users may read TI-OTP but it cannot be programmed or erased. For memory map and size information of the Flash Banks, TI-OTP, USER OTP, and corresponding ECC locations, refer to the device data manual.

[Figure 5-2](#) shows the user-programmable OTP locations in USER-OTP. For more information on the functionality of these fields, refer to the *Dual Code Security Module (DCSM)* and the *ROM Code and Peripheral Booting* chapters.

### 6.3 Flash Module Controller (FMC)

The CPU interfaces with the FMC, which in turn interfaces with the Flash bank and the pump, to perform erase or program operations, to read data, and execute code from the Flash bank.

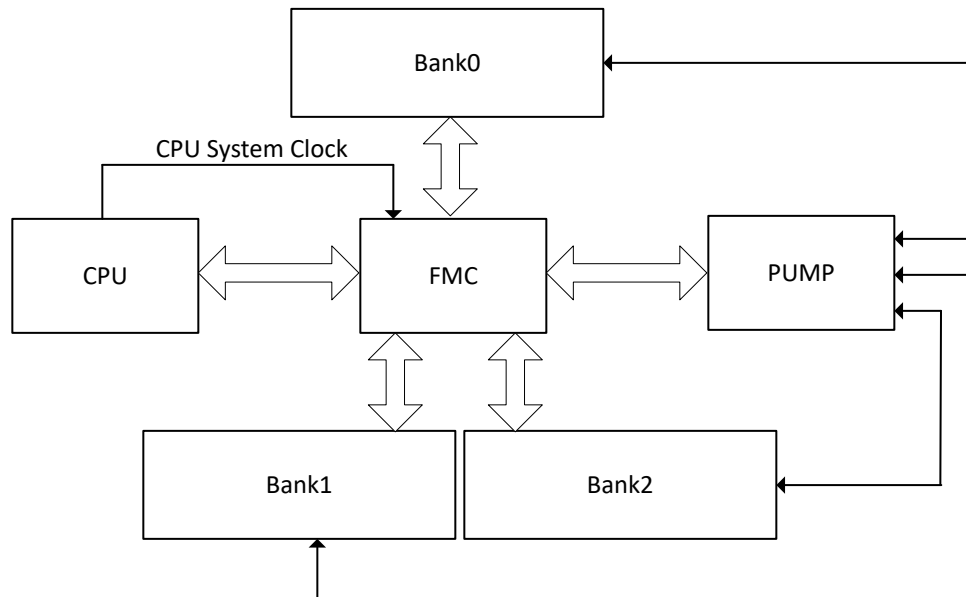

Figure 6-1. FMC Interface with Core, Bank and Pump

## 6.4 Flash and OTP Power-Down Modes and Wakeup

The Flash bank and pump consume a significant amount of power when active. The Flash module provides a mechanism to power-down Flash banks and pump. Special timers automatically sequence the power-up of the CPU Flash bank. The charge pump module has its own independent power-up timer as well.

The Flash bank and OTP operate in three power modes: Sleep (lowest power), Standby, and Active (highest power)

- **Sleep State**  
This is the state after a device reset. In this state, a CPU data read or opcode fetch will automatically initiate a change in power mode to the standby state and then to the active state. During this transition time to the active state, the CPU will automatically be stalled.
- **Standby State**  
This state uses more power than the sleep state, but takes a shorter time to transition to the active or read state. In this state, a CPU data read or opcode fetch will automatically initiate a change in power mode to the active state. During this transition time to the active state, the CPU will automatically be stalled. Once the Flash/OTP has reached the active state, the CPU access will complete as normal.
- **Active or Read State**  
In this state, the bank and pump are in active power mode state (highest power)

The charge pump operates in two power modes:

- Sleep (lowest power)
- Active (highest power)

Any access to any Flash bank/OTP causes the charge pump to go into active mode, if it is in sleep mode.

An erase or program command causes the charge pump and bank to become active. If any bank is in active or in standby mode, the charge pump will be in active mode, independent of the pump power mode control configuration (PMPPWR bit field in the FPAC1 register). While the pump is in sleep state, a charge pump sleep down counter holds a user-configurable value (PSLEEP bit field in the FPAC1 register) and when the charge pump exits sleep power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles (prescaled clock is  $\text{SYSCLK}/2$ ) before putting the charge pump into active power mode.

Following are the number of cycles it will take for the bank and pump to wake up from low power modes.

1. Pump sleep to active =  $\text{PSLEEP} * (\text{SYSCLK}/2)$  cycles
2. Bank sleep to standby = 254 Flash clock cycles
3. Bank standby to active = 55 Flash clock cycles

Where: Flash clock =  $\text{SYSCLK}/(\text{RWAIT}+1)$

## 6.5 Active Grace Period

The active grace period (AGP) can be used to optimize the Flash module power consumption versus access time. Faster access times are associated with higher-power modes of operation. At one extreme, the power control logic could attempt to reduce power consumption by putting the bank and charge pump into a low-power mode immediately at the end of every Flash access. However, if accesses are only a few cycles apart, this can actually increase power consumption versus leaving the Flash powered, because the bank and charge pump consume more power during Flash startup and access.

The active grace periods allows the bank and/or charge pump to be maintained in active mode for a specified period following an access. This is done in anticipation of another read within the AGP time, to allow the subsequent read to have a faster access and spend less time dissipating power, than if the bank went into one of the low power modes immediately. If the next access does not occur within the AGP time, the power control logic can automatically put the bank and/or charge pump into a low-power mode to reduce power consumption during long periods of inactivity.

The AGP value is programmed by a set of programmable counters (FBAC and FPAC2) which keep the Flash bank or charge pump in active mode until the counter expires, at which time the bank or charge pump reverts to its fallback power mode as defined in the FBFALLBACK and FPAC1 (refer to PMPPWR bit-field) registers. The application software can configure the fallback power mode to reduce power consumption, or configure it to be active mode to keep the bank active regardless of counter settings (default is SLEEP). The charge pump AGP counter remains in its initialized state when the bank is active, including the AGP counter of the bank. The charge pump AGP counter begins counting when the bank has become inactive.

The application software can check the current power mode of Flash bank and charge pump by reading the FBPRDY register.

## 6.6 Flash and OTP Performance

Once the Flash bank and pump are in the active power state, a read or fetch access can be classified as a Flash access (access to an address location in Flash) or an OTP access (access to an address location in OTP).

Once the CPU throws an access to a Flash memory address, data is returned after RWAIT+1 number of SYSCLK cycles.

For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait-states and is configurable using the RWAIT bit-field in the FRDCNTL register. At reset, the RWAIT bit-field defaults to a worst-case wait-state count (15), and therefore needs to be initialized for the appropriate number of wait states to improve performance, based on the CPU clock rate and the access time of the Flash. The Flash supports 0-wait accesses when the RWAIT bits are set to zero. This assumes that the CPU speed is low enough to accommodate the access time.

For a given system clock frequency, RWAIT has to be configured using the following formula:

For C28x Flash Bank: 
$$RWAIT = \text{ceiling}[(SYSCLK/FCLK)-1]$$

where SYSCLK is the system operating frequency for CPU1 and CPU2

where FCLK is Flash clock frequency

FCLK should be  $\leq FCLK_{\text{max}}$ , allowed maximum Flash clock frequency at RWAIT=0.

If RWAIT results in a fractional value when calculated using the above formula, RWAIT has to be rounded up to the nearest integer.

## 6.7 Flash Read Interface

This section provides details about the data read modes to access Flash bank/OTP and the configuration registers that control the read interface. In addition to a standard read mode, the FMC has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

### 6.7.1 C28x-FMC Flash Read Interface

#### 6.7.1.1 Standard Read Mode

Standard read mode is defined as the read mode in effect when code prefetch-mechanism and data cache are disabled. It is also the default read mode after reset. During this mode, each read access to Flash is decoded by the Flash wrapper to fetch the data from the addressed location and the data is returned after the RWAIT+1 number of cycles (except User OTP).

Prefetch buffers associated with prefetch mechanism and data cache are bypassed in standard read mode; therefore, every access to the Flash/OTP is used by the CPU immediately, and every access creates a unique Flash bank access.

Standard read mode is the recommended mode for lower system frequency operation in which RWAIT can be set to zero to provide single-cycle access operation. The FMC can operate at higher frequencies using standard read mode at the expense of adding wait states. At higher system frequencies, it is recommended to enable cache and prefetch mechanisms to improve performance. Refer to the device specific data manual to determine the maximum Flash frequency allowed in standard read mode (that is, maximum Flash clock frequency with RWAIT=0, FCLK<sub>MAX</sub>).

#### 6.7.1.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from sequential memory addresses, except when a discontinuity occurs. Usually the portion of the code that resides in sequential addresses makes up the majority of the application code and is referred to as linear code. To improve the performance of linear code execution, a Flash prefetch-mechanism has been implemented. [Figure 6-2](#) illustrates how this mode functions.

This prefetch mechanism does a look-ahead prefetch on linear address increments starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. Setting the PREFETCH\_EN bit in the FRD\_INTF\_CTRL register enables this prefetch mode.

An instruction fetch from the Flash or OTP reads out 128 bits per access. The starting address of the access from Flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. With the Flash prefetch mode enabled, the 128 bits read from the instruction fetch are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the Flash bank, it is likely that there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time it takes to process these instructions, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 128 bits. In this manner, the Flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash or OTP is improved significantly.

---

#### Note

If the prefetch mechanism is enabled, then the last two rows (16 16-bit words, 256 bits) of the bank that does not have a valid address beyond its boundary should not be used, because the prefetch logic that does a look-ahead prefetch will try to fetch from outside the bank and would result in an ECC error.

---

**Figure 6-2. Flash Prefetch Mode**

The Flash prefetch is aborted only on a PC discontinuity caused by executing an instruction such as a branch, BANZ, call, or loop. When this occurs, the prefetch mechanism is aborted and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the Flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the Flash and OTP, the prefetch is aborted and begins again only when a branch is made back into the Flash or OTP. The Flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch buffer capability and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When this read happens, the prefetch buffer is bypassed but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read will be stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

### 6.7.1.2.1 Data Cache

Along with the prefetch mechanism, a data cache of 128-bits wide is also implemented to improve data-space read performance. This data cache will not be filled by the prefetch mechanism. When any kind of data-space read is made by the CPU from an address in the bank, and if the data corresponding to the requested address is not in the data cache, then 128 bits of data will be read from the bank and loaded in the data cache. This data is eventually sent to the CPU for processing. The starting address of the access from Flash is automatically aligned to a 128-bit boundary such that the requested address location is within the 128 bits to be read from the bank. By default, this data cache is disabled and can be enabled by setting DATA\_CACHE\_EN bit in the FRD\_INTF\_CTRL register. Note that the data cache gets bypassed when RWAIT is configured as zero.

Some other points to keep in mind when working with Flash/ OTP:

- Reads of the USER OTP locations are hardwired for 10 wait states. The RWAIT bits have no effect on these locations.
- CPU writes to the Flash or OTP memory map areas are ignored. They complete in a single cycle.
- If a security zone is in the locked state and the respective password lock bits are not all 1s, then,
  - Data reads to Zx-CSMPSWD will return 0
  - Program space reads to Zx-CSMPSWD will return 0
  - Program fetches to Zx-CSMPSWD will return 0
- When the Code Security Module (CSM) is secured, reads to the Flash/OTP memory map area from outside the secure zone take the same number of cycles as a normal access. However, the read operation returns a zero.
- The arbitration scheme in FMC prioritizes CPU accesses in the fixed priority order of data read (highest priority), program space read and program fetches/program prefetches (lowest priority).
- When FSM interface is active for erase/program operations, data in the prefetch buffers and data cache in FMC will be flushed.
- When data cache is enabled, the debugger memory window open to Flash/OTP space will invoke data caching. Hence, debugger memory window should not be left open for Flash/OTP space when benchmarking the code for performance.

---

#### Note

Flash contents are verified for ECC correctness before they enter prefetch buffer or data cache and not inside the prefetch buffer or data cache itself.

---

## 6.8 Erase/Program Flash

Flash memory may be programmed either by using the CCS Flash plugin or by using Uniflash. If these methods are not feasible in an application, the API may be used. The Flash memory should be programmed, erased, and verified only by using the Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations.

A typical flow to program Flash is:

Erase → Program → Verify

### 6.8.1 Erase

When the target Flash is erased, it reads as all 1's. This state is called 'blank.' The erase function must be executed before programming. The user should NOT skip erase on sectors that read as 'blank' because these sectors may require additional erasing due to marginally erased bits columns. The FSM provides an Erase Sector command to erase the target sector. The erase function erases the data and the ECC together. Bank erase is also supported in this device.

---

**Note**

It is important to provide the correct sector mask for the bank erase command. If the mask is mistakenly chosen to erase an inaccessible sector (belongs to another security zone), the bank erase command will continue attempting to erase the sector endlessly and the FSM will never exit (since erase will not succeed). To avoid such a situation, user must take care to provide the correct mask. However, given that there is a chance of choosing an incorrect mask, TI suggests to initialize the max allowed erase pulses to zero after the max number of pulses are issued by the FSM for the bank erase operation. This will ensure that the FSM will end the bank erase command after trying to erase the inaccessible sector up to the max allowed erase pulses.

The Example\_EraseBanks() function in the C2000Ware's Flash API usage example depicts the implementation of this sequence (content of the while loop waiting for the FSM to complete the bank erase command). Users must use this code as-is irrespective of whether or not security is used by the application to also ensure that the FSM exits from bank erase operations in case of an erase-failure.

---

**6.8.2 Program**

The FSM provides a command to program the USER OTP and Flash. This command is also used to program ECC check bits.

---

**Note**

The main array Flash programming must be aligned to 64-bit address boundaries and each 64-bit word may only be programmed once per write/erase cycle.

The DCSM OTP programming must be aligned to 128-bit address boundaries and each 128-bit word may only be programmed once. The exceptions are:

- The DCSM Zx-LINKPOINTER1 and Zx-LINKPOINTER2 values in the DCSM OTP should be programmed together, and may be programmed one bit at a time as required by the DCSM operation.
  - The DCSM Zx-LINKPOINTER3 values in the DCSM OTP may be programmed one bit at a time as required by the DCSM operation.
- 

**6.8.3 Verify**

After programming, the user must perform verify using API function Fapi\_doVerify(). This function verifies the Flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default), catches single-bit errors, double-bit errors, and address errors whenever the CPU reads/fetches from a Flash address.

**6.9 Error Correction Code (ECC) Protection**

CPU1-FMC and CPU2-FMC contain an embedded single error correction and double error detection (SECEDED) module. SECEDED, when enabled, provides the capability to screen out memory faults. SECEDED can detect and correct single-bit data errors and detect address errors/double-bit data errors. For every 64 bits of Flash/OTP data (aligned on a 64-bit memory boundary) that is programmed, eight ECC check bits have to be calculated and programmed in ECC memory space. Refer to the device data manual for the Flash/OTP ECC memory map. SECEDED works with a total of eight user-calculated error correction code (ECC) check bits associated with each 64-bit wide data word and its corresponding 128-bit memory-aligned address. Users must program ECC check bits along with Flash data. TI recommends using the AutoEccGeneration option available in the Plugin/API to program ECC. Users can use the Flash API to calculate and program ECC data along with Flash data. Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the

Flash programming tool integrated with the Code Composer Studio™ IDE, uses the Flash API to generate and program ECC data.

Figure 6-3 illustrates the ECC logic inputs and outputs.

During an instruction fetch or a data read operation, the 19 most significant address bits (three least significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of Flash banks/ECC memory map area, pass through the SECDDED logic and the eight checkbits are produced in FMC. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the SECDDED module to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- A non-correctable error (double bit data error or address error) occurred

**Figure 6-3. ECC Logic Inputs and Outputs**

If the SECDDED logic finds a single-bit error in the address field, then it is considered to be a non-correctable error.

**Note**

Since ECC is calculated for an entire 64-bit data, a non 64-bit read such as a byte read or a half-word read will still force the entire 64-bit data to be read and calculated, but only the byte or half-word will be actually used by the CPU.

This ECC (SECDDED) feature is enabled at reset. The ECC\_ENABLE register can be used to configure (enable/disable) the ECC feature. The ECC for the application code must be programmed. There are two SECDDED modules in each FMC. Out of the 128-bit data (aligned on a 128-bit memory boundary) read from the bank/OTP

address, the lower 64 bits of data and corresponding 8 ECC bits (read from user programmable ECC memory area) are fed as inputs to one SECDED module along with 128-bit aligned 19-bit address from where data has been read. The upper 64 bits of data and corresponding 8 ECC bits are fed as inputs to another SECDED module in parallel, along with 128-bit aligned 19-bit address. Each of the SECDED modules evaluate their inputs and determine if there is any single-bit data error or double-bit data error/address error.

ECC logic will be bypassed when the 64 data bits and the associated ECC bits fetched from the bank are either all ones or zeros.

### 6.9.1 Single-Bit Data Error

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in Flash data or in ECC data, then it is considered as a single-bit data error. The SECDED module detects and corrects single-bit errors, if any, in the 64-bit Flash data or eight ECC check bits read from the Flash/ECC memory map before the read data is provided to the CPU.

When SECDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the single-bit error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the SINGLE\_ERR\_ADDR\_LOW register. If the single-bit error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the SINGLE\_ERR\_ADDR\_HIGH register.
- Whether the error occurred in data bits or ECC bits – the ERR\_TYPE\_L and ERR\_TYPE\_H bit fields in the ERR\_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64-bits, or the upper 64-bits respectively, of a 128-bit memory-aligned data.
- Bit position at which error occurred – the ERR\_POS\_L and ERR\_POS\_H bit fields in the ERR\_POS register indicate the bit position of the error in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned data.
- Whether the corrected value is 0 (FAIL\_0\_L, FAIL\_0\_H flags in ERR\_STATUS register)
- Whether the corrected value is 1 (FAIL\_1\_L, FAIL\_1\_H flags in ERR\_STATUS register)
- A single bit error counter that increments on every single bit error occurrence (ERR\_CNT register) until a user-configurable threshold (see ERR\_THRESHOLD) is met
- A flag that gets set when one or more single-bit errors occurs after ERR\_CNT equals ERR\_THRESHOLD (SINGLE\_ERR\_INT\_FLG flag in the ERR\_INTFLG register)

When the ERR\_CNT value equals THRESHOLD+1 value and a single bit error occurs, the SINGLE\_ERR\_INT flag is set, and an interrupt (FLASH\_CORRECTABLE\_ERR on C28x PIE has to be enabled for interrupt, if needed) is fired. The SINGLE\_ERR interrupt will not be fired again until the SINGLE\_ERR\_INTFLG is cleared. If the single error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR\_INTCLR register, the error interrupt will not come again, as this is an edge-based interrupt.

When multiple single-bit errors get caught by ECC logic, Flash ECC registers will hold the information related to the latest ECC error. When multiple single-bit errors get caught, both FAIL\_0\_L and FAIL\_1\_L (and/or FAIL\_0\_H and FAIL\_1\_H) might get set, indicating that single-bit fail0/fail1 occurred in different 64-bit aligned addresses.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash memory will cause the single-bit error flag to get set when there is a single-bit error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

### 6.9.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data/ECC. When SECDED finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the uncorrectable error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the UNC\_ERR\_ADDR\_LOW register. If the uncorrectable error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the UNC\_ERR\_ADDR\_HIGH register.

- A flag is set indicating that an uncorrectable error occurred – the UNC\_ERR\_L and UNC\_ERR\_H flags in the ERR\_STATUS register indicate the uncorrectable error occurrence in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned data.
- A flag is set indicating that an uncorrectable error interrupt is fired (UNC\_ERR\_INTFLG in ERR\_INTFLG register)

When an uncorrectable error occurs, the UNC\_ERR\_INTFLG bit is set and an uncorrectable error interrupt is fired. This uncorrectable error interrupt generates an NMI, if enabled. If an uncorrectable error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR\_INTCLR register, an error interrupt will not come again, as this is an edge based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash memory will cause the uncorrectable error flag to get set when there is a uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data. NMI will occur on the CPU for a read of any address location within a 128-bit aligned Flash memory, when there is an uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

### 6.9.3 SECEDED Logic Correctness Check

Since error detection and correction logic are part of safety-critical logic, safety applications may need to ensure that the SECEDED logic is always working properly. For these safety concerns, in order to ensure the correctness of the SECEDED logic, an ECC test mode is provided to test the correctness of ECC logic periodically. In this ECC test mode, data/ECC and address inputs to the ECC logic are controlled by the ECC test mode registers FDATAH\_TEST, FDATA\_L\_TEST, FECC\_TEST, and FADDR\_TEST, respectively. Using this test mode, users can introduce single-bit errors, double-bit errors, or address errors and check whether or not SECEDED logic is catching those errors. Users can also check if SECEDED logic is reporting any false errors when no errors are introduced.

This ECC test mode can be enabled by setting the ECC\_TEST\_EN bit in the FECC\_CTRL register. When ECC test mode is enabled, the CPU cannot read the data from Flash and instead the CPU gets data from the ECC test mode registers (FDATAH\_TEST/FDATA\_L\_TEST). This is because ECC test mode registers (FDATAH\_TEST, FDATA\_L\_TEST, FECC\_TEST) are multiplexed with data from the Flash. Hence, the CPU should not read/fetch from Flash when ECC test mode is enabled. For this reason, ECC test mode code should be executed from RAM and not from Flash.

Only one of the SECEDED modules (out of the two SECEDED modules that work on lower 64 bits and upper 64 bits of a read 128-bit data) at a time can be tested. The ECC\_SELECT bit in the FECC\_CTRL register can be configured by users to select one of the SECEDED modules for test.

To test the ECC logic using ECC test mode, you can follow the steps:

1. Obtain the ECC for a given Flash address (128-bit aligned) and 64-bit data by using the Auto ECC generation option provided in Flash API.
2. Develop an application to test ECC logic using the above data. In this application:
  - Write the 128-bit aligned 19-bit Flash address in FADDR\_TEST
  - Write 64-bit data in FDATAx\_TEST (FDATA\_L\_TEST and FDATAH\_TEST) registers
  - Write the corresponding 8-bit ECC in the FECC\_TEST register
  - In any of the above three steps, users can insert errors (single-bit data error or double-bit data error or address error or single-bit ECC error or double-bit ECC error) so that they can check whether or not ECC logic is able to catch the errors
  - Select the ECC logic block (lower 64-bits or upper 64-bits) which needs to be tested using the ECC\_SELECT bit in the FECC\_CTRL register
  - Enable ECC test mode using the ECC\_TEST\_EN bit in FECC\_CTRL register
  - Write a value of 1 in the DO\_ECC\_CALC bit in FECC\_CTRL register to enable ECC test logic for a single cycle to evaluate the address, data, ECC in FADDR\_TEST, FDATAx\_TEST and FECC\_TEST registers for ECC errors

Once the above ECC test mode registers are written by the user:

- The FECC\_OUTH register holds the data output bits 63:32 from the SECDED block under test.
- The FECC\_OUTL register holds the data output bits 31:0 from the SECDED block under test.
- The FECC\_STATUS register holds the status of single-bit error occurrence, uncorrectable error occurrence, and error position of single-bit error in data/check bits.

## 6.10 Reserved Locations Within Flash and OTP

When allocating code and data to Flash and OTP memory, keep the following reserved locations in mind:

- The entire OTP has reserved user-configurable locations for security and boot process. For more details on the functionality of these fields, refer to *Dual Code Security Module (DCSM)* and the *ROM Code and Peripheral Booting* chapters.
- Refer to the *ROM Code and Peripheral Booting* chapter for reserved locations in Flash for real-time operating system usage and a boot-to-Flash entry point. A boot-to-Flash entry point is reserved for an entry-into-Flash branch instruction. When the boot-to-Flash boot option is used, the boot ROM will jump to this address in Flash. If the user programs a branch instruction here, that will then redirect code execution to the entry point of the application.

## 6.11 Procedure to Change the Flash Control Registers

During Flash configuration, no accesses to the Flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, you should follow the procedure shown below for any code that modifies the Flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the Flash configuration code (that writes to Flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the Flash configuration cannot execute from the Flash or OTP. It must reside in RAM.
3. Execute the Flash configuration code (should be located in RAM) that writes to Flash control registers like FRDCNTL, FRD\_INTF\_CTRL, and so on.
4. At the end of the Flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function that might reside in RAM or Flash/OTP and continue execution.

## 6.12 Software

### 6.12.1 FLASH Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/f28003x/examples/flash

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 6.12.1.1 Flash ECC Test Mode

FILE: flash\_ex2\_ecc\_test\_mode.c

This example demonstrates ECC Test mode.

#### 6.12.1.2 Flash Programming with AutoECC, DataAndECC, DataOnly and EccOnly

FILE: flashapi\_ex1\_programming.c

This example demonstrates how to program Flash using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

#### External Connections

- None.

#### Watch Variables

- None.

## 6.13 Flash Registers

This section describes the Flash Module Registers.

### 6.13.1 FLASH Base Address Table

**Table 6-1. FLASH Base Address Table**

| Bit Field Name |                 | DriverLib Name  | Base Address | CPU1 | DMA | HIC | CLA | Pipeline Protected |
|----------------|-----------------|-----------------|--------------|------|-----|-----|-----|--------------------|
| Instance       | Structure       |                 |              |      |     |     |     |                    |
| Flash0CtrlRegs | FLASH_CTRL_REGS | FLASH0CTRL_BASE | 0x0005_F800  | YES  | -   | -   | -   | YES                |
| Flash0EccRegs  | FLASH_ECC_REGS  | FLASH0ECC_BASE  | 0x0005_FB00  | YES  | -   | -   | -   | YES                |

### 6.13.2 FLASH\_CTRL\_REGS Registers

Table 6-2 lists the memory-mapped registers for the FLASH\_CTRL\_REGS registers. All register offset addresses not listed in Table 6-2 should be considered as reserved locations and the register contents should not be modified.

**Table 6-2. FLASH\_CTRL\_REGS Registers**

| Offset | Acronym       | Register Name                         | Write Protection | Section            |
|--------|---------------|---------------------------------------|------------------|--------------------|
| 0h     | FRDCNTL       | Flash Read Control Register           | EALLOW           | <a href="#">Go</a> |
| 1Eh    | FBAC          | Flash Bank Access Control Register    | EALLOW           | <a href="#">Go</a> |
| 20h    | FBFALLBACK    | Flash Bank Fallback Power Register    | EALLOW           | <a href="#">Go</a> |
| 22h    | FBPRDY        | Flash Bank Pump Ready Register        | EALLOW           | <a href="#">Go</a> |
| 24h    | FPAC1         | Flash Pump Access Control Register 1  | EALLOW           | <a href="#">Go</a> |
| 26h    | FPAC2         | Flash Pump Access Control Register 2  | EALLOW           | <a href="#">Go</a> |
| 2Ah    | FMSTAT        | Flash Module Status Register          | EALLOW           | <a href="#">Go</a> |
| 180h   | FRD_INTF_CTRL | Flash Read Interface Control Register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 6-3 shows the codes that are used for access types in this section.

**Table 6-3. FLASH\_CTRL\_REGS Access Type Codes**

| Access Type              | Code | Description  |
|--------------------------|------|--|
| Read Type                |      |  |
| R                        | R    | Read   |
| Write Type               |      |  |
| W                        | W    | Write  |
| Reset or Default Value   |      |  |
| -n                       |      | Value after reset or the default value   |
| Register Array Variables |      |  |
| i,j,k,l,m,n              |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                        |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 6.13.2.1 FRDCNTL Register (Offset = 0h) [Reset = F00h]

FRDCNTL is shown in [Figure 6-4](#) and described in [Table 6-4](#).

Return to the [Summary Table](#).

Flash Read Control Register

**Figure 6-4. FRDCNTL Register**

|          |    |    |    |        |    |    |    |          |    |    |    |    |    |    |    |
|----------|----|----|----|--------|----|----|----|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27     | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RESERVED |    |    |    |        |    |    |    |          |    |    |    |    |    |    |    |
| R-0h     |    |    |    |        |    |    |    |          |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11     | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RESERVED |    |    |    | RWAIT  |    |    |    | RESERVED |    |    |    |    |    |    |    |
| R-0h     |    |    |    | R/W-Fh |    |    |    | R-0h     |    |    |    |    |    |    |    |

**Table 6-4. FRDCNTL Register Field Descriptions**

| Bit   | Field    | Type | Reset | Description   |
|-------|----------|------|-------|---|
| 31-16 | RESERVED | R    | 0h    | Reserved  |
| 15-12 | RESERVED | R    | 0h    | Reserved  |
| 11-8  | RWAIT    | R/W  | Fh    | Random read waitstate<br>These bits indicate how many waitstates are added to a flash read/ fetch access. The RWAIT value can be set anywhere from 0 to 0xF. For a flash access, data is returned in RWAIT+1 SYSCLK cycles.<br>Note: The required wait states for each SYSCLK frequency can be found in the device data manual.<br>Reset type: SYSRSn |
| 7-0   | RESERVED | R    | 0h    | Reserved  |

### 6.13.2.2 FBAC Register (Offset = 1Eh) [Reset = Fh]

FBAC is shown in [Figure 6-5](#) and described in [Table 6-5](#).

Return to the [Summary Table](#).

Flash Bank Access Control Register

**Figure 6-5. FBAC Register**

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |          |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|----------|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14 | 13 | 12 | 11 | 10 | 9        | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | BAGP   |    |    |    |    |    | RESERVED |   |   |   |   |   |   |   |   |   |
| R-0h     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | R/W-0h |    |    |    |    |    | R/W-Fh   |   |   |   |   |   |   |   |   |   |

**Table 6-5. FBAC Register Field Descriptions**

| Bit   | Field    | Type | Reset | Description  |
|-------|----------|------|-------|--|
| 31-16 | RESERVED | R    | 0h    | Reserved   |
| 15-8  | BAGP     | R/W  | 0h    | Bank Active Grace Period. These bits contain the starting count value for the BAGP down counter. Any access to a given bank causes its BAGP counter to reload the BAGP value for that bank. After the last access to this flash bank, the down counter delays from 0 to 255 prescaled SYSCLK clock cycles before putting the bank into one of the fallback power modes as determined by the FBFALLBACK register. This value must be greater than 1 when the fallback mode is not ACTIVE.<br>Note: The prescaled clock used for the BAGP down counter is a clock divided by 16 from input SYSCLK.<br>Reset type: SYSRSn |
| 7-0   | RESERVED | R/W  | Fh    | Reserved   |

### 6.13.2.3 FBFALLBACK Register (Offset = 20h) [Reset = 0h]

FBFALLBACK is shown in [Figure 6-6](#) and described in [Table 6-6](#).

Return to the [Summary Table](#).

Flash Bank Fallback Power Register

**Figure 6-6. FBFALLBACK Register**

**Table 6-9. FPAC2 Register Field Descriptions**

| Bit   | Field    | Type | Reset | Description   |
|-------|----------|------|-------|---|
| 31-16 | RESERVED | R    | 0h    | Reserved  |
| 15-0  | PAGP     | R/W  | 0h    | <p>Pump Active Grace Period. This register contains the starting count value for the PAGP mode down counter. Any access to flash memory causes the counter to reload with the PAGP value. After the last access to flash memory, the down counter delays from 0 to 65535 prescaled SYSCLK clock cycles before entering one of the charge pump fallback power modes as determined by PUMPPWR in the FPAC1 register.</p> <p>Note: The PAGP down counter is clocked by the same prescaled clock as the BAGP down counter which is divided by 16 of input SYSCLK.</p> <p>Reset type: SYSRSn</p> |

### 6.13.2.7 FMSTAT Register (Offset = 2Ah) [Reset = 0h]

FMSTAT is shown in [Figure 6-10](#) and described in [Table 6-10](#).

Return to the [Summary Table](#).

Flash Module Status Register

| 20h    | FECC_CTRL            | ECC Control                      | EALLOW           | <a href="#">Go</a> |
| 22h    | FOUTH_TEST           | Test Data Out High               | EALLOW           | <a href="#">Go</a> |
| 24h    | FOUTL_TEST           | Test Data Out Low                | EALLOW           | <a href="#">Go</a> |
| 26h    | FECC_STATUS          | ECC Status                       | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 6-13 shows the codes that are used for access types in this section.

**Table 6-13. FLASH\_ECC\_REGS Access Type Codes**

| Access Type              | Code    | Description                               |
|--------------------------|---------|---|
| Read Type                |         |   |
| R                        | R       | Read                                      |
| R-0                      | R<br>-0 | Read<br>Returns 0s                        |
| Write Type               |         |   |
| W                        | W       | Write                                     |
| W1S                      | W<br>1S | Write<br>1 to set                         |
| Reset or Default Value   |         |   |
| -n                       |         | Value after reset or the default<br>value |
| Register Array Variables |         |   |

**Table 6-13. FLASH\_ECC\_REGS Access Type Codes  
(continued)**

| Access Type | Code | Description  |
|-------------|------|--|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.  |

### 6.13.3.1 ECC\_ENABLE Register (Offset = 0h) [Reset = Ah]

ECC\_ENABLE is shown in [Figure 6-12](#) and described in [Table 6-14](#).

Return to the [Summary Table](#).

ECC Enable

**Figure 6-12. ECC\_ENABLE Register**

|          |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows it to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

## 7.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

### 7.1.2 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
  - Complete bus architecture:
    - Program Address Bus (PAB) and Program Data Bus (PDB)
    - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
  - Independent eight stage pipeline.
  - 16-bit program counter (MPC)
  - Four 32-bit result registers (MR0-MR3)
  - Two 16-bit auxiliary registers (MAR0, MAR1)
  - Status register (MSTF)
- Instruction set includes:
  - IEEE single-precision (32-bit) floating point math operations
  - Floating-point math with parallel load or store
  - Floating-point multiply with parallel add or subtract
  - 1/X and 1/sqrt(X) estimations
  - Data type conversions.
  - Conditional branch and call
  - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines
  - The start address of each task is specified by the MVECT registers.
  - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
  - One task is serviced at a time until its completion. There is no nesting of tasks.
  - Upon task completion a task-specific interrupt is flagged within the PIE.
  - When a task finishes the next highest-priority pending task is automatically started.

- Task trigger mechanisms:
  - C28x CPU via the IACK instruction
  - Task1 to Task8: trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
- Memory and Shared Peripherals:
  - Two dedicated message RAMs for communication between the CLA and the main CPU.
  - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

### 7.1.3 Block Diagram

Figure 7-1 is a block diagram.

Figure 7-1. CLA (Type 2) Block Diagram

## 7.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and vice versa.

### 7.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter. The CLA RAMs are protected by the DCSM module. Refer to the *Dual Code Security Module (DCSM)* chapter for more details on the security scheme.

- **CLA Program Memory**

The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

Once the memory is initialized with CLA code, the CPU maps it to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit.

When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the Memory Controller Module section of the *System Control and Interrupts* chapter.

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the CPU maps it to the CLA data space by

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. The value of this bit at reset is 0.

When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the Memory Controller Module section of the *System Control and Interrupts* chapter.

- **CLA Shared Message RAMs**

There are two memory blocks for data sharing and communication between the CLA and the CPU. The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.

- **CLA to CPU Message RAM**

The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.

- **CPU to CLA Message RAM**

The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

### 7.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA will begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has an access range of 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of blocks. This number is device-dependent and will be described in the device-specific data manual.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and will automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus will automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

### 7.2.3 Shared Peripherals and EALLOW Protection

Refer to the device data manual for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise the MEDIS CLA instruction will disable write access. This way the CLA can enable/disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, the user may use the intervening cycles, until the completion of the conversion, to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 7.5](#).

### 7.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, Task 8, as a background task that, once triggered, runs continuously until the user either terminates it or resets the CLA or the device. The remaining tasks, 1 through 7, maintain their priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives its interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in [Table 7-1](#).

For example, Task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.bit.TASK1. To disable the triggering of a task by a peripheral, the user must set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. It should be noted that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

**Table 7-1. Configuration Options**

| Select Value (8-bit) | CLA Trigger Source |
|----------------------|--------------------|
| 0                    | Software Trigger   |
| 1                    | ADCA1_INT          |
| 2                    | ADCA2_INT          |
| 3                    | ADCA3_INT          |
| 4                    | ADCA4_INT          |
| 5                    | ADCA_EVT_INT       |
| 6                    | ADCB1_INT          |
| 7                    | ADCB2_INT          |
| 8                    | ADCB3_INT          |
| 9                    | ADCB4_INT          |
| 10                   | ADCB_EVT_INT       |
| 11                   | ADCC1_INT          |
| 12                   | ADCC2_INT          |
| 13                   | ADCC3_INT          |
| 14                   | ADCC4_INT          |
| 15                   | ADCC_EVT_INT       |
| 16                   | Reserved           |
| 17                   | Reserved           |
| 18                   | Reserved           |
| 19                   | Reserved           |
| 20                   | Reserved           |
| 21-28                | Reserved           |

- **Software Trigger**

CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because it does not require you to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example IACK #0x0001 will set bit 0 in the MIFR register to start task 1. Likewise IACK #0x0003 will set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

The Type-2 CLA allows the user to use Task 8 as a background task that runs continuously until the user disables it or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and its operation controlled by the MCTLBGRND register; it is enabled by setting the BGEN bit to 1. The user can then kick off the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default the background task is interruptible; the highest priority pending task will be executed first. When a task completes, and there aren't any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. The user may choose to make sections of the background task un-interruptible; it is possible to do this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task; if it is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while it has already started the overflow (BGOVF) bit is set.

The CLA has its own fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task is enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled, and running, it is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags will remain set until they are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) will start.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

### 7.2.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. See for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt will not be issued to the C28x CPU when that task completes.

## 7.3 CLA and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure will occur. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

They are covered in detail in the Memory Controller Module section of the *System Control and Interrupts* chapter.

### 7.3.1 CLA Message RAM

Message RAMs consist of blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM

These blocks are useful for passing data between the CLA and CPU. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
  - The following accesses are allowed:
    - CPU reads
    - CLA data reads and writes
    - CPU debug reads and writes
  - The following accesses are ignored:
    - CPU writes
- CPU to CLA Message RAM:
  - The following accesses are allowed:
    - CPU reads and writes
    - CLA reads
    - CPU debug reads and writes
  - The following accesses are ignored:
    - CLA writes

## 7.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

### 7.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in [Section 7.6](#), or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in its own assembly section. This can be easily done using the `.sect` assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This would typically be done in C or C++ but can also include C28x assembly code. The main CPU will also copy the CLA code to the program memory and, if needed, initialize the CLA data RAM(s). Once system initialization is complete and the application begins, the CLA will service its interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

## 7.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

### 1. Copy CLA code into the CLA program RAM

The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access it. The debugger can also be used to load code directly to the CLA program RAM during development.

### 2. Initialize CLA data RAM, if necessary

Populate the CLA data RAM with any required data coefficients or constants.

### 3. Configure the CLA registers

Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):

- **Enable the CLA peripheral clock using the assigned PCLKCRn register**

The peripheral clock control (PCLKCRn) registers are defined in [Section 3.15.4](#).

- **Populate the CLA task interrupt vectors**

- MVECT1 to MVECT8

- **Select the task interrupt sources**

For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt.

- **Enable IACK to start a task from software, if desired**

To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit.

- **Map CLA data RAM to CLA space, if necessary**

- **Map CLA program RAM to CLA space**

### 4. Initialize the PIE vector table and registers

When a CLA task completes, the associated interrupt in the PIE will be flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.

### 5. Enable CLA tasks/interrupts

Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. It should be noted that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA will not see the interrupt edge and will not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.

### 6. Initialize other peripherals

Initialize any peripherals (such as ePWM, ADC, and others) that will generate interrupt triggers for enabled CLA tasks.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

### 7.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. .

#### 7.4.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction will flush all the instructions that have already been fetched; on a single-step or run-free command, the CLA will re-fetch the same instruction which it replaced. [Table 7-2](#) illustrates the pipeline behavior.

**Table 7-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction**

| Cycles | F1               | F2               | D1               | D2               | R1             | R2             | E              | W              | Comments     |
|--------|------------------|------------------|------------------|------------------|----------------|----------------|----------------|----------------|--------------|
| 1      | i1               |                  |                  |                  |                |                |                |                |              |
| 2      | i2               | i1               |                  |                  |                |                |                |                |              |
| 3      | i3               | i2               | i1               |                  |                |                |                |                |              |
| 4      | i4               | i3               | i2               | i1               |                |                |                |                |              |
| 5      | MDEBUG STOP1     | i4               | i3               | i2               | i1             |                |                |                |              |
| 6      | i6               | MDEBUG STOP1     | i4               | i3               | i2             | i1             |                |                |              |
| 7      | i7               | i6               | MDEBUG STOP1     | i4               | i3             | i2             | i1             |                |              |
| 9      | i8               | Flushed (MNOP)   | Flushed (MNOP)   | Flushed (MNOP)   | i4             | i3             | i2             | i1             | CLA halted   |
| 10     | i5(MDEBUGS TOP1) | Flushed (MNOP)   | Flushed (MNOP)   | Flushed (MNOP)   | Flushed (MNOP) | i4             | i3             | i2             | CLA step/run |
| 11     | i6               | i5(MDEBUGS TOP1) | Flushed (MNOP)   | Flushed (MNOP)   | Flushed (MNOP) | Flushed (MNOP) | i4             | i3             | CLA step/run |
| 12     | i7               | i6               | i5(MDEBUGS TOP1) | Flushed (MNOP)   | Flushed (MNOP) | Flushed (MNOP) | Flushed (MNOP) | i4             | CLA step/run |
| 13     | i8               | i7               | i6               | i5(MDEBUGS TOP1) | Flushed (MNOP) | Flushed (MNOP) | Flushed (MNOP) | Flushed (MNOP) | CLA step/run |

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUGSTOP1. It takes 3 cycles for the MDEBUGSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then re-fetched and execution continues as before.

#### 7.4.3.2 Breakpoint Support (MDEBUGSTOP)

##### 1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where you want the CLA to halt, then rebuild and reload the code. Because the CLA does not flush its pipeline when you single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert it as needed.

If CLA breakpoints are not enabled, then the MDEBUGSTOP will be ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as it is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler will ensure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

## 2. Enable CLA breakpoints

Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.

## 3. Start the task

There are three ways to start the task:

- a. The peripheral can assert an interrupt,
- b. The main CPU can execute an IACK instruction, or
- c. The user can manually write to the MIFRC register in the debugger window

When the task starts, the CLA will execute instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA will halt and the pipeline will be frozen. The MPC register will reflect the address of the MDEBUGSTOP instruction.

## 4. Single-step the CLA code

Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

You can also run to the next MDEBUGSTOP or to the end of the task. If another task is pending, it will automatically start when you run to the end of the task.

---

### Note

A CLA fetch has higher priority than CPU debug reads. For this reason, it is possible for the CLA to permanently block CPU debug accesses if the CLA is executing in a loop. This might occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory will return all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in an infinite loop, you can use a soft or hard reset to exit the condition. A debugger reset will also exit the condition.

---

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

- **MPC halts at or after the MSTOP with a task already pending**

If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" will start if you continue to step through the MSTOP instruction. Basically if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

- **MPC halts at or after the MSTOP with no task pending**

In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, it will be flagged in the MIFR register but it may or may not start if you continue to single-step through the MSTOP instruction of "task A."

It depends on exactly when the new task comes in. To reliably start "task B" perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

## 5. Disable CLA breakpoints, if desired

In the Code Composer Studio™ IDE, you can disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA will be halted and no other tasks will start.

### 7.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, it will behave as follows:

- The CLA will halt with the illegal opcode in the D2 phase of the pipeline as if it were a breakpoint. This will occur whether CLA breakpoints are enabled or not.
- The CLA will issue the task-specific interrupt to the PIE.
- The MIRUN bit for the task will remain set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 7.4.5](#).

### 7.4.5 Resetting the CLA

There may be times when you need to reset the CLA. For example, during code debug the CLA may enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

#### • Hard Reset

Writing a 1 to the MCTL[HARDRESET] bit will perform a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (via XRS or the debugger). In this case all CLA configuration and execution registers will be set to their default state and CLA execution will halt.

#### • Soft Reset

Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing it will halt and the associated MIRUN bit will be cleared. All bits within the interrupt enable (MIER) register will also be cleared so that no new tasks start.

## 7.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

### 7.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage will be stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage will be stalled.

## 7.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read will complete first as shown in [Table 7-3](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in [Table 7-4](#).

This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write will complete before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame will always complete before a read to the frame. The CLA does not have this protection mechanism. Instead the code must wait to perform the read.

**Table 7-3. Write Followed by Read - Read Occurs First**

| Instruction          | F1 | F2 | D1 | D2 | R1 | R2 | E  | W  |
|----------------------|----|----|----|----|----|----|----|----|
| I1 MMOV16 @Reg1, MR3 | I1 |    |    |    |    |    |    |    |
| I2 MMOV16 MR2, @Reg2 | I2 | I1 |    |    |    |    |    |    |
|                      |    | I2 | I1 |    |    |    |    |    |
|                      |    |    | I2 | I1 |    |    |    |    |
|                      |    |    |    | I2 | I1 |    |    |    |
|                      |    |    |    |    | I2 | I1 |    |    |
|                      |    |    |    |    |    | I2 | I1 |    |
|                      |    |    |    |    |    |    | I2 | I1 |

**Table 7-4. Write Followed by Read - Write Occurs First**

| Instruction          | F1 | F2 | D1 | D2 | R1 | R2 | E  | W  |
|----------------------|----|----|----|----|----|----|----|----|
| I1 MMOV16 @Reg1, MR3 | I1 |    |    |    |    |    |    |    |
| I2                   | I2 | I1 |    |    |    |    |    |    |
| I3                   | I3 | I2 | I1 |    |    |    |    |    |
| I4                   | I4 | I3 | I2 | I1 |    |    |    |    |
| I5 MMOV16 MR2, @Reg2 | I5 | I4 | I3 | I2 | I1 |    |    |    |
|                      |    | I5 | I4 | I3 | I2 | I1 |    |    |
|                      |    |    | I5 | I4 | I3 | I2 | I1 |    |
|                      |    |    |    | I5 | I4 | I3 | I2 | I1 |
|                      |    |    |    |    | I5 | I4 | I3 | I1 |
|                      |    |    |    |    |    | I5 | I4 | I1 |
|                      |    |    |    |    |    |    | I5 | I1 |

- **Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD**

Referring to [Example 7-1](#), the following applies to delayed conditional instructions:

- **I1**

I1 is the last instruction that can effect the CNDF flags for the branch, call or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.

- **I2, I3, and I4**

The three instructions preceding MBCNDD can change MSTF flags but will have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification will occur after the D2 phase of the branch, call or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

- **I5, I6, and I7**

The three instructions following a branch, call or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

For a more detailed description refer to the functional description for [MBCNDD](#), [MCCNDD](#), and [MRCNDD](#).

**Example 7-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD**

```

<Instruction 1>    ; I1 Last instruction that can affect flags for
                  ;   the branch, call or return operation
<Instruction 2>    ; I2 Cannot be stop, branch, call or return
<Instruction 3>    ; I3 Cannot be stop, branch, call or return
<Instruction 4>    ; I4 Cannot be stop, branch, call or return
<branch/call/ret> ; MBCNDD, MCCNDD or MRCNDD
                  ; I5-I7: Three instructions after are always
                  ;   executed whether the branch/call or return is
                  ;   taken or not
<Instruction 5>    ; I5 Cannot be stop, branch, call or return
<Instruction 6>    ; I6 Cannot be stop, branch, call or return
<Instruction 7>    ; I7 Cannot be stop, branch, call or return
<Instruction 8>    ; I8
<Instruction 9>    ; I9
.....
    
```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to [Example 7-1](#). To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

- **Loading MAR0 or MAR1**

A load of auxiliary register MAR0 or MAR1 will occur in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing will occur in the D2 phase of the pipeline. Referring to [Example 7-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following the load instruction will use the value in MAR0 or MAR1 before the update occurs.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there will be a conflict. In the case of a conflict, the update due to address-mode post increment will win and the auxiliary register will not be updated with #\_X.

- **I4**

Starting with the 4th instruction MAR0 or MAR1 will have the new value.

**Example 7-2. Code Fragment for Loading MAR0 or MAR1**

```

; Assume MAR0 is 50 and #_X is 20

MMOVI16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1>   ; I1 Will use the old value of MAR0 (50)
<Instruction 2>   ; I2 Will use the old value of MAR0 (50)
<Instruction 3>   ; I3 Cannot use MAR0
<Instruction 4>   ; I4 Will use the new value of MAR0 (20)
<Instruction 5>   ; I5 Will use the new value of MAR0 (20)
....
  
```

### 7.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA will be able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user will have to account for the conversion time in SYSCLK cycles.

From a CLA perspective, the pipeline activity is shown in [Table 7-5](#) for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction will arrive in the R2 phase just in time to read the result register. While the prior instructions will enter the R2 phase of the pipeline too soon to read the conversion, they can be efficiently used for pre-processing calculations needed by the task.

**Table 7-5. ADC to CLA Early Interrupt Response**

| ADC Activity                      | CLA Activity             | F1                       | F2                       | D1                       | D2                       | R1                        | R2                        | E | W |
|-----------------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|---------------------------|---------------------------|---|---|
| Sample                            |                          |                          |                          |                          |                          |                           |                           |   |   |
| Sample                            |                          |                          |                          |                          |                          |                           |                           |   |   |
| ...                               |                          |                          |                          |                          |                          |                           |                           |   |   |
| Sample                            |                          |                          |                          |                          |                          |                           |                           |   |   |
| Conversion <sub>(Cycle 1)</sub>   | Interrupt Received       |                          |                          |                          |                          |                           |                           |   |   |

| RESULT Latched                    |                          |                          |                          |                          |                          | <b>Read RESULT</b>        | I <sub>(Cycle N-3)</sub>  |   |   |
| <b>RESULT Available</b>           |                          |                          |                          |                          |                          |                           | <b>Read RESULT</b>        |   |   |

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is (N-2) - 4 = N-6.

### 7.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

#### Example 7-3. Math Operation with Parallel Load

```

; MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADDF32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
  MADDF32 MR0, MR1, #2      ; MR0 = MR1 + 2,
  || MMOV32 MR1, @Val       ; MR1 gets the contents of Val
                           ; <-- MMOV32 completes here (MR1 is valid)
                           ; <-- DDF32 completes here (MR0 is valid)
  MMPYF32 MR0, MR0, MR1    ; Any instruction, can use MR1 and/or MR0

```

#### Example 7-4. Multiply with Parallel Add

```

; MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MMPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
  MMPYF32 MR0, MR1, MR3     ; MR0 = MR1 * MR3
  || MADDF32 MR1, MR2, MR0  ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
                           ; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
  MMPYF32 MR1, MR1, MR0    ; Any instruction, can use MR1 and/or MR0

```

## 7.6 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

### 7.6.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction may present the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you will find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x; the source operand(s) are always on the right and the destination operand(s) are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the C28x CLA are given in [Table 7-6](#).

**Table 7-6. Operand Nomenclature**

| Symbol    | Description   |
|-----------|---|
| #16FHi    | 16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero. |
| #16FHiHex | 16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.            |
| #16FLoHex | A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value   |
| #32Fhex   | 32-bit immediate value that represents an IEEE 32-bit floating-point value  |
| #32F      | Immediate float value represented in floating-point representation  |
| #0.0      | Immediate zero  |
| #SHIFT    | Immediate value of 1 to 32 used for arithmetic and logical shifts.  |
| addr      | Opcode field indicating the addressing mode   |
| CNDF      | Condition to test the flags in the MSTF register  |
| FLAG      | Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change  |
| MAR0      | auxiliary register 0  |
| MAR1      | auxiliary register 1  |
| MARx      | Either MAR0 or MAR1   |
| mem16     | 16-bit memory location accessed using direct, indirect, or offset addressing modes  |
| mem32     | 32-bit memory location accessed using direct, indirect, or offset addressing modes  |
| MRa       | MR0 to MR3 registers  |
| MRb       | MR0 to MR3 registers  |
| MRc       | MR0 to MR3 registers  |
| MRd       | MR0 to MR3 registers  |
| MRe       | MR0 to MR3 registers  |
| MRf       | MR0 to MR3 registers  |
| MSTF      | CLA Floating-point Status Register  |
| shift     | Opcode field indicating the number of bits to shift.  |

**Table 7-6. Operand Nomenclature (continued)**

| Symbol | Description  |
|--------|--|
| VALUE  | Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1 |

Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).

**Table 7-7. INSTRUCTION dest, source1, source2 Short Description**

|              | Description  |
|--------------|--|
| dest1        | Description for the 1st operand for the instruction  |
| source1      | Description for the 2nd operand for the instruction  |
| source2      | Description for the 3rd operand for the instruction  |
| Opcode       | This section shows the opcode for the instruction  |
| Description  | Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.   |
| Restrictions | Any constraints on the operands or use of the instruction imposed by the processor are discussed.  |
| Pipeline     | This section describes the instruction in terms of pipeline cycles as described in <a href="#">Section 7.5</a>   |
| Example      | Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed it data. |
| Operands     | Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).   |

## 7.6.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA will access it using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 7-8](#).

**Table 7-8. Addressing Modes**

| Addressing Mode | 'addr' Opcode Field Encode <sup>(1)</sup> | Description  |
|-----------------|---|--|
| @dir            | 0000                                      | <b>Direct Addressing Mode</b><br>Example 1: MMOV32 MR1, @_VarA<br>Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all<br>In this case the 'mmm mmmm mmmm mmmm' opcode field will be populated with the 16-bit address of the variable. This is the low 16-bits of the address that you would use to access the variable using the main CPU.<br>For example @_VarA will populate the address of the variable VarA. and @_EPwm1Regs.CMPA.all will populate the address of the CMPA register.   |
| *MAR0[#imm16]++ | 0001                                      | <b>MAR0 Indirect Addressing with 16-bit Immediate Post Increment</b><br><b>MAR1 Indirect Addressing with 16-bit Immediate Post Increment</b><br>addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1).<br>MAR0 (or MAR1) += #imm16 Then post increment MAR0 (or MAR1) by #imm16.<br>#imm16<br>Example 1: MMOV32 MR0, *MAR0[2]++<br>Example 2: MMOV32 MR1, *MAR1[-2]++<br>For a post increment of 0 the assembler will accept both *MAR0 and *MAR0[0]++.<br>The 'mmm mmmm mmmm mmmm' opcode field will be populated with the signed 16-bit pointer offset. For example if #imm16 is 2, then the opcode field will be 0x0002. Likewise if #imm16 is -2, then the opcode field will be 0xFFFE.<br>If addition of the 16-bit immediate causes overflow, then the value will wrap around on a 16-bit boundary. |
| *MAR1[#imm16]++ | 0010                                      |  |

(1) Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in [Table 7-9](#).

**Table 7-9. Shift Field Encoding**

| Shift Value | 'shift' Opcode Field Encode |
|-------------|-----------------------------|
| 1           | 0000                        |
| 2           | 0001                        |
| 3           | 0010                        |
| ....        | ....                        |
| 32          | 1111                        |

For instructions that use MR<sub>x</sub> (where x could be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to [Table 7-10](#).

**Table 7-10. Operand Encoding**

| Two-Bit Field | Working Register |
|---------------|------------------|
| 00            | MR0              |
| 01            | MR1              |
| 10            | MR2              |
| 11            | MR3              |

Table 7-11 shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

**Table 7-11. Condition Field Encoding**

| Encode <sup>(1)</sup> | CNDF                | Description                          | MSTF Flags Tested   |
|-----------------------|---------------------|--------------------------------------|---------------------|
| 0000                  | NEQ                 | Not equal to zero                    | ZF == 0             |
| 0001                  | EQ                  | Equal to zero                        | ZF == 1             |
| 0010                  | GT                  | Greater than zero                    | ZF == 0 AND NF == 0 |
| 0011                  | GEQ                 | Greater than or equal to zero        | NF == 0             |
| 0100                  | LT                  | Less than zero                       | NF == 1             |
| 0101                  | LEQ                 | Less than or equal to zero           | ZF == 1 OR NF == 1  |
| 1010                  | TF                  | Test flag set                        | TF == 1             |
| 1011                  | NTF                 | Test flag not set                    | TF == 0             |
| 1100                  | LU                  | Latched underflow                    | LUF == 1            |
| 1101                  | LV                  | Latched overflow                     | LVF == 1            |
| 1110                  | UNC                 | Unconditional                        | None                |
| 1111                  | UNCF <sup>(2)</sup> | Unconditional with flag modification | None                |

(1) Values not shown are reserved.

(2) This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

### 7.6.3 Instructions

The instructions are listed alphabetically.

**MABSF32 MRa, MRb****32-Bit Floating-Point Absolute Value****Operands**

|     |  |
|-----|--|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3)      |

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

**Description**

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MABSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

**Flags**

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MABSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MABSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MABSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

## MADD32 MRa, MRb, MRc

### 32-Bit Integer Add

#### Operands

|     |  |
|-----|--|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point destination register (MR0 to MR3) |
| MRc | CLA floating-point destination register (MR0 to MR3) |

#### Opcode

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

#### Description

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

#### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_ClalTask1:
    MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFFC)
    MMOV32 @_y2, MR3     ; Store y2
    MSTOP                ; end of task
```

**MADDF32 MRa, #16FHi, MRb****32-Bit Floating-Point Addition****Operands**

|        |   |
|--------|---|
| MRa    | CLA floating-point destination register (MR0 to MR3)  |
| #16FHi | A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. |
| MRb    | CLA floating-point source register (MR0 to MR3)   |

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

**Description**

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

**Flags**

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1 ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3 ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

## MADDF32 MRa, MRb, #16FHi

### 32-Bit Floating-Point Addition

#### Operands

|        |   |
|--------|---|
| MRa    | CLA floating-point destination register (MR0 to MR3)  |
| MRb    | CLA floating-point source register (MR0 to MR3)   |
| #16FHi | A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. |

#### Opcode

```
LSW: I I I I I I I I I I I I I I I I
MSW: 0 1 1 1 0 1 1 1 1 1 0 0 b b a a
```

#### Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, #16FHi, MRb.

#### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

#### Pipeline

This is a single-cycle instruction.

**MADDF32 MRa, MRb, #16FHi** (continued)

**32-Bit Floating-Point Addition**
**Example 1**

```

; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store it in Result
;
;
_Cla1Task1:
    MMOV16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len       ; Length of the array
    MNOP      ; delay for MAR1 load
    MNOP      ; delay for MAR1 load
    MMOV32    MR1, *MAR1[2]++   ; MR1 = X0
LOOP
    MMOV32    MR2, *MAR1[2]++   ; MR2 = next element
    MMAXF32   MR1, MR2          ; MR1 = MAX(MR1, MR2)
    MADDF32   MR0, MR0, #-1.0   ; Decrement the counter
    MCMPPF32  MR0, #0.0         ; Set/clear flags for MBCNDD
    MNOP
    MNOP
    MNOP
    MBCNDD    LOOP, NEQ         ; Branch if not equal to zero
    MMOV32    @_Result, MR1     ; Always executed
    MNOP      ; Always executed
    MNOP      ; Always executed
    MSTOP
    ; End of task

```

**Example 2**

```

; Show the basic operation of MADDF32
;
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
    MADDF32 MR0, MR1, #2.0     ; MR0 = MR1 + 2.0
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
    MADDF32 MR2, MR3, #-2.5    ; MR2 = MR3 + (-2.5)
; Add to MR0 the value 0x3FC00000 (1.5)
; Store the result in MR0
    MADDF32 MR0, MR0, #0x3FC0  ; MR0 = MR0 + 1.5

```

## MADDF32 MRa, MRb, MRc

### 32-Bit Floating-Point Addition

#### Operands

|     |  |
|-----|--|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3)      |
| MRc | CLA floating-point source register (MR0 to MR3)      |

#### Opcode

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

#### Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

#### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Given M1, X1 and B1 are 32-bit floating point numbers
; Calculate Y1 = M1*X1+B1
;
; ClalTask1:
- MMOV32 MR0,@M1      ; Load MR0 with M1
  MMOV32 MR1,@X1      ; Load MR1 with X1
  MMPYF32 MR1,MR1,MR0 ; Multiply M1*X1
|| MMOV32 MR0,@B1     ; and in parallel load MR0 with B1
  MADDF32 MR1,MR1,MR0 ; Add M*X1 to B1 and store in MR1
  MMOV32 @Y1,MR1     ; Store the result
  MSTOP              ; end of task
```

**32-Bit Floating-Point Addition with Parallel Move**
**Operands**

|       |  |
|-------|--|
| MRd   | CLA floating-point destination register for the MADDF32 (MR0 to MR3)   |
| MRe   | CLA floating-point source register for the MADDF32 (MR0 to MR3)  |
| MRf   | CLA floating-point source register for the MADDF32 (MR0 to MR3)  |
| mem32 | 32-bit memory location accessed using one of the available addressing modes. This will be the destination of the MMOV32. |
| MRa   | CLA floating-point source register for the MMOV32 (MR0 to MR3)   |

**Opcode**

```
LSW: rrrrrm rrrrrm rrrrrm rrrrrm
MSW: 0101 ffee ddaa addr
```

**Description**

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

Both MADDF32 and MMOV32 complete in a single cycle.

**Example**

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_ClalTask2:
  MMOV32  MR0, @_A      ; Load MR0 with A
  MMOV32  MR1, @_B      ; Load MR1 with B
  MPPYF32 MR1, MR1, MR0 ; Multiply A*B
  || MMOV32 MR0, @_C    ; and in parallel load MR0 with C
  MADDF32 MR1, MR1, MR0 ; Add (A*B) to C
  || MMOV32 @_Y2, MR1   ; and in parallel store A*B
  MMOV32  @_Y3, MR1    ; Store the A*B + C
  MSTOP                    ; end of task
```

**32-Bit Floating-Point Addition with Parallel Move**
**Operands**

|       |  |
|-------|--|
| MRd   | CLA floating-point destination register for the MADDF32 (MR0 to MR3).<br>MRd cannot be the same register as MRa. |
| MRe   | CLA floating-point source register for the MADDF32 (MR0 to MR3)  |
| MRf   | CLA floating-point source register for the MADDF32 (MR0 to MR3)  |
| MRa   | CLA floating-point destination register for the MMOV32 (MR0 to MR3).<br>MRa cannot be the same register as MRd.  |
| mem32 | 32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.  |

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

**Description**

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

**Restrictions**

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

**Flags**

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction will set the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

**Pipeline**

The MADDF32 and the MMOV32 both complete in a single cycle.

**MADDF32 MRd, MRe, MRf || MMOV32 MRa, mem32 (continued)**
**32-Bit Floating-Point Addition with Parallel Move**
**Example 1**

```

; Given A, B and C are 32-bit floating-point numbers

## MBCNDD 16BitDest {, CNDF}

### Branch Conditional Delayed

#### Operands

|           |   |
|-----------|---|
| 16BitDest | 16-bit destination if condition is true |
| CNDF      | Optional condition tested               |

#### Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

#### Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, it wraps around. Therefore a value of "0xFFFFE" will put the MPC back to the MBCNDD instruction.

Please refer to the pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

| Encode <sup>(1)</sup> | CNDF                | Description                          | MSTF Flags Tested   |
|-----------------------|---------------------|--------------------------------------|---------------------|
| 0000                  | NEQ                 | Not equal to zero                    | ZF == 0             |

| 1111                  | UNCF <sup>(2)</sup> | Unconditional with flag modification | None                |

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

#### Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD or MRCNDD instruction. Refer to the pipeline section for more information.

#### Flags

This instruction does not modify flags in the MSTF register.

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | No  | No  |

**MBCNDD 16BitDest {, CNDF}** (continued)

**Branch Conditional Delayed**
**Pipeline**

The MBCNDD instruction by itself is a single-cycle instruction. As shown in [Table 7-12](#) for each branch 6 instruction slots are executed; three before the branch instruction (I2-I4) and three after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken may not be the same as for a branch not taken.

Referring to [Table 7-12](#) and [Table 7-13](#), the instructions before and after MBCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3 and I4**
  - The three instructions proceeding MBCNDD can change MSTF flags but will have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification will occur after the D2 phase of the MBCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.
- **I5, I6 and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

```

[MRCNDD CNDF](#)

**MCCNDD 16BitDest {, CNDF}****Call Conditional Delayed****Operands**

|           |   |
|-----------|---|
| 16BitDest | 16-bit destination if condition is true |
| CNDF      | Optional condition to be tested         |

**Opcode**

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

**Description**

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, it wraps around. Therefore a value of "0xFFFFE" will put the MPC back to the MCCNDD instruction.

Please refer to the pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

| Encode <sup>(1)</sup> | CNDF                | Description                          | MSTF Flags Tested   |
|-----------------------|---------------------|--------------------------------------|---------------------|
| 0000                  | NEQ                 | Not equal to zero                    | ZF == 0             |
| 0001                  | EQ                  | Equal to zero                        | ZF == 1             |
| 0010                  | GT                  | Greater than zero                    | ZF == 0 AND NF == 0 |
| 0011                  | GEQ                 | Greater than or equal to zero        | NF == 0             |
| 0100                  | LT                  | Less than zero                       | NF == 1             |
| 0101                  | LEQ                 | Less than or equal to zero           | ZF == 1 OR NF == 1  |
| 1010                  | TF                  | Test flag set                        | TF == 1             |
| 1011                  | NTF                 | Test flag not set                    | TF == 0             |
| 1100                  | LU                  | Latched underflow                    | LUF == 1            |
| 1101                  | LV                  | Latched overflow                     | LVF == 1            |
| 1110                  | UNC                 | Unconditional                        | None                |
| 1111                  | UNCF <sup>(2)</sup> | Unconditional with flag modification | None                |

(1) Values not shown are reserved.

(2) This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

**Restrictions**

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

**Flags**

This instruction does not modify flags in the MSTF register.

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | No  | No  |

**MCCNDD 16BitDest {, CNDF}** (continued)

**Call Conditional Delayed**
**Pipeline**

The MCCNDD instruction by itself is a single-cycle instruction. As shown in [Table 7-14](#), for each call 6 instruction slots are executed; three before the call instruction (I2-I4) and three after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken may not be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 7-14](#) and [Table 7-15](#), the instructions before and after MCCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3 and I4**
  - The three instructions proceeding MCCNDD can change MSTF flags but will have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification will occur after the D2 phase of the MCCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.
- **I5, I6 and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

```

**MCLRC BGINTM****Clear Background Task Interrupt Mask****Operands**

|      |   |
|------|---|
| None | This instruction does not have any operands |
|------|---|

**Opcode**

|                          |
|--------------------------|
| LSW: 0000 0000 0000 0000 |
| MSW: 0111 1111 0111 0000 |

**Description**

This instruction will clear the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, allowing any code thereafter to be interrupted by a higher priority task. This instruction clears the BGINTM bit at the end of its D2 phase.

Note: This instruction does not require the MEALLOW bit to be asserted before or deasserted after clearing BGINTM.

**Flags**

This instruction does not modify flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | No  | No  |

**Pipeline**

This is a single-cycle instruction.

**Example**

|              |                                   |
|--------------|-----------------------------------|
| MCLRC BGINTM | ; Allow the background task to be |
|              | ; interrupted by clearing the     |
|              | ; MSTSBGRND.BGINTM bit            |

## MCMP32 MRa, MRb

### 32-Bit Integer Compare for Equal, Less Than or Greater Than

#### Operands

|     |   |
|-----|---|
| MRa | CLA floating-point source register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3) |

#### Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

#### Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating point compare refer to [MCMFP32](#).

#### Note

A known hardware issue exists in the MCMP32 instruction. Signed integer comparisons using MCMP32 by itself will set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag `--cla_signed_compare_workaround` enables this workaround.

#### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFFF9)
MCMP32 MR2, MR2 ; NF = 0, ZF = 1
MCMP32 MR0, MR1 ; NF = 1, ZF = 0
MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

## MCMPF32 MRa, MRb

### 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

#### Operands

|     |   |
|-----|---|
| MRa | CLA floating-point source register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3) |

#### Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000
```

#### Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero will be treated as positive zero.
- A denormalized value will be treated as positive zero.
- Not-a-Number (NaN) will be treated as infinity.

#### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified as follows:

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, MR0 ; ZF = 0, NF = 1
MCMPF32 MR0, MR1 ; ZF = 0, NF = 0
MCMPF32 MR0, MR0 ; ZF = 1, NF = 0
```

**MCMPF32 MRa, #16FHi****32-Bit Floating-Point Compare for Equal, Less Than or Greater Than****Operands**

|        |   |
|--------|---|
| MRa    | CLA floating-point source register (MR0 to MR3)   |
| #16FHi | A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. |

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

**Description**

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero will be treated as positive zero.
- Denormalized value will be treated as positive zero.
- Not-a-Number (NaN) will be treated as infinity.

**Flags**

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

**Pipeline**

This is a single-cycle instruction

**Example 1**

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, #-2.2 ; ZF = 0, NF = 0
MCMPF32 MR0, #6.5 ; ZF = 0, NF = 1
MCMPF32 MR0, #5.0 ; ZF = 1, NF = 0
```

**MCMPF32 MRa, #16FHi** (continued)

**32-Bit Floating-Point Compare for Equal, Less Than or Greater Than**
