**Table 17-111. OUTPUT1MUXENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux31 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux31 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux30 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux30 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux29 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux29 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux28 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux28 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
27	MUX27	R/W	0h	Selects the output of Mux27 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux27 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux27 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-111. OUTPUT1MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	MUX26	R/W	0h	Selects the output of Mux26 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux26 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux26 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux25 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux25 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux24 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux24 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux23 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux23 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux22 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux22 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux21 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux21 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-111. OUTPUT1MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-111. OUTPUT1MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-111. OUTPUT1MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 17.3.6.18 OUTPUT2MUXENABLE Register (Offset = 22h) [Reset = 0h]

OUTPUT2MUXENABLE is shown in [Figure 17-100](#) and described in [Table 17-112](#).

Return to the [Summary Table](#).

Output X-BAR Mux Enable for Output 2

16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-112. OUTPUT2MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-112. OUTPUT2MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT2 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT2 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT2 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 17.3.6.19 OUTPUT3MUXENABLE Register (Offset = 24h) [Reset = 0h]

OUTPUT3MUXENABLE is shown in [Figure 17-101](#) and described in [Table 17-113](#).

Return to the [Summary Table](#).

Output X-BAR Mux Enable for Output 3

17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-114. OUTPUT4MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-116. OUTPUT6MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Reset type: CPU1.SYSRSn

**Table 17-118. OUTPUT8MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-118. OUTPUT8MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 17-118. OUTPUT8MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 17.3.6.25 OUTPUTLATCH Register (Offset = 30h) [Reset = 0h]

OUTPUTLATCH is shown in [Figure 17-107](#) and described in [Table 17-119](#).

Return to the [Summary Table](#).

Output X-BAR Output Latch

The following chapters describe the analog peripherals.

### 18.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown in [Figure 18-1](#). This Technical Reference Manual is organized into five major sections:

- [C28x SYSTEM RESOURCES](#)

These chapters describe the C28x CPU subsystem, C28x Boot ROM, device configuration, and other system peripherals.

- [ANALOG PERIPHERALS](#)

These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.

- [CONTROL PERIPHERALS](#)

These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- [COMMUNICATION PERIPHERALS](#)

These chapters describe the communication peripherals available to the C28x subsystem such as the I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.

- [CONNECTIVITY MANAGER \(CM\)](#)

These chapters describe the Connectivity Manager (CM) subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Figure 18-1. F2838x Block Diagram

The analog subsystem module is described in this chapter.

<b>19.1 Introduction</b> .....	<b>2504</b>
<b>19.2 Lock Registers</b> .....	<b>2507</b>
<b>19.3 Analog Subsystem Registers</b> .....	<b>2507</b>

## 19.1 Introduction

The analog modules on this device include the Analog-to-Digital Converter (ADC), Temperature Sensor, Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

### 19.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references
  - The ADCs are referenced to VREFH1x and VREFLOx pins
    - VREFH1x pin voltage must be driven in externally
- The buffered DACs are referenced to VREFH1x and VSSA
  - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- The comparator DACs are referenced to VDDA and VSSA
  - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC and comparator subsystem functions multiplexed with ADC inputs
- Internal connection to VREFLO on all ADCs for offset self-calibration

### 19.1.2 Block Diagram

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

The reference pins, VREFH1A to VREFH1D and VREFLOA to VREFLOD, can be used to externally supply the reference to the ADC. VREFH1A can also be used to supply the reference voltage to DAC A and DAC B and VREFH1B can be used to supply the reference to DAC C.

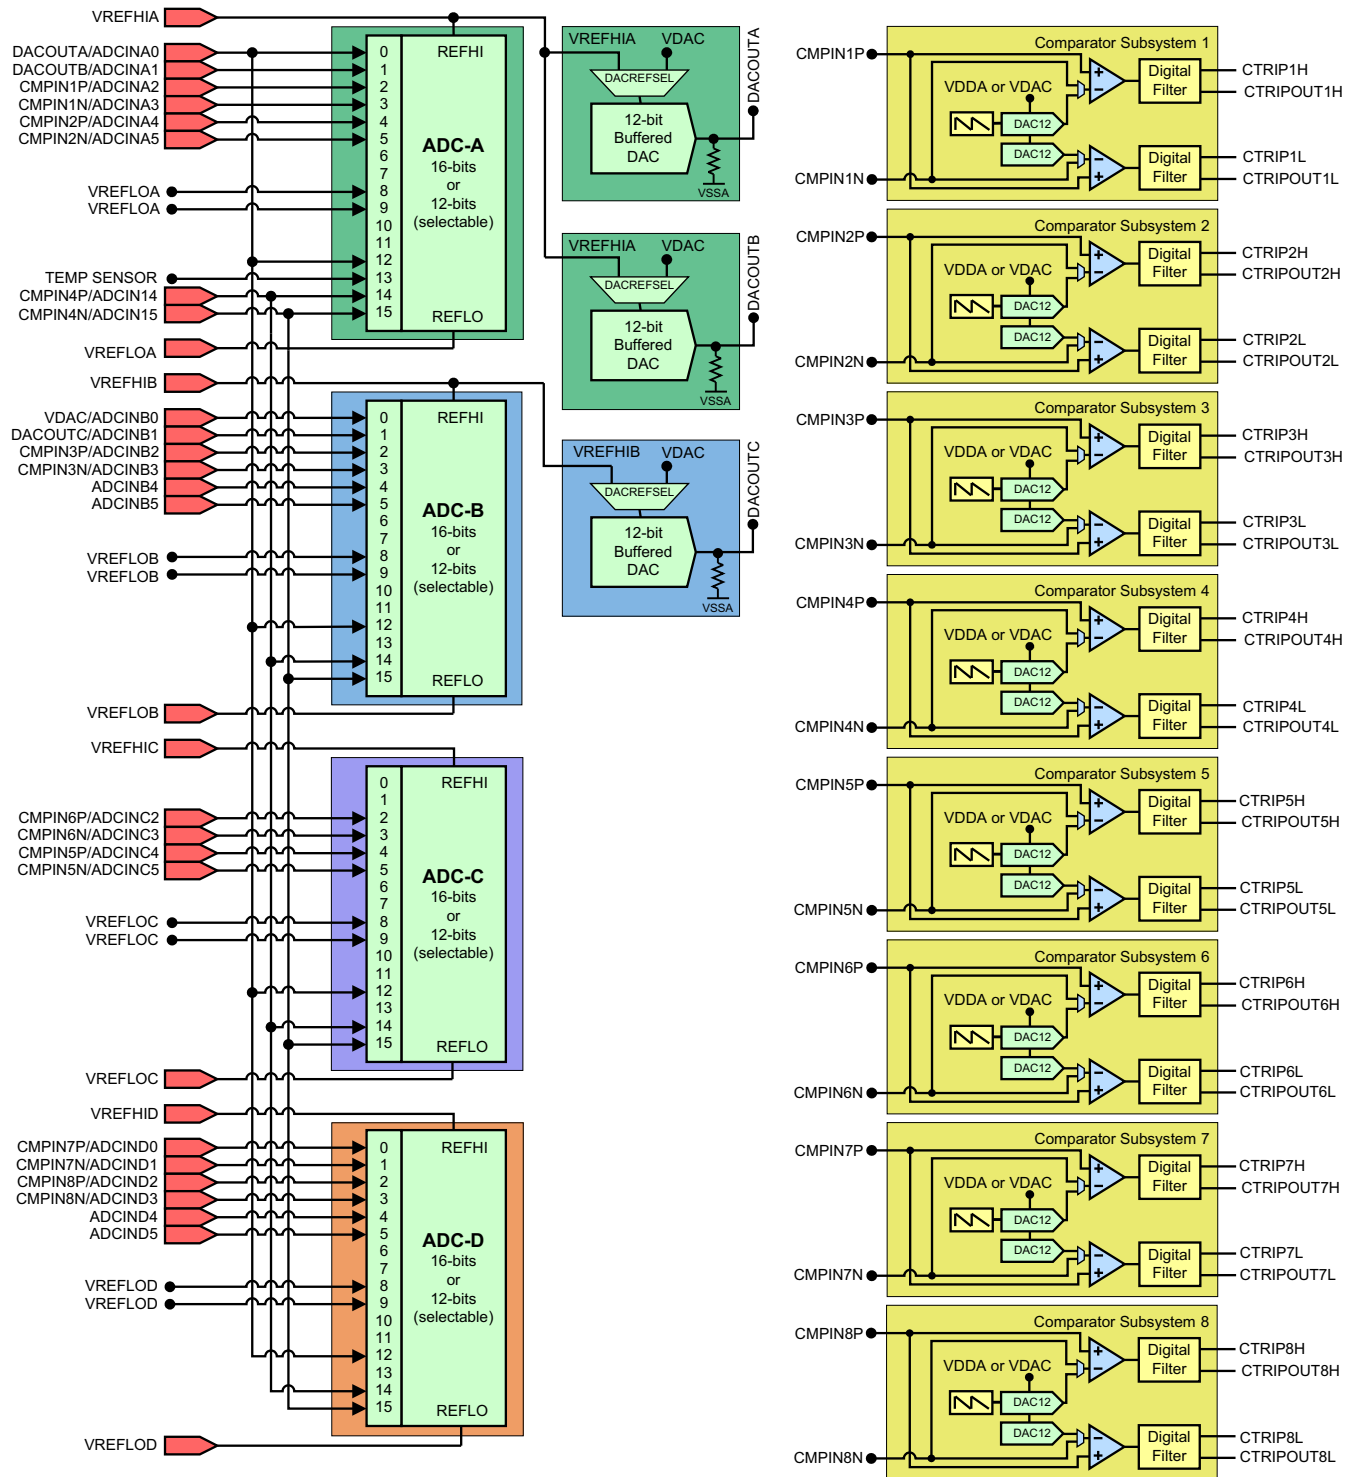

The analog module input/outputs are all ADC inputs by default. The pins which connect to CMPSS inputs can be used for the CMPSS without further action and without preventing use as an ADC input simultaneously. DAC outputs must be enabled; this will prevent the channel from simultaneously being used as an ADC input (but the ADC can be used to sample the DAC output voltage if desired).

The VDAC reference pin can be used to set an alternate range for DAC A, DAC B, and DAC C and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per-module for each CMPSS or buffered DAC, and the selection is made via the module's configuration registers.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See your device-specific datasheet to determine which pins are available.
- See your device-specific data sheet to determine the allowable voltage range for VREFH1 and VREFLO
- An external capacitor is required on the VREFH1 pins. See your device-specific data sheet for the specific value required.
- For buffered DAC modules, VSSA will be the low reference whether VREFH1x or VDAC is selected as the high reference.
- For CMPSS modules, VSSA will be the low reference whether VDAC or VDDA is selected as the high reference.

**Figure 19-1. Analog Subsystem Block Diagram (337-Ball ZWT)**

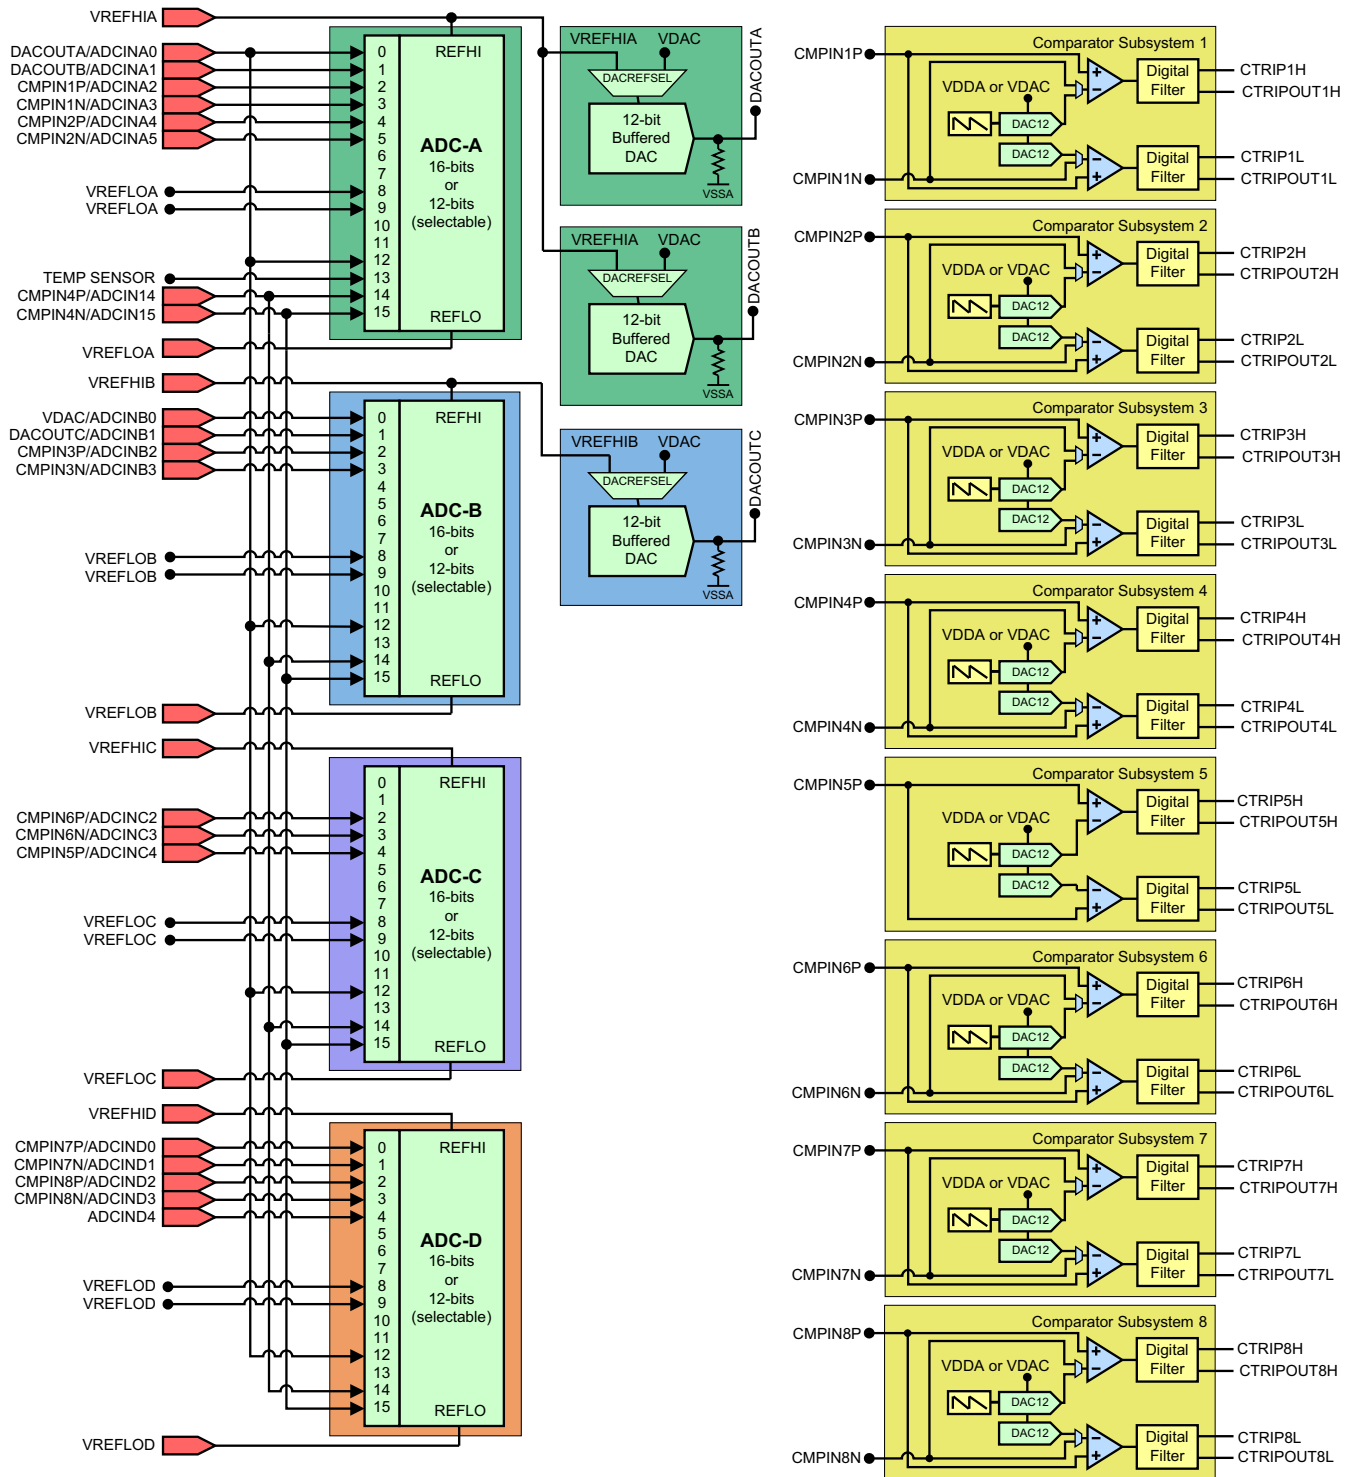

Figure 19-2. Analog Subsystem Block Diagram (176-Pin PTP)

**Table 19-1. Analog Signal Descriptions**

Signal Name	Description
ADCINAx	ADC A Input
ADCINBx	ADC B Input
ADCINCx	ADC C Input
ADCINDx	ADC D Input
CMPINxP	Comparator subsystem positive input
CMPINxN	Comparator subsystem negative input
DACOUTx	Buffered DAC Output
TEMP SENSOR	Internal temperature sensor
VDAC	Optional external reference voltage for on-chip DACs. There is a 100-pF capacitor to VSSA on this pin whether used for ADC input or DAC reference which cannot be disabled. If this pin is being used as a reference for the on-chip DACs, place at least a 1-uF capacitor on this pin.

**Table 19-2. Reference Summary**

Module	Reference Option	Configured Where?	Register	Driverlib Function	Notes
ADC	External or Internal	Not Configurable	N/A	N/A	VREFHI must always be driven externally on this device.
Buffered DAC	VREFHI or VDAC	DAC Module	DacxRegs. DACCTL.bit.DACR EFSEL	DAC_CTL_DACREFSEL	
	External or Internal	Not Configurable	N/A	N/A	VREFHI must always be driven externally on this device.
CMPSS DACs	VDDA or VDAC	CMPSS Module	CmpssxRegs. COMPDACCTL.bit. SELREF	CMPSS_COMPDACCTL_ SELREF	

## 19.2 Lock Registers

Setting one of the bits in the lock registers prevents further writes to the associated analog subsystem configuration register. This lock can only be cleared by a device reset.

## 19.3 Analog Subsystem Registers

This section describes the Analog Subsystem Registers.

### 19.3.1 ASBSYS Base Address Table (C28)

**Table 19-3. ASBSYS Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
AnalogSubsysRegs	ANALOG_SUBSYS_REGS	ANALOGSUBSYS_BASE	0x0005_D700	YES	-	-	-	YES

### 19.3.2 ANALOG\_SUBSYS\_REGS Registers

Table 19-4 lists the memory-mapped registers for the ANALOG\_SUBSYS\_REGS registers. All register offset addresses not listed in Table 19-4 should be considered as reserved locations and the register contents should not be modified.

**Table 19-4. ANALOG\_SUBSYS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
20h	INTOSC1TRIM	Internal Oscillator 1 Trim Register	EALLOW	<a href="#">Go</a>
22h	INTOSC2TRIM	Internal Oscillator 2 Trim Register	EALLOW	<a href="#">Go</a>
26h	TSNSCTL	Temperature Sensor Control Register	EALLOW	<a href="#">Go</a>
2Eh	LOCK	Lock Register	EALLOW	<a href="#">Go</a>
36h	ANAREFTRIMA	Analog Reference Trim A Register	EALLOW	<a href="#">Go</a>
38h	ANAREFTRIMB	Analog Reference Trim B Register	EALLOW	<a href="#">Go</a>
3Ah	ANAREFTRIMC	Analog Reference Trim C Register	EALLOW	<a href="#">Go</a>
3Ch	ANAREFTRIMD	Analog Reference Trim D Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 19-5 shows the codes that are used for access types in this section.

**Table 19-5. ANALOG\_SUBSYS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 19.3.2.1 INTOSC1TRIM Register (Offset = 20h) [Reset = 0h]

INTOSC1TRIM is shown in [Figure 19-3](#) and described in [Table 19-6](#).

Return to the [Summary Table](#).

Internal Oscillator 1 Trim Register

**Figure 19-3. INTOSC1TRIM Register**

R/W-0h					R/W-0h					R/W-0h					

**Table 19-13. ANAREFTRIMD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RESERVED	R/W	0h	Reserved
15-11	IREFTRIM	R/W	0h	Reference Current Trim. This bit field defines the reference current trim value. 0x0 - Untrimmed all other values - Trimmed Reset type: XRSn
10-6	BGSLOPETRIM	R/W	0h	Bandgap Slope Trim. This bit field defines the bandgap slope trim value. 0x0 - Untrimmed all other values - Trimmed Reset type: XRSn
5-0	BGVALTRIM	R/W	0h	Bandgap Value Trim. This bit field defines the bandgap voltage offset trim value. 0x0 - Untrimmed all other values - Trimmed Reset type: XRSn

The analog-to-digital converter (ADC) module described in this chapter is a Type 4 ADC. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 20.1 Introduction

The ADC module is a successive approximation (SAR) style ADC with selectable resolution of either 16 bits or 12 bits. The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (S/H) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see [Section 20.3](#)).

### 20.1.2 Features

Each ADC has the following features:

- Selectable resolution of 12 bits or 16 bits
- Ratiometric external reference set by VREFHI and VREFLO pins
- Differential signal conversions (16-bit mode only)
- Single-ended signal conversions
- Input multiplexer with up to 16 channels (single-ended) or 8 channels (differential)
- 16 configurable SOCs
- 16 individually addressable result registers
- Multiple trigger sources
  - S/W - software immediate start
  - All ePWMs - ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2 (from each C28x core present)
  - ADCINT1/2
- Four flexible PIE interrupts
- Configurable interrupt placement
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from setpoint calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture

---

#### Note

Not every channel may be pinned out from all ADCs. Check the device datasheet to determine which channels are available.

---

### 20.1.3 Block Diagram

Figure 20-1 shows the block diagram for the ADC core and ADC wrapper.

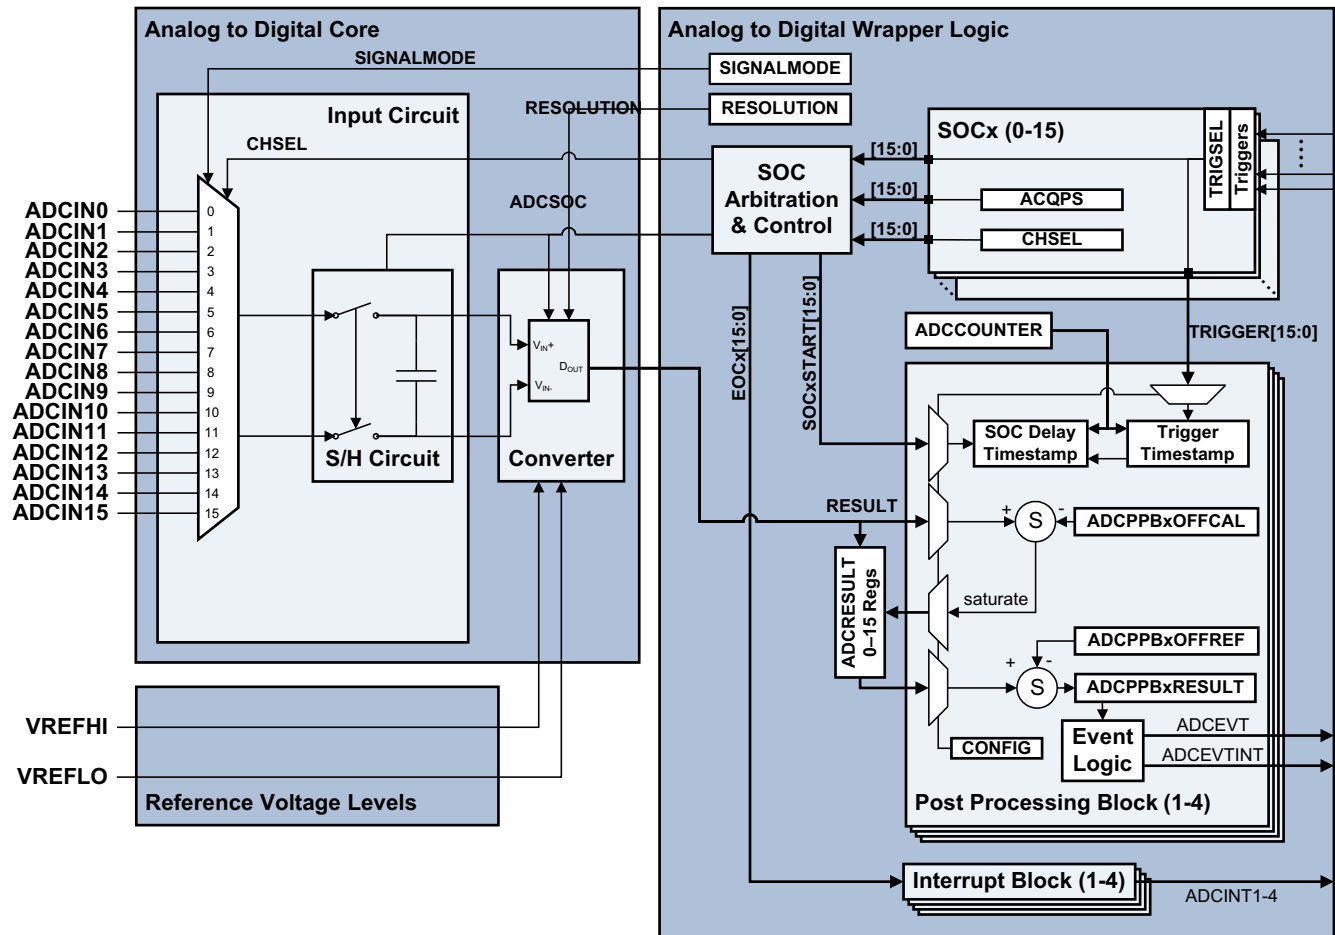

Figure 20-1. ADC Module Block Diagram

## 20.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. [Table 20-1](#) summarizes the basic ADC options and their level of configurability. The subsequent sections discuss these configurations.

**Table 20-1. ADC Options and Configuration Levels**

Options	Configurability
Clock	Per module <sup>(1)</sup>
Resolution	Per module <sup>(1)</sup>
Signal mode	Per module
Reference voltage source	Not configurable (external reference only)
Trigger source	Per SOC <sup>(1)</sup>
Converted channel	Per SOC
Acquisition window duration	Per SOC <sup>(1)</sup>
EOC location	Per module
Burst Mode	Per module <sup>(1)</sup>

(1) Writing these values differently to different ADC modules could cause the ADCs to operate asynchronously. See [Section 20.13.1](#) for guidance on when the ADCs are operating synchronously or asynchronously.

### 20.2.1 Clock Configuration

The base ADC clock is provided directly by the system clock (SYSCLK). SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. The ADCCLK is used to clock the converter.

In 16-bit mode, the core requires approximately 29.5 ADCCLK cycles to process a voltage into a conversion result, while in 12-bit mode, this process requires approximately 10.5 ADCCLK cycles. The choice of resolution will also determine the necessary duration of the acquisition window, see [Section 20.13.2](#).

---

#### Note

To determine an appropriate value for ADCCTL2.PRESCALE, see your device-specific datasheet to determine the maximum SYSCLK and ADCCLK frequency.

---

### 20.2.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. This ADC supports a configurable resolution of 16 bits or 12 bits.

The resolution should be configured by using either the `AdcSetMode()` or `ADC_setMode()` functions, depending on the header files used, provided in C2000ware in `F2838x_Adc.c` `F28006x_Adc.c`. These functions ensure that the correct trim is loaded into the ADC trim registers, and must be called at least once after a device reset. Do not configure the resolution by directly writing to the ADCCTL2 register.

The resolution can be changed at any time when the ADC is idle (no active or pending SOCs). No wait time is necessary after changing the resolution before conversions can be initiated. If SOCs are active or pending when the resolution is changed, those SOCs may produce incorrect conversion results.

## 20.2.3 Voltage Reference

### 20.2.3.1 External Reference Mode

Each ADC has a VREFHI input and a VREFLO input. In external reference mode, these pins are used as a ratiometric reference to determine the ADC conversion input range.

See [Section 20.13.6](#) for information on how to supply the reference voltage.

---

#### Note

- On devices with no external VREFLO signals, VREFLO is internally connected to the device analog ground, VSSA.
  - See your device-specific datasheet to determine the allowable voltage range for VREFHI and VREFLO.
  - The external reference mode requires an external capacitor on the VREFHI pin. See your device-specific datasheet for the specific value required.
-

## 20.2.4 Signal Mode

The ADC supports two signal modes: single-ended and differential.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCIN<sub>x</sub>), referenced to VREFLO.

In differential signaling mode, the input voltage to the converter is sampled through a pair of input pins, one of which is the positive input (ADCIN<sub>xP</sub>) and the other is the negative input (ADCIN<sub>xN</sub>). The actual input voltage is the difference between the two (ADCIN<sub>xP</sub> – ADCIN<sub>xN</sub>).

### NOTES:

- In 16-bit differential signaling mode, VREFLO must be connected to VSSA.
- In differential signal mode, the common mode voltage is  $V_{CM} = (ADCIN_{xP} + ADCIN_{xN})/2$

The data sheet for a particular device will place some requirements on how close this voltage needs to be to:  $(VREFHI + VREFLO)/2$

**Note:** The above condition is not met by connecting the negative input to VSSA or VREFLO.

- Differential signaling mode is advantageous because noise encountered on both inputs will be largely canceled. The effect can be maximized by routing the positive and negative traces for the same differential input as close together as possible and keeping them symmetrical with respect to the signal reference.

The signal mode should be configured by using either the ADC\_setMode() or AdcSetMode() functions, depending on the header files used, provided in C2000ware in F2838x\_Adc.c. These functions ensure that the correct trim is loaded into the ADC trim registers. These functions must be called at least once after a device reset. The signal mode should not be configured by writing to the ADCCTL2 register directly.

## 20.2.5 Expected Conversion Results

Based on a given analog input voltage, the ideal expected digital conversion is given in [Table 20-2](#) and [Table 20-3](#). Fractional values are truncated.

**Table 20-2. Analog to 12-bit Digital Formulas**

	Analog Input	Digital Result
<b>Single-Ended</b>	when ADCIN <sub>y</sub> ≤ VREFLO	ADCRESULT <sub>x</sub> = 0
	when VREFLO < ADCIN <sub>y</sub> < VREFHI	ADCRESULT <sub>x</sub> = 4096 $\left( \frac{ADCIN_y - VREFLO}{VREFHI - VREFLO} \right)$
	when ADCIN <sub>y</sub> ≥ VREFHI	ADCRESULT <sub>x</sub> = 4095
<b>Differential</b>	Invalid Mode	Invalid Mode

**Table 20-3. Analog to 16-bit Digital Formulas**

	Analog Input	Digital Result
<b>Single-Ended</b>	when ADCIN <sub>y</sub> ≤ VREFLO	ADCRESULT <sub>x</sub> =0
	when VREFLO < ADCIN <sub>y</sub> < VREFHI	ADCRESULT <sub>x</sub> =65536 $\left( \frac{ADCIN_y - VREFLO}{VREFHI - VREFLO} \right)$
	when ADCIN <sub>y</sub> ≥ VREFHI	ADCRESULT <sub>x</sub> =65535
<b>Differential</b>	when ADCIN <sub>yP</sub> - ADCIN <sub>yN</sub> ≤ -VREFHI	ADCRESULT <sub>x</sub> = 0
	when -VREFHI < ADCIN <sub>yP</sub> - ADCIN <sub>yN</sub> ≤ VREFHI	ADCRESULT <sub>x</sub> = 65536 $\left( \frac{ADCIN_{yP} - ADCIN_{yN} + VREFHI}{2 VREFHI} \right)$
	when ADCIN <sub>yP</sub> - ADCIN <sub>yN</sub> ≥ VREFHI	ADCRESULT <sub>x</sub> = 65535

## 20.2.6 Interpreting Conversion Results

Based on a given ADC conversion result, the ideal corresponding analog input is given in [Table 20-4](#) and [Table 20-5](#). This corresponds to the center of the possible range of analog voltages that could have produced this conversion result.

**Table 20-4. 12-Bit Digital-to-Analog Formulas**

	Digital Value	Analog Equivalent
<b>Single-Ended</b>	when ADCRESULTy = 0	$ADCIN_x \leq VREFLO$ (2)
	when $0 < ADCRESULTy < 4095$	$ADCIN_x = (VREFHI - VREFLO) \left( \frac{ADCRESULTy}{4096} \right) + VREFLO$
	when ADCRESULTy = 4095	$ADCIN_x \geq VREFHI$
<b>Differential</b>	Invalid Mode	Invalid Mode

**Table 20-5. 16-Bit Digital-to-Analog Formulas**

	Digital Value	Analog Equivalent
<b>Single-Ended</b>	when ADCRESULTy = 0	$ADCIN_x \leq VREFLO$
	when $0 < ADCRESULTy < 65535$	$ADCIN_x = (VREFHI - VREFLO) \left( \frac{ADCRESULTy}{65536} \right) + VREFLO$
	when ADCRESULTy = 65535	$ADCIN_x \geq VREFHI$
<b>Differential</b>	when ADCRESULTy = 0	$ADCIN_{xP} - ADCIN_{xN} \leq VREFHI$
	when $0 < ADCRESULTy < 65534$	$ADCIN_{xP} - ADCIN_{xN} = VREFHI \times \left( \frac{2 \times ADCRESULTy}{65536} - 1 \right)$
	when ADCRESULTy = 65535	$ADCIN_{xP} - ADCIN_{xN} \geq VREFHI$

### 20.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper will ensure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and/or acquisition window as desired. Configuring multiple SOCs to use the same trigger will allow the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel will allow for oversampling.

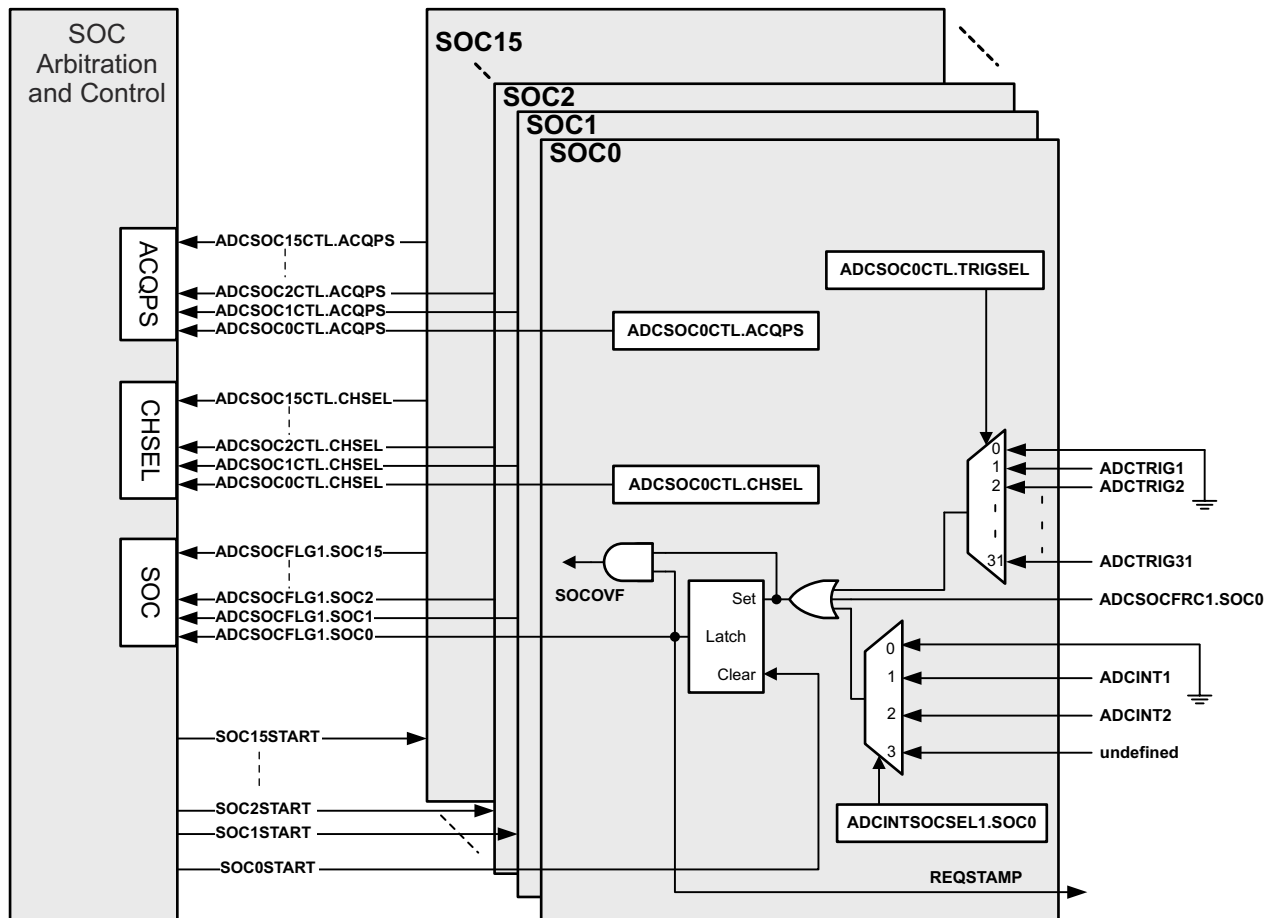

Figure 20-2. SOC Block Diagram

### 20.3.1 SOC Configuration

Each SOC has its own configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, and acquisition (sample) window duration.

### 20.3.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2 (from each C28x core present)
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCB from each ePWM module

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

### 20.3.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in their ability to drive an analog signal quickly and effectively. In order to achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5 LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

Acquisition window = (ACQPS + 1) · (System Clock (SYSCLK) cycle time)

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The datasheet will specify a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

### 20.3.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see [Figure 20-3](#)) can be found in the device-specific datasheet.

Figure 20-3. Single-Ended Input Model

For differential operation, the ADC input characteristics for values in the differential input model (see [Figure 20-4](#)) can be found in the device-specific data sheet.

These input models should be used along with actual signal source impedance to determine the acquisition window duration. See [Section 20.13.2](#) for more information.

Figure 20-4. Differential Input Model

### 20.3.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. Depending on the signal mode, the selection is different. For single-ended signal mode, the value in CHSEL selects a single pin as the input. For differential signal mode, the value in CHSEL selects an even-odd pin pair to be the positive and negative inputs. This is summarized in [Table 20-6](#).

#### Note

Regardless of configured resolution and signal mode, channel 13 on ADC-A (temperature sensor) and channel 12 on all ADCs will be sampled in 12-bit single-ended mode.

**Table 20-6. Channel Selection of Input Pins**

Input Mode	CHSEL	Input	
Single-Ended	0	ADCIN0	
	1	ADCIN1	
	2	ADCIN2	
	3	ADCIN3	
	4	ADCIN4	
	5	ADCIN5	
	6	ADCIN6	
	7	ADCIN7	
	8	ADCIN8	
	9	ADCIN9	
	10	ADCIN10	
	11	ADCIN11	
	12	ADCIN12	
	13	ADCIN13	
	14	ADCIN14	
	15	ADCIN15	
	CHSEL	Positive Input	Negative Input
Differential	0 or 1	ADCIN0	ADCIN1
	2 or 3	ADCIN2	ADCIN3
	4 or 5	ADCIN4	ADCIN5
	6 or 7	ADCIN6	ADCIN7
	8 or 9	ADCIN8	ADCIN9
	10 or 11	ADCIN10	ADCIN11
	12 or 13	ADCIN12	ADCIN13
	14 or 15	ADCIN14	ADCIN15

## 20.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

### 20.4.1 Single Conversion from ePWM Trigger

SOC5 is chosen arbitrarily. Any of the 16 SOCs could be used.

Assuming a 100 ns sample window is desired with a SYSCLK frequency of 200 MHz, then the acquisition window duration should be  $100 \text{ ns} / 5 \text{ ns} = 20 \text{ SYSCLK cycles}$ . The ACQPS field should therefore be set to .

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 will convert ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;     //SOC5 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 will begin conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches its period and generates the SOCB signal, the ADC will begin sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 will begin sampling when SOC5 gains priority (see [Section 20.5](#)). The ADC control logic will sample ADCINA1 with the specified acquisition window width of 100 ns. Immediately after the acquisition is complete, the ADC will begin converting the sampled voltage to a digital value. When the ADC conversion is complete, the results will be available in the ADCRESULT5 register (see [Section 20.12](#) for exact sample, conversion, and result latch timings).

### 20.4.2 Oversampled Conversion from ePWM Trigger

To configure the ADC to oversample ADCINA1 4 times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 will convert ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;     //SOC5 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 will begin conversion on ePWM3 SOCB
AdcaRegs.ADCSOC6CTL.bit.CHSEL = 1;      //SOC6 will convert ADCINA1
AdcaRegs.ADCSOC6CTL.bit.ACQPS = 19;     //SOC6 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC6CTL.bit.TRIGSEL = 10;   //SOC6 will begin conversion on ePWM3 SOCB
AdcaRegs.ADCSOC7CTL.bit.CHSEL = 1;      //SOC7 will convert ADCINA1
AdcaRegs.ADCSOC7CTL.bit.ACQPS = 19;     //SOC7 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC7CTL.bit.TRIGSEL = 10;   //SOC7 will begin conversion on ePWM3 SOCB
AdcaRegs.ADCSOC8CTL.bit.CHSEL = 1;      //SOC8 will convert ADCINA1
AdcaRegs.ADCSOC8CTL.bit.ACQPS = 19;     //SOC8 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC8CTL.bit.TRIGSEL = 10;   //SOC8 will begin conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches its period and generates the SOCB signal, the ADC will begin sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 will begin sampling when SOC5 gains priority (see [Section 20.5](#)). Once the conversion is complete for SOC5, SOC6 will begin converting ADCINA1 and the results for SOC5 will be placed in the ADCRESULT5 register. All four conversions will eventually be completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

#### Note

It is possible, but unlikely, that the ADC could begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See [Section 20.5](#) to understand how the next SOC to be converted is chosen.

### 20.4.3 Multiple Conversions from CPU Timer Trigger

This example will show how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 will be used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and their required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in [Table 20-7](#), where a SYCLK of 200 MHz is assumed (5ns cycle time).

**Table 20-7. Example Requirements for Multiple Signal Sampling**

Signal Name	Acquisition Window Requirement (ns)	Acquisition Window SYSCLK Cycles	ACQPS Register Value
Signal 1	>120ns	120ns/5ns = 24	24 – 1 = 23
Signal 2	>444ns	444ns/5ns = 89 (round up)	89 – 1 = 88
Signal 3	>110ns	110ns/5ns = 22	22 – 1 = 21
Signal 4	>291ns	291ns/5ns = 59 (round up)	59 – 1 = 58

Next decide which ADC pins to connect to each signal. This will be highly dependent on application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see [Table 20-8](#)).

**Table 20-8. Example Connections for Multiple Signal Sampling**

Signal Name	ADC Pin	CHSEL Register Value
Signal 1	ADCINA5	5
Signal 2	ADCINA0	0
Signal 3	ADCINA3	3
Signal 4	ADCINA2	2

With the information tabulated, it is easy to generate the SOC configurations:

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;         //SOC0 will use sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;        //SOC0 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;         //SOC1 will convert ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;        //SOC1 will use sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;        //SOC1 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;         //SOC2 will convert ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;        //SOC2 will use sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;        //SOC2 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;         //SOC3 will convert ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;        //SOC3 will use sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;        //SOC3 will begin conversion on CPU1 Timer 2
    
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 will eventually be sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) will be in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) will be in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

---

### Note

It is possible, but unlikely, that the ADC could begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See [Section 20.5](#) to understand how the next SOC to be converted is chosen.

---

#### 20.4.4 Software Triggering of SOCs

At any point, whether or not the SOCs have been configured to accept a specific trigger, a software trigger can set the SOCs to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger could be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;           //set SOC flags for SOC0 to SOC3
```

#### 20.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the order in which they are converted. The default priority method is round robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the SOCPRIORITY register is written. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round robin priority method is given in [Figure 20-5](#).

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOCs. When configured as high priority, an SOC will interrupt the round robin wheel after any current conversion completes and insert itself in as the next conversion. After its conversion completes, the round robin wheel will continue where it was interrupted. If two high priority SOC's are triggered at the same time, the SOC with the lower number will take precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in [Figure 20-6](#).

- A** After reset, SOC0 is highest priority SOC ; SOC7 receives trigger ; SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ; SOC8 is now highest priority SOC .
- C** SOC2 & SOC12 triggers rcvd . simultaneously ; SOC12 is first on round robin wheel ; SOC12 configured channel is converted while SOC2 stays pending .
- D** RRPOINTER changes to point to SOC 12 ; SOC2 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 2 ; SOC3 is now highest priority SOC .

**Figure 20-5. Round Robin Priority Example**

Example when SOC PRIORITY = 4

- A** After reset, SOC4 is 1<sup>st</sup> on round robin wheel ;  
SOC7 receives trigger ;  
SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ;  
SOC8 is now 1<sup>st</sup> on round robin wheel .
- C** SOC2 & SOC12 triggers rcvd. simultaneously ;  
SOC2 interrupts round robin wheel and SOC 2 configured channel is converted while SOC 12 stays pending .
- D** RRPOINTER stays pointing to 7 ;  
SOC12 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 12 ;  
SOC13 is now 1<sup>st</sup> on round robin wheel .

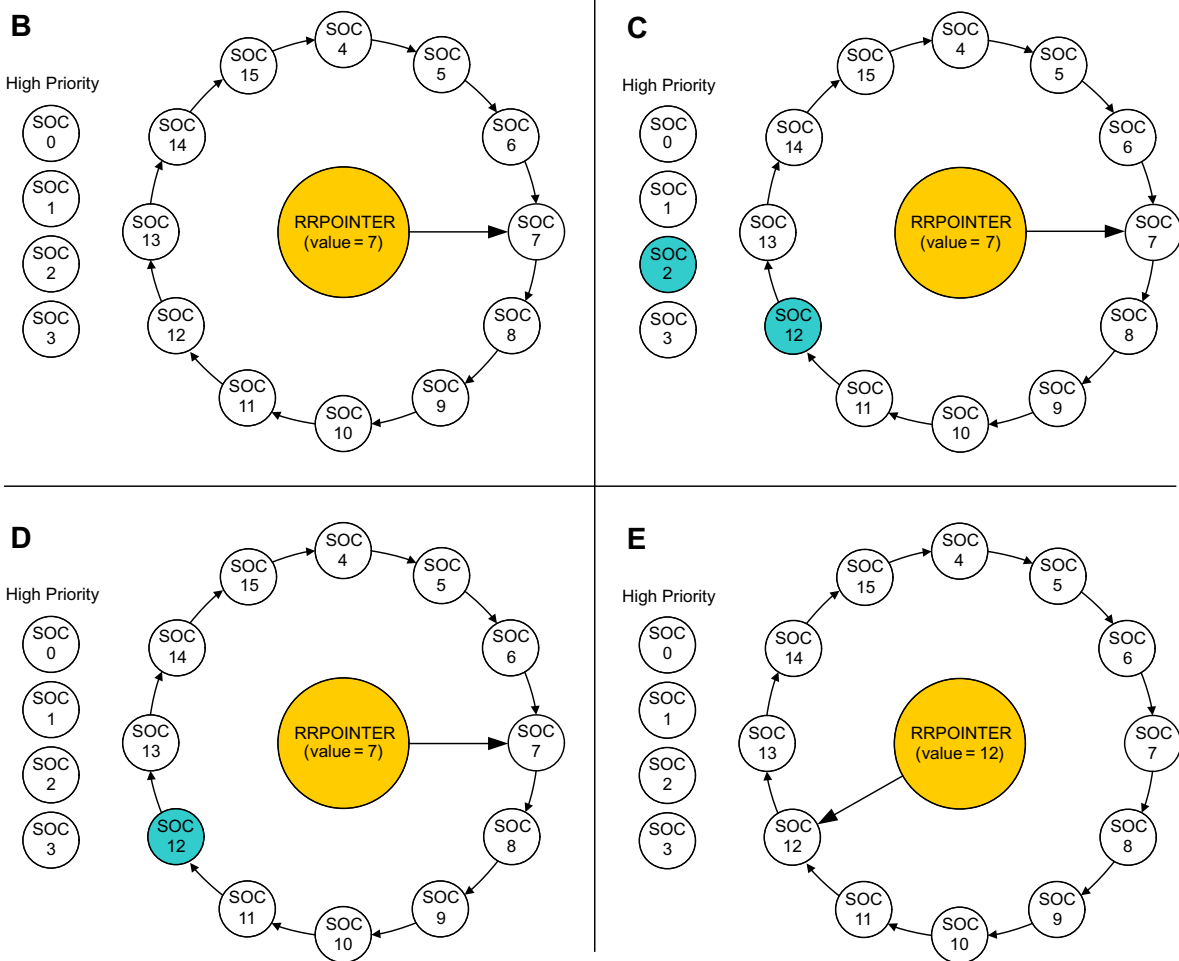

Figure 20-6. High Priority Example

## 20.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOCs one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOCs that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOCs are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper will not set all round-robin SOCs to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOCs. The first SOC to be set will be that with the highest priority based on the round-robin pointer, and subsequent SOCs will be set until BURSTSIZE SOCs have been set.

---

### Note

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received.

For example, if SOC PRIORITY = 12, that is, SOC12, SOC13, SOC14, and SOC15 are in round-robin, ADCBURSTCTL.BURSTSIZE setting should be  $\leq 3$  for burst mode to operate correctly.

---

### 20.6.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations could be configured for each SOC as desired.

```

AdcaRegs.BURSTCTL.BURSTEN = 1;           //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;         //CPU1 Timer 2 will trigger burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;        //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICTL.bit.SOC PRIORITY = 12; //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;     //SOC12 will convert ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;    //SOC12 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;     //SOC13 will convert ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;    //SOC13 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;     //SOC14 will convert ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;    //SOC14 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;     //SOC15 will convert ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;    //SOC15 will use sample duration of 20 SYSCLK cycles
    
```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 will be converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 will be converted once their SOCs gain priority. The results for SOC12 and SOC13 will be in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round robin pointer will give highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 will be set as pending and eventually be converted. The results for SOC14 and SOC15 will be in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers will continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions could be achieved using a similar approach.

### 20.6.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOC's is presented in [Figure 20-7](#).

Example when SOC PRIORITY = 4, BURSTEN = 1, and BURSTSIZE = 1

- After reset, SOC4 is 1<sup>st</sup> on round robin wheel; BURSTTRIG trigger is received;
- A** SOC4 & SOC5 are set and configured channels converted immediately.
- B** RRPOINTER changes to point to SOC5; SOC6 is now 1<sup>st</sup> on round robin wheel.
- C** BURSTTRIG & SOC1 triggers rcvd. simultaneously; SOC1, SOC6, and SOC7 are set; SOC1 interrupts round robin wheel and SOC1 configured channel is converted while SOC6 and SOC7 stay pending.
- D** RRPOINTER stays pointing to 5; SOC6/SOC7 configured channels are now converted.
- E** RRPOINTER changes to point to SOC7; SOC8 is now 1<sup>st</sup> on round robin wheel, waiting for BURSTTRIG.

Figure 20-7. Burst Priority Example

## 20.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See [Section 20.12](#) for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the PIE.

### Note

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 20-8 shows a block diagram of the ADC interrupt structure.

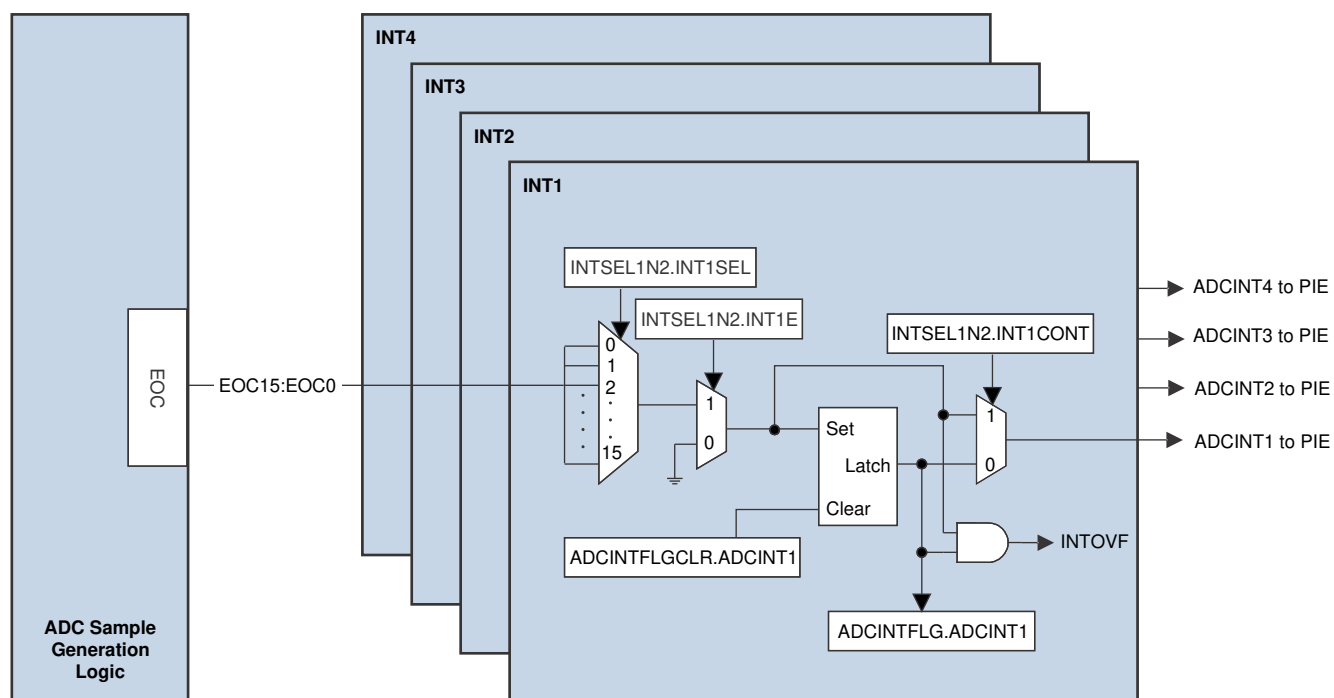

Figure 20-8. ADC EOC Interrupts

### 20.7.1 Interrupt Overflow

If the EOC signal would set a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts will not be passed on to the PIE module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; it does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow could occur, the application should check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;      //clear INT1 flag for ADC-A

// Check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)     //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1   //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1   //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// Check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

### 20.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts will not be issued to the PIE. By activating this mode ADC interrupts will always reach the PIE. The ADCINTOVF register will still be set if an interrupts occur while ADCINTFLG is still set regardless of this configuration.

### 20.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when they become available. However, the timing of the early interrupt may be too early and the application may need to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt will be generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 will not have any effect on the interrupt generation.

## 20.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. The post-processing blocks have the ability to:

- Remove an offset associated with the ADCIN channel
- Subtract out a reference value
- Flag a zero-crossing point, with the option to trip a PWM and/or generate an interrupt
- Flag a high or low compare limit, with the option to trip a PWM and/or generate an interrupt
- Record the delay between the associated SOC trigger and when sampling actually begins

Figure 20-9 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

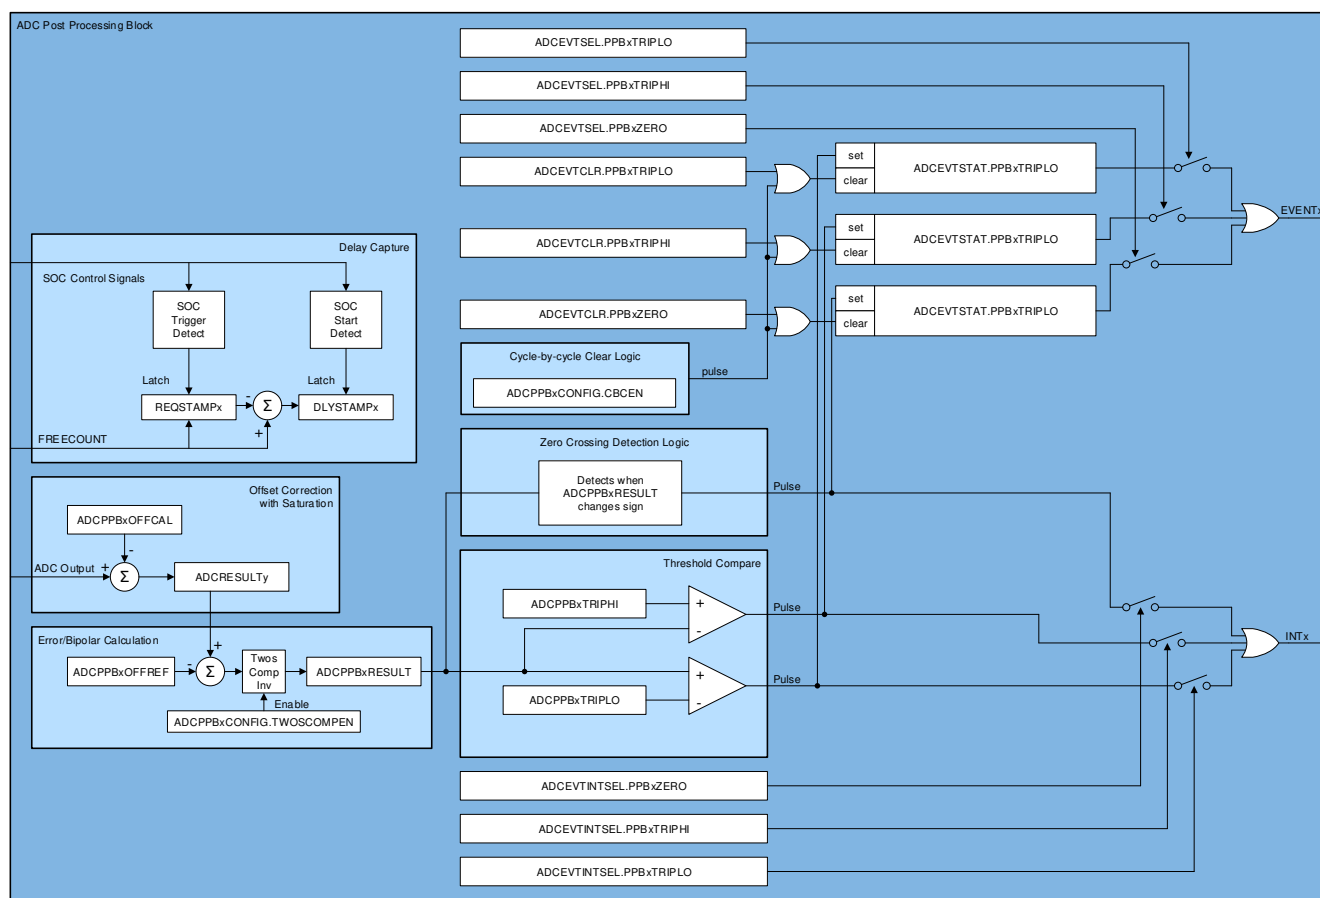

Figure 20-9. ADC PPB Block Diagram

### 20.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block will automatically add or subtract the value in the OFFCAL register from the raw conversion result and store it in the ADCRESULT register. This addition/subtraction will saturate at 0 on the low end and either 4095 or 65535 on the high end for 12-bit or 16-bit mode, respectively.

---

#### Note

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
  - It is possible to point multiple PPBs to the same SOC. In this case, the OFFCAL value that will actually be applied will be that of the PPB with the highest number.
  - In particular, care needs to be taken when using the PPB on SOC0, as all the PPB point to this SOC by default. This may cause unintentional overwriting of offset correction of a lower numbered PPB by a higher numbered PPB.
- 

### 20.8.2 PPB Error Calculation

In many applications, an error from a setpoint or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these functions automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block will automatically subtract the value in the OFFREF register from the ADCRESULT value and store it in the ADCPPBxRESULT register. This subtraction will produce a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

---

#### Note

- In 12-bit mode, do not write a value larger than 12 bits to the OFFREF register.
  - Since the PPBxRESULT register is unique for each PPB, it is possible to point multiple PPBs to the same SOC and get different results for each PPB.
  - Writing a 0 to the OFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.
- 

### 20.8.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against high and low limits, or whenever ADCPPBxRESULT changes sign. Based on these comparisons, it can generate a trip to the PWM and/or an interrupt automatically, lowering the sample to ePWM latency and reducing software overhead. This functionality also enables safety-conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

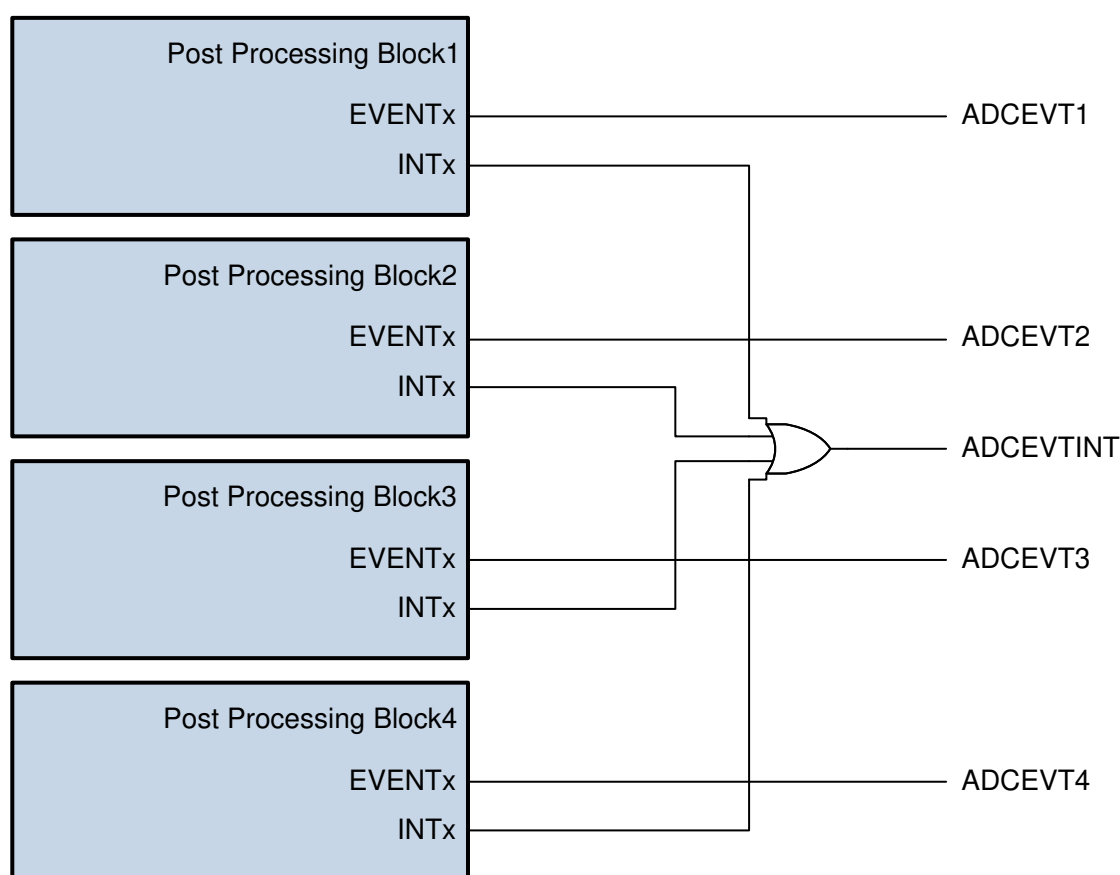

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zero-crossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit will be set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT

register is gated by end-of-conversion (EOC), not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCINTSEL register has corresponding bits which allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in [Figure 20-10](#).

#### Note

- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR will have to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and/or zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

**Figure 20-10. ADC PPB Interrupt Event**

#### 20.8.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops will collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field will contain the number of SYSCLK cycles between when the associate SOC was triggered and when it began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

**Note**

If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register may overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

The sample delay capture will not function if the associated SOC is triggered via software. It will, however, correctly record the delay if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

**20.9 Opens/Shorts Detection Circuit (OSDETECT)**

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 20-11.

**Note**

- The divider resistance tolerances can vary widely, hence this feature should not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum will be needed.

**Figure 20-11. Opens/Shorts Detection Circuit**

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This will cause the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 20-9.

**Table 20-9. DETECTCFG Settings**

ADCOSDETECT. DETECTCFG	Source Voltage	S4	S3	S2	S1	Drive Impedance
0	Off	Open	Open	Open	Open	Open
1	Zero Scale	Closed	Open	Open	Closed	5K    7K
2	Full Scale	Open	Closed	Closed	Open	5K    7K
3	5/12 VDDA	Open	Closed	Open	Closed	5K    7K
4	7/12 VDDA	Closed	Open	Closed	Open	5K    7K
5	Zero Scale	Open	Open	Open	Closed	5K
6	Full Scale	Open	Open	Closed	Open	5K
7	Zero Scale	Closed	Open	Open	Open	7K

### 20.9.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance  $R_S$ , shunt capacitor  $C_P$ , the equivalent OSDETECT resistance  $R_{OSDETECT}$  and voltage  $V_{OSDETECT}$  is shown in Figure 20-12 and can be used as a basis to calculate the signal level going in to the sampling capacitor.  $R_{OSDETECT}$  and  $V_{OSDETECT}$  are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 20-9 for the different configuration settings. Refer to Figure 20-12 when deriving the input signal to S/H if signal source  $V_S$  is driving while the OSDETECT feature is enabled.

**Figure 20-12. Input Circuit Equivalent with OSDETECT Enabled**

The input impedance  $R_S$  and  $C_P$  may be integral parts of the signal source or these could have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature as this would affect the conversion results. For instance, driving an input signal when this feature is enabled would connect signal  $V_S$  to the OSDETECT circuit through  $R_S$  and affecting the ADC results. Larger  $C_P$  values (in the order greater than hundreds of pF) would require using higher ACQPS to ensure that signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 20-9.
3. Initiate a conversion and inspect the conversion result.

You must interpret the results based on what is driving on the input side and what are the values of  $R_S$  and  $C_P$ . If the  $V_S$  signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

### 20.9.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal will be pulled towards the sourced voltages. An input with good drive strength (pin not open) will be minimally affected. However, if the pin is open, the sampled voltages will be close to the source voltages specified in [Table 20-9](#).

### 20.9.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal will be pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) will be pulled toward each sourced voltage. However, if the pin is shorted, the signal will remain at the same voltage.

## 20.10 Power-Up Sequence

Upon device power-up or system level reset, the ADC will be powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data manual for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as it occurs after all the ADCs have begun powering up.

## 20.11 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are embedded into TI reserved OTP memory as part of C-callable functions.

- The `Device_cal()` function copies the trim values for ADC and DAC offset from OTP memory to their respective trim registers.
- The `CalAdcXINL()` functions copy the trim values for linearity from OTP memory to the respective trim registers.
- A different offset trim is required for each possible combination of resolution and signal mode. The `GetAdcOffsetTrimOTP(Uint16)` function takes an input value corresponding to the ADC, resolution, and signal mode and returns the corresponding offset trim value from OTP memory, which the user then moves into the ADC offset trim register.
- The trim functions in `Device_cal()` are callable in C2000ware as `ADC_setOFFSETTRIM()`, `ADC_setINLTRIM()`, and `DAC_setDACTRIM()`. These functions fetch trim values from the TI reserved OTP memory source locations where the values are stored during test process as well as the analog module register destinations where the trim values are copied to.

Until the appropriate factory trim is loaded, the ADC (and other modules) will not be assured to operate within data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) will not be assured to operate within data sheet specifications.

The boot ROM will call the calibration functions, so trim values should be initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user can call the calibration functions (defined in the headerfiles).

Refer to [Section 20.11.2](#) for ADC registers being populated during ADC calibration.

### 20.11.1 ADC Zero Offset Calibration

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO (single-ended operation) or the difference from (maximum code/2) when converting  $ADCINxP = ADCINxN$  (differential mode). The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIM register. The value contained in this register will be applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results will not be affected and the full dynamic range of the ADC will be maintained for any trim value.

Using the `GetAdcOffsetTrimOTP(Uint16)` function, the ADCOFFTRIM register can be loaded with the factory calibrated offset error correction. You can modify the ADCOFFTRIM register to compensate for additional offset error induced by the application environment if desired, but this is not typically necessary to achieve data sheet specified performance.

---

#### Note

Regardless of the converter resolution, the size of each ADCOFFTRIM step is  $(VREFHI-VREFLO)/65536$ .

---

Use the following procedure to re-calibrate the ADC offset in 12-bit, single-ended mode:

1. Set ADCOFFTRIM to +112 steps (0x70). This adds an artificial offset to account for negative offset that may reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example,  $32 \times 16$  conversions = 512 conversions).
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIM to 112 – result from step 3.

Use the following procedure to re-calibrate the ADC offset in 16-bit, differential mode:

1. Set ADCOFFTRIM to no adjustment (0x00).
2. Short  $ADCINxP$  and  $ADCINyN$  together (external connection) to a voltage near  $Vrefcm$  and accumulate some multiple of 16 conversions (for example,  $32 \times 16$  conversions = 512 conversions).
3. Divide the accumulated result by the number of conversions (for example, for 512 conversions, divide by 512).
4. Set ADCOFFTRIM to 0 – result from step 3).

### 20.11.2 ADC Calibration Routines in OTP

During factory testing, the calibration values for ADC offset (ADCOFFTRIM register) and ADC linearity correction (ADCINLTRIM1-6 registers) are measured per device. The resulting correction values for ADC offset and linearity and the associated functions to populate these into the corresponding ADC registers are stored in the OTP.

## 20.12 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must ensure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the data sheet. The conversion time is approximately 10.5 ADCCLK cycles in 12-bit mode and 29.5 ADCCLK cycles in 16-bit mode. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in [Section 20.12.1](#) for exact timings.

### 20.12.1 ADC Timing Diagrams

The following diagrams show the ADC conversion timings for two SOC's given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOC's are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

[Table 20-10](#) describes the parameters in the following timing diagrams. [Table 20-11](#) and [Table 20-12](#) list the ADC timings.

**Table 20-10. ADC Timing Parameter Descriptions**

Parameter	Description
$t_{SH}$	<p>The duration of the S+H window.</p> <p>At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by <math>(ACQPS + 1)</math> SYSCLK cycles. ACQPS can be configured individually for each SOC, so <math>t_{SH}</math> will not necessarily be the same for different SOC's.</p> <p><b>Note:</b> The value on the S+H capacitor will be captured approximately 5ns before the end of the S+H window regardless of device clock settings.</p>
$t_{LAT}$	<p>The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register.</p> <p>If the ADCRESULTx register is read before this time, the previous conversion results will be returned.</p>
$t_{EOC}$	<p>The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. In 16-bit mode, this will coincide with the latching of the conversion results, while in 12-bit mode, the subsequent sample can start before the conversion results are latched.</p>
$t_{INT}$	<p>The time from the end of the S+H window until an ADCINT flag is set (if configured).</p> <p>If the INTPULSEPOS bit in the ADCCTL1 register is set, <math>t_{INT}</math> will coincide with the end of conversion (EOC) signal.</p> <p>If the INTPULSEPOS bit is 0, <math>t_{INT}</math> will coincide with the end of the S+H window. If <math>t_{INT}</math> triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to ensure the read occurs after the results latch (otherwise, the previous results will be read).</p> <p>If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there will be a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR or trigger the DMA exactly when the sample is ready.</p>

## 20.13 Additional Information

The following sections contain additional practical information.

### 20.13.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device should be operated synchronously. The device datasheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To ensure synchronous operation, all ADCs on the device should operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration).

#### 20.13.1.1 Basic Synchronous Operation

The following example configures two SOC's each on ADCA and ADCB with identical trigger select and ACQPS values. This will result in synchronous operation between ADCA and ADCB. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

```

Example: Basic Synchronous Operation
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
    
```

Figure 20-17. Example: Basic Synchronous Operation

Several things should be noted from [Figure 20-17](#). First, while the ACQPS values must be the same for SOC's with the same number, different ACQPS values can be used for SOC's with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high priority SOC's are to be used, the priority must be configured the same on all ADCs.

### 20.13.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCB while using three SOCs and two trigger sources. Figure 20-18 demonstrates that any combination of relative trigger timings still results in synchronous operation.

**Example: Synchronous Operation With Multiple Trigger Sources**

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0; //SOC2 will convert ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 will begin conversion on CPU Timer1
AdcbRegs.ADCSOC2CTL.bit.CHSEL = 2; //SOC2 will convert ADCINB2
AdcbRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 will begin conversion on CPU Timer1
    
```

**Figure 20-18. Example: Synchronous Operation with Multiple Trigger Sources**

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so it will likely result in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

### 20.13.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOC's than the other ADCs while still operating synchronously.

**Example: Synchronous Operation With Uneven SOC Numbers**

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;    //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;  //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;     //SOC0 will convert ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;    //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;  //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;     //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;    //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;  //SOC1 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;     //SOC1 will convert ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;    //SOC1 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;  //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;     //SOC2 will convert ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;    //SOC2 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10;  //SOC2 will begin conversion on ePWM3 SOCB
    
```

**Figure 20-19. Example: Synchronous Operation with Uneven SOC Numbers**

Note that if the trigger comes again before all SOC's have completed their conversions, ADCB will begin converting immediately on SOC0 while ADCA will not start converting SOC0 again until SOC2 is complete. This will result in asynchronous operation, so care must be taken to not overflow the trigger.

**Figure 20-20. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow**

### 20.13.1.4 Synchronous Operation with Different Resolutions

Configuring different ADCs to use different resolutions will result in asynchronous operation. This will occur because the conversion time for 12-bit mode and 16-bit mode are different. Synchronous operation requires both the start and end of the conversion phase to be aligned, so even using the same S+H window duration will not result in synchronous operation.

**Example: Asynchronous Operation with Different Resolutions**

```
//ADCA = 12-bit mode
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 will use sample duration of 51 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 will begin conversion on ePWM3 SOCB

//ADCB = 16-bit mode
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 will convert ADCINB0/B1
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 will use sample duration of 51 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 will begin conversion on ePWM3 SOCB
```

**Figure 20-21. Example: Asynchronous Operation with Different Resolutions**

In order to achieve synchronous operation while using both 12-bit and 16-bit resolution, conversions must be done in parallel at one resolution. Once conversions are complete at one resolution, the CPU must switch the resolution on all ADCs and then cause another trigger (this trigger should not be a software SOC force, as all ADCs can't be started simultaneously via this method).

**Figure 20-22. Example: Synchronous Operation with Different Resolutions**

### 20.13.1.5 Non-overlapping Conversions

If conversion timings can be guaranteed to not overlap by the user, then it is not necessary to configure all SOC0s identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources which are always 180 degrees out-of-phase, then SOC0 could be used for both ADCA and ADCB with different trigger sources and different ACQPS values.

**Example: Operation with Non-overlapping Conversions**

```
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 9; //SOC0 will begin conversion on ePWM3 SOCA
```

Figure 20-23. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions

### 20.13.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor will be charged to within 1/2 LSB or 1/4 LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to ensure adequate settling performance. See TI application reports [ADC Input Circuit Evaluation for C2000 MCUs](#) and [Charge-Sharing Driving Circuits for C2000 ADCs](#) for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_s + R_{on}) \cdot C_h + R_s \cdot (C_s + C_p) \tag{3}$$

And the number of time constants needed is given by the equation:

$$k = \ln \left( \frac{2^n}{\text{settling error}} \right) - \ln \left( \frac{C_s + C_p}{C_h} \right) \tag{4}$$

So the total S+H time should be set to at least:

$$t = k \cdot \tau \tag{5}$$

Where the following parameters are provided by the ADC input model in the device data manual:

- n = ADC resolution (in bits)
- R<sub>ON</sub> = ADC sampling switch resistance (in Ohms)
- C<sub>H</sub> = ADC sampling capacitor (in pF)

- $C_p$  = ADC channel parasitic input capacitance (in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- $R_s$  = ADC driving circuit source impedance (in Ohms)
- $C_s$  = capacitance on ADC input pin (in pF)

For example, assuming the following parameters:

- $n$  = 12-bits
- $R_{ON}$  = 500Ω
- $C_H$  = 12.5pF
- $C_p$  = 12.7pF
- settling error = ¼ LSB
- $R_s$  = 180Ω
- $C_s$  = 150pF

The time constant would be calculated as:

$$\tau = (180\Omega + 500\Omega) \cdot 12.5\text{pF} + 180\Omega \cdot (150\text{pF} + 12.7\text{pF}) = 8.5\text{ns} + 29.3\text{ns} = 37.8\text{ns} \quad (6)$$

And the number of required time constants would be:

$$k = \ln\left(\frac{2^{12}}{0.25}\right) - \ln\left(\frac{150\text{pF} + 12.7\text{pF}}{12.5\text{pF}}\right) = 9.70 - 2.57 = 7.13 \quad (7)$$

So the S+H time should be set to at least:

$$37.8\text{ns} \cdot 7.13 = 270\text{ns}$$

If SYSCLK = 100 MHz, then each SYSCLK cycle is 10 ns. S+H duration should be 270 ns/10 ns = 27.0 SYSCLK cycles, so ACQPS for this input should be set to at least CEILING(27.0) – 1 = 26.

While this gives a rough estimate of the required acquisition window, a better method would be to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

---

#### Note

The device datasheet will specify a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

---

### 20.13.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, it is easy to achieve simultaneous sampling. This is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The example below demonstrates simultaneous sampling on 4 ADCs based on an ePWM3 event. ADCINA3, ADCINB5, ADCINC5, and ADCIND2 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;           //SOC0 will convert ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINB5
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdcdRegs.ADCSOC0CTL.bit.CHSEL = 2;           //SOC0 will convert ADCIND2
AdcdRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcdRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB

```

When the ePWM3 trigger is received, all four ADCs will begin converting in parallel immediately. All results will be in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples will not happen at exactly the same time.

### 20.13.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all C28x CPUs, C28x DMAs, and CLAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

### 20.13.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN13 on ADCA by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the GetTemperatureC() function in F2838x\_TempSensorConv.c.

---

#### Note

To sample the temperature sensor, the ADC must be in single-ended 12-bit mode.

If the temperature sensor is sampled in 16-bit mode, the ADC will switch to 12-bit mode to perform the conversion. This could cause incorrect ADC results.

---

### 20.13.6 Designing an External Reference Circuit

Figure 20-24 shows the basic organization of the external voltage reference generation circuitry. A single reference voltage generation source should be shared by all ADC modules. This will minimize reference voltage mismatch between ADC modules. The reference voltage should then be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the reference pin. A capacitor between the high and low reference pins should be placed on the PCB as close to the pins as practical to help absorb high frequency currents. A series resistor (typically <math><1\Omega</math>) in series with this capacitor may be necessary to ensure op-amp stability.

It is also possible to share two reference pins between one op-amp driver. This organization is shown in Figure 20-25. This gives slightly reduced performance compared to the case where each reference pin has a dedicated op-amp buffer, but it should still be possible to achieve all ADC specifications in the data sheet.

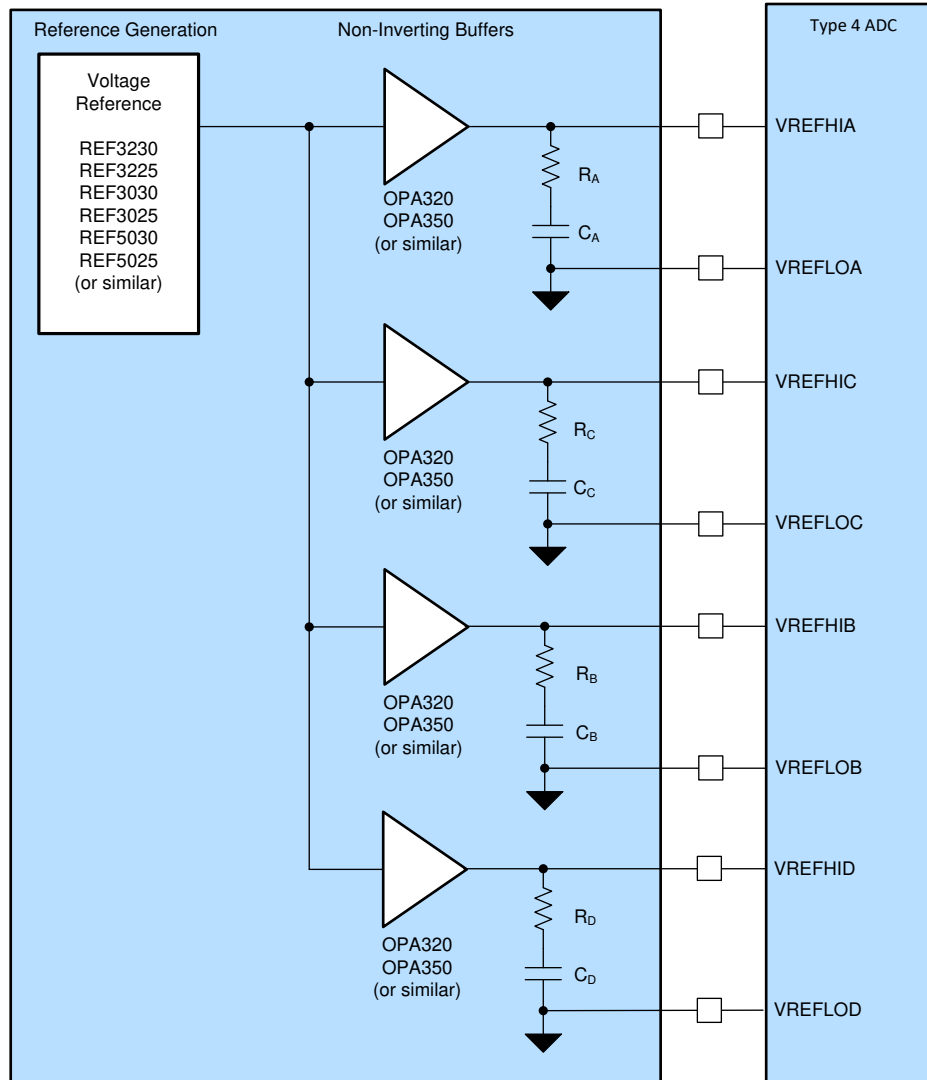

Figure 20-24. ADC Reference System

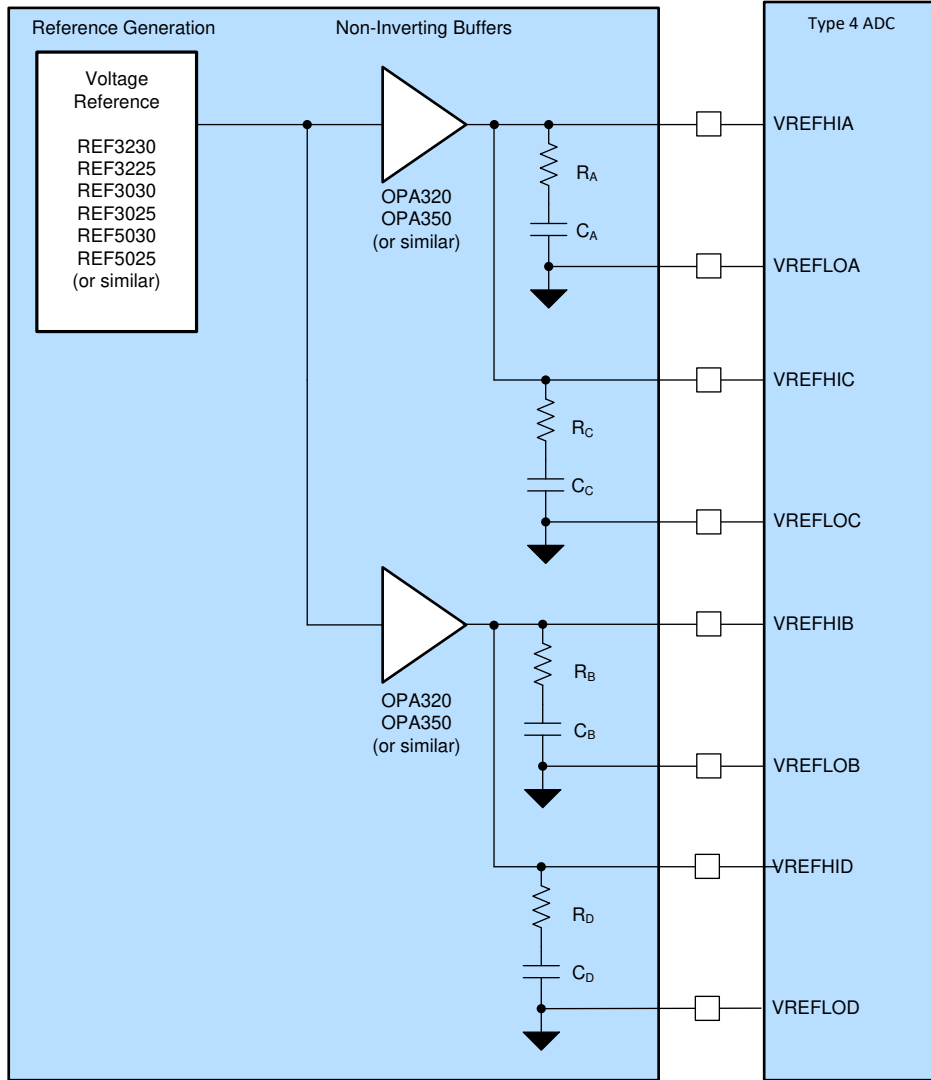

Figure 20-25. ADC Shared Reference System

## 20.14 Software

### 20.14.1 ADC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/adc

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 20.14.1.1 ADC Software Triggering

FILE: adc\_ex1\_soc\_software.c

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

##### External Connections

- A0, A1, C2, and C3 should be connected to signals to convert

##### Watch Variables

- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1
- *myADC1Result0* - Digital representation of the voltage on pin C2
- *myADC1Result1* - Digital representation of the voltage on pin C3

#### 20.14.1.2 ADC ePWM Triggering

FILE: adc\_ex2\_soc\_epwm.c

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

##### External Connections

- A0 should be connected to a signal to convert

##### Watch Variables

- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

#### 20.14.1.3 ADC Temperature Sensor Conversion

FILE: adc\_ex3\_temp\_sensor.c

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the `ADC_getTemperatureC()` function.

##### Watch Variables

- *sensorSample* - The raw reading from the temperature sensor
- *sensorTemp* - The interpretation of the sensor sample as a temperature in degrees Celsius.

#### 20.14.1.4 ADC Synchronous SOC Software Force (*adc\_soc\_software\_sync*)

FILE: adc\_ex4\_soc\_software\_sync.c

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

##### External Connections

- A2, A3, C2, C3 pins should be connected to signals to convert

##### Watch Variables

- *myADC0Result0* : a digital representation of the voltage on pin A2

- *myADC0Result1* : a digital representation of the voltage on pin A3
- *myADC1Result0*: a digital representation of the voltage on pin C2
- *myADC1Result1*: a digital representation of the voltage on pin C3

#### 20.14.1.5 ADC Continuous Triggering (*adc\_soc\_continuous*)

FILE: *adc\_ex5\_soc\_continuous.c*

This example sets up the ADC to convert continuously, achieving maximum sampling rate.

##### External Connections

- A0 pin should be connected to signal to convert

##### Watch Variables

- *adcAResults* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is the minimum possible based on the ADC speed.

#### 20.14.1.6 ADC Continuous Conversions Read by DMA (*adc\_soc\_continuous\_dma*)

FILE: *adc\_ex6\_soc\_continuous\_dma.c*

This example sets up two ADC channels to convert simultaneously. The results will be transferred by the DMA into a buffer in RAM.

##### External Connections

- A3 & C3 pins should be connected to signals to convert

##### Watch Variables

- *myADC0DataBuffer* : a digital representation of the voltage on pin A3
- *myADC1DataBuffer*: a digital representation of the voltage on pin C3

#### 20.14.1.7 ADC PPB Offset (*adc\_ppb\_offset*)

FILE: *adc\_ex7\_ppb\_offset.c*

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

##### External Connections

- A2, C2 pins should be connected to signals to convert

##### Watch Variables

- *myADC0Result* : a digital representation of the voltage on pin A2
- *myADC0PPBResult* : a digital representation of the voltage on pin A2, minus 100 LSBs of automatically added offset
- *myADC1Result*: a digital representation of the voltage on pin C2
- *myADC1PPBResult*: a digital representation of the voltage on pin C2 plus 100 LSBs of automatically added offset

#### 20.14.1.8 ADC PPB Limits (*adc\_ppb\_limits*)

FILE: *adc\_ex8\_ppb\_limits.c*

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

##### External Connections

- A0 should be connected to a signal to convert

##### Watch Variables

- None

### 20.14.1.9 ADC PPB Delay Capture (*adc\_ppb\_delay*)

FILE: *adc\_ex9\_ppb\_delay.c*

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
  - ePWM2, with period 9999, triggering SOC1 to convert on pin A2
- Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
- After the program runs, the memory will contain:

*conversion* : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

### 20.14.1.10 ADC ePWM Triggering Multiple SOC

FILE: *adc\_ex10\_multiple\_soc\_epwm.c*

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

#### External Connections

- A0, A1, A2 and C2, C3, C4 pins should be connected to signals to be converted.

#### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcCResult0* - Digital representation of the voltage on pin C2
- *adcCResult1* - Digital representation of the voltage on pin C3
- *adcCResult2* - Digital representation of the voltage on pin C4

### 20.14.1.11 ADC Burst Mode

FILE: *adc\_ex11\_burst\_mode\_epwm.c*

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

#### External Connections

- A0, A1, A2, A3, A4

#### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcAResult3* - Digital representation of the voltage on pin A3
- *adcAResult4* - Digital representation of the voltage on pin A4

### 20.14.1.12 ADC Burst Mode Oversampling

FILE: *adc\_ex12\_burst\_mode\_oversampling.c*

This example sets up ePWM1 to periodically trigger SOC0 and SOC1 on ADCA (to sample A0 and A1). Additionally, the ADC burst mode is also triggered using ePWM1. The burst SOCs are used to accumulate multiple conversions to oversample A2 over multiple ePWM periods.

#### External Connections

- A0, A1, A2

#### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

#### 20.14.1.13 ADC SOC Oversampling

FILE: `adc_ex13_soc_oversampling.c`

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA including multiple SOCs that all convert A2 to achieve oversampling on A2.

ADCA Interrupt ISRs are used to read results of ADCA.

#### External Connections

- A0, A1, A2 should be connected to signals to be converted.

#### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

#### 20.14.1.14 ADC PPB PWM trip (*adc\_ppb\_pwm\_trip*)

FILE: `adc_ex14_ppb_pwm_trip.c`

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block (PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases

- one-shot
- cycle-by-cycle
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

#### External Connections

- A2 should be connected to a signal to convert
- Observe the following signals on an oscilloscope
  - ePWM1(GPIO0 - GPIO1)
  - ePWM2(GPIO2 - GPIO3)
  - ePWM3(GPIO4 - GPIO5)
- 

#### Watch Variables

- *adcA2Results* - digital representation of the voltage on pin A2

#### 20.14.1.15 ADC High Priority SOC (*adc\_high\_priority\_soc*)

FILE: `adc_ex15_high_priority_soc.c`

This example demonstrates configuration of ADC high priority SOCs in order to sample fastest control loop signals with high priority while low priority signals are sampled with default round robin priority.

ADC PPB block is configured to capture delay between SOC trigger and actual start of the SOC sampling in order to quantify the jitters in sampling high priority signals due to low priority signals. The delay in processing an SOC is captured in ADCPPBxSTAMP.DLYSTAMP register field and the total delay in sampling an SOC is equal to (DLYSTAMP - 2) cycles. In an optimal design the high priority SOC is expected to have less delay between SOC trigger and actual start of the sample.

In this example ADCA, ADCB and ADCD are configured to sample both high and low priority signals. SOC0-3 are configured as high priority SOCs while rest are configured with default round-robin priority. ADCA SOC0-3 are configured as high priority SOCs sampling channels A0-A3, ADCB SOC0-1 are configured as high priority SOCs sampling channels B0-B1 and ADCD SOC0-1 are configured as high priority SOCs sampling channels D0-D1. For sampling low priority signals SOC4-SOC5 are configured sampling channel 4 and channel 13 respectively for ADCA and channel 4 and 5 for ADCB and ADCD. For ADCA, channel 13 is connected to internal temperature sensor output and hence no signal needs to be connected to channel A13. High priority SOC results are read in ADCINT1 ISR while low priority SOC results are read in idle loop.

This example has two modes of operation as follows. Desired mode can be selected by configuring the EX\_ADC\_LP\_SOC\_TRIGGER macro accordingly. Mode 0: ADCINT as round robin SOC trigger Mode 1: EPWM2 as round robin SOC trigger

In mode 0, EPWM1 is configured as trigger for high priority SOCs while ADCINT1 is configured as low priority SOC trigger. ADCINT1 is configured to be triggered on completion of SOC1 conversion which in turn trigger low priority SOCs 4 and 5 and ADCINT2 is configured to be triggered on completion of SOC5. ADC result for high priority SOCs are read in ADCINT ISR while low priority SOC results are read in idle loop. ADCINT3 is configured to be triggered on completion of SOC3 and hence SOC2-SOC3 results for ADCA are read post checking if the conversion is complete in ADCINT1 ISR.

In mode 0, SOC0-SOC1 for all ADCs will experience minimal delay(0 and 1 conversions) in processing due to the high priority configuration. For ADCA, SOC4-SOC5 are triggered when SOC2-SOC3 conversion is ongoing, hence SOC4-SOC5 will see some delay(2 and 3 conversions) in processing as expected. For ADCB and ADCD, SOC4-SOC5 will see minimal delay (0 and 1 conversions) in processing as expected.

In mode 1, EPWM1 is configured as trigger for high priority SOCs while EPWM2 is configured as low priority SOC trigger. ADCINT1 is configured to be triggered on completion of SOC3 conversion and ADC result for high priority SOCs are read in the ADCINT ISR. Low priority SOCs 4 and 5 are triggered through EPWM2 and ADCINT2 is configured to be triggered on completion of SOC5. The result for low priority SOCs are read in background loop. Since, SOC4-5 are triggered post SOC2-3 conversion(due to configured EPWM1 and EPWM2 trigger frequency and duty), SOC4-SOC5 will have minimal delay(0 and 1 conversions respectively) in SOC processing as expected.

Optimization Level: Example is expected to run with opt level = O2.

To view ADC results, put breakpoint at the statement where indexB is reset to zero in idle loop.

#### External Connections

- A0-A4, B0-B1, B4-B5, D0-D1 and D4-D5 pins should be connected to signals to be converted.
- Observe ePWM1, ePWM2 signals on oscilloscope

#### Watch Variables

ADC Results:

- adcA0Results - adcA4Results - ADC result of channels A0-A4
- adcA13Results - ADC result of channels A13(Temp Sensor output)
- adcB0Results - adcB1Results - ADC result of channels B0-B1
- adcB4Results - ADC result of channel B4
- adcB5Results - ADC result of channel B5
- adcD0Results - adcD1Results - ADC result of channels D0-D1
- adcD4Results - ADC result of channel D4
- adcD5Results - ADC result of channel D5

SOC conversion delays:

- delaySocA0 - Delay in sampling ADCA SOC0
- delaySocA3 - Delay in sampling ADCA SOC3
- delaySocA4-delaySocA5 - Delay in sampling ADCA SOC4-SOC5
- delaySocB0-delaySocB1 - Delay in sampling ADCB SOC0-SOC1
- delaySocB4-delaySocB5 - Delay in sampling ADCB SOC4-SOC5
- delaySocD0-delaySocD1 - Delay in sampling ADCD SOC0-SOC1
- delaySocD4-delaySocD5 - Delay in sampling ADCD SOC4-SOC5

#### 20.14.1.16 ADC Interleaved Averaging in Software

FILE: adc\_ex16\_sw\_interleaved\_averaging.c

This example demonstrates software interleaved averaging of ADC input channels. ADCA/B channel 0 and 1 are sampled one after another in order to achieve interleaved averaging. SOC0-15 of ADCA and ADCB are configured to sample channel 0 and 1 alternatively with channel 0 being sampled by even SOC's namely SOC0, 2, 4, 6, 8, 10, 12 & 14 and channel 1 being sampled by odd SOC's namely SOC1, 3, 5, 7, 9, 11, 13 & 15.

Sampling is initially triggered through external GPIO signal through enabling ADCEXTSOC signal via input XBAR and thereafter through ADCINT1. GPIO33 is configured to trigger ADCA and B SOC's for the first time in order to ensure synchronous operation. GPIO33 needs to be connected to GPIO32 which in turn is driven by software to trigger the respective ADC SOC's.

ADCA Interrupt ISR's are used to read results of both ADCA and ADCB to demonstrate parallel operation of multiple ADC's. ADCINT2 is configured to be triggered after completion of SOC7 while ADCINT1 is configured to be triggered after completion of SOC15 conversion and respective SOC results of ADCA and ADCB are read in ADCAINT2 and ADCAINT1 ISR's. Read SOC0-SOC15 ADC results are then averaged in ADCINT1 ISR to get the filtered ADC output.

Early interrupt mode is configured to trigger the ADC interrupt just at the end of acquisition window in order to save cycles (~42 cycles) since ADCA result of SOC7 in ADCINT2 and SOC15 in ADCINT1 are read post around 60 and 65 cycles respectively. Also, Fast ISR's are configured in the example to save some cycles during compiler specific context save and restore.

Optimization level: This example is expected to be run with opt level = 2

Sampling rate related calculations:

- ADC acquisition cycles programmed( S + H ) = 15 SYSCLKS
- Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCLKs
- Time from 1st SOC trigger to interrupt trigger:  $15 * 57 + 15 = 870$  SYSCLKs
- Next ADC trigger will come after 870 SYSCLKs
- Approximate ISR trigger frequency =  $1/(870 * 5ns) = 1/4350ns = 229$  KSPS
- Time taken in ADCINT1 ISR : 132 SYSCLKs (Fast ISR)(O2)
- Time taken in ADCINT2 ISR : 76 SYSCLKs (Fast ISR)(O2)

To view results in graph window, add breakpoint inside while(1) loop in main() where bufferFull flag is cleared and plot the watch variables.

#### External Connections

- A0, A1, B0 and B1 pins should be connected to signals to be converted
- Connect GPIO32 to GPIO33 to trigger ADC channels for the first time

#### Watch Variables

- *adcA0Results* - A sequence of analog-to-digital conversion samples from pin A0.
- *adcA1Results* - A sequence of analog-to-digital conversion samples from pin A1.
- *adcB0Results* - A sequence of analog-to-digital conversion samples from pin B0.
- *adcB1Results* - A sequence of analog-to-digital conversion samples from pin B1.

#### 20.14.1.17 ADC Open Shorts Detection (adc\_open\_shorts\_detection)

FILE: adc\_ex17\_open\_shorts\_detection.c

This example demonstrates the ADC open/shorts detection(ADCOSDETECT) circuit configuration for detecting pin faults in the system. The example enables the open/shorts detection circuit along with mandatory ADC configurations and diagnoses ADCA A0 input pin state before starting normal ADC conversions.

To enable the ADC OSDetect circuit:

1. Configure the ADC for conversion (E.g. channel, SOC, ACQPS, prescalar, trigger etc). The OSDetect functionality is available in 12-bit only, hence ADCA is configured in 12-bit mode in the example.
2. Set up the ADCOSDETECT register for the desired voltage divider connection. Refer device TRM for details on available OSDetect configurations.
3. Initiate a conversion and inspect the conversion result. Note: The results must be interpreted based on what is driving on the input side and what are the values of Rs and Cp. If the Vs signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins. In the example, after configuring ADCA A0 channel in 12-bit mode along with other required ADC configurations, following algorithm is used to check the A0 pin status: Step 1: Configure full scale OSDetect mode & capture ADC results(resultHi) Step 2: Configure zero scale OSDetect mode & capture ADC results(resultLo) Step 3: Disable OSDetect mode and capture ADC results(resultNormal) Step 4: Determine the state of the ADC pin a. If the pin is open, resultLo would be equal to Vreflo and resultHi would be equal to Vrefhi b. If the pin is shorted to Vrefhi, resultLo should be approximately equal to Vrefhi and resultHi should be equal to Vrefhi c. If the pin is shorted to Vreflo, resultLo should be equal to Vreflo and resultHi should be approximately equal to Vreflo d. If the pin is connected to a valid signal, resultLo should be greater than osdLoLimit but less than resultNormal while resultHi

should be less than osdHiLimit but greater than resultNormal Input | Full-Scale output | Zero-scale Output | Pin Status

Unknown| VREFHI | VREFLO | Open VREFHI | VREFHI | approx. VREFHI | Shorted to VREFHI VREFLO | approx. VREFLO | VREFLO | Shorted to VREFLO

$V_n$  |  $V_n < \text{resultHi} < VREFHI$  |  $VREFLO < \text{resultLo} < V_n$  | Good

Step 5: osDetectStatusVal of value greater than 4 would mean that there is no pin fault. a. If osDetectStatusVal == 1, means pin A0 is OPEN b. If osDetectStatusVal == 2, means pin A0 is shorted to VREFLO c. If osDetectStatusVal == 4, means pin A0 is shorted to VREFHI d. If osDetectStatusVal == 8, means pin A0 is in GOOD/VALID state e. Any value of osDetectStatusVal > 4, means pin A0 is in VALID state

Following points should be noted while configuring the ADC in OSDetect mode.

1. The divider resistance tolerances can vary widely, hence this feature should not be used to check for conversion accuracy.
2. Consult the device data manual for implementation and availability of analog input channels.
3. Due to high drive impedance, a S+H duration much longer than the ADC minimum will be needed.

#### External Connections

- A0 pin should be connected to signals to convert

#### Watch Variables

- *osDetectStatusVal* : OS detection status of voltage on pin A0
- *adcAResult0* : a digital representation of the voltage on pin A0

## 20.15 ADC Registers

This section describes the Analog-to-Digital Converter Registers.

### 20.15.1 ADC Base Address Table (C28)

15-10	RESERVED	R	0h	Reserved
9-5	RRPOINTER	R	10h	Round Robin Pointer. Holds the value of the last converted round robin SOCx to be used by the round robin scheme to determine order of conversions. 00h SOC0 was last round robin SOC to convert, SOC1 is highest round robin priority. 01h SOC1 was last round robin SOC to convert, SOC2 is highest round robin priority. 02h SOC2 was last round robin SOC to convert, SOC3 is highest round robin priority. 03h SOC3 was last round robin SOC to convert, SOC4 is highest round robin priority. 04h SOC4 was last round robin SOC to convert, SOC5 is highest round robin priority. 05h SOC5 was last round robin SOC to convert, SOC6 is highest round robin priority. 06h SOC6 was last round robin SOC to convert, SOC7 is highest round robin priority. 07h SOC7 was last round robin SOC to convert, SOC8 is highest round robin priority. 08h SOC8 was last round robin SOC to convert, SOC9 is highest round robin priority. 09h SOC9 was last round robin SOC to convert, SOC10 is highest round robin priority. 0Ah SOC10 was last round robin SOC to convert, SOC11 is highest round robin priority. 0Bh SOC11 was last round robin SOC to convert, SOC12 is highest round robin priority. 0Ch SOC12 was last round robin SOC to convert, SOC13 is highest round robin priority. 0Dh SOC13 was last round robin SOC to convert, SOC14 is highest round robin priority. 0Eh SOC14 was last round robin SOC to convert, SOC15 is highest round robin priority. 0Fh SOC15 was last round robin SOC to convert, SOC0 is highest round robin priority. 10h Reset value to indicate no SOC has been converted. SOC0 is highest round robin priority. Set to this value when the ADC module is reset by SOFTPRES or when the ADCSOCPRICTL register is written. In the latter case, if a conversion is currently in progress, it will complete and then the new priority will take effect. Others Invalid value. Reset type: SYSRSn

**Table 20-25. ADCSOCPRCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4-0	SOC PRIORITY	R/W	0h	<p>SOC Priority</p> <p>Determines the cutoff point for priority mode and round robin arbitration for SOCx</p> <p>00h SOC priority is handled in round robin mode for all channels.</p> <p>01h SOC0 is high priority, rest of channels are in round robin mode.</p> <p>02h SOC0-SOC1 are high priority, SOC2-SOC15 are in round robin mode.</p> <p>03h SOC0-SOC2 are high priority, SOC3-SOC15 are in round robin mode.</p> <p>04h SOC0-SOC3 are high priority, SOC4-SOC15 are in round robin mode.</p> <p>05h SOC0-SOC4 are high priority, SOC5-SOC15 are in round robin mode.</p> <p>06h SOC0-SOC5 are high priority, SOC6-SOC15 are in round robin mode.</p> <p>07h SOC0-SOC6 are high priority, SOC7-SOC15 are in round robin mode.</p> <p>08h SOC0-SOC7 are high priority, SOC8-SOC15 are in round robin mode.</p> <p>09h SOC0-SOC8 are high priority, SOC9-SOC15 are in round robin mode.</p> <p>0Ah SOC0-SOC9 are high priority, SOC10-SOC15 are in round robin mode.</p> <p>0Bh SOC0-SOC10 are high priority, SOC11-SOC15 are in round robin mode.</p> <p>0Ch SOC0-SOC11 are high priority, SOC12-SOC15 are in round robin mode.</p> <p>0Dh SOC0-SOC12 are high priority, SOC13-SOC15 are in round robin mode.</p> <p>0Eh SOC0-SOC13 are high priority, SOC14-SOC15 are in round robin mode.</p> <p>0Fh SOC0-SOC14 are high priority, SOC15 is in round robin mode.</p> <p>10h All SOCx are in high priority mode, arbitrated by SOC number.</p> <p>Others Invalid selection.</p> <p>Reset type: SYSRSn</p>

### 20.15.2.11 ADCINTSOCSEL1 Register (Offset = Ah) [Reset = 0h]

ADCINTSOCSEL1 is shown in [Figure 20-36](#) and described in [Table 20-26](#).

Return to the [Summary Table](#).

ADC Interrupt SOC Selection 1 Register

**Figure 20-36. ADCINTSOCSEL1 Register**

7	6	5	4	3	2	1	0
SOC3		SOC2		SOC1		SOC0	
R/W-0h		R/W-0h		R/W-0h		R/W-0h	

**Table 20-26. ADCINTSOCSEL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	SOC7	R/W	0h	SOC7 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC7. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC7. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC7. 10 ADCINT2 will trigger SOC7. 11 Invalid selection. Reset type: SYSRSn
13-12	SOC6	R/W	0h	SOC6 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC6. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC6. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC6. 10 ADCINT2 will trigger SOC6. 11 Invalid selection. Reset type: SYSRSn
11-10	SOC5	R/W	0h	SOC5 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC5. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC5. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC5. 10 ADCINT2 will trigger SOC5. 11 Invalid selection. Reset type: SYSRSn
9-8	SOC4	R/W	0h	SOC4 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC4. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC4. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC4. 10 ADCINT2 will trigger SOC4. 11 Invalid selection. Reset type: SYSRSn

**Table 20-26. ADCINTSOCSEL1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-6	SOC3	R/W	0h	SOC3 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC3. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC3. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC3. 10 ADCINT2 will trigger SOC3. 11 Invalid selection. Reset type: SYSRSn
5-4	SOC2	R/W	0h	SOC2 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC2. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC2. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC2. 10 ADCINT2 will trigger SOC2. 11 Invalid selection. Reset type: SYSRSn
3-2	SOC1	R/W	0h	SOC1 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC1. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC1. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC1. 10 ADCINT2 will trigger SOC1. 11 Invalid selection. Reset type: SYSRSn
1-0	SOC0	R/W	0h	SOC0 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC0. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC0. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC0. 10 ADCINT2 will trigger SOC0. 11 Invalid selection. Reset type: SYSRSn

### 20.15.2.12 ADCINTSOCSEL2 Register (Offset = Bh) [Reset = 0h]

ADCINTSOCSEL2 is shown in [Figure 20-37](#) and described in [Table 20-27](#).

Return to the [Summary Table](#).

ADC Interrupt SOC Selection 2 Register

Bit	Field	Type	Reset	Description
15-14	SOC15	R/W	0h	SOC15 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC15. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC15. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC15. 10 ADCINT2 will trigger SOC15. 11 Invalid selection. Reset type: SYSRSn
13-12	SOC14	R/W	0h	SOC14 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC14. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC14. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC14. 10 ADCINT2 will trigger SOC14. 11 Invalid selection. Reset type: SYSRSn
11-10	SOC13	R/W	0h	SOC13 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC13. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC13. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC13. 10 ADCINT2 will trigger SOC13. 11 Invalid selection. Reset type: SYSRSn
9-8	SOC12	R/W	0h	SOC12 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC12. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC12. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC12. 10 ADCINT2 will trigger SOC12. 11 Invalid selection. Reset type: SYSRSn

**Table 20-27. ADCINTSOCSEL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-6	SOC11	R/W	0h	SOC11 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC11. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC11. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC11. 10 ADCINT2 will trigger SOC11. 11 Invalid selection. Reset type: SYSRSn
5-4	SOC10	R/W	0h	SOC10 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC10. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC10. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC10. 10 ADCINT2 will trigger SOC10. 11 Invalid selection. Reset type: SYSRSn
3-2	SOC9	R/W	0h	SOC9 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC9. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC9. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC9. 10 ADCINT2 will trigger SOC9. 11 Invalid selection. Reset type: SYSRSn
1-0	SOC8	R/W	0h	SOC8 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC8. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register. 00 No ADCINT will trigger SOC8. TRIGSEL field alone determines SOC0 trigger. 01 ADCINT1 will trigger SOC8. 10 ADCINT2 will trigger SOC8. 11 Invalid selection. Reset type: SYSRSn

### 20.15.2.13 ADCSOCFLG1 Register (Offset = Ch) [Reset = 0h]

ADCSOCFLG1 is shown in [Figure 20-38](#) and described in [Table 20-28](#).

Return to the [Summary Table](#).

ADC SOC Flag 1 Register

**Figure 20-38. ADCSOCFLG1 Register**

15	14	13	12	11	10	9	8

R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h

**Table 20-28. ADCSOCFLG1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	SOC15	R	0h	SOC15 Start of Conversion Flag. Indicates the state of SOC15 conversions. 0 No sample pending for SOC15. 1 Trigger has been received and sample is pending for SOC15. This bit will be automatically cleared when the SOC15 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
14	SOC14	R	0h	SOC14 Start of Conversion Flag. Indicates the state of SOC14 conversions. 0 No sample pending for SOC14. 1 Trigger has been received and sample is pending for SOC14. This bit will be automatically cleared when the SOC14 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
13	SOC13	R	0h	SOC13 Start of Conversion Flag. Indicates the state of SOC13 conversions. 0 No sample pending for SOC13. 1 Trigger has been received and sample is pending for SOC13. This bit will be automatically cleared when the SOC13 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

**Table 20-28. ADCSOCFLG1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	SOC12	R	0h	<p>SOC12 Start of Conversion Flag. Indicates the state of SOC12 conversions.</p> <p>0 No sample pending for SOC12. 1 Trigger has been received and sample is pending for SOC12.</p> <p>This bit will be automatically cleared when the SOC12 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
11	SOC11	R	0h	<p>SOC11 Start of Conversion Flag. Indicates the state of SOC11 conversions.</p> <p>0 No sample pending for SOC11. 1 Trigger has been received and sample is pending for SOC11.</p> <p>This bit will be automatically cleared when the SOC11 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
10	SOC10	R	0h	<p>SOC10 Start of Conversion Flag. Indicates the state of SOC10 conversions.</p> <p>0 No sample pending for SOC10. 1 Trigger has been received and sample is pending for SOC10.</p> <p>This bit will be automatically cleared when the SOC10 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
9	SOC9	R	0h	<p>SOC9 Start of Conversion Flag. Indicates the state of SOC9 conversions.</p> <p>0 No sample pending for SOC9. 1 Trigger has been received and sample is pending for SOC9.</p> <p>This bit will be automatically cleared when the SOC9 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
8	SOC8	R	0h	<p>SOC8 Start of Conversion Flag. Indicates the state of SOC8 conversions.</p> <p>0 No sample pending for SOC8. 1 Trigger has been received and sample is pending for SOC8.</p> <p>This bit will be automatically cleared when the SOC8 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

**Table 20-28. ADCSOCFLG1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7	SOC7	R	0h	<p>SOC7 Start of Conversion Flag. Indicates the state of SOC7 conversions.</p> <p>0 No sample pending for SOC7. 1 Trigger has been received and sample is pending for SOC7.</p> <p>This bit will be automatically cleared when the SOC7 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
6	SOC6	R	0h	<p>SOC6 Start of Conversion Flag. Indicates the state of SOC6 conversions.</p> <p>0 No sample pending for SOC6. 1 Trigger has been received and sample is pending for SOC6.</p> <p>This bit will be automatically cleared when the SOC6 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
5	SOC5	R	0h	<p>SOC5 Start of Conversion Flag. Indicates the state of SOC5 conversions.</p> <p>0 No sample pending for SOC5. 1 Trigger has been received and sample is pending for SOC5.</p> <p>This bit will be automatically cleared when the SOC5 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
4	SOC4	R	0h	<p>SOC4 Start of Conversion Flag. Indicates the state of SOC4 conversions.</p> <p>0 No sample pending for SOC4. 1 Trigger has been received and sample is pending for SOC4.</p> <p>This bit will be automatically cleared when the SOC4 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
3	SOC3	R	0h	<p>SOC3 Start of Conversion Flag. Indicates the state of SOC3 conversions.</p> <p>0 No sample pending for SOC3. 1 Trigger has been received and sample is pending for SOC3.</p> <p>This bit will be automatically cleared when the SOC3 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

**Table 20-28. ADCSOCFLG1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	SOC2	R	0h	<p>SOC2 Start of Conversion Flag. Indicates the state of SOC2 conversions.</p> <p>0 No sample pending for SOC2.                      1 Trigger has been received and sample is pending for SOC2.                      This bit will be automatically cleared when the SOC2 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.                      Reset type: SYSRSn</p>
1	SOC1	R	0h	<p>SOC1 Start of Conversion Flag. Indicates the state of SOC1 conversions.</p> <p>0 No sample pending for SOC1.                      1 Trigger has been received and sample is pending for SOC1.                      This bit will be automatically cleared when the SOC1 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.                      Reset type: SYSRSn</p>
0	SOC0	R	0h	<p>SOC0 Start of Conversion Flag. Indicates the state of SOC0 conversions.</p> <p>0 No sample pending for SOC0.                      1 Trigger has been received and sample is pending for SOC0.                      This bit will be automatically cleared when the SOC0 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.                      Reset type: SYSRSn</p>

### 20.15.2.14 ADCSOCFRC1 Register (Offset = Dh) [Reset = 0h]

ADCSOCFRC1 is shown in [Figure 20-39](#) and described in [Table 20-29](#).

Return to the [Summary Table](#).

ADC SOC Force 1 Register

**Figure 20-39. ADCSOCFRC1 Register**

**Table 20-29. ADCSOCFRC1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	SOC15	R-0/W1S	0h	<p>SOC15 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC15 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC15 flag bit to 1. This will cause a conversion to start once priority is given to SOC15.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC15 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
14	SOC14	R-0/W1S	0h	<p>SOC14 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC14 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC14 flag bit to 1. This will cause a conversion to start once priority is given to SOC14.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC14 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
13	SOC13	R-0/W1S	0h	<p>SOC13 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC13 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC13 flag bit to 1. This will cause a conversion to start once priority is given to SOC13.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC13 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

**Table 20-29. ADCSOCFRC1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	SOC12	R-0/W1S	0h	<p>SOC12 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC12 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC12 flag bit to 1. This will cause a conversion to start once priority is given to SOC12.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC12 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
11	SOC11	R-0/W1S	0h	<p>SOC11 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC11 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC11 flag bit to 1. This will cause a conversion to start once priority is given to SOC11.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC11 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
10	SOC10	R-0/W1S	0h	<p>SOC10 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC10 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC10 flag bit to 1. This will cause a conversion to start once priority is given to SOC10.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC10 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
9	SOC9	R-0/W1S	0h	<p>SOC9 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC9 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC9 flag bit to 1. This will cause a conversion to start once priority is given to SOC9.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC9 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

**Table 20-29. ADCSOCFRC1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	SOC8	R-0/W1S	0h	<p>SOC8 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC8 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC8 flag bit to 1. This will cause a conversion to start once priority is given to SOC8.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC8 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
7	SOC7	R-0/W1S	0h	<p>SOC7 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC7 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC7 flag bit to 1. This will cause a conversion to start once priority is given to SOC7.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC7 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
6	SOC6	R-0/W1S	0h	<p>SOC6 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC6 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC6 flag bit to 1. This will cause a conversion to start once priority is given to SOC6.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC6 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
5	SOC5	R-0/W1S	0h	<p>SOC5 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC5 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC5 flag bit to 1. This will cause a conversion to start once priority is given to SOC5.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC5 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

**Table 20-29. ADCSOCFRC1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	SOC4	R-0/W1S	0h	<p>SOC4 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC4 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC4 flag bit to 1. This will cause a conversion to start once priority is given to SOC4.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC4 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
3	SOC3	R-0/W1S	0h	<p>SOC3 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC3 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC3 flag bit to 1. This will cause a conversion to start once priority is given to SOC3.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC3 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
2	SOC2	R-0/W1S	0h	<p>SOC2 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC2 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC2 flag bit to 1. This will cause a conversion to start once priority is given to SOC2.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC2 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>
1	SOC1	R-0/W1S	0h	<p>SOC1 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC1 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC1 flag bit to 1. This will cause a conversion to start once priority is given to SOC1.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC1 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

**Table 20-29. ADCSOCFRC1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SOC0	R-0/W1S	0h	<p>SOC0 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC0 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.</p> <p>0 No action.</p> <p>1 Force SOC0 flag bit to 1. This will cause a conversion to start once priority is given to SOC0.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC0 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.</p> <p>Reset type: SYSRSn</p>

### 20.15.2.15 ADCSOCOVF1 Register (Offset = Eh) [Reset = 0h]

ADCSOCOVF1 is shown in [Figure 20-40](#) and described in [Table 20-30](#).

Return to the [Summary Table](#).

ADC SOC Overflow 1 Register

**Figure 20-40. ADCSOCOVF1 Register**

15	14	13	12	11	10	9	8
SOC15	SOC14	SOC13	SOC12	SOC11	SOC10	SOC9	SOC8
R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h

SOC7	SOC6	SOC5	SOC4	SOC3	SOC2	SOC1	SOC0
R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h

**Table 20-30. ADCSOCOVF1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	SOC15	R	0h	SOC15 Start of Conversion Overflow Flag. Indicates an SOC15 event was generated in hardware while an existing SOC15 event was already pending. 0 No SOC15 event overflow. 1 SOC15 event overflow. An overflow condition does not stop SOC15 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
14	SOC14	R	0h	SOC14 Start of Conversion Overflow Flag. Indicates an SOC14 event was generated in hardware while an existing SOC14 event was already pending. 0 No SOC14 event overflow. 1 SOC14 event overflow. An overflow condition does not stop SOC14 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
13	SOC13	R	0h	SOC13 Start of Conversion Overflow Flag. Indicates an SOC13 event was generated in hardware while an existing SOC13 event was already pending. 0 No SOC13 event overflow. 1 SOC13 event overflow. An overflow condition does not stop SOC13 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
12	SOC12	R	0h	SOC12 Start of Conversion Overflow Flag. Indicates an SOC12 event was generated in hardware while an existing SOC12 event was already pending. 0 No SOC12 event overflow. 1 SOC12 event overflow. An overflow condition does not stop SOC12 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

**Table 20-30. ADCSOCOVF1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	SOC11	R	0h	SOC11 Start of Conversion Overflow Flag. Indicates an SOC11 event was generated in hardware while an existing SOC11 event was already pending. 0 No SOC11 event overflow. 1 SOC11 event overflow. An overflow condition does not stop SOC11 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
10	SOC10	R	0h	SOC10 Start of Conversion Overflow Flag. Indicates an SOC10 event was generated in hardware while an existing SOC10 event was already pending. 0 No SOC10 event overflow. 1 SOC10 event overflow. An overflow condition does not stop SOC10 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
9	SOC9	R	0h	SOC9 Start of Conversion Overflow Flag. Indicates an SOC9 event was generated in hardware while an existing SOC9 event was already pending. 0 No SOC9 event overflow. 1 SOC9 event overflow. An overflow condition does not stop SOC9 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
8	SOC8	R	0h	SOC8 Start of Conversion Overflow Flag. Indicates an SOC8 event was generated in hardware while an existing SOC8 event was already pending. 0 No SOC8 event overflow. 1 SOC8 event overflow. An overflow condition does not stop SOC8 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
7	SOC7	R	0h	SOC7 Start of Conversion Overflow Flag. Indicates an SOC7 event was generated in hardware while an existing SOC7 event was already pending. 0 No SOC7 event overflow. 1 SOC7 event overflow. An overflow condition does not stop SOC7 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
6	SOC6	R	0h	SOC6 Start of Conversion Overflow Flag. Indicates an SOC6 event was generated in hardware while an existing SOC6 event was already pending. 0 No SOC6 event overflow. 1 SOC6 event overflow. An overflow condition does not stop SOC6 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
5	SOC5	R	0h	SOC5 Start of Conversion Overflow Flag. Indicates an SOC5 event was generated in hardware while an existing SOC5 event was already pending. 0 No SOC5 event overflow. 1 SOC5 event overflow. An overflow condition does not stop SOC5 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

**Table 20-30. ADCSOCOVF1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	SOC4	R	0h	SOC4 Start of Conversion Overflow Flag. Indicates an SOC4 event was generated in hardware while an existing SOC4 event was already pending. 0 No SOC4 event overflow. 1 SOC4 event overflow. An overflow condition does not stop SOC4 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
3	SOC3	R	0h	SOC3 Start of Conversion Overflow Flag. Indicates an SOC3 event was generated in hardware while an existing SOC3 event was already pending. 0 No SOC3 event overflow. 1 SOC3 event overflow. An overflow condition does not stop SOC3 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
2	SOC2	R	0h	SOC2 Start of Conversion Overflow Flag. Indicates an SOC2 event was generated in hardware while an existing SOC2 event was already pending. 0 No SOC2 event overflow. 1 SOC2 event overflow. An overflow condition does not stop SOC2 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
1	SOC1	R	0h	SOC1 Start of Conversion Overflow Flag. Indicates an SOC1 event was generated in hardware while an existing SOC1 event was already pending. 0 No SOC1 event overflow. 1 SOC1 event overflow. An overflow condition does not stop SOC1 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
0	SOC0	R	0h	SOC0 Start of Conversion Overflow Flag. Indicates an SOC0 event was generated in hardware while an existing SOC0 event was already pending. 0 No SOC0 event overflow. 1 SOC0 event overflow. An overflow condition does not stop SOC0 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

### 20.15.2.16 ADCSOCOVFCLR1 Register (Offset = Fh) [Reset = 0h]

ADCSOCOVFCLR1 is shown in [Figure 20-41](#) and described in [Table 20-31](#).

Return to the [Summary Table](#).

ADC SOC Overflow Clear 1 Register

**Table 20-31. ADCSOCOVFCLR1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	SOC15	R-0/W1S	0h	SOC15 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC15 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC15 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
14	SOC14	R-0/W1S	0h	SOC14 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC14 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC14 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
13	SOC13	R-0/W1S	0h	SOC13 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC13 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC13 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
12	SOC12	R-0/W1S	0h	SOC12 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC12 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC12 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

**Table 20-31. ADCSOCOVFCLR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	SOC11	R-0/W1S	0h	<p>SOC11 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC11 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC11 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
10	SOC10	R-0/W1S	0h	<p>SOC10 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC10 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC10 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
9	SOC9	R-0/W1S	0h	<p>SOC9 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC9 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC9 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
8	SOC8	R-0/W1S	0h	<p>SOC8 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC8 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC8 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
7	SOC7	R-0/W1S	0h	<p>SOC7 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC7 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC7 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
6	SOC6	R-0/W1S	0h	<p>SOC6 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC6 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC6 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
5	SOC5	R-0/W1S	0h	<p>SOC5 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC5 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action. 1 Clear SOC5 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>

**Table 20-31. ADCSOCOVFCLR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	SOC4	R-0/W1S	0h	<p>SOC4 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC4 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action.</p> <p>1 Clear SOC4 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
3	SOC3	R-0/W1S	0h	<p>SOC3 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC3 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action.</p> <p>1 Clear SOC3 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
2	SOC2	R-0/W1S	0h	<p>SOC2 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC2 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action.</p> <p>1 Clear SOC2 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
1	SOC1	R-0/W1S	0h	<p>SOC1 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC1 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action.</p> <p>1 Clear SOC1 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>
0	SOC0	R-0/W1S	0h	<p>SOC0 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC0 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0.</p> <p>0 No action.</p> <p>1 Clear SOC0 overflow flag.</p> <p>If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set..</p> <p>Reset type: SYSRSn</p>

### 20.15.2.17 ADCSOC0CTL Register (Offset = 10h) [Reset = 0h]

ADCSOC0CTL is shown in [Figure 20-42](#) and described in [Table 20-32](#).

Return to the [Summary Table](#).

### 20.15.3 ADC\_RESULT\_REGS Registers

Table 20-87 lists the memory-mapped registers for the ADC\_RESULT\_REGS registers. All register offset addresses not listed in Table 20-87 should be considered as reserved locations and the register contents should not be modified.

**Table 20-87. ADC\_RESULT\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	ADCRESULT0	ADC Result 0 Register		<a href="#">Go</a>
1h	ADCRESULT1	ADC Result 1 Register		<a href="#">Go</a>
2h	ADCRESULT2	ADC Result 2 Register		<a href="#">Go</a>
3h	ADCRESULT3	ADC Result 3 Register		<a href="#">Go</a>
4h	ADCRESULT4	ADC Result 4 Register		<a href="#">Go</a>
5h	ADCRESULT5	ADC Result 5 Register		<a href="#">Go</a>
6h	ADCRESULT6	ADC Result 6 Register		<a href="#">Go</a>
7h	ADCRESULT7	ADC Result 7 Register		<a href="#">Go</a>
8h	ADCRESULT8	ADC Result 8 Register		<a href="#">Go</a>
9h	ADCRESULT9	ADC Result 9 Register		<a href="#">Go</a>
Ah	ADCRESULT10	ADC Result 10 Register		<a href="#">Go</a>
Bh	ADCRESULT11	ADC Result 11 Register		<a href="#">Go</a>
Ch	ADCRESULT12	ADC Result 12 Register		<a href="#">Go</a>
Dh	ADCRESULT13	ADC Result 13 Register		<a href="#">Go</a>
Eh	ADCRESULT14	ADC Result 14 Register		<a href="#">Go</a>
Fh	ADCRESULT15	ADC Result 15 Register		<a href="#">Go</a>
10h	ADCPPB1RESULT	ADC Post Processing Block 1 Result Register		<a href="#">Go</a>
12h	ADCPPB2RESULT	ADC Post Processing Block 2 Result Register		<a href="#">Go</a>
14h	ADCPPB3RESULT	ADC Post Processing Block 3 Result Register		<a href="#">Go</a>
16h	ADCPPB4RESULT	ADC Post Processing Block 4 Result Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 20-88 shows the codes that are used for access types in this section.

**Table 20-88. ADC\_RESULT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

**Table 20-88. ADC\_RESULT\_REGS Access Type Codes (continued)**

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 20.15.3.1 ADCRESULT0 Register (Offset = 0h) [Reset = 0h]

ADCRESULT0 is shown in [Figure 20-97](#) and described in [Table 20-89](#).

Return to the [Summary Table](#).

ADC Result 0 Register

**Figure 20-97. ADCRESULT0 Register**

15-0	RESULT	R	0h	ADC Result 15 16-bit ADC result. After the ADC completes a conversion of SOC15, the digital result is placed in this bit field. Reset type: SYSRSn

### 20.15.3.17 ADCPPB1RESULT Register (Offset = 10h) [Reset = 0h]

ADCPPB1RESULT is shown in [Figure 20-113](#) and described in [Table 20-105](#).

Return to the [Summary Table](#).

ADC Post Processing Block 1 Result Register

**Figure 20-113. ADCPPB1RESULT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIGN																PPBRESULT															
R-0h																R-0h															

**Table 20-105. ADCPPB1RESULT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	SIGN	R	0h	Sign Extended Bits. These bits reflect the same value as bit 16. NOTE: If the conversion associated with this Post Processing Block is a 12-bit conversion, the SIGN bits extend down to bit 12, and all reflect the same value as bit 12. Reset type: SYSRSn
15-0	PPBRESULT	R	0h	ADC Post Processing Block Result 1 The result of the offset/reference subtraction post conversion processing is stored in this register. This result is available 1 SYSCLK cycle after the associated ADCRESULT is available. If ADCINTFLG is polled to determine when to read the PPBRESULT, it may be necessary to add a NOP instruction to ensure that the updated post conversion processing result has posted to the register. NOTE: If the conversion associated with this Post Processing Block is a 12-bit conversion, the PPBRESULT bits are limited to bits 12:0. Reset type: SYSRSn

### 20.15.3.18 ADCPPB2RESULT Register (Offset = 12h) [Reset = 0h]

ADCPPB2RESULT is shown in [Figure 20-114](#) and described in [Table 20-106](#).

Return to the [Summary Table](#).

ADC Post Processing Block 2 Result Register

**Figure 20-114. ADCPPB2RESULT Register**

15-0	PPBRESULT	R	0h	ADC Post Processing Block Result 4 The result of the offset/reference subtraction post conversion processing is stored in this register. This result is available 1 SYSCLK cycle after the associated ADCRESULT is available. If ADCINTFLG is polled to determine when to read the PPBRESULT, it may be necessary to add a NOP instruction to ensure that the updated post conversion processing result has posted to the register. NOTE: If the conversion associated with this Post Processing Block is a 12-bit conversion, the PPBRESULT bits are limited to bits 12:0. Reset type: SYSRSn

### 20.15.4 ADC Registers to Driverlib Functions

## **Buffered Digital-to-Analog Converter (DAC)**

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

<b>21.1 Introduction</b> .....	<b>2730</b>
<b>21.2 Using the DAC</b> .....	<b>2731</b>
<b>21.3 Lock Registers</b> .....	<b>2732</b>
<b>21.4 Software</b> .....	<b>2733</b>
<b>21.5 DAC Registers</b> .....	<b>2734</b>

## 21.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. An integrated pull-down resistor on the DAC output helps to provide a known pin voltage when the output buffer is disabled. This pull-down resistor cannot be disabled and remains as a passive component on the pin, even for other shared pinmux functions. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

### 21.1.1 DAC Related Collateral

#### Foundational Materials

- [C2000 Academy - Analog Subsystem](#)
- [High Speed, Digital to Analog Converters Basics Application Report](#)
- [Real-Time Control Reference Guide](#)
  - Refer to the DAC section
- [Understanding Data Converters Application Report](#)

#### Getting Started Materials

- [MathWorks F2807x/F2837xD/F2837xS/F28004x/F2838x DAC](#)
  - NOTE: This is a non-TI (third party) site.

### 21.1.2 Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- Pull-down resistor on output
- Ability to synchronize with EPWMSYNCPER

### 21.1.3 Block Diagram

The block diagram for the buffered DAC is shown in Figure 21-1.

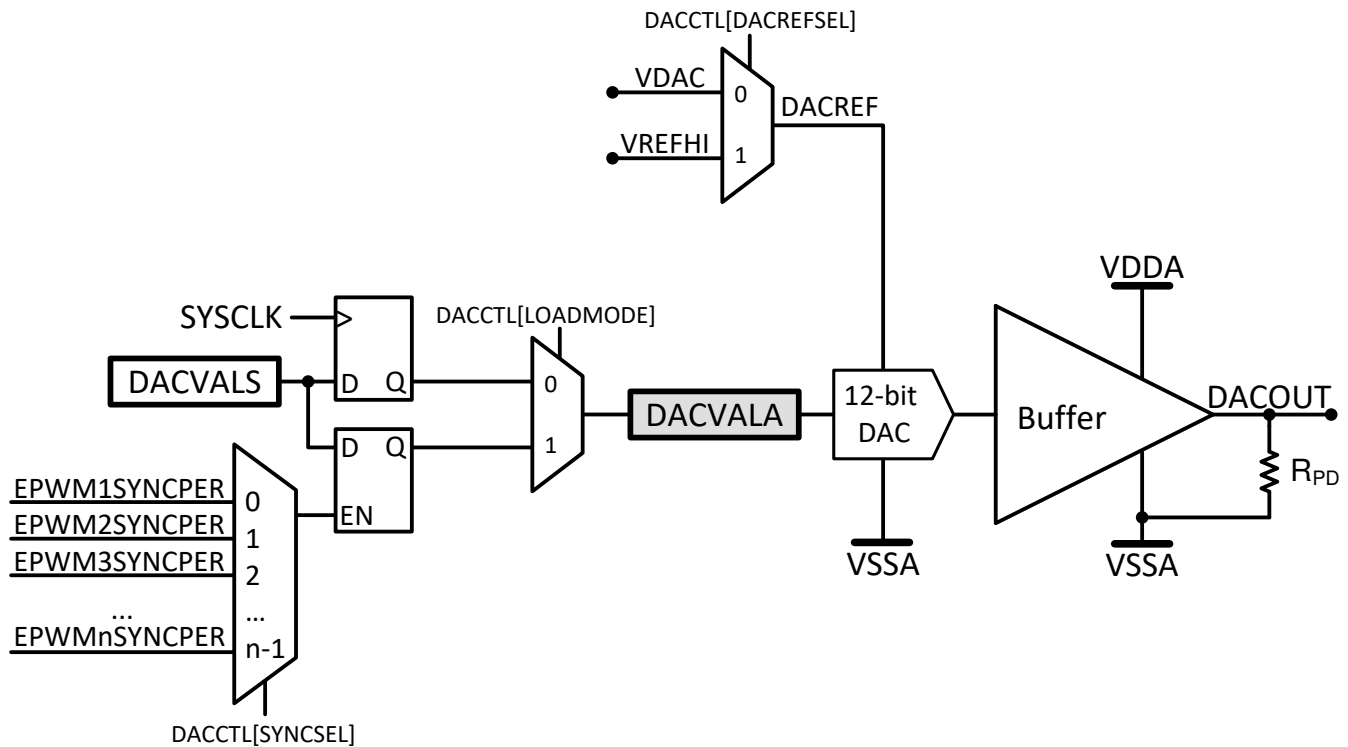

Figure 21-1. DAC Module Block Diagram

## 21.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDAC and VREFHI.

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS will no longer be updated with register writes. Enabling the clock to the buffered DAC restores it to the state before the clock was disabled.

The ideal output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (8)$$

The output buffer of the buffered DAC may exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data manual.

### 21.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device-specific data manual.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS should be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device-specific data manual.

### 21.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25v (for 2.5v reference voltage). DAC offset error is calibrated at 2.5v reference voltage and loaded into the DAC offset trim register as part of the Device\_cal() function. If the DAC is used at any reference voltage other than 2.5v, the offset trim must be adjusted to ensure the offset error performance stays within the device-specific data manual limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call DAC\_tuneOffsetTrim() found in C2000Ware to adjust the offset.

### 21.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the Time-Base Submodule section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER will be held at level high and DACVALA will be loaded immediately from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, it is recommended to configure the EPWM first before setting DACCTL [LOADMODE] to 1.

---

#### Note

The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

---

## 21.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access will be locked out until the device is reset.

## 21.4 Software

### 21.4.1 DAC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/dac

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 21.4.1.1 Buffered DAC Enable

FILE: buffdac\_ex1\_enable.c

This example generates a voltage on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

##### External Connections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

##### Watch Variables

- None.

#### 21.4.1.2 Buffered DAC Random

FILE: buffdac\_ex2\_random.c

This example generates random voltages on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

##### External Connections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

##### Watch Variables

- None.

#### 21.4.1.3 Buffered DAC Sine (*buffdac\_sine*)

FILE: buffdac\_ex3\_waveform.c

This example generates a sine wave on the buffered DAC output, DACOUTA/ADCINA0 (HSEC Pin 9) and uses the default DAC reference setting of VDAC.

When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

Run the included .js file to add the watch variables. This example uses the SGEN module. Documentation for the SGEN module can be found in the SGEN library directory.

The generated waveform can be adjusted with the following variables while running:

- *waveformGain* : Adjust the magnitude of the waveform. Range is from 0.0 to 1.0. The default value of 0.8003 centers the waveform within the linear range of the DAC
- *waveformOffset* : Adjust the offset of the waveform. Range is from -1.0 to 1.0. The default value of 0 centers the waveform
- *outputFreq\_hz* : Adjust the output frequency of the waveform. Range is from 0 to maxOutputFreq\_hz
- *maxOutputFreq\_hz* : Adjust the max output frequency of the waveform. Range - See SGEN module documentation for how this affects other parameters

The generated waveform can be adjusted with the following variables/macros but require recompile:

- *samplingFreq\_hz* : Adjust the rate at which the DAC is updated. Range - See SGEN module documentation for how this affects other parameters
- *SINEWAVE\_TYPE* : The type of sine generated. Range - LOW\_THD\_SINE, HIGH\_PRECISION\_SINE

The following variables give additional information about the generated waveform: See SGEN module documentation for details

- *freqResolution\_hz*
- *maxOutput\_lsb* : Maximum value written to the DAC.
- *minOutput\_lsb* : Minimum value written to the DAC.
- *pk\_to\_pk\_lsb* : Magnitude of generated waveform.
- *cpuPeriod\_us* : Period of cpu.
- *samplingPeriod\_us* : The rate at which the DAC is updated. Note that *samplingPeriod\_us* has to be greater than the DAC settling time.
- *interruptCycles* : Interrupt duration in cycles.
- *interruptDuration\_us* : Interrupt duration in uS.
- *sgen* : The SGEN module instance.
- *DataLog* : Circular log of writes to the DAC.

## 21.5 DAC Registers

This section describes the Buffered Digital to Analog Converter registers.

### 21.5.1 DAC Base Address Table (C28)

**Table 21-1. DAC Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
DacaRegs	DAC_REGS	DACA_BASE	0x0000_5C00	YES	YES	YES	YES	YES
DacbRegs	DAC_REGS	DACB_BASE	0x0000_5C10	YES	YES	YES	YES	YES
DaccRegs	DAC_REGS	DACC_BASE	0x0000_5C20	YES	YES	YES	YES	YES

## 21.5.2 DAC\_REGS Registers

Table 21-2 lists the memory-mapped registers for the DAC\_REGS registers. All register offset addresses not listed in Table 21-2 should be considered as reserved locations and the register contents should not be modified.

**Table 21-2. DAC\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	DACREV	DAC Revision Register		<a href="#">Go</a>
1h	DACCTL	DAC Control Register	EALLOW	<a href="#">Go</a>
2h	DACVALA	DAC Value Register - Active		<a href="#">Go</a>
3h	DACVALS	DAC Value Register - Shadow		<a href="#">Go</a>
4h	DACOUTEN	DAC Output Enable Register	EALLOW	<a href="#">Go</a>
5h	DACLOCK	DAC Lock Register	EALLOW	<a href="#">Go</a>
6h	DACTRIM	DAC Trim Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 21-3 shows the codes that are used for access types in this section.

**Table 21-3. DAC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 21.5.2.1 DACREV Register (Offset = 0h) [Reset = 0h]

## 22.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes one ramp generator. The ramp generator ramps down only. Comparators are denoted "H" or "L" within each module where "H" and "L" represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin (see the *Analog Subsystem* chapter for mux options available to the CMPSS). The negative input can be driven by an external pin or by the programmable reference 12-bit DAC. Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required. A ramp generator circuit is optionally available to control the reference 12-bit DAC value for the high comparator in the subsystem.

### 22.1.1 CMPSS Related Collateral

#### Foundational Materials

### 22.1.2 Features

Each CMPSS includes:

- Two analog comparators
- Two programmable reference 12-bit DACs
- One decrementing ramp generator
- Two digital filters, max filter clock prescale =  $2^{10}$
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to extend clear signal with EPWMBLANK
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDAC

### 22.1.3 Block Diagram

The block diagram for the CMPSS is shown in [Figure 22-1](#).

- CTRIP<sub>x</sub>(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *Enhanced Pulse Width Modulator (ePWM)* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIP<sub>x</sub>OUT<sub>x</sub>(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.

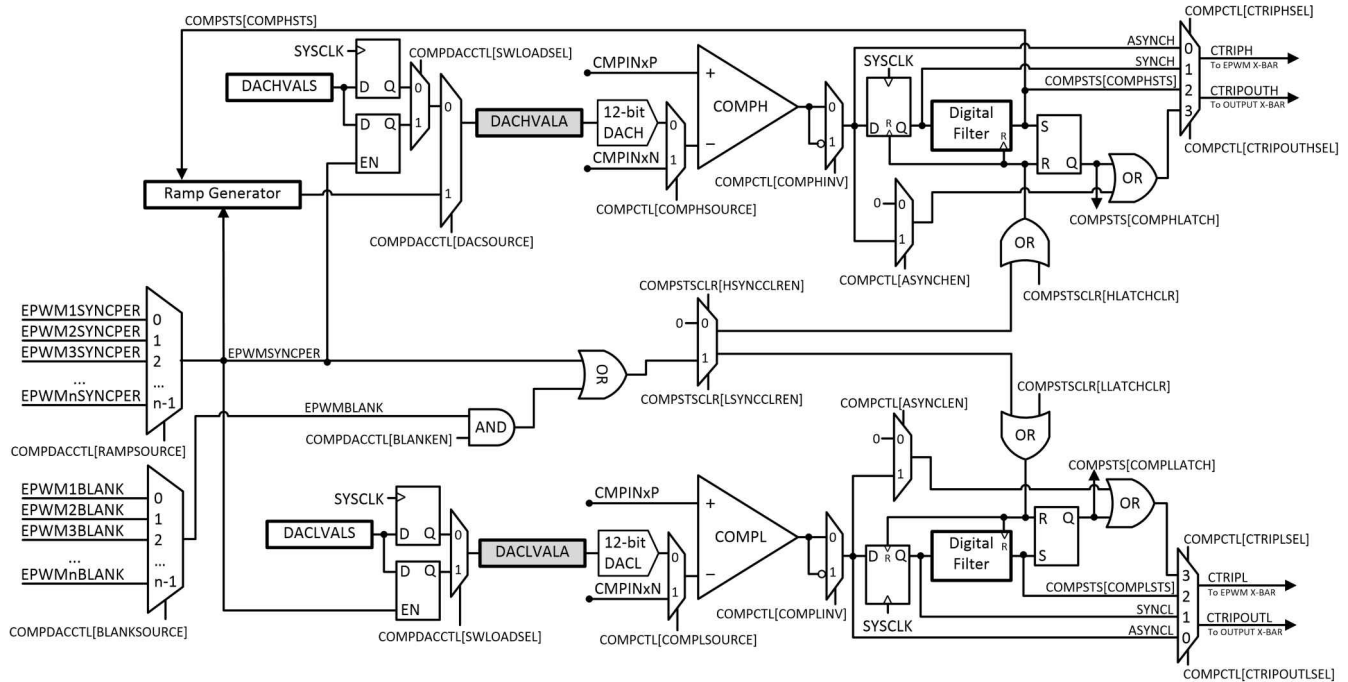

Figure 22-1. CMPSS Module Block Diagram

## 22.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 22-2.

Figure 22-2. Comparator Block Diagram

Voltages	Output
Voltage A > Voltage B	1
Voltage A < Voltage B	0

## 22.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of its respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high reference 12-bit DAC (DACH) can optionally source its DACHVALA value from the ramp generator instead of DACHVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high voltage reference is VDDA by default, but it can be configured to be VDAC. The reference 12-bit DAC is illustrated in [Figure 22-3](#).

**Figure 22-3. Reference DAC Block Diagram**

The ideal output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (9)$$

### Note

The CMPSS instance should be enabled before programming the reference DAC values.

## 22.4 Ramp Generator

This section discusses the characteristics of the ramp generator and its behavior.

### 22.4.1 Ramp Generator Overview

The ramp generator produces a falling ramp input for the high reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most significant 12 bits of the RAMPSTS countdown register as its input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling ramp rate configurable with RAMPDECVALA..

The ramp generator is enabled by setting DACSOURCE = 1. On setting DACSOURCE = 1, the value of RAMPSTS is loaded from RAMPMAXREFS and the register remains static until the selected EPWMSYNCPER signal is received. After receiving the selected EPWMSYNCPER signal, the value of RAMPDECVALA. is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a EPWMSYNCPER event, the RAMPDLYA register which serves as a delay counter can be used to hold off the RAMPSTS subtraction. On receiving a EPWMSYNCPER event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. The RAMPSTS subtraction will only begin when RAMPDLYA is zero.

### 22.4.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, EPWMSYNCPER and COMPSTS.

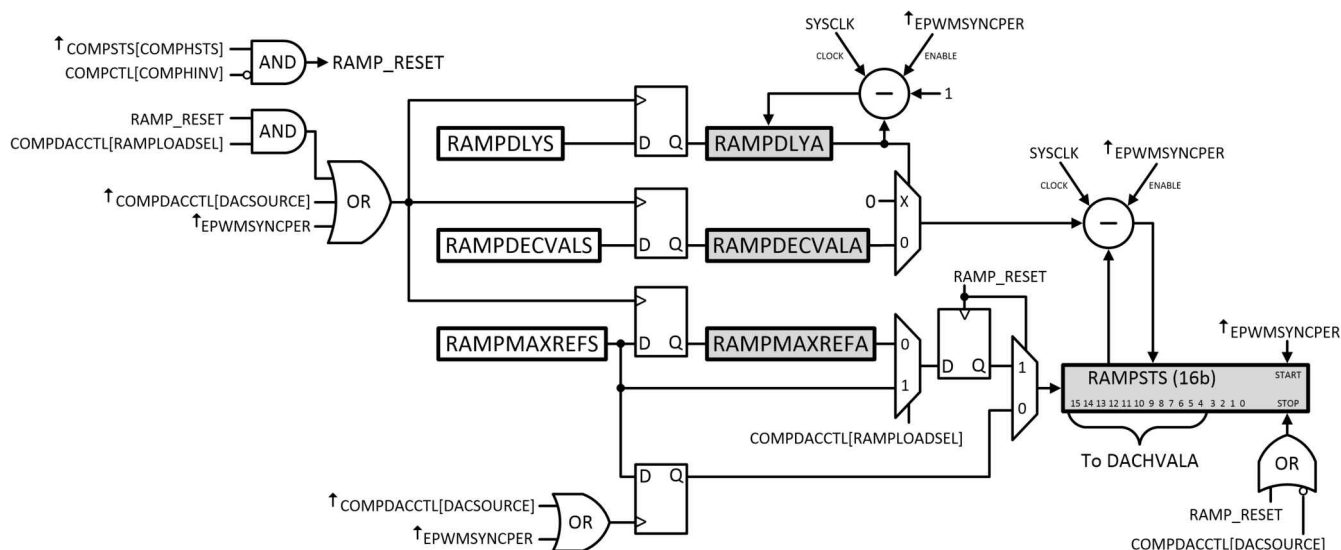

On the rising edge of DACSOURCE, RAMPMAXREFA, RAMPDECVALA and RAMPDLYA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS.

On the rising edge of the selected EPWMSYNCPER, RAMPMAXREFA, RAMPDECVALA and RAMPDLYA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS and starts decrementing when RAMPDLYA counter reaches zero.

On the rising edge of COMPSTS with RAMPLOADSEL = 1, RAMPMAXREFA, RAMPDECVALA and RAMPDLYA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS and stops decrementing.

On the rising edge of COMPSTS with RAMPLOADSEL = 0, RAMPSTS is loaded with RAMPMAXREFA and stops decrementing.

Additionally, if the value of RAMPSTS reaches zero, the RAMPSTS register will remain static at zero until the next EPWMSYNCPER is received. These state changes are illustrated in the ramp generator block diagram in Figure 22-4.

**Figure 22-4. Ramp Generator Block Diagram**

### 22.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of EPWMSYNCPER and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before EPWMSYNCPER rising edge. RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on EPWMSYNCPER rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as EPWMSYNCPER rising edge. EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

Case 3: COMPHSTS rising edge occurs one or more cycles after EPWMSYNCPER rising edge but before RAMPDLYA reaches 0. RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from EPWMSYNCPER rising edge. RAMPSTS does not decrement.

This behavior is also illustrated in [Figure 22-5](#).

Figure 22-5. Ramp Generator Behavior

## 22.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than  $SAMPWIN / 2$  and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 22-6.

**Figure 22-6. Digital Filter Behavior**

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
    
```

### 22.5.1 Filter Initialization Sequence

To ensure proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
  - Set SAMPWIN for the number of samples to monitor in the FIFO window.
  - Set THRESH for the threshold required for majority qualification.
  - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch via COMPSTSCLR if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

## 22.6 Using the CMPSS

### 22.6.1 LATCHCLR, EPWMSYNCPER and EPWMBLANK Signals

The LATCHCLR signal holds the digital filter, synchronization block and the latch output in reset (0) after the required delays. It is activated in software using xLATCHCLR(x= "H" or "L"). It can also be activated by EPWMSYNCPER when xSYNCCLREN(x= "H" or "L") is set. If a longer LATCHCLR signal is required, the EPWMBLANK signal can be used to extend it by setting BLANKEN.

EPWMSYNCPER and EPWMBLANK (BLANKWDW) come from the Time-Base and Digital Compare submodules of the EPWM, respectively. For a detailed description of how these two signals are generated, refer to the respective submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACCTL [SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER will be held at level high and DACxVALA will be loaded immediately from DACxVALS irrespective of the value of COMPDACCTL [SWLOADSEL]. Due to this, it is recommended to configure the EPWM first before setting COMPDACCTL [SWLOADSEL] to 1.

---

#### Note

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCL and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

---

### 22.6.2 Synchronizer, Digital Filter and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter will add a delay of 2 sysclks. The latch adds 1 sysclk delay.

### 22.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data manual, the comparator offset error is referred to as **Input referred offset error** and compdac offset error is referred to as **Static offset error**. See the device specific data manual for their values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, it is recommended that the CMPSS be calibrated to ensure trips happen at the expected levels. The flow below outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis should be disabled for calibration. It can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult so it is recommended to use the latch with non-zero filter settings depending on how noisy the signal on the non-inverting input is.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFFF.
  - Optional: Instead of setting the starting compdac value to max, it can be set to **Vtarget + Static offset error + Margin**. Where **Vtarget** is the approximate DC voltage on the non-inverting input, **Static offset error** is the compdac offset error specification and **Margin** is some amount of guard band. This can lead to a faster calibration but will only work if **Vtarget** is known. Alternatively if **Vtarget** is unknown, the ADC can be used to convert it.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
  - Optional: The trip code can be double checked by:
    - a. Increasing compdac value by 1.
    - b. Clear latch.
    - c. Wait for possible latch set.
    - d. Latch should be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

### 22.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and will continue to trip from voltages on its inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA would no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on their current states.

Enabling the clock to the CMPSS restores it to the state before the clock was disabled.

## 22.7 Software

### 22.7.1 CMPSS Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/cmpss

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 22.7.1.1 CMPSS Asynchronous Trip

FILE: cmpss\_ex1\_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO14/OUTPUTXBAR3 pin and CTRIPH to GPIO15/EPWM8B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO15 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,

- Trip signal(GPIO14) output is low
- PWM8B(GPIO15) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,

- Trip signal(GPIO14) output turns high
- PWM8B(GPIO15) gets tripped and outputs as high

#### External Connections

- Give input on CMPIN1P (HSEC Pin 15)
- Outputs can be observed on GPIO14 and GPIO15 using an oscilloscope

#### Watch Variables

- None

#### 22.7.1.2 CMPSS Digital Filter Configuration

FILE: cmpss\_ex2\_digital\_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO14/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,

- GPIO14 output is low

When a high input(higher than VDD/2) is provided to CMPIN1P,

- GPIO14 output turns high

## 22.8 CMPSS Registers

This section describes the CMPSS Registers.

### 22.8.1 CMPSS Base Address Table (C28)

**Table 22-1. CMPSS Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure

Complex bit access types are encoded to fit into small table cells. Table 22-3 shows the codes that are used for access types in this section.

**Table 22-3. CMPSS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WSONCE	WSONCE	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 22-3. CMPSS\_REGS Access Type Codes  
(continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 22.8.2.1 COMPCTL Register (Offset = 0h) [Reset = 0h]

COMPCTL is shown in [Figure 22-7](#) and described in [Table 22-4](#).

Return to the [Summary Table](#).

1	HLATCHCLR	R-0/W1S	0h	High comparator latch software clear. Perform software reset of high comparator digital filter output latch COMPSTS[COMPHLATCH]. Reads always return 0. 0 No effect 1 Generate a single pulse of latch reset signal for COMPSTS[COMPHLATCH] Reset type: SYSRSn
0	RESERVED	R	0h	Reserved

### 22.8.2.5 COMPDACCTL Register (Offset = 4h) [Reset = 0h]

COMPDACCTL is shown in [Figure 22-11](#) and described in [Table 22-8](#).

Return to the [Summary Table](#).

CMPSS DAC Control Register

**Figure 22-11. COMPDACCTL Register**

15	14	13	12	11	10	9	8
FREESOFT		RESERVED	BLANKEN	BLANKSOURCE			
R/W-0h		R-0h	R/W-0h	R/W-0h			
7	6	5	4	3	2	1	0
SWLOADSEL	RAMPLOADSEL	SELREF	RAMPSOURCE			DACSOURCE	
R/W-0h	R/W-0h	R/W-0h	R/W-0h			R/W-0h	

**Table 22-8. COMPDACCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	FREESOFT	R/W	0h	Free-run or software-run emulation behavior. Behavior of the ramp generator during emulation suspend. 00b Ramp generator stops immediately during emulation suspend 01b Ramp generator completes current ramp and stops at next EPWMSYNCPER during emulation suspend 1Xb Ramp generator runs freely Reset type: SYSRSn
13	RESERVED	R	0h	Reserved
12	BLANKEN	R/W	0h	EPWMBLANK enable. This bit enables the EPWMBLANK signal. 0 EPWMBLANK signal is disabled. 1 EPWMBLANK signal is enabled. Reset type: SYSRSn
11-8	BLANKSOURCE	R/W	0h	EPWMBLANK source select. This bit field determines which EPWMnBLANK is passed on as the EPWMBLANK signal. Where n represents the maximum number of EPWMBLANK signals available on the device: 0 EPWM1BLANK 1 EPWM2BLANK 2 EPWM3BLANK ... n-1 EPWMnBLANK Reset type: SYSRSn
7	SWLOADSEL	R/W	0h	Software load select. Determines whether DACxVALA is updated from DACxVALS on SYSCLK or EPWMSYNCPER. 0 DACxVALA is updated from DACxVALS on SYSCLK 1 DACxVALA is updated from DACxVALS on EPWMSYNCPER Reset type: SYSRSn
6	RAMPLOADSEL	R/W	0h	Ramp load select. Determines whether RAMPSTS is updated from RAMPMAXREFA or RAMPMAXREFS when COMPSTS[COMPSTS] is triggered. 0 RAMPSTS is loaded from RAMPMAXREFA 1 RAMPSTS is loaded from RAMPMAXREFS Reset type: SYSRSn
5	SELREF	R/W	0h	DAC reference select. Determines which voltage supply is used as the reference for the internal comparator DACs. 0 VDDA is the voltage reference for the DAC 1 VDAC is the voltage reference for the DAC Reset type: SYSRSn

**Table 22-8. COMPDACCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4-1	RAMPSOURCE	R/W	0h	EPWMSYNCPER source select. Determines which EPWMnSYNCPER signal is used within the CMPSS module. Where n represents the maximum number of EPWMSYNCPER signals available on the device: 0 EPWM1SYNCPER 1 EPWM2SYNCPER 2 EPWM3SYNCPER ... n-1 EPWMnSYNCPER Reset type: SYSRSn
0	DACSOURCE	R/W	0h	DAC source select. Determines whether DACHVALA is updated from DACHVALS or from the ramp generator. 0 DACHVALA is updated from DACHVALS 1 DACHVALA is updated from the ramp generator Reset type: SYSRSn

### 22.8.2.6 DACHVALS Register (Offset = 6h) [Reset = 0h]

DACHVALS is shown in [Figure 22-12](#) and described in [Table 22-9](#).

Return to the [Summary Table](#).

CMPSS High DAC Value Shadow Register

The following chapters describe the control peripherals.

### 23.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown in [Figure 23-1](#). This Technical Reference Manual is organized into five major sections:

- **C28x SYSTEM RESOURCES**

These chapters describe the C28x CPU subsystem, C28x Boot ROM, device configuration, and other system peripherals.

- **ANALOG PERIPHERALS**

These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.

- **CONTROL PERIPHERALS**

These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- **COMMUNICATION PERIPHERALS**

These chapters describe the communication peripherals available to the C28x subsystem such as the I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.

- **CONNECTIVITY MANAGER (CM)**

These chapters describe the Connectivity Manager (CM) subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Figure 23-1. F2838x Block Diagram

This chapter describes the enhanced capture (eCAP) module, which is used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 2 eCAP. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an eCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

<b>24.1 Introduction</b> .....	2786

## 24.1 Introduction

### 24.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

The capture functionality of the Type 1 eCAP is enhanced from the Type 0 eCAP with the following added features:

- Event filter reset bit
  - Writing a 1 to ECCTL2[CTRFILTRESET] will clear the event filter, the modulo counter, and any pending interrupts flags. Resetting the bit is useful for initialization and debug.
- Modulo counter status bits
  - The modulo counter (ECCTL2 [MODCNRSTS]) indicates which capture register will be loaded next. In the Type 0 eCAP, it was not possible to know current state of modulo counter.
- DMA trigger source
  - eCAPxDMA was added as a DMA trigger. CEVT[1-4] can be configured as the source for eCAPxDMA.
- Input multiplexer
  - ECCTL0 [INPUTSEL] selects one of 128 input signals, which are detailed in [Section 24.3](#).
- EALLOW protection
  - EALLOW protection was added to critical registers. To maintain software compatibility with Type-0, configure DEV\_CFG\_REGS.ECAPTYPE to make these registers unprotected.

The capture functionality of the Type 2 eCAP is enhanced from the Type 1 eCAP with the following added features:

- Added ECAPxSYNCINSEL register
  - ECAPxSYNCINSEL register is added for each eCAP to select an external SYNCIN. Every eCAP can have a separate SYNCIN signal.

### 24.1.2 eCAP Related Collateral

## 24.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Capture inputs can be connected using the Input X-BAR
- 128:1 input multiplexer
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Modulo counter status register (MODCNRSTS) to indicate sequencer state
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Ability to reset event filter, modulo counter, and interrupt flags
- Interrupt capabilities on any of the four capture events
- Separate DMA trigger
- EALLOW protection to control registers

### 24.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPxQSELn register bits. Using synchronized inputs can help with noise immunity but will affect the eCAP's accuracy by  $\pm 2$  cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

New to the Type 1 eCAP module, a 128:1 input multiplexer must also be configured (see [Figure 24-3](#)). This multiplexer can select a variety of inputs detailed in [Table 24-1](#) by configuring ECCTL0.INPUTSEL.

Input X-BAR INPUT[16:1]	15:0

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

---

**Note**

ECAPxIN has to be at least 2\*SYSCLK cycles wide to be properly captured by the ECAP module. Otherwise the input pulse might get missed from sampling by the SYSCLK.

---

## 24.4 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 24-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 24-2 further describes the output of the eCAP in APWM mode based on the CMP and PRD values.

- A. A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

**Figure 24-1. Capture and APWM Modes of Operation**

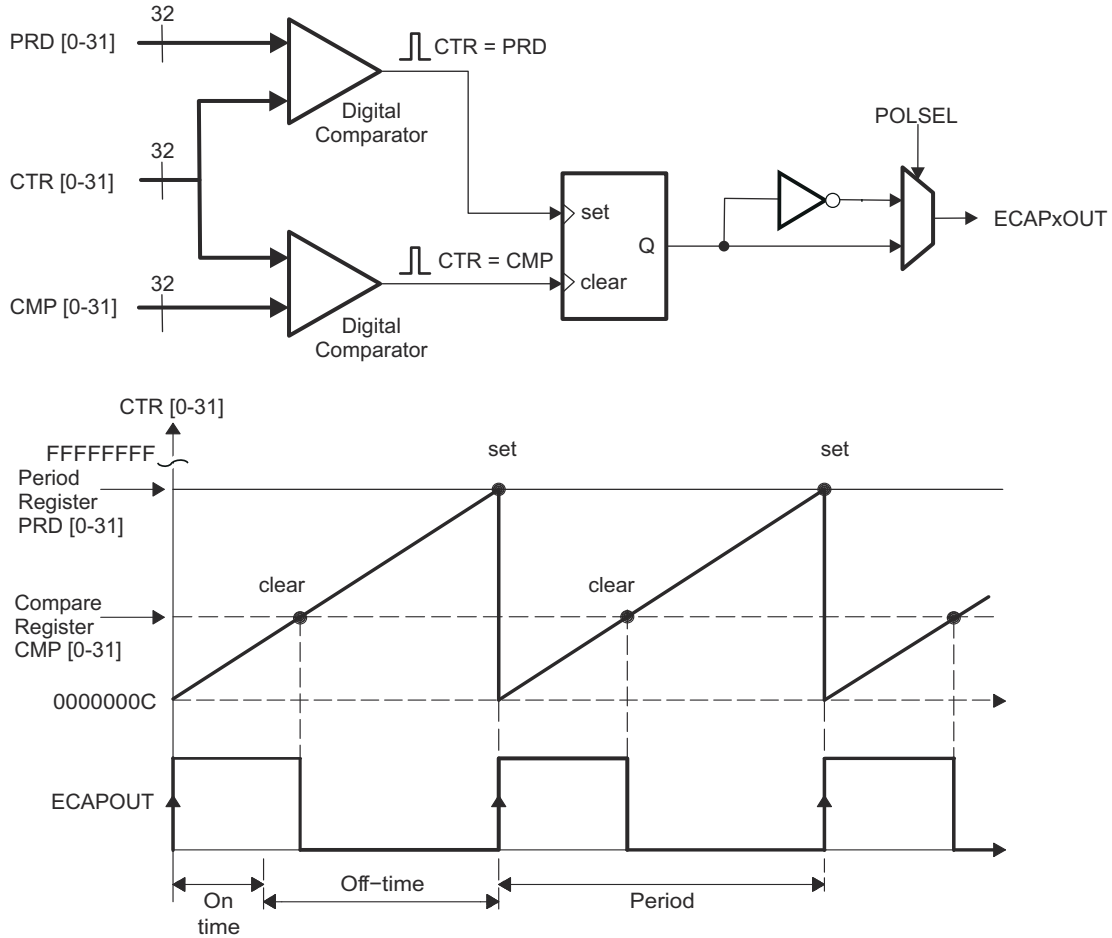

Figure 24-2. Counter Compare and PRD Effects on the eCAP Output in APWM Mode

## 24.5 Capture Mode Description

Figure 24-3 shows the various components that implement the capture function.

Copyright © 2018, Texas Instruments Incorporated

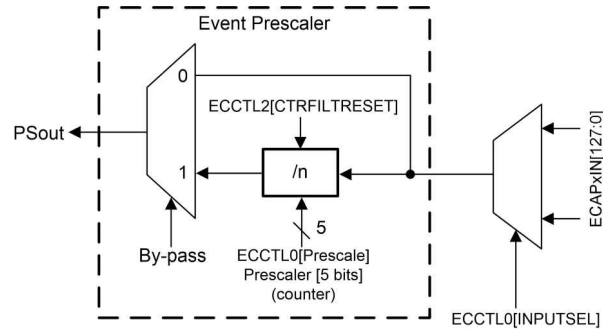

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 24-3. eCAP Block Diagram

### 24.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 24-4 shows a functional diagram and Figure 24-5 shows the operation of the prescale function. The event prescaler can be reset by setting the ECCTL2.CTRFILTRESET register bit.

- A. When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.
- B. The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

Figure 24-4. Event Prescale Control

Figure 24-5. Prescale Function Waveforms

### 24.5.2 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

### 24.5.3 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

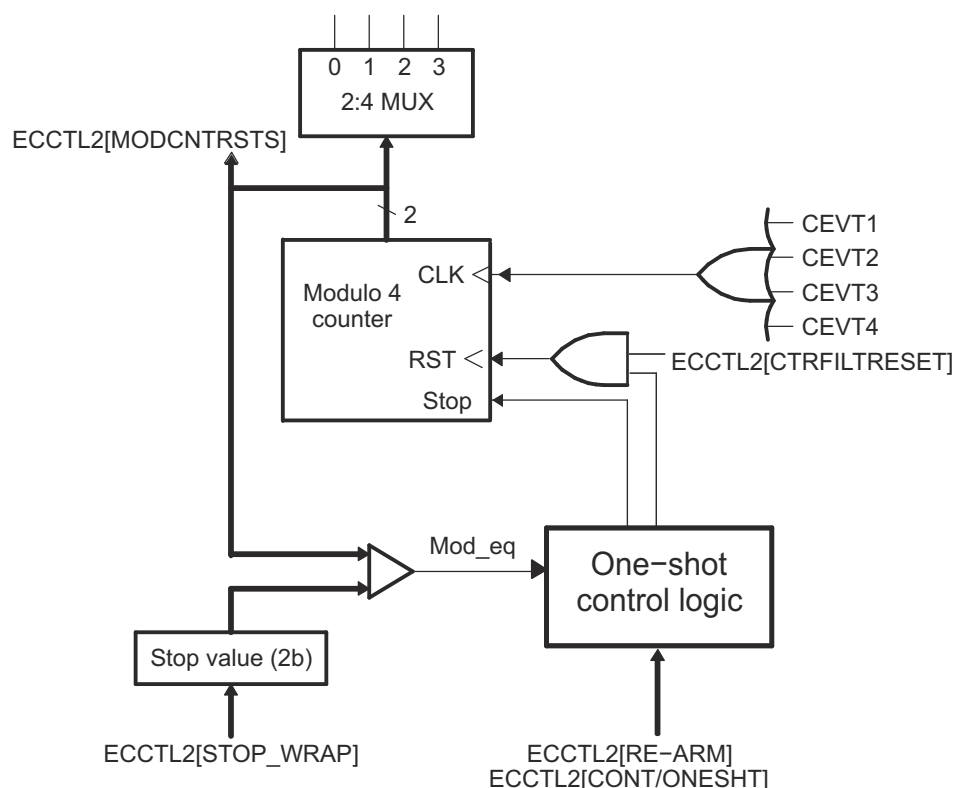

- The Mod4 (2-bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP\_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, it will still keep resetting the TSCCTR counter on capture event (CEVTx) after the STOP\_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

**Figure 24-6. Details of the Continuous/One-shot Block**

### 24.5.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

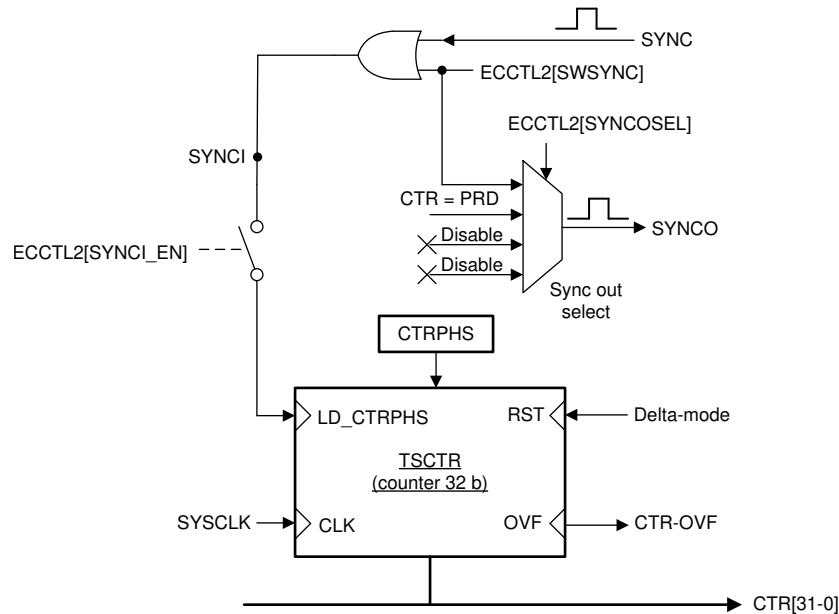

Figure 24-7. Details of the Counter and Synchronization Block

### 24.5.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

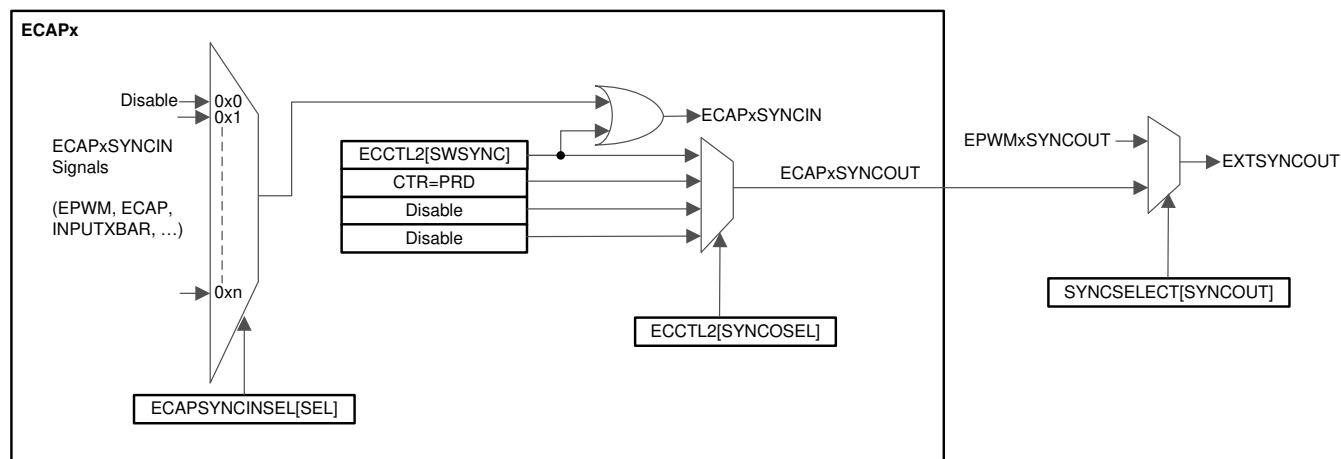

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACOMP) for CAP1 and CAP2 during APWM operation.

### 24.5.6 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from EtherCat, eCAP, X-Bar or EPWM. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 24-7. The SYNC signal is defined by the selection of ECAPxSYNCINSEL[SEL] as shown in Figure 24-8.

**Figure 24-8. eCAP Synchronization Scheme**

#### 24.5.6.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP2.

- Configure ECAP[1..2].ECAPxSYNCINSEL.SEL = 0x0 to disable external SYNCIN coming to eCAP1.
- Configure ECAP[1..2].ECCTL2.SWSYNC = 0x1, to force Software Synchronization of the TSCTR counter.

To use SWSYNC with other eCAP modules, ensure that the previous eCAP chain is not generating a SYNCOUT signal which will interfere with the software synchronization.

### 24.5.7 Interrupt Control

Operation and features of the eCAP interrupt control include (see [Figure 24-9](#)):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE and CLA.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. All interrupt flags will be cleared upon an event filter reset by writing a "1" to ECCTL2[CLRFILTRESET]. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

---

#### Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

---

Figure 24-9. Interrupts in eCAP Module

### 24.5.8 DMA Interrupt

On Type 0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type 1 eCAP, a separate DMA Trigger (ECAP\_DMA\_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events (CEVT1, CEVT2, CEVT3 and CEVT4) can be selected as the trigger source for ECAP\_DMA\_INT using ECCTL2 [DMAEVTSEL].

### 24.5.9 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal,  $CTR[31:0] = PRD[31:0]$ .

### 24.5.10 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a  $CTR = PRD$  trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

**Figure 24-10. PWM Waveform Details Of APWM Mode Operation**

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

**Figure 24-11. Time-Base Frequency and Period Calculation**

## 24.6 Application of the eCAP Module

The following sections will provide applications examples to show how to operate the eCAP module.

### 24.6.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 24-12 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), it wraps around to 00000000 (not shown in Figure 24-12), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the 4th event), hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

**Figure 24-12. Capture Sequence for Absolute Time-stamp and Rising Edge Detect**

### 24.6.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 24-13, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...and so on. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , and so on. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , and so on.

Figure 24-13. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect

### 24.6.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

Figure 24-14 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (Max value), before the next event, it wraps around to 00000000 and continues, a CNTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is,  $Period1 = T_1$ ,  $Period2 = T_2$ , and so on. As shown in Figure 24-14, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

**Figure 24-14. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect**

### 24.6.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger

In Figure 24-15, the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information, that is:  $Period1 = T_1 + T_2$ ,  $Period2 = T_3 + T_4$ , and so on.  $Duty Cycle1 (on-time \%) = T_1 / Period1 \times 100\%$ ,  $Duty Cycle1 (off-time \%) = T_2 / Period1 \times 100\%$ , and so on.

During initialization, you must write to the active registers for both period and compare. This action will automatically copy the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

Figure 24-15. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect

## 24.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

### 24.7.1 Example 1 - Simple PWM Generation (Independent Channel/s)

**Figure 24-16. PWM Waveform Details of APWM Mode Operation**

## 24.8 Software

### 24.9 eCAP Registers

This section describes the Enhanced Capture Registers.

#### 24.9.1 ECAP Base Address Table (C28)

**Table 24-2. ECAP Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
ECap1Regs	ECAP_REGS	ECAP1_BASE	0x0000_5200	YES	YES	YES	YES	YES

## 24.9.2 ECAP\_REGS Registers

Table 24-3 lists the memory-mapped registers for the ECAP\_REGS registers. All register offset addresses not listed in Table 24-3 should be considered as reserved locations and the register contents should not be modified.

**Table 24-3. ECAP\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	TSCTR	Time-Stamp Counter		<a href="#">Go</a>
2h	CTRPHS	Counter Phase Offset Value Register		<a href="#">Go</a>
4h	CAP1	Capture 1 Register		<a href="#">Go</a>
6h	CAP2	Capture 2 Register		<a href="#">Go</a>
8h	CAP3	Capture 3 Register		<a href="#">Go</a>
Ah	CAP4	Capture 4 Register		<a href="#">Go</a>
12h	ECCTL0	Capture Control Register 0	EALLOW	<a href="#">Go</a>
14h	ECCTL1	Capture Control Register 1	EALLOW	<a href="#">Go</a>
15h	ECCTL2	Capture Control Register 2	EALLOW	<a href="#">Go</a>
16h	ECEINT	Capture Interrupt Enable Register	EALLOW	<a href="#">Go</a>
17h	ECFLG	Capture Interrupt Flag Register		<a href="#">Go</a>
18h	ECCLR	Capture Interrupt Clear Register		<a href="#">Go</a>
19h	ECFRC	Capture Interrupt Force Register	EALLOW	<a href="#">Go</a>
1Eh	ECAPSYNCINSEL	SYNC source select register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 24-4 shows the codes that are used for access types in this section.

**Table 24-4. ECAP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

**Table 24-4. ECAP\_REGS Access Type Codes  
(continued)**

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 24.9.2.1 TSCTR Register (Offset = 0h) [Reset = 0h]

TSCTR is shown in [Figure 24-17](#) and described in [Table 24-5](#).

Return to the [Summary Table](#).

Time-Stamp Counter

**Figure 24-17. TSCTR Register**

**Table 24-12. ECCTL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Control Reset type: SYSRSn 0h (R/W) = TSCTR counter stops immediately on emulation suspend 1h (R/W) = TSCTR counter runs until = 0 2h (R/W) = TSCTR counter is unaffected by emulation suspend (Run Free) 3h (R/W) = TSCTR counter is unaffected by emulation suspend (Run Free)
13-9	PRESCALE	R/W	0h	Event Filter prescale select Reset type: SYSRSn 0h (R/W) = Divide by 1 (that is, no prescale, by-pass the prescaler) 1h (R/W) = Divide by 2 2h (R/W) = Divide by 4 3h (R/W) = Divide by 6 4h (R/W) = Divide by 8 5h (R/W) = Divide by 10 1Eh (R/W) = Divide by 60 1Fh (R/W) = Divide by 62
8	CAPLDEN	R/W	0h	Enable Loading of CAP1-4 registers on a capture event. Note that this bit does not disable CEVTn events from being generated. Reset type: SYSRSn 0h (R/W) = Disable CAP1-4 register loads at capture event time. 1h (R/W) = Enable CAP1-4 register loads at capture event time.
7	CTRRST4	R/W	0h	Counter Reset on Capture Event 4 Reset type: SYSRSn 0h (R/W) = Do not reset counter on Capture Event 4 (absolute time stamp operation) 1h (R/W) = Reset counter after Capture Event 4 time-stamp has been captured (used in difference mode operation)
6	CAP4POL	R/W	0h	Capture Event 4 Polarity select Reset type: SYSRSn 0h (R/W) = Capture Event 4 triggered on a rising edge (RE) 1h (R/W) = Capture Event 4 triggered on a falling edge (FE)
5	CTRRST3	R/W	0h	Counter Reset on Capture Event 3 Reset type: SYSRSn 0h (R/W) = Do not reset counter on Capture Event 3 (absolute time stamp) 1h (R/W) = Reset counter after Event 3 time-stamp has been captured (used in difference mode operation)
4	CAP3POL	R/W	0h	Capture Event 3 Polarity select Reset type: SYSRSn 0h (R/W) = Capture Event 3 triggered on a rising edge (RE) 1h (R/W) = Capture Event 3 triggered on a falling edge (FE)

**Table 24-12. ECCTL1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	CTRRST2	R/W	0h	Counter Reset on Capture Event 2 Reset type: SYSRSn 0h (R/W) = Do not reset counter on Capture Event 2 (absolute time stamp) 1h (R/W) = Reset counter after Event 2 time-stamp has been captured (used in difference mode operation)
2	CAP2POL	R/W	0h	Capture Event 2 Polarity select Reset type: SYSRSn 0h (R/W) = Capture Event 2 triggered on a rising edge (RE) 1h (R/W) = Capture Event 2 triggered on a falling edge (FE)
1	CTRRST1	R/W	0h	Counter Reset on Capture Event 1 Reset type: SYSRSn 0h (R/W) = Do not reset counter on Capture Event 1 (absolute time stamp) 1h (R/W) = Reset counter after Event 1 time-stamp has been captured (used in difference mode operation)
0	CAP1POL	R/W	0h	Capture Event 1 Polarity select Reset type: SYSRSn 0h (R/W) = Capture Event 1 triggered on a rising edge (RE) 1h (R/W) = Capture Event 1 triggered on a falling edge (FE)

### 24.9.2.9 ECCTL2 Register (Offset = 15h) [Reset = 6h]

ECCTL2 is shown in [Figure 24-25](#) and described in [Table 24-13](#).

Return to the [Summary Table](#).

Capture Control Register 2

**Figure 24-25. ECCTL2 Register**

15	14	13	12	11	10	9	8
MODCNRSTS		DMAEVTSEL		CTRFILTRESE T	APWMPOL	CAP_APWM	SWSYNC
R-0h		R/W-0h		R-0/W1C-0h	R/W-0h	R/W-0h	R-0/W1S-0h
7	6	5	4	3	2	1	0
SYNCO_SEL		SYNCl_EN	TSCTRSTOP	REARM	STOP_WRAP		CONT_ONESH T
R/W-0h		R/W-0h	R/W-0h	R-0/W1S-0h	R/W-3h		R/W-0h

**Table 24-13. ECCTL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	MODCNRSTS	R	0h	This bit field reads current status on modulo counter 00b (R) = CAP1 register gets loaded on next capture event. 01b (R) = CAP2 register gets loaded on next capture event. 10b (R) = CAP3 register gets loaded on next capture event. 11b (R) = CAP4 register gets loaded on next capture event. Reset type: CPU1.SYSRSn
13-12	DMAEVTSEL	R/W	0h	DMA event select 00b (R/W) = DMA interrupt source is CEVT1 01b (R/W) = DMA interrupt source is CEVT2 10b (R/W) = DMA interrupt source is CEVT3 11b (R/W) = DMA interrupt source is CEVT4 Note: ECCTL1.CAPLDEN also needs to be set to "1" for ECAPxDMA_INT to be generated Reset type: CPU1.SYSRSn
11	CTRFILTRESET	R-0/W1C	0h	Reset Bit 0h (R) = No effect 1h (W) = Resets event filter, counter, modulo counter and CEVT[1,2,3,4] and CNTOVF, HRERROR flags Note: This provides an ability start capture module from known state in case spurious inputs are captured while ECAP is configured. Reset type: CPU1.SYSRSn
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode. Reset type: SYSRSn 0h (R/W) = Output is active high (Compare value defines high time) 1h (R/W) = Output is active low (Compare value defines low time)
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select Reset type: SYSRSn 0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration: - Inhibits TSCTR resets via CTR = PRD event - Inhibits shadow loads on CAP1 and 2 registers - Permits user to enable CAP1-4 register load - CAPx/APWMx pin operates as a capture input 1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration: - Resets TSCTR on CTR = PRD event (period boundary) - Permits shadow loading on CAP1 and 2 registers - Disables loading of time-stamps into CAP1-4 registers - CAPx/APWMx pin operates as a APWM output

**Table 24-13. ECCTL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	SWSYNC	R-0/W1S	0h	Software-forced Counter (TSCTR) Synchronizer. This provides the user a method to generate a synchronization pulse through software. In APWM mode, the synchronization pulse can also be sourced from the CTR = PRD event. Reset type: SYSRSn 0h (R/W) = Writing a zero has no effect. Reading always returns a zero 1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero. Note: Selection CTR = PRD is meaningful only in APWM mode however, you can choose it in CAP mode if you find doing so useful.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select Reset type: SYSRSn 0h (R/W) = sync out signal is SWSYNC 1h (R/W) = Select CTR = PRD event to be the sync-out signal 2h (R/W) = Disable sync out signal 3h (R/W) = Disable sync out signal
5	SYNCI_EN	R/W	0h	Counter (TSCTR) Sync-In select mode Reset type: SYSRSn 0h (R/W) = Disable sync-in option 1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control Reset type: SYSRSn 0h (R/W) = TSCTR stopped 1h (R/W) = TSCTR free-running
3	REARM	R-0/W1S	0h	Re-Arming Control. Note: The re-arm function is valid in one shot or continuous mode Reset type: SYSRSn 0h (R/W) = Has no effect (reading always returns a 0) 1h (R/W) = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero 2) Unfreezes the Mod4 counter 3) Enables capture register loads
2-1	STOP_WRAP	R/W	3h	Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur: - Mod4 counter is stopped (frozen) - Capture register loads are inhibited In one-shot mode, further interrupt events are blocked until re-armed. Reset type: SYSRSn 0h (R/W) = Stop after Capture Event 1 in one-shot mode Wrap after Capture Event 1 in continuous mode. 1h (R/W) = Stop after Capture Event 2 in one-shot mode Wrap after Capture Event 2 in continuous mode. 2h (R/W) = Stop after Capture Event 3 in one-shot mode Wrap after Capture Event 3 in continuous mode. 3h (R/W) = Stop after Capture Event 4 in one-shot mode Wrap after Capture Event 4 in continuous mode.
0	CONT_ONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) Reset type: SYSRSn 0h (R/W) = Operate in continuous mode 1h (R/W) = Operate in one-Shot mode

### 24.9.2.10 ECEINT Register (Offset = 16h) [Reset = 0h]

ECEINT is shown in [Figure 24-26](#) and described in [Table 24-14](#).

Return to the [Summary Table](#).

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is as follows:

- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

**Figure 24-26. ECEINT Register**

This chapter describes the operation of the high resolution capture (HRCAP) module. The HRCAP submodule described here is part of the Type1 eCAP. HRCAP measures the width of external pulses to a higher degree of accuracy than the eCAP module. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an HRCAP module of the same type, to determine the differences between types, and for a list of device-specific differences within a type. A detailed description of all referenced functions can be found in the C2000Ware documentation.

<b>25.1 Introduction</b> .....	<b>2830</b>
<b>25.2 Operational Details</b> .....	<b>2830</b>
<b>25.3 Known Exceptions</b> .....	<b>2834</b>
<b>25.4 Software</b> .....	<b>2835</b>
<b>25.5 HRCAP Registers</b> .....	<b>2835</b>

## 25.1 Introduction

Uses for the HRCAP module include:

- Capacitive touch applications
- High-resolution period and duty cycle measurements of pulse train cycles
- Instantaneous speed measurements
- Instantaneous frequency measurements
- Voltage measurements across an isolation boundary
- Distance/sonar measurement and scanning
- Measuring flow

### 25.1.1 HRCAP Related Collateral

#### Foundational Materials

- [C2000 Academy - Control Peripherals](#)

#### Getting Started Materials

- [Leveraging High Resolution Capture \(HRCAP\) for Single Wire Data Transfer Application Report](#)

### 25.1.2 Features

The HRCAP module includes the following features:

- Pulse-width capture in either non-high-resolution or high-resolution modes
- Absolute mode pulse-width capture
- Continuous or one-shot capture
- Interrupt on either falling or rising edge
- Continuous mode capture of pulse widths in 4-deep buffer
- Hardware calibration logic for precision high-resolution capture

All of the previous resources are available on any pin using the Input X-BAR.

### 25.1.3 Description

Improvements from the Type 0 HRCAP are:

- Simplified calibration scheme:
  - HRCAP is always functional; never offline to perform calibration
  - Calibration is always running in the background; drastically reduced software overhead to calibrate
- Reduced software overhead to compute fractional bits
- Fractional and integer portions are packed into 32 bits
- All eCAP hardware is accessible when using the HRCAP enhancements. See [Section 25.3](#) for practical considerations.
- Usage of the HRCAP is now unified with the eCAP

The HRCAP enhancement has been added to eCAP 6 and eCAP 7 to allow signals to be captured asynchronously to SYSCLK. Each HRCAP submodule includes one capture channel in addition to a hardware calibration block. All eCAP hardware is accessible when using the HRCAP enhancements; however, using the Event Filter or the Input Qualifier is not valid, as these are synchronous to SYSCLK.

Each HRCAP-capable channel has the following independent key resources:

- All hardware of the respective eCAP
- High-resolution calibration logic
- Dedicated calibration interrupt

## 25.2 Operational Details

[Figure 25-1](#) shows the various components that implement the high-resolution capture functionality of the eCAP module. Note that existing eCAP resources are reused, which requires that the eCAP module is set up before

using the HRCAP enhancements. For simplicity, absolute timestamp measurements are recommended. See [Section 25.3](#) for more details.

All HRCAP measurements are relative-time measures, in terms of minimum step size. Calibration hardware as well as software functions, have been provided to convert relative-time measurements to time-converted measurements in terms of seconds. The calibration hardware and software is only required if time-converted measurements are required.

Copyright © 2018, Texas Instruments Incorporated

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

**Figure 25-1. HRCAP Operations Block Diagram**

### 25.2.1 HRCAP Clocking

Unlike previous Type-0 HRCAP modules, the Type-1 eCAP, with HRCAP functionality, does not require a second PLL. However, the module still requires both SYSCLK and a second asynchronous clock source called HRCLK. The HRCLK is sensitive to changes in both temperature and voltage. For this reason, when using time-converted measurements, it is required to make periodic continuous calibrations.

### 25.2.2 HRCAP Initialization Sequence

Following are the HRCAP initialization sequence steps. When using the HRCAP to take relative-time measurements, only steps 1-5 are required. When using the HRCAP to take time-converted measurements, all steps are required.

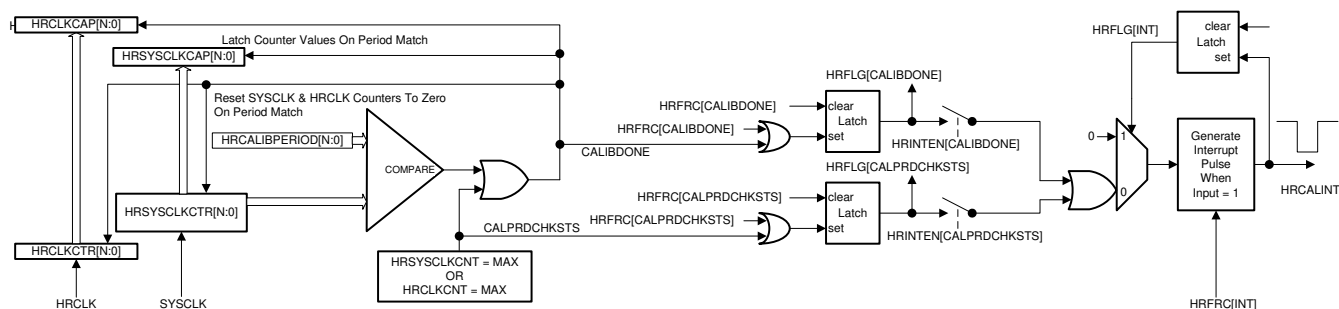

1. Enable HRCLK using `HRCAP_enableHighResolutionClock()`
2. Delay 1  $\mu$ S
3. Enable HR mode using `HRCAP_enableHighResolution()`
4. Delay 1  $\mu$ S
5. Configure the eCAP module as desired, including interrupts
6. Set calibration period using `HRCAP_setCalibrationPeriod()`
7. Enable continuous calibration using `HRCAP_setCalibrationMode()`
8. Enable interrupts using `HRCAP_enableCalibrationInterrupt()`
9. Start calibration using `HRCAP_startCalibration()`

### 25.2.3 HRCAP Interrupts

The HRCAP enhancements leverage the existing eCAP interrupts (see *Interrupt Control* in the ECAP chapter) in addition to HRCALINT, which is used exclusively by the hardware calibration block. HRCALINT can be triggered by the following conditions:

1. `SYSCLKCTR = HRCALIBPERIOD`
2. `SYSCLKCTR` or `HRCLKCTR` experience an overflow condition

Figure 25-2 shows this logic.

**Figure 25-2. HRCAP Calibration**

## 25.2.4 HRCAP Calibration

---

### Note

For HRCAP calibration to work, the system needs to operate at SYSCLK frequency > 100 MHz.

---

The following section applies only to time-converted measurements; calibration for relative-time measurements is not required. All values captured by the HRCAP submodule are in number of HRCLK cycles. The HRCLK speed varies widely with temperature and voltage, thus a scale factor is required to convert the capture value to the SYSCLK domain. For the same reason, it is required to periodically recalculate the scale factor. The HRCAP submodule has a calibration block to reduce software overhead when calculating a scale factor between HRCLK and SYSCLK.

The calibration block contains the following key resources:

- **HRSYSCLKCNT:** A 32-bit counter connected to SYSCLK. The counter will start counting when CALIBSTART is set.
- **HRCLKCNT:** A 32-bit counter connected to HRCLK. The counter will start counting when CALIBSTART is set.
- **HRCALIBPERIOD:** Calibration period, calibration is stopped when HRSYSCLKCNT is equal to the value in this register.
- **HRSYSCLKCAP:** On a calibration period match, the value of HRSYSCLKCNT is captured into HRSYSCLKCAP.
- **HRCLKCAP:** On a calibration period match, the value of HRCLKCNT is captured into HRCLKCAP.
- **HRCALINT:** An interrupt that occurs on a calibration period match, or when one of the counter registers experiences an overflow condition.

The calibration logic consists of two free-running counters; one clocked by HRCLK(HRCLKCTR) and the other clocked by SYSCLK(HRSYSCLKCTR). When HRSYSCLKCTR is equal to HRCALIBPERIOD, the calibration block will capture and reset both counter values, then trigger an interrupt, indicating a new scale factor is ready to be calculated. The scale factor can be found by dividing HRSYSCLKCAP by HRCLKCAP (see [Equation 10](#)). A DriverLib function, HRCAP\_getScaleFactor, has been provided to determine the scale factor. This function should be called inside of the calibration interrupt service routine. If one of the counters experiences overflow, the CALPRDCHKSTS flag will be set. The full details of the calibration block are described in [Figure 25-2](#).

$$ScaleFactor = \frac{HRSYSCLKCAP}{HRCLKCAP} \quad (10)$$

---

### Note

- Even with calibration, noise on the 1.2V VDD supply will negatively affect the standard deviation of the HRCAP submodule. Care should be taken to ensure that the 1.2V supply is clean, and that noisy internal events such as enabling and disabling clock trees have been minimized while using the HRCAP submodule.
  - When HRCLK > SYSCLK, calibration stops immaturely, in order to mitigate improper calibration, SYSCLK must be set to at least 100 MHz.
-

### 25.2.4.1 Applying the Scale Factor

A DriverLib function has been provided to apply the scale factor to a capture value, `HRCAP_getEventTimeStampNanoseconds()`. shows how to convert a raw count to seconds without using the DriverLib function.

$$Measurement(ns) = \frac{RawCount \times scaleFactor}{128} * SysClkPrd(ns) \quad (11)$$

**Table 25-1. Scale Factor**

Parameter	Explanation
RawCount	Capture value as read from ECAP_REGS_CAP1-4
ScaleFactor <sup>(1)</sup>	The Scale factor as calculated from <a href="#">Equation 10</a>
128	Constant determined by the hardware of the HRCAP submodule
SysClkPrd(nS)	Period of the system clock
Measurement(nS)	Signal converted to nS

(1) The scale factor is not automatically applied to captured values. You are required to apply the scale factor to all captured values as shown in [Equation 10](#).

## 25.2.5 DriverLib Functions

## 25.3 Known Exceptions

In HRCAP mode:

- Enabling and disabling core clocks negatively affects the standard deviation of the HRCAP submodule. Do not enable or disable core clocks while taking measurements.
- TSCTR is not writable; however, it can be reset using ECCTL2[CTRFILTRESET]
- Input synchronization is not applicable when using the HRCAP enhancements, because the HRCAP submodule is asynchronous to SYSCLK.
- The Event Filter functionality is not applicable for HRCAP, which defeats the purpose of HRCAP as the Event Filter's output is synchronous to SYSCLK.
- The best practice is to use absolute time mode for high resolution mode. If time difference mode is used, it may lead to inaccurate results if the fractional value is not taken into consideration for capture events that have reset the time base counter.
  - Actual Capture Value = (Capture Value) – (fractional value of reference event that reset the counter)
- For high-frequency input signals, the CPU may not be able cope with the speed of the captures. In such a case, One-Shot mode is recommended. This mode allows the device to capture up to four edges before waiting to be serviced when the CPU is ready. This is applicable for the eCAP as well; however in that case the event filter can be used to reduce the rate of captures.

## 25.4 Software

### 25.4.1 HRCAP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/hrcap

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 25.4.1.1 HRCAP Capture and Calibration Example

FILE: hrcap\_ex1\_capture.c

This example configures an ECAP to use HRCAP functionality to capture time between edges on input GPIO2.

##### External Connections

The user must provide a signal to GPIO2. XCLKOUT has been configured to an output GPIO and can be externally jumped to serve this purpose. See Sysconfig file for XCLKOUT GPIO selected.

##### Watch Variables

- onTime1, onTime2
- offTime1, offTime2
- period1, period2

## 25.5 HRCAP Registers

This section describes the High-Resolution Capture Registers.

### 25.5.1 HRCAP Base Address Table (C28)

**Table 25-2. HRCAP Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
HRCap6Regs	HRCAP_REGS	HRCAP6_BASE	0x0000_5360	YES	YES	YES	YES	YES
HRCap7Regs	HRCAP_REGS	HRCAP7_BASE	0x0000_53A0	YES	YES	YES	YES	YES

## 25.5.2 HRCAP\_REGS Registers

Table 25-3 lists the memory-mapped registers for the HRCAP\_REGS registers. All register offset addresses not listed in Table 25-3 should be considered as reserved locations and the register contents should not be modified.

**Table 25-3. HRCAP\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	HRCTL	High-Res Control Register	EALLOW	<a href="#">Go</a>
4h	HRINTEN	High-Res Calibration Interrupt Enable Register	EALLOW	<a href="#">Go</a>
6h	HRFLG	High-Res Calibration Interrupt Flag Register		<a href="#">Go</a>
8h	HRCLR	High-Res Calibration Interrupt Clear Register		<a href="#">Go</a>
Ah	HRFRC	High-Res Calibration Interrupt Force Register	EALLOW	<a href="#">Go</a>
Ch	HRCALPRD	High-Res Calibration Period Register	EALLOW	<a href="#">Go</a>
Eh	HRSYSCLKCTR	High-Res Calibration SYSCLK Counter Register		<a href="#">Go</a>
10h	HRSYSCLKCAP	High-Res Calibration SYSCLK Capture Register		<a href="#">Go</a>
12h	HRCLKCTR	High-Res Calibration HRCLK Counter Register		<a href="#">Go</a>
14h	HRCLKCAP	High-Res Calibration HRCLK Capture Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 25-4 shows the codes that are used for access types in this section.

**Table 25-4. HRCAP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 25.5.2.1 HRCTL Register (Offset = 0h) [Reset = 0h]

HRCTL is shown in [Figure 25-3](#) and described in [Table 25-5](#).

Return to the [Summary Table](#).

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital to analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 4 with added register protection capability. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

Further information can be found in the [Flexible PWMs Enable Multi-Axis Drives, Multi-Level Inverters Technical Brief](#).

## 26.1 Introduction

This chapter includes an overview and information about each submodule:

- Time-Base Submodule
- Counter Compare Submodule
- Action Qualifier Submodule
- Dead-Band Generator Submodule
- PWM Chopper (PC) Submodule
- Trip Zone Submodule
- Event Trigger Submodule
- Digital Compare Submodule

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map**

Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.

- **Delayed Trip Functionality**

Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform will not take place immediately. Instead, they will synchronize to the next TBCLK.

- **Dead-Band Generator Submodule Enhancements**

Shadowing of the DBCTL register to allow dynamic configuration changes.

- **One Shot and Global Load of Registers**

The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. It also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and ensuring that all registers are loaded at the same time.

- **Trip Zone Submodule Enhancements**

Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip zone submodule to support certain power converter switching techniques like valley switching.

- **Digital Compare Submodule Enhancements**

Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.

- **PWM SYNC Related Enhancements**

The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High Resolution Dead-Band Capability**

High resolution capability is added to dead-band RED and FED in half-cycle clocking mode.

- **Dead-Band Generator Submodule Enhancements**

The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed

- **High Resolution Extension available on ePWMxB outputs**

Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in [Section 26.15](#).

- **Counter Compare Submodule Enhancements**

The ePWM Type 2 allows Interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.

- **Event Trigger Submodule Enhancements**

Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. It allows software initialization of event counters on SYNC event.

- **Digital Compare Submodule Enhancements**

Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.

- **Simultaneous Writes to TBPRD and CMPx Registers**

This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.

- **Shadow to Active Load on SYNC of TBPRD and CMP Registers**

This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

## Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution**

Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.

- **Enhanced Interrupt and SOC Generation**

Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.

- **High Resolution Period Capability**

Provides the ability to enable high-resolution period. This is discussed in more detail in the device-specific *High-Resolution Pulse Width Modulator (HRPWM)* document..

- **Digital Compare Submodule**

The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

### Note

The name of the sync signal that goes to the CMPSS and GPDAC has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCl and EPWMSYNCO. For a description of these signals, see [Table 26-2](#).

## 26.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 26-1](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 26.15](#). See the device-specific data manual to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

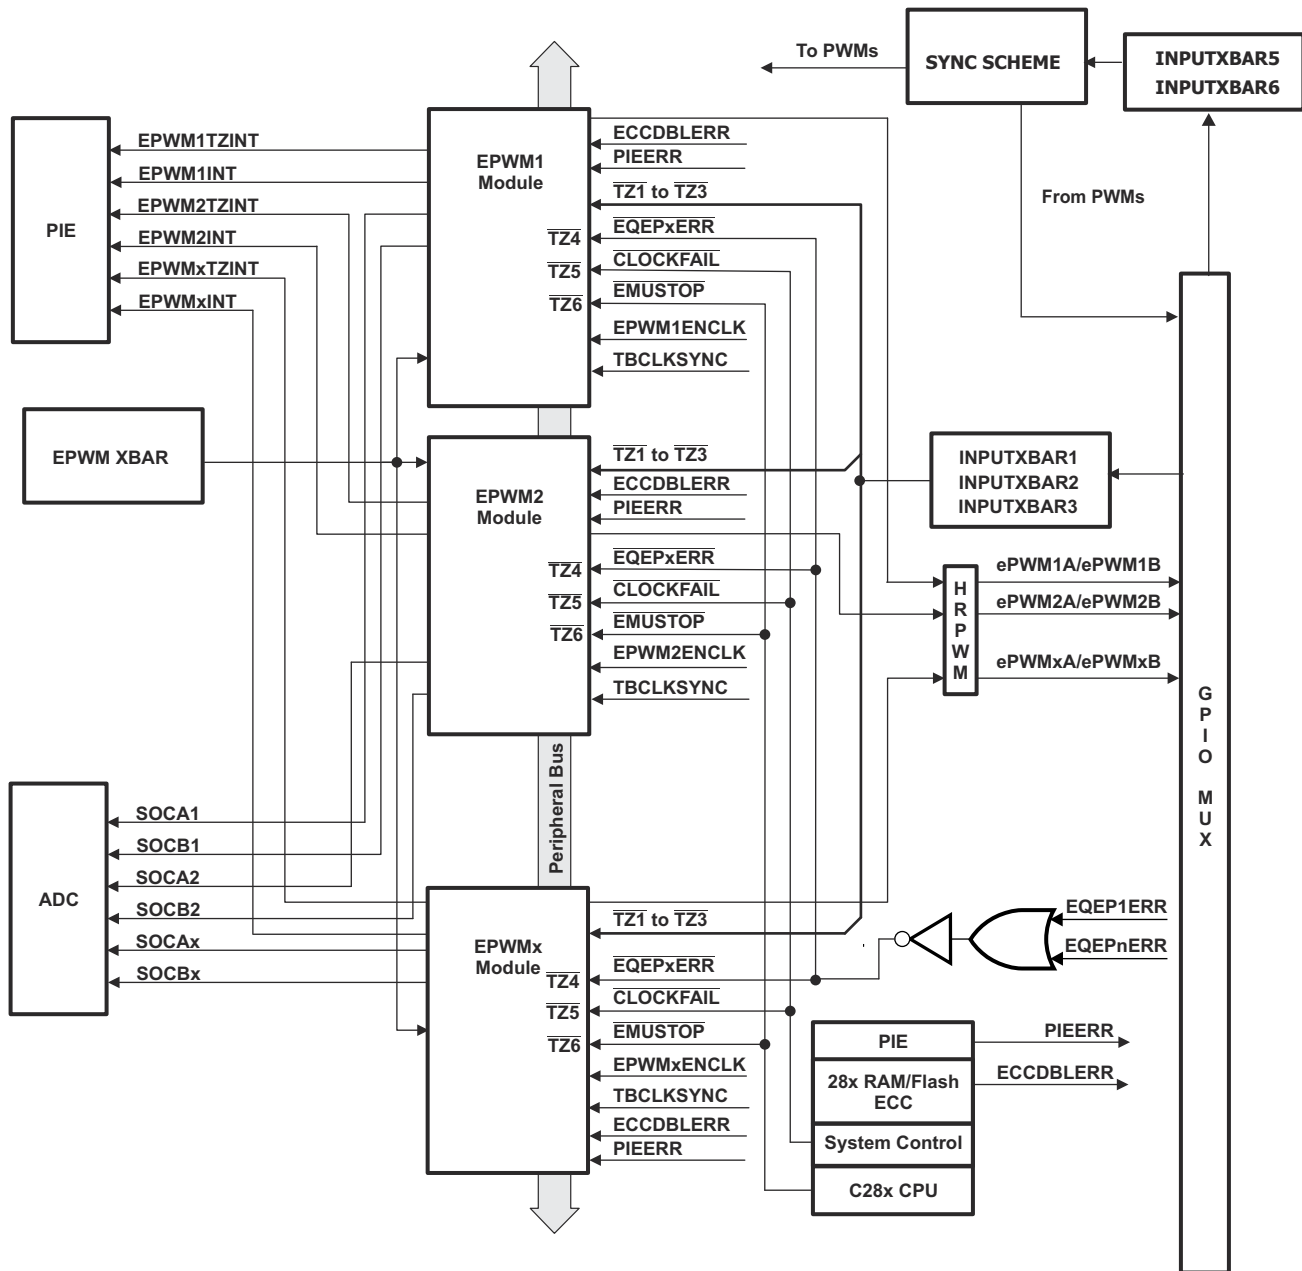

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.

- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 26-1](#). The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in [Figure 26-1](#). See [Section 26.4.3.3](#) for the synchronization scheme for a particular device. Each ePWM module consists of eight submodules and is connected within a system by way of the signals shown in [Figure 26-2](#).

Copyright © 2017, Texas Instruments Incorporated

A. This signal exists only on devices with an eQEP submodule.

**Figure 26-1. Multiple ePWM Modules**

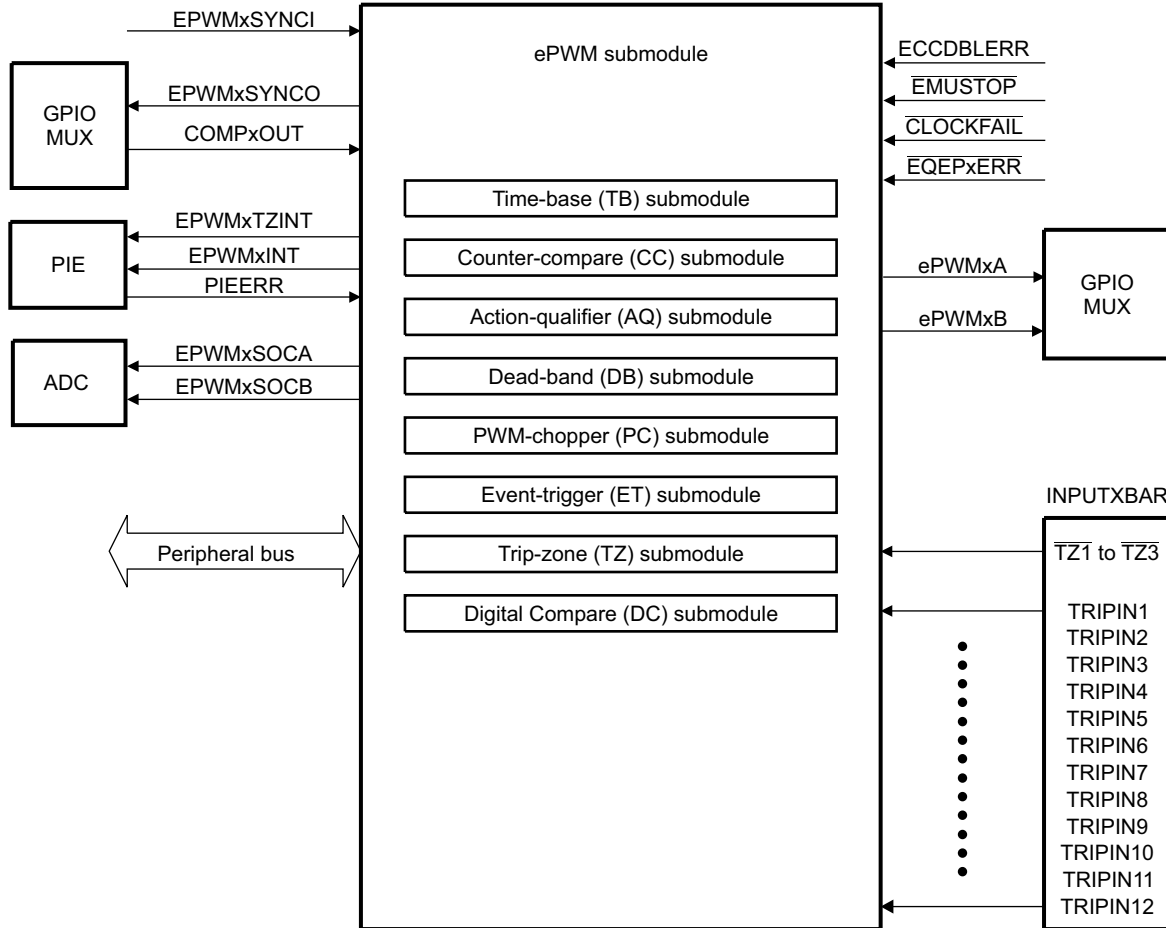

Figure 26-2. Submodules and Signal Connections for an ePWM Module

Figure 26-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**

The PWM output signals are made available external to the device through the GPIO peripheral described in the *System Control and Interrupts* chapter.

- **Trip-zone signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ )**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The  $\overline{TZ1}$  to  $\overline{TZ3}$  trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 26-51.  $\overline{TZ4}$  is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module).  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is connected to the EMUSTOP output from the CPU. This allows you to configure a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals**

Each ePWM module can be synchronized with other ePWM modules or other peripherals, using EPWMSYNClNSEL. Each ePWM module can also generate a synchronization output signal. The source of the EPWMxSYNCO can be selected and enabled by EPWMSYNCOEN and TBCTL2.OSHTSYNCSOURCE. For more information, see Section 26.4.3.3.

Each ePWM module also generates another PWMSYNCSIGNAL signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. It is configured using the HRPCTL register but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see their respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT)**

Output signals from the comparator module can be fed through the Input X-BAR to one or all of the 12 trip inputs [TRIPIN1 - TRIPIN12] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

**Figure 26-3. ePWM Modules and Critical Internal Signal Interconnects**

## 26.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR must be used. Some examples of when an external signal may be needed are TZx, TRIPx, and EXTSYNCLIN. Any GPIO on the device can be configured as an input. The GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals. Additionally, some TRIPx (TRIP4-12 excluding TRIP6) signals must be routed through the ePWM X-Bar in addition to the Input X-Bar.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *GPIO* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

## 26.3 ePWM Modules Overview

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

[Table 26-1](#) lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in [Section 26.5](#) for relevant details.

**Table 26-1. Submodule Configuration Parameters**

Submodule	Configuration Parameter or Option
Time Base (TB)	<ul style="list-style-type: none"> <li>• Scale the time-base clock (TBCLK) relative to the ePWM clock (EPWMCLK).</li> <li>• Configure the PWM time-base counter (TBCTR) frequency or period.</li> <li>• Set the mode for the time-base counter:               <ul style="list-style-type: none"> <li>– count-up mode: used for asymmetric PWM</li> <li>– count-down mode: used for asymmetric PWM</li> <li>– count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>• Configure the time-base phase relative to another ePWM module.</li> <li>• Synchronize the time-base counter between modules through hardware or software.</li> <li>• Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>• Simultaneous writes to the TBPRD registers on all PWM's corresponding to the configuration on EPWMXLINK.</li> <li>• Configure how the time-base counter will behave when the device is halted by an emulator.</li> <li>• Specify the source for the synchronization output of the ePWM module</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>
Counter Compare (CC)	<ul style="list-style-type: none"> <li>• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB</li> <li>• Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> <li>• Specify the programmable delay for interrupt and SOC generation with additional comparators</li> <li>• Simultaneous writes to the CMPA, CMPB, CMPC, CMPD registers on all PWM's corresponding to the configuration on EPWMXLINK.</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>
Action Qualifier (AQ)	<ul style="list-style-type: none"> <li>• Specify the type of action taken when a time-base counter-compare, trip-zone submodule, or comparator event occurs:               <ul style="list-style-type: none"> <li>– No action taken</li> <li>– Output EPWMxA and/or EPWMxB switched high</li> <li>– Output EPWMxA and/or EPWMxB switched low</li> <li>– Output EPWMxA and/or EPWMxB toggled</li> </ul> </li> <li>• Force the PWM output state through software control</li> <li>• Configure and control the PWM dead band through software</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>

**Table 26-1. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Dead Band (DB)	<ul style="list-style-type: none"> <li>Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>Specify the output rising-edge-delay value</li> <li>Specify the output falling-edge delay value</li> <li>Bypass the dead-band module entirely. ## 26.4 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 26-4 illustrates the time-base module's place within the ePWM.

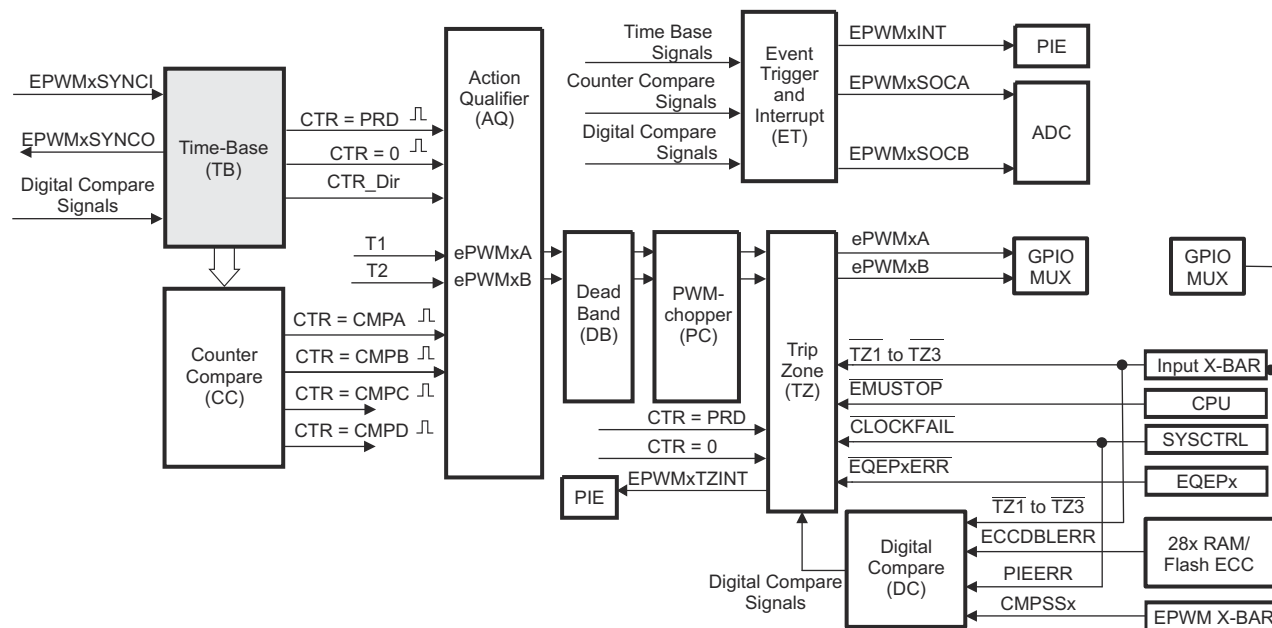

Figure 26-4. Time-Base Submodule

### 26.4.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

#### Note

If it is required by the application code to updated the TBCTR value through software, while the TBCTR is counting, it is important to note that the Time-Base module will need at least 1 TBCLK cycle for the Time-Base related events to be realized. Hence the TBCTR should either be written with TBCTR = PRD-1 instead of TBCTR = PRD (in case the counter is counting up) and should be written as TBCTR = 1 instead of TBCTR = 0 (in case the counter is counting down) for the events to be realized.

### 26.4.2 Controlling and Monitoring the Time-Base Submodule

The block diagram in Figure 26-5 shows the critical signals and registers of the time-base submodule. Table 26-2 provides descriptions of the key signals associated with the time-base submodule.

A. These signals are generated by the digital compare (DC) submodule.

**Figure 26-5. Time-Base Submodule Signals and Registers**

**Table 26-2. Key Time-Base Signals**

Signal	Description
EPWMxSYNCl	<p>Time-base synchronization input.</p> <p>Input pulse used to synchronize the time-base counter with the counter of other ePWM modules. For more information on all of the signals available for synchronization, see EPWMSYNClNSEL. For information on the synchronization order of a particular device, see <a href="#">Section 26.4.3.3</a>.</p>
EPWMxSYNCO	<p>Time-base synchronization output.</p> <p>This output pulse is used to synchronize the counter of other ePWM modules. Using EPWMSYNCOOUTEN, TBCTL2, TBCTL3 and GLDCTL2, the source of the output pulse is selected.</p>
EPWMxSYNCPER	<p>Time-base peripheral synchronization output.</p> <p>This output signal is used to synchronize the GPDAC and CMPSS to the EPWM. It can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM.</p>
CTR = PRD	<p>Time-base counter equal to the specified period.</p> <p>This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.</p>
CTR = Zero	<p>Time-base counter equal to zero</p> <p>This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.</p>
CTR = CMPB	<p>Time-base counter equal to active counter-compare B register (TBCTR = CMPB).</p> <p>This event is generated by the counter-compare submodule and used by the synchronization out logic</p>
CTR_dir	<p>Time-base counter direction.</p> <p>Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.</p>
CTR_max	<p>Time-base counter equal max value. (TBCTR = 0xFFFF)</p> <p>Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit</p>
TBCLK	<p>Time-base clock.</p> <p>This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.</p>

### 26.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 26-6 shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

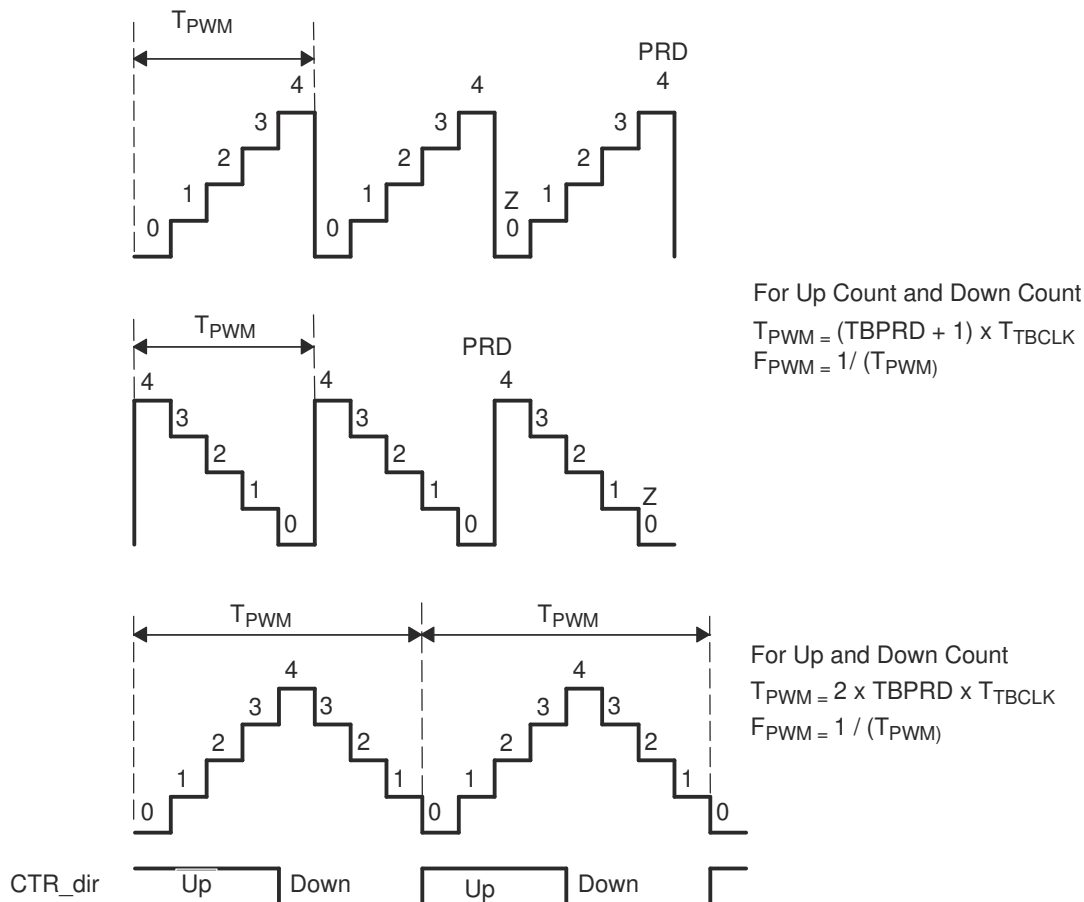

Figure 26-6. Time-Base Frequency and Period

### 26.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDL] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in [Section 26.4.3.3](#).

The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in [Section 26.4.7](#).

- **Time-Base Period Immediate Load Mode:**

If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 26.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC= 0
3. Configure ePWM modules
4. Set TBCLKSYNC= 1

In a multi-core environment, GBCLKSYNC can be used to override the core-specific TBCLKSYNC. When GBCLKSYNC is set, TBCLKSYNC is ignored in all cores and therefore clearing or setting the TBCLKSYNC has no affect. If this feature is not required, GBCLKSYNC should be cleared. In a multi-core environment where different ePWM modules are assigned to different cores, the GBCLKSYNC bit can be used to enable and disable the Time-Base clock of all ePWM modules simultaneously.

### 26.4.3.3 Time-Base Counter Synchronization

The ePWM type 4 introduces a new synchronization scheme that allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCI), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 26-7, EXTSYNC1 is sourced from INPUTXBAR5 and EXTSYNC2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. Refer to for a list of all sync inputs including INPUTXBAR5 and INPUTXBAR6. Figure 26-8 shows the sources that can be used for EXTSYNCOOUT.

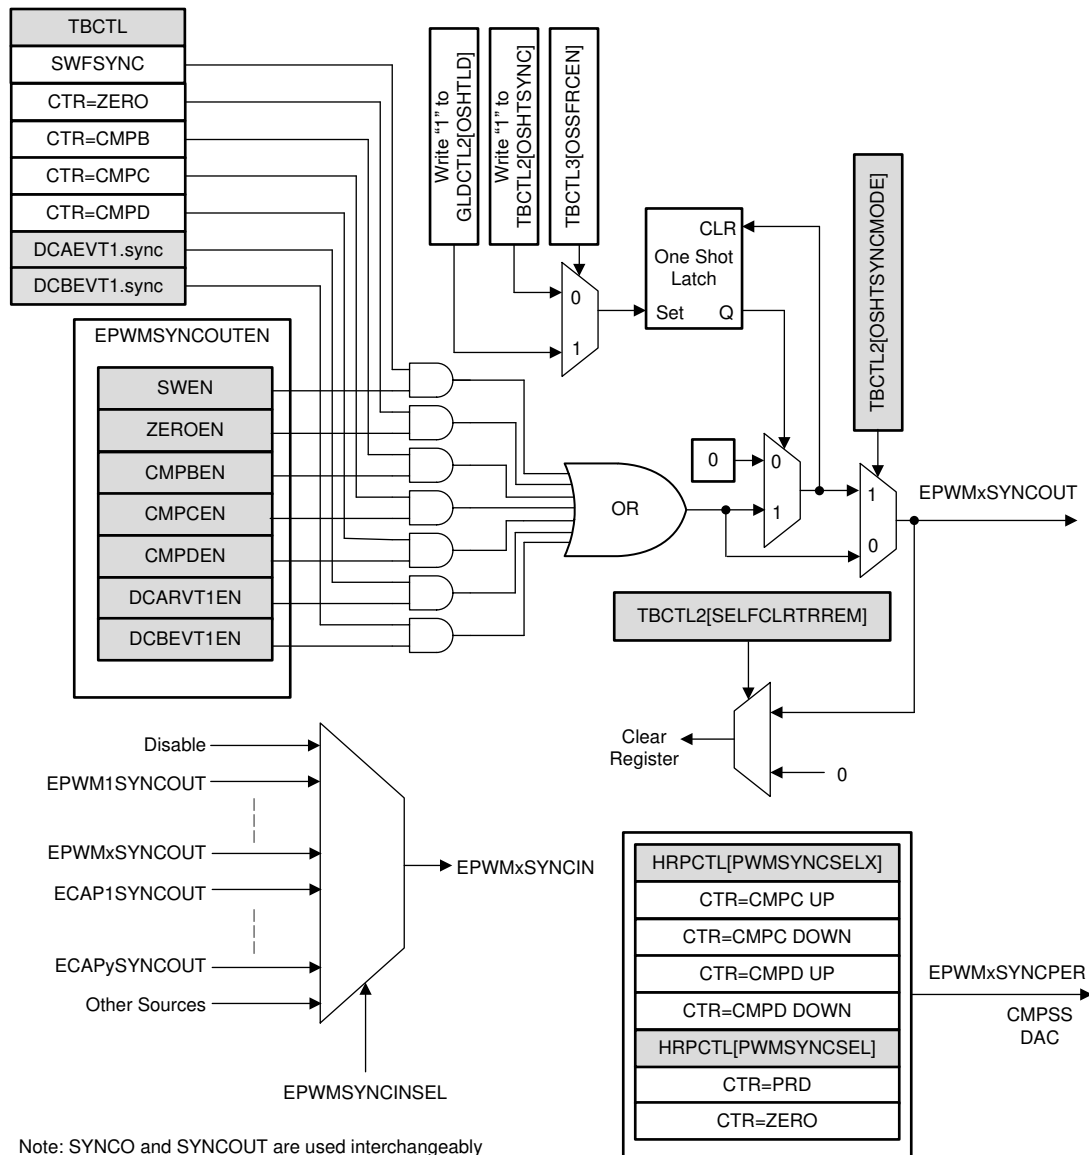

Figure 26-7. Time-Base Counter Synchronization Scheme

**Figure 26-8. ePWM External SYNC Output**
**Note**

See the data manual for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:**

The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

- **Software Forced Synchronization Pulse:**

Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

- **Digital Compare Event Synchronization Pulse:**

DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

**Note**

If the EPWMxSYNCl signal is held HIGH, the sync will NOT continuously occur. The EPWMxSYNCl is rising edge activated.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PSHDIR bit is ignored in count-up or count-down modes. See [Figure 26-9](#) through [Figure 26-12](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse.

#### 26.4.3.4 ePWM SYNC Selection

[Table 26-3](#) specifies the sources for the ePWM SYNC input and output.

**Table 26-3. ePWM SYNC Selection**

EPWMSYNCINSEL.SEL, ECAPSYNCINSEL.SEL	SYNC Source
0x0	Reserved
0x1	EPWM1.SYNCOUT
0x2	EPWM2.SYNCOUT
0x3	EPWM3.SYNCOUT
0x4	EPWM4.SYNCOUT
0x5	EPWM5.SYNCOUT

#### 26.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC= 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

#### 26.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

For a particular ePWM module # A , user code writes “B+1”, to the linked register bit-field in EPWMXLINK. “B” is the ePWM module # being linked to (that is, writes to the ePWM module “B” TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, or CMPC will simultaneously be written to corresponding register in ePWM module “A”). For instance if ePWM3 EPWMXLINK register is configured so that CMPA:CMPAHR are linked to ePWM1, then a write to CMPA:CMPAHR in ePWM 1 will simultaneously write the same value to CMPA:CMPAHR in ePWM3. If ePWM4 also has its CMPA:CMPAHR registers linked to ePWM1, then a write to ePWM 1 will write the same value to the CMPA:CMPAHR registers in both ePWM3 and ePWM4.

The register description for EPWMXLINK clearly explains the linked register bit-field values for corresponding ePWM. An example of using the EPWMXLINK is linking ePWM2 CMPA with CMPA of ePWM1. In this case, a write to CMPA of ePWM1 will also change the CMPA value for ePWM2.

### 26.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

Figure 26-9. Time-Base Up-Count Mode Waveforms

Figure 26-10. Time-Base Down-Count Mode Waveforms

Figure 26-11. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

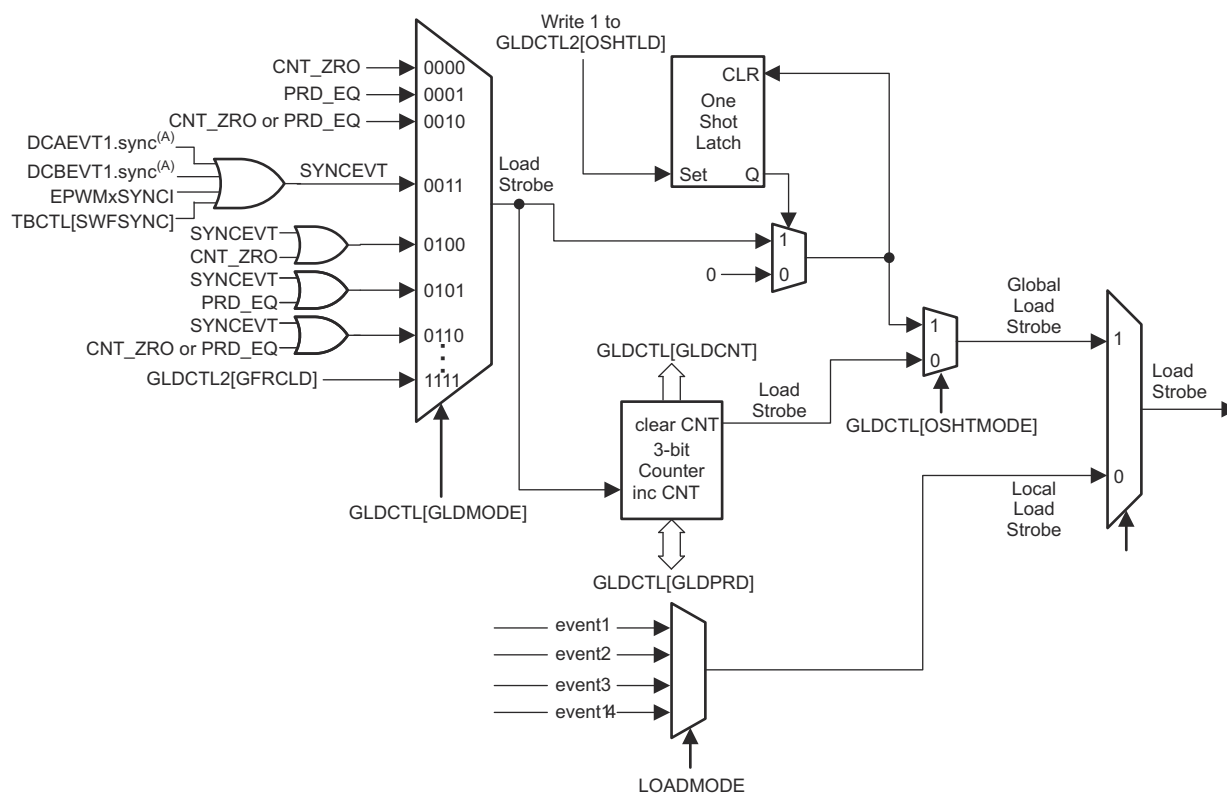

Figure 26-12. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

## 26.4.7 Global Load

Figure 26-13 illustrates the signals and registers associated with the global load feature.

**Figure 26-13. Global Load: Signals and Registers**

### Note

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = '1', shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = '1' and GLDCFG[REGx] = '0' global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

### 26.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = '0' or GLDCFG[REGx] = '0').

### 26.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When `GLDCTL2[OSHTLD] = '1'` the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by `GLDCTL[GLDMODE]`.

Software force loading of contents from shadow register to active register is possible by using `GLDCTL2[GFRCLD]`. The `GLDCTL2` register can also be linked across multiple PWM modules by using `EPWMXLINK[GLDCTL2LINK]`. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

#### Note

One-shot load mode should **NOT** be used when high-resolution mode is enabled.

### 26.4.7.3 One-Shot Sync Mode

You can enable the one-shot sync mode to generate a `SYNCOUT` pulse by configuring `TBCLT2[OSHTSYNCMODE]` and setting the `TBCLT2[OSHTSYNC]` bit as shown in [Figure 26-14](#).

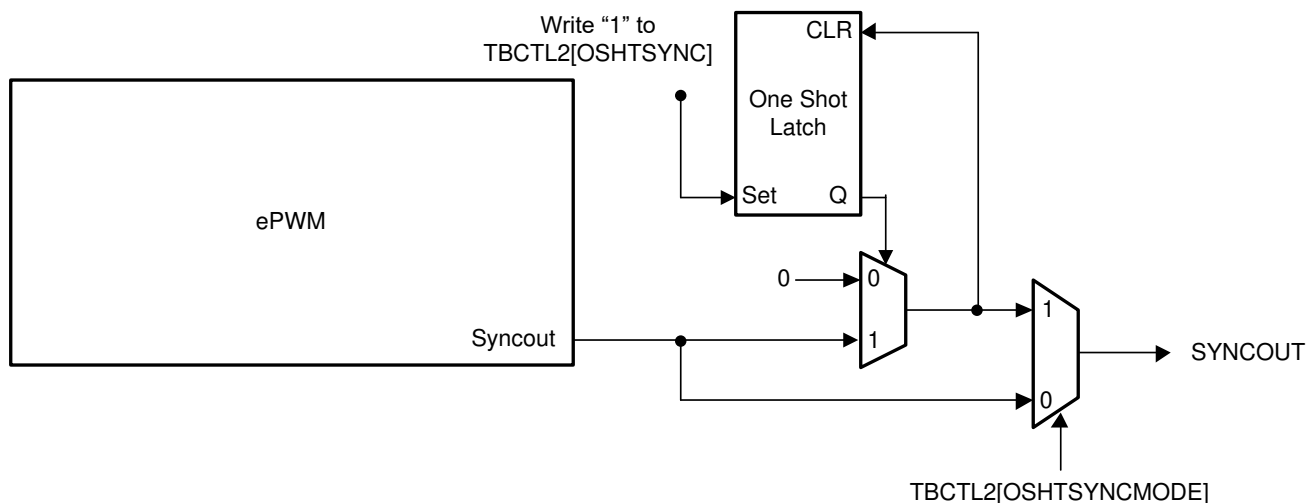

Figure 26-14. One-Shot Sync Mode

## 26.5 Counter-Compare (CC) Submodule

Figure 26-15 illustrates the counter-compare submodule within the ePWM.

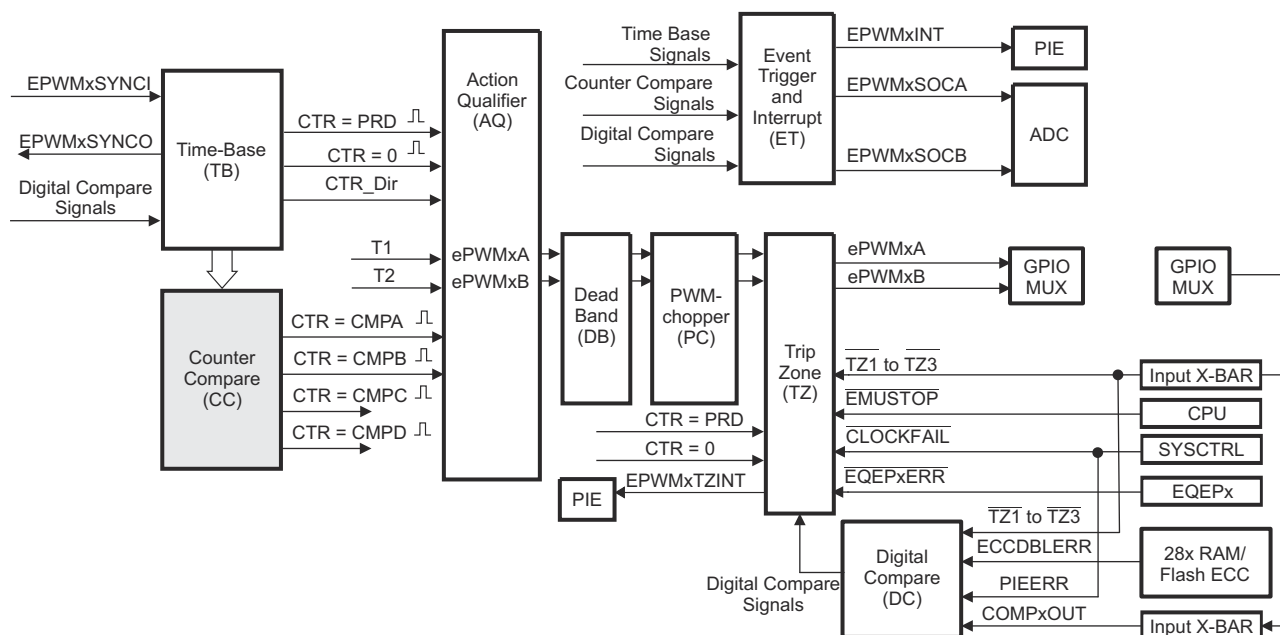

Figure 26-15. Counter-Compare Submodule

### 26.5.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 26.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 26-16.

A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 26-16. Detailed View of the Counter-Compare Submodule**

### 26.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events which can be used in the action-qualifier and/or event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only.

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode each event occurs twice per cycle if the compare value is between 0x00-TBPRD and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 26.6.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

#### Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

#### Immediate Mode:

If immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

## Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

### Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

### Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register will go directly to the active register.

### Global Load Support

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 26.4.7](#).

### 26.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 26-17](#) through [Figure 26-20](#) show when events are generated and how the EPWMxSYNCl signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 26-17. Counter-Compare Event Waveforms in Up-Count Mode**

**Figure 26-18. Counter-Compare Events in Down-Count Mode**

Figure 26-19. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

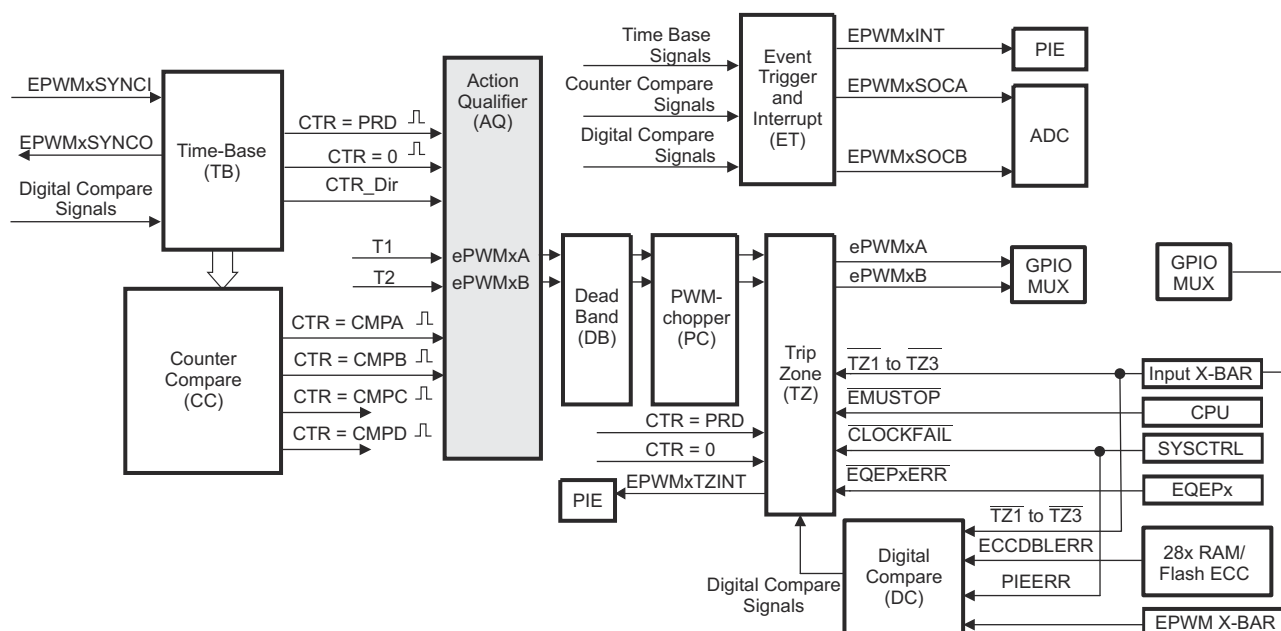

Figure 26-20. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

## 26.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 26-21 shows the action-qualifier (AQ) submodule in the ePWM system.

**Figure 26-21. Action-Qualifier Submodule**

### 26.6.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

### 26.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in Figure 26-22 and monitored by way of the registers in Section 26.17 .

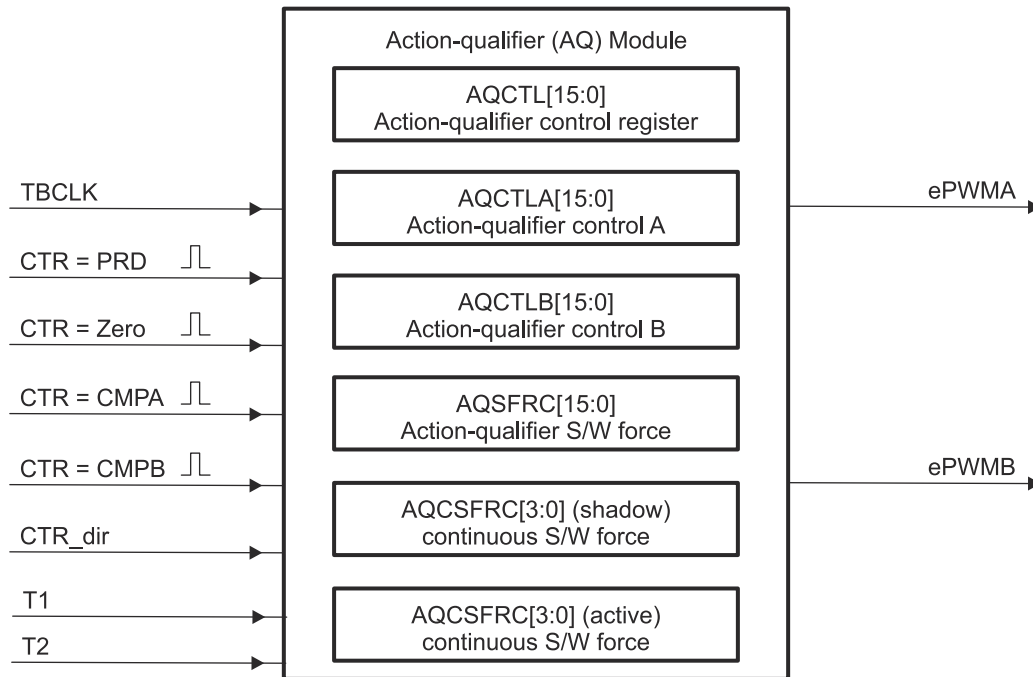

Figure 26-22. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in Table 26-4.

Table 26-4. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to zero	TBCTR = 0x00
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
T1 event	Based on comparator, trip or syncin events	None
T2 event	Based on comparator, trip or syncin events	None
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

**Note**

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**  
Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**  
Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**  
If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:**  
Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in [Section 26.10](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 26-23](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

SW force	TB Counter equals			Trigger Events			Actions
	Zero	Comp A	Comp B	Period	T1	T2	
							Do Nothing
							Clear Lo
							Set Hi
							Toggle

**Figure 26-23. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event may or may not be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

### 26.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 26-5](#). A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

**Table 26-5. Action-Qualifier Event Priority for Up-Down-Count Mode**

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	T1 on up-count (T1U)	T1 on down-count (T1D)
3	T2 on up-count (T2U)	T2 on down-count (T2D)
4	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
5	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
6	Counter equals zero	Counter equals period (TBPRD)
7	T1 on down-count (T1D)	T1 on up-count (T1U)
8	T2 on down-count (T2D)	T2 on up-count (T2U)
9	Counter equals CMPB on down-count (CBD)	Counter equals CMPB on up-count (CBU)
10 (Lowest)	Counter equals CMPA on down-count (CAD)	Counter equals CMPA on up-count (CAU)

[Table 26-6](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and therefore, down-count events will never be taken.

**Table 26-6. Action-Qualifier Event Priority for Up-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	T1 on up-count (T1U)
4	T2 on up-count (T2U)
5	Counter equal to CMPB on up-count (CBU)
6	Counter equal to CMPA on up-count (CAU)
7 (Lowest)	Counter equal to Zero

[Table 26-7](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 26-7. Action-Qualifier Event Priority for Down-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	T1 on down-count (T1D)
4	T2 on down-count (T2D)
5	Counter equal to CMPB on down-count (CBD)
6	Counter equal to CMPA on down-count (CAD)
7 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 26-8](#).

**Table 26-8. Behavior if CMPA/CMPB is Greater than the Period**

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match (TBCTR=CMPA or CMPB). If $CMPA/CMPB > TBPRD$ , then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If $CMPA/CMPB < TBPRD$ , the event will occur on a compare match (TBCTR=CMPA or CMPB). If $CMPA/CMPB \geq TBPRD$ , the event will occur on a period match (TBCTR=TBPRD).
Up-Down-Count Mode	If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If $CMPA/CMPB \geq TBPRD$ , the event will occur on a period match (TBCTR = TBPRD).	If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If $CMPA/CMPB \geq TBPRD$ , the event occurs on a period match (TBCTR=TBPRD).

#### 26.6.4 AQCTLA and AQCTLB Shadow Mode Operations

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is:

##### Shadow Mode

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE], AQCTL[LDAQBMODE], AQCTL[LDAQASYNC], and AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

##### Global Load Support

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2, and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 26.4.7](#).

##### Immediate Load Mode

If immediate load mode is selected (that is, AQCTL[SHDWAQAMODE] = 0 or AQCTL[SHDWAQBMODE] = 0), then a read from or a write to the register will go directly to the active register. See [Figure 26-24](#) and [Figure 26-25](#).

**Note**

Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA and AQCTLB] on CMPA = 0 or CMPB = 0 boundary

If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA=0 and AQCTLA shadow to active load on TBCTR=0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention and it is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 26-24. AQCTL[SHDWAQAMODE]**

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 26-25. AQCTL[SHDWAQBMODE]**

## 26.6.5 Waveforms for Common Configurations

### Note

The waveforms in this document show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

#### Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

#### Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

#### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

#### When using up-count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met ( $CMPX < Deadband$ ) or ( $CMPX > PRD - Deadband$ ) the actions specified by the AQCTL register for CMPX will not take effect. To avoid this, the AQCTL settings will have to be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Ensure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

#### When using up-down-count mode to generate an asymmetric PWM with deadband enabled:

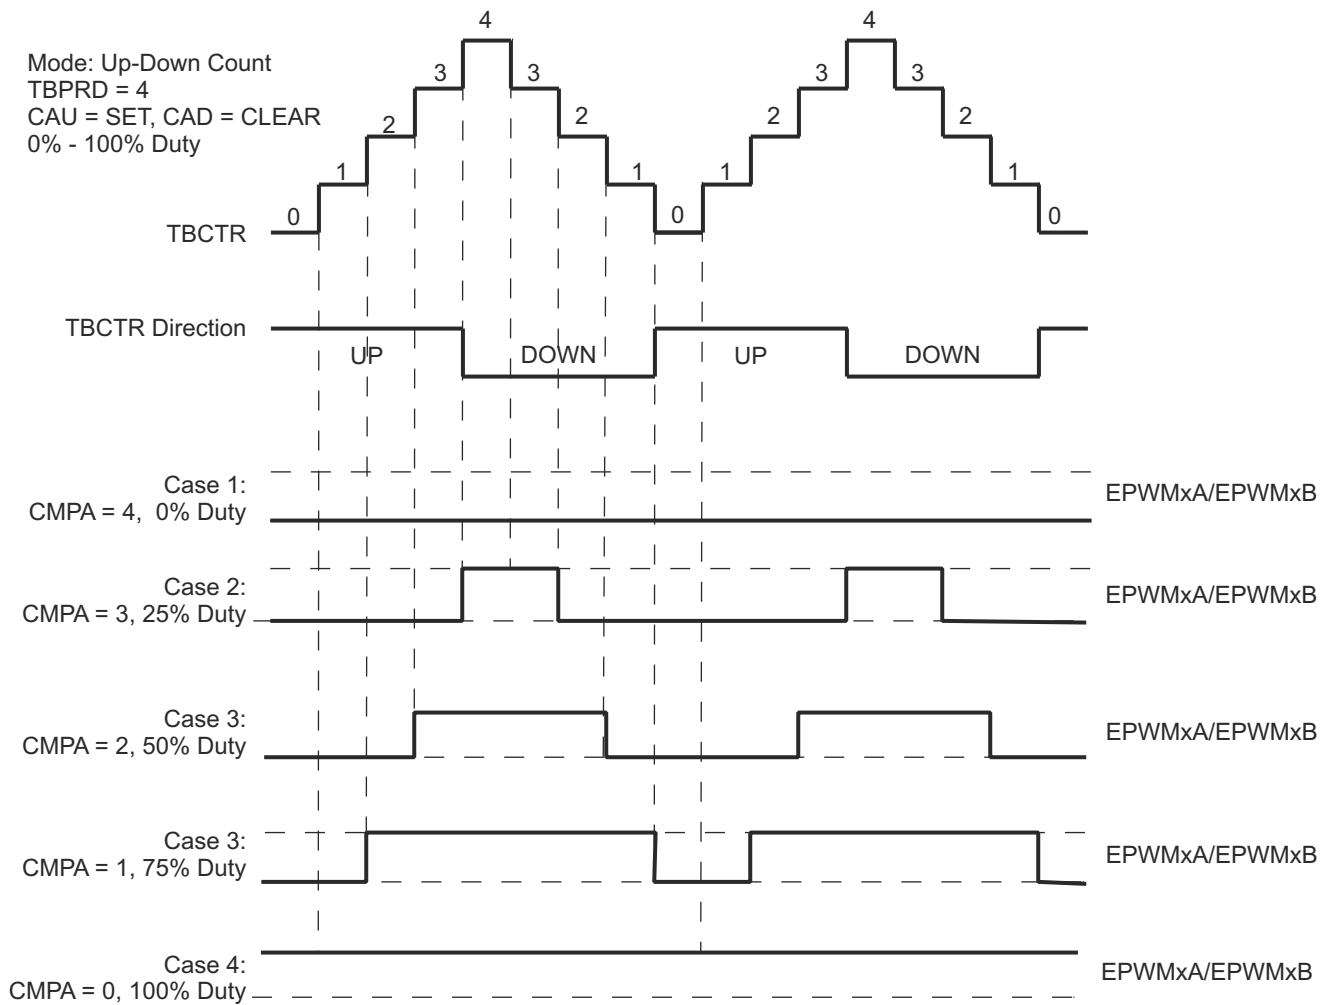

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met ( $CMPX < Deadband/2$ ) or ( $CMPX > PRD - (Deadband)/2$ ) the actions specified by the AQCTL register for CMPX will not take effect. To avoid this, the AQCTL settings will have to be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Ensure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

See the [Using Enhanced Pulse Width Modulator \(ePWM\) Module for 0-100% Duty Cycle Control Application Report](#).

Figure 26-26 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode, 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When  $CMPA = 0$ , the PWM signal is high for the entire period giving a 100% duty waveform. When  $CMPA = TBPRD$ , the PWM signal is low achieving 0% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal

to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 26-26. Up-Down-Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 26-27](#) through [Figure 26-32](#) show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

- PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 26-27. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High**

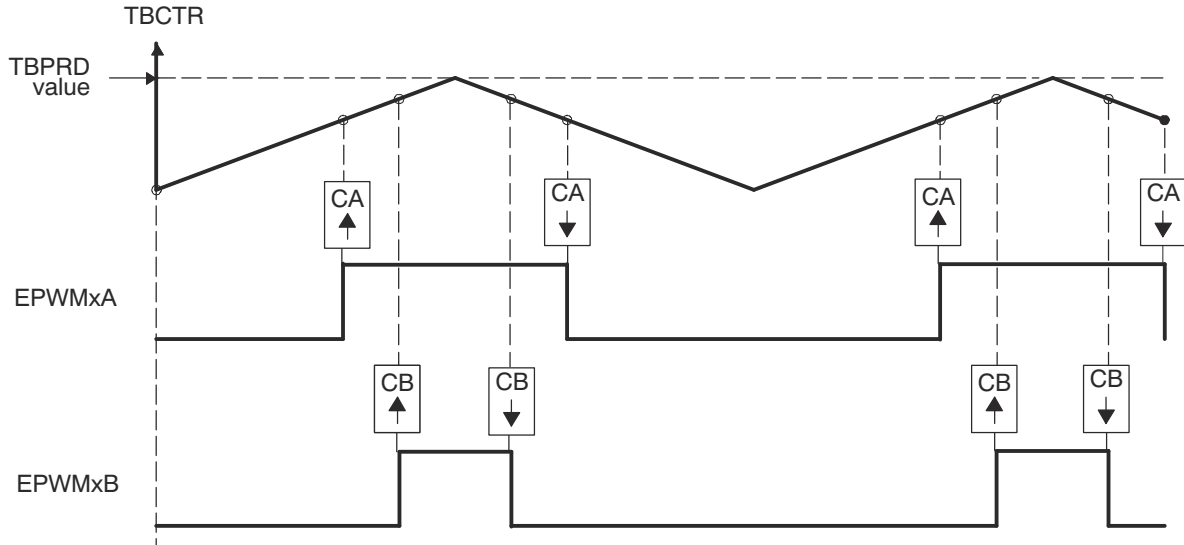

- A.  $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 26-28. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low**

- A.  $\text{PWM frequency} = 1 / ((\text{TBPRD} + 1) \times T_{\text{TBCLK}})$
- B. Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
- C. High time duty proportional to (CMPB - CMPA)

**Figure 26-29. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA**

- A.  $PWM\ period = 2 \times TBPRD \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. Outputs EPWMxA and EPWMxB can drive independent power switches.

**Figure 26-30. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low**

- A.  $PWM\ period = 2 \times TBPRD \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.
- C. Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.
- D. Outputs EPWMx can drive upper/lower (complementary) power switches.
- E. Dead-band =  $CMPB - CMPA$  (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

**Figure 26-31. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary**

- A. PWM period =  $2 \times \text{TBPRD} \times \text{TBCLK}$
- B. Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- C. Duty modulation for EPWMxA is set by CMPA and CMPB.
- D. Low time duty for EPWMxA is proportional to  $(\text{CMPA} + \text{CMPB})$ .
- E. To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).
- F. Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

**Figure 26-32. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low**

- A.  $\text{PWM period} = 2 \times \text{TBPRD} \times \text{TTBCLK}$
- B. Independent T1 event actions when counter is counting up and when it is counting down are used to generate EPWMxA output.
- C. Independent T2 event actions when counter is counting up and when it is counting down are used to generate EPWMxB output.
- D. TZ1 is selected as the source for T1.
- E. TZ2 is selected as the source for T2.

**Figure 26-33. Up-Down-Count, PWM Waveform Generation Utilizing T1 and T2 Events**

## 26.7 Dead-Band Generator (DB) Submodule

Figure 26-34 illustrates the dead-band submodule within the ePWM module.

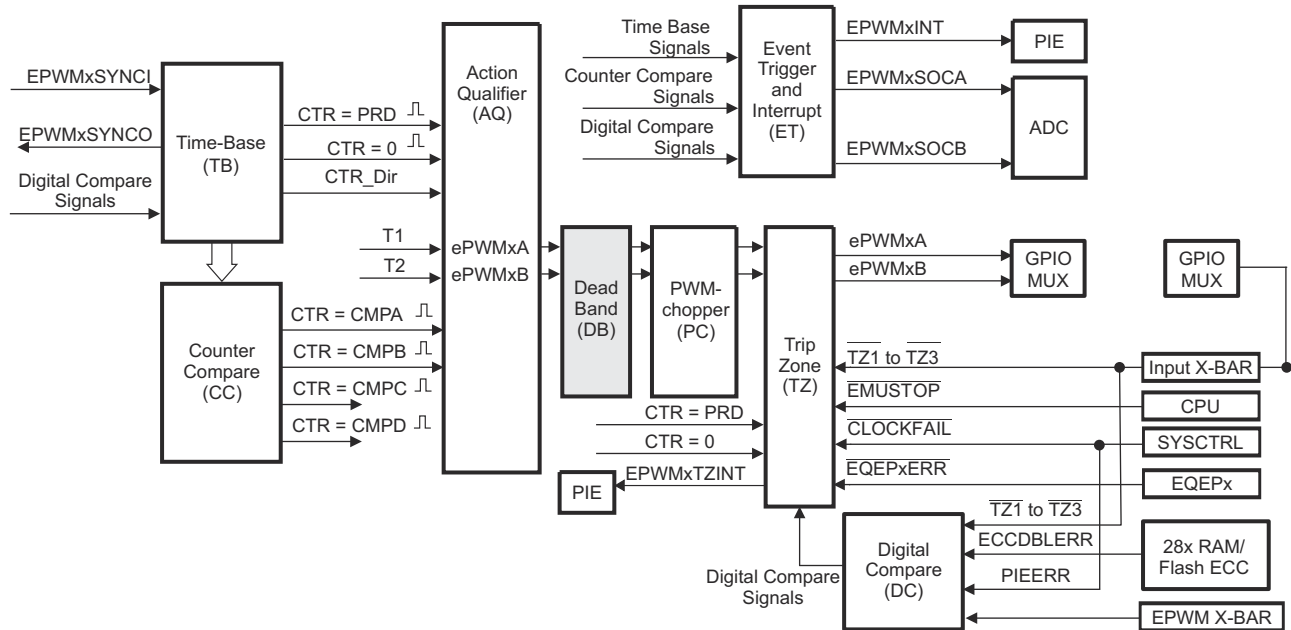

Figure 26-34. Dead\_Band Submodule

### 26.7.1 Purpose of the Dead-Band Submodule

The action-qualifier (AQ) module section discussed how it is possible to generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

### 26.7.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED could appear on one channel output and FED could appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in [Figure 26-35](#), RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

---

#### Note

Phase shifting B-channel with respect to the A-channel using the dead-band submodule additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

---

- The dead-band counters have also been increased to 14 bits
- Dead-band and dead-band High-resolution registers are now shadowed
- High-resolution dead-band RED and FED have been enabled using the DBREDHR and DBFEDHR registers

---

#### Note

The PWM chopper will not be enabled when high-resolution dead band is enabled.

High-resolution dead-band RED and FED requires Half-Cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB\_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. It is recommended to make sure the duty cycle value of the current waveform fed to the dead-band module is greater than the required phase shift amount.

The Type 4 action qualifier and dead-band outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

---

## Shadow Mode

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDDMODE] and DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

## Global Load Support

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR, and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in [Section 26.4.7](#).

---

### Note

When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED/DBFED value only affects the NEXT PWMx edge and not the current edge.

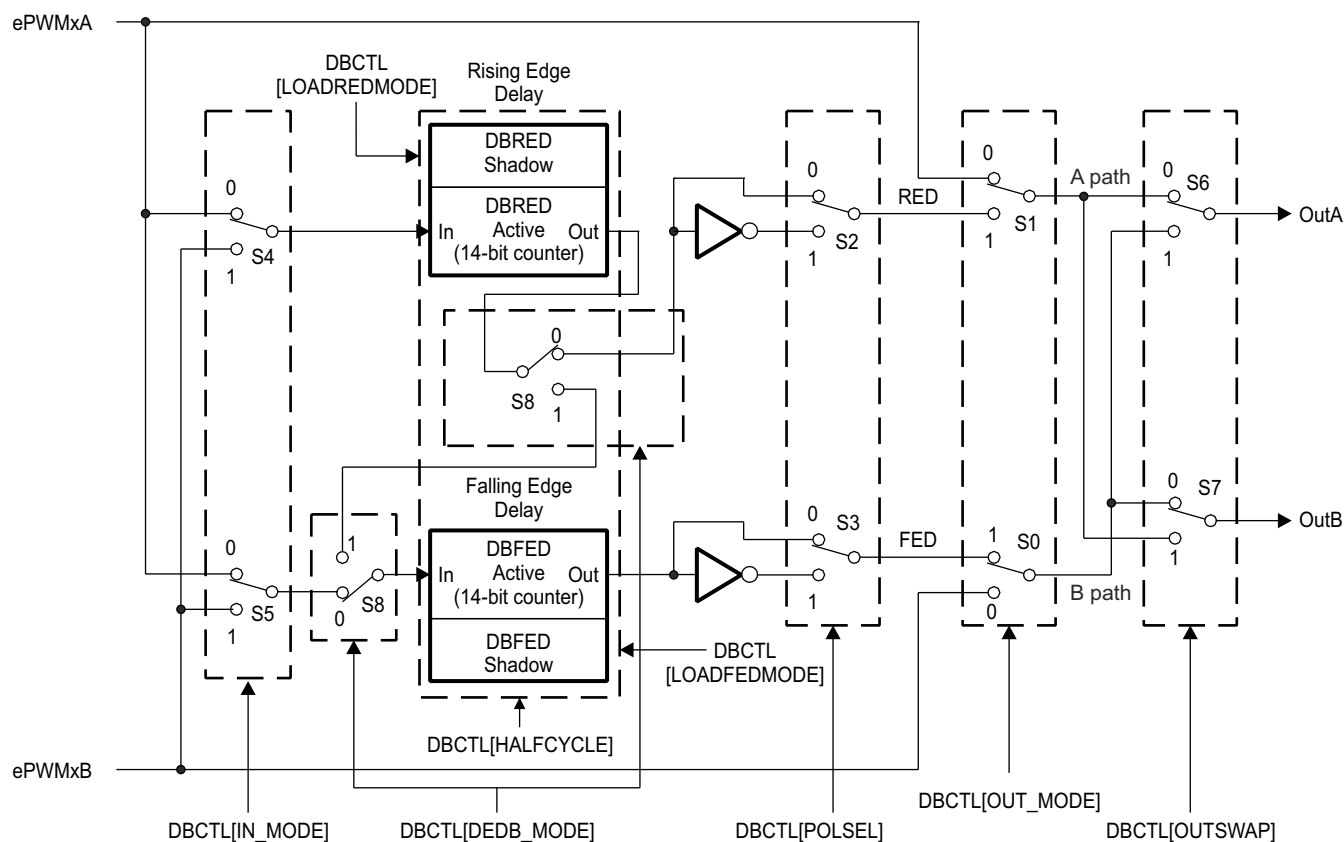

A Dead-band value of zero should not be used when the Global Shadow to Active Load is set to occur at CTR=ZERO. Similarly, a Dead-band value of PRD should not be used when the Global Shadow to Active Load is set to occur at CTR=PRD.

TBPRDHR should not be used with Global load. If high resolution period must be changed in the application, users must write to the individual period registers from an ePWM ISR (The ISR must be synchronous with the PWM switching period), where the Global Load One-Shot bit is also written to.

---

### 26.7.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in [Figure 26-35](#).

**Figure 26-35. Configuration Options for the Dead-Band Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 26-9](#) documents some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 26-9](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**

Allows you to fully disable the dead-band submodule from the PWM signal path.

- **Mode 2-5: Classical Dead-Band Polarity Settings:**

These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 26-36](#). Note that to generate equivalent waveforms to [Figure 26-36](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.

- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**

Finally the last two entries in [Table 26-9](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

[Figure 26-36](#) shows waveforms for typical cases where  $0\% < \text{duty} < 100\%$ .

**Table 26-9. Classical Dead-Band Operating Modes**

Mode	Mode Description	DBCTL[POLSEL]		DBCTL[OUT_MODE]	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay)	0 or 1	0 or 1	0	1
	EPWMxB Out = EPWMxA In with Falling Edge Delay				
7	EPWMxA Out = EPWMxA In with Rising Edge Delay	0 or 1	0 or 1	1	0
	EPWMxB Out = EPWMxB In with No Delay				

**Table 26-10. Additional Dead-Band Operating Modes**

Mode Description	DBCTL[DEDB-MODE]	DBCTL[OUTSWAP]	
	S8	S6	S7
EPWMxA and EPWMxB signals are as defined by OUT-MODE bits.	0	0	0
EPWMxA = A-path as defined by OUT-MODE bits.	0	0	1
EPWMxB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A-signal path)			
EPWMxA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B-signal path)	0	1	0
EPWMxB = B-path as defined by OUT-MODE bits			
EPWMxA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B-signal path)	0	1	1
EPWMxB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A-signal path)			
Rising edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only.	0	X	X
Falling edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only.			
Rising edge delay and falling edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only. <sup>(1)</sup>	1	X	X

- (1) When this bit is set to 1, user should always either set OUT\_MODE bits such that Apath = InA **or** OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA will be invalid.

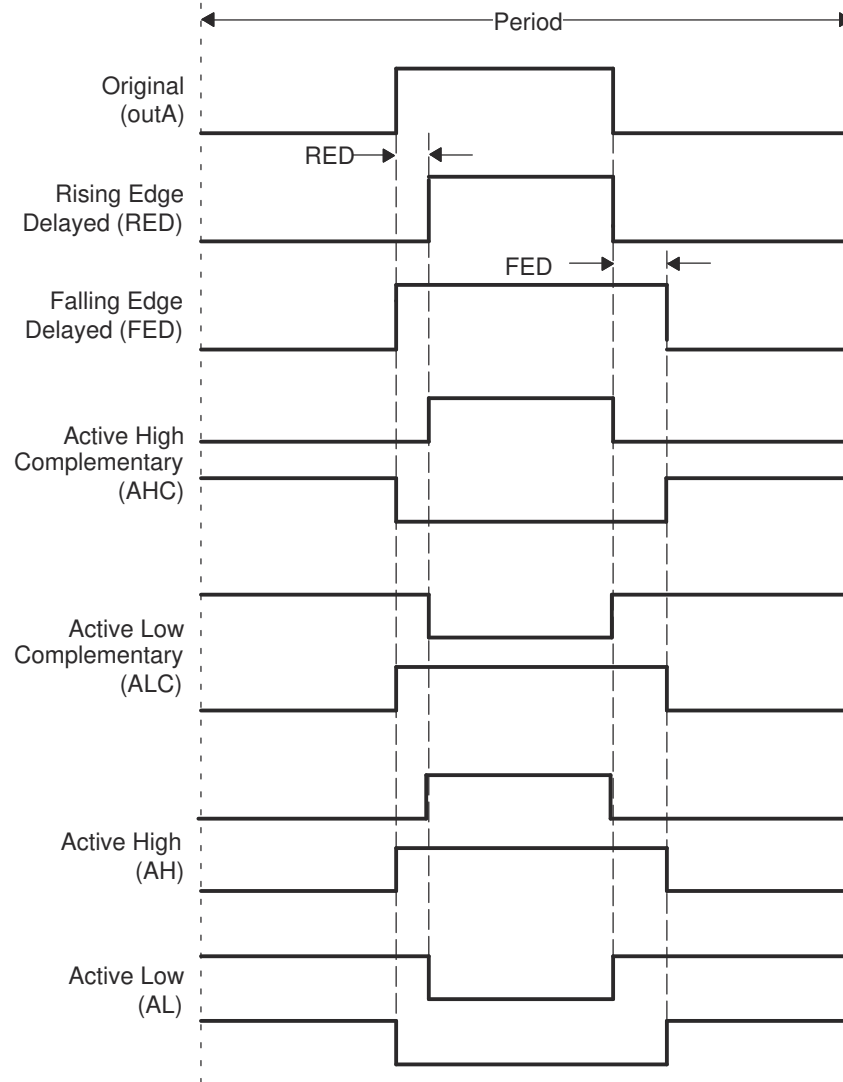

Figure 26-36. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}$$

Where  $T_{\text{TBCLK}}$  is the period of TBCLK, the prescaled version of EPWMCLK.

For convenience, delay values for various TBCLK options are shown in [Table 26-11](#). The ePWM input clock frequency that these delay values been computed by is 100 MHz.

**Table 26-11. Dead-Band Delay Values in  $\mu\text{S}$  as a Function of DBFED and DBRED**

Dead-Band Value	Dead-Band Delay in $\mu\text{S}$			
	DBFED, DBRED	TBCLK = EPWMCLK/1	TBCLK = EPWMCLK /2	TBCLK = EPWMCLK/4
1		0.01 $\mu\text{S}$	0.02 $\mu\text{S}$	0.04 $\mu\text{S}$
5		0.05 $\mu\text{S}$	0.10 $\mu\text{S}$	0.20 $\mu\text{S}$
10		0.10 $\mu\text{S}$	0.20 $\mu\text{S}$	0.40 $\mu\text{S}$
100		1.00 $\mu\text{S}$	2.00 $\mu\text{S}$	4.00 $\mu\text{S}$
200		2.00 $\mu\text{S}$	4.00 $\mu\text{S}$	8.00 $\mu\text{S}$
400		4.00 $\mu\text{S}$	8.00 $\mu\text{S}$	16.00 $\mu\text{S}$
500		5.00 $\mu\text{S}$	10.00 $\mu\text{S}$	20.00 $\mu\text{S}$
600		6.00 $\mu\text{S}$	12.00 $\mu\text{S}$	24.00 $\mu\text{S}$
700		7.00 $\mu\text{S}$	14.00 $\mu\text{S}$	28.00 $\mu\text{S}$
800		8.00 $\mu\text{S}$	16.00 $\mu\text{S}$	32.00 $\mu\text{S}$
900		9.00 $\mu\text{S}$	18.00 $\mu\text{S}$	36.00 $\mu\text{S}$
1000		10.00 $\mu\text{S}$	20.00 $\mu\text{S}$	40.00 $\mu\text{S}$

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

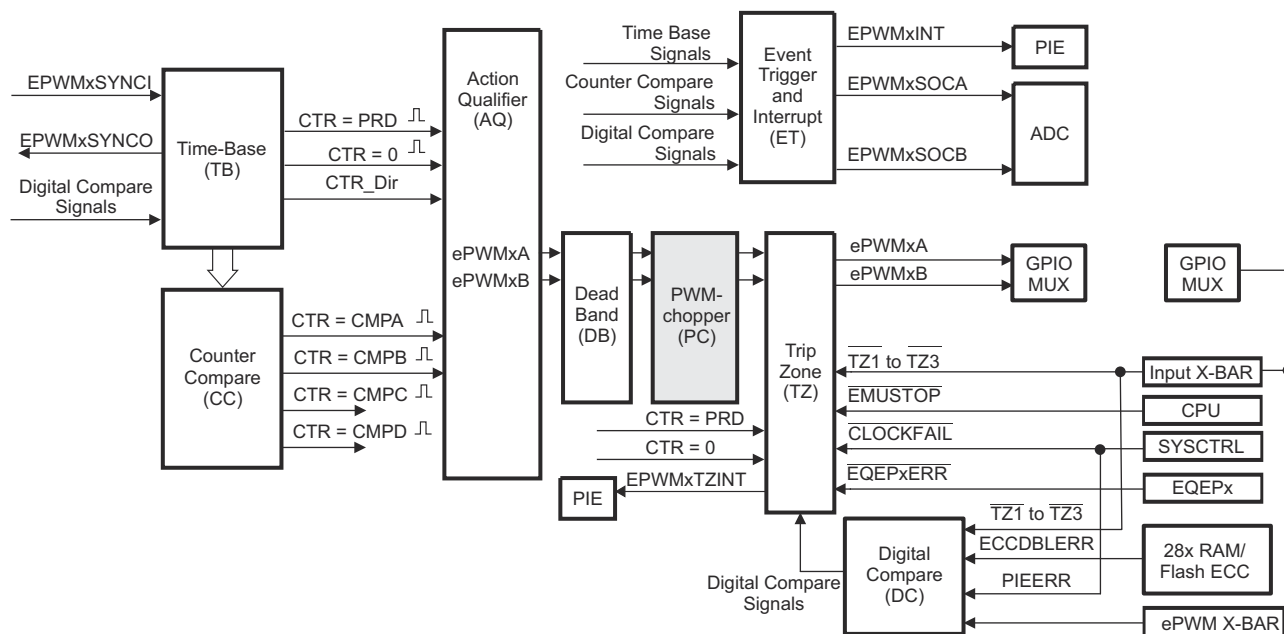

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}/2$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}/2$$

## 26.8 PWM Chopper (PC) Submodule

Figure 26-37 illustrates the PWM chopper (PC) submodule within the ePWM module.

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

**Figure 26-37. PWM Chopper Submodule**

### 26.8.1 Purpose of the PWM Chopper Submodule

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

### 26.8.2 Operational Highlights for the PWM Chopper Submodule

Figure 26-38 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 26-38. PWM Chopper Submodule Operational Details

### 26.8.3 Waveforms

Figure 26-39 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 26-39. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only

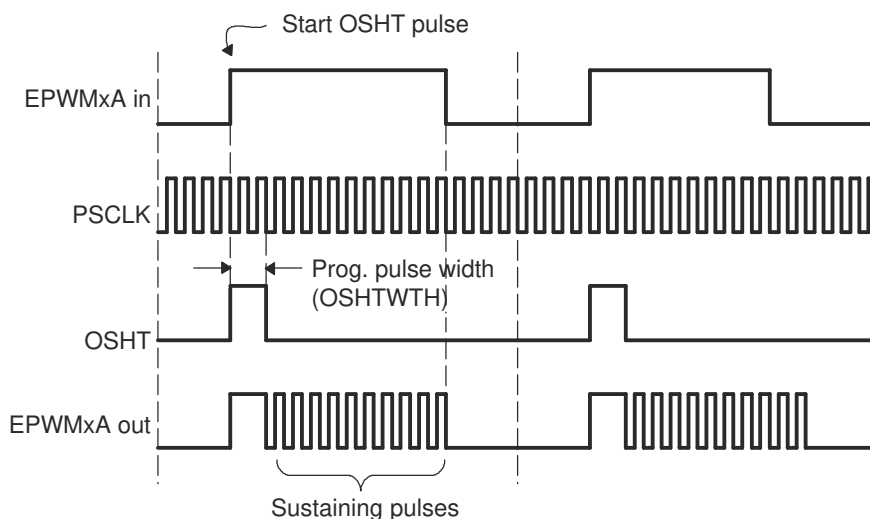

### 26.8.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1\text{stpulse}} = T_{\text{EPWMCLK}} \times 8 \times \text{OSHTWTH}$$

Where  $T_{\text{EPWMCLK}}$  is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 26-40 shows the first and subsequent sustaining pulses and Table 26-12 gives the possible pulse width values for a EPWMCLK = 80 MHz.

**Figure 26-40. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

**Table 26-12. Possible Pulse Width Values for EPWMCLK = 80 MHz**

OSHTWTHz (hex)	Pulse Width (nS)
0	100
1	200
2	300
3	400
4	500
5	600
6	700
7	800
8	900
9	1000
A	1100
B	1200
C	1300
D	1400
E	1500
F	1600

### 26.8.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 26-41 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

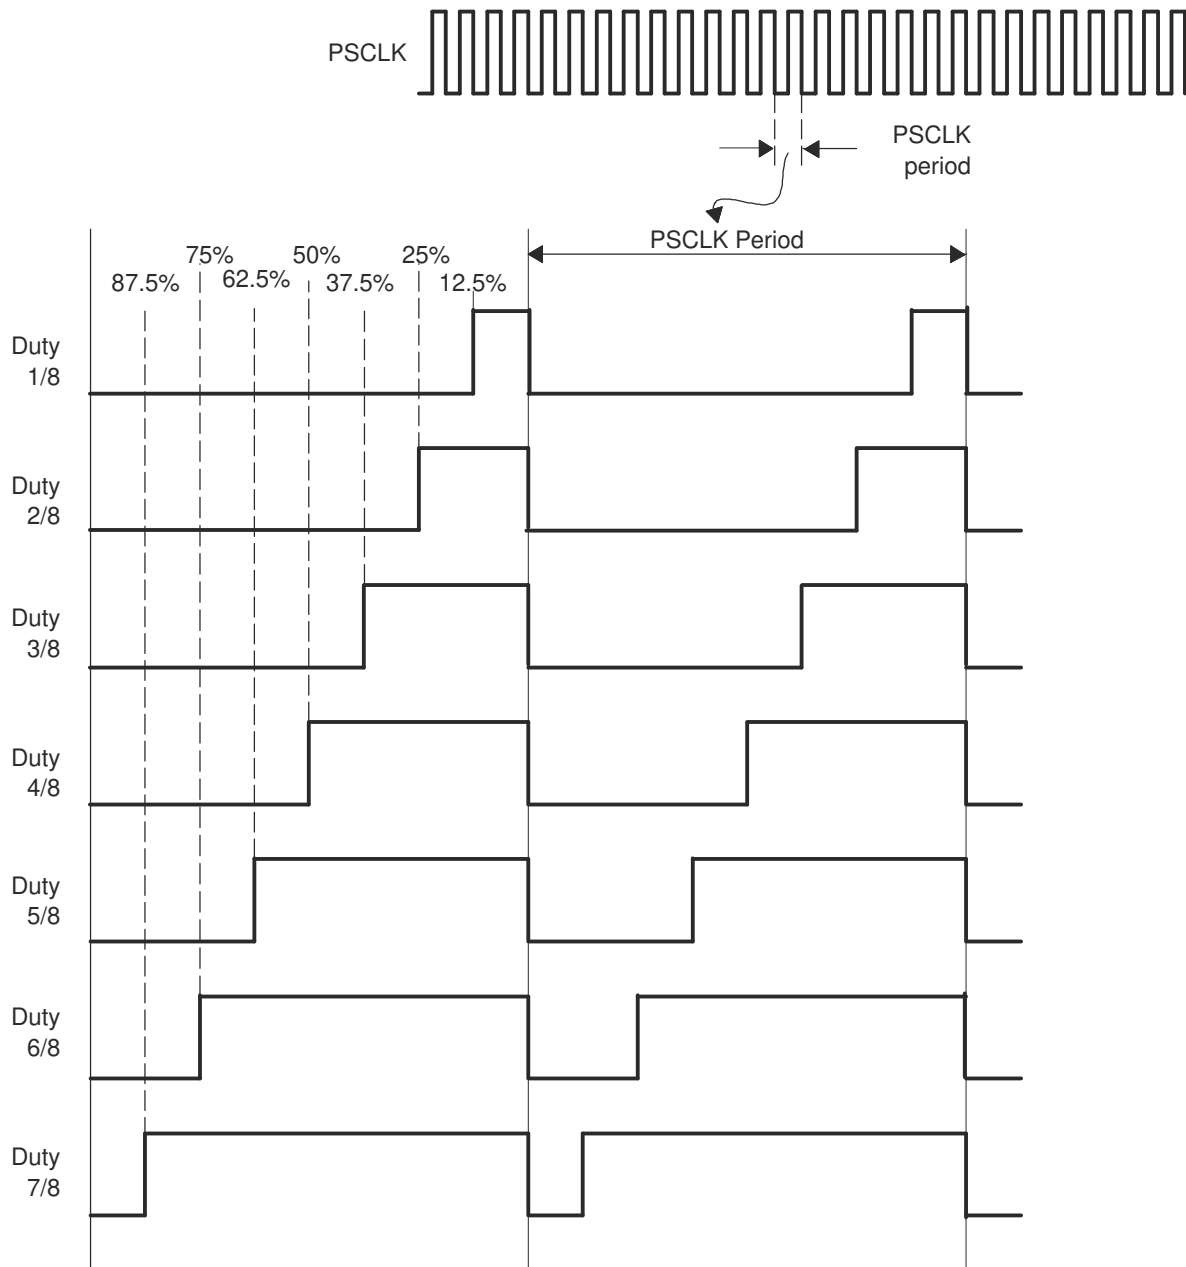

Figure 26-41. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

## 26.9 Trip-Zone (TZ) Submodule

Figure 26-42 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six  $\overline{TZn}$  signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).  $\overline{TZ1}$  to  $\overline{TZ3}$  are sourced from the GPIO mux.  $\overline{TZ4}$  is sourced from an inverted EQEPxERR signal on those devices with an EQEP module.  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

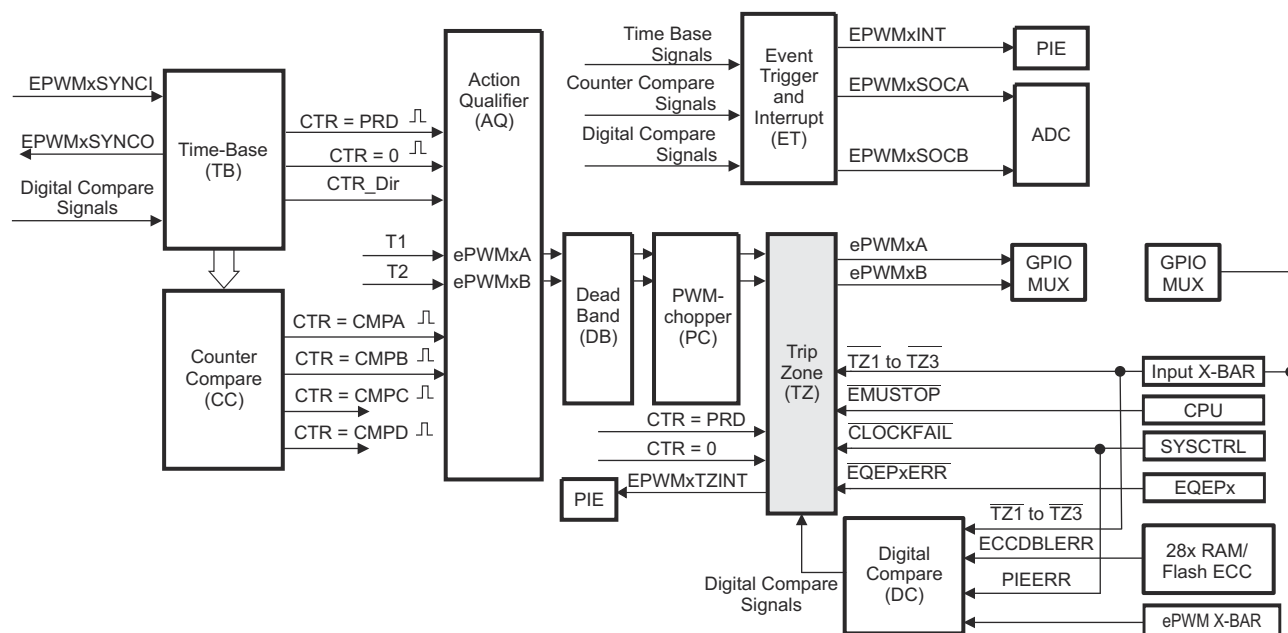

Figure 26-42. Trip-Zone Submodule

### 26.9.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZ6}$  can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or  $\overline{TZ1}$  to  $\overline{TZ3}$  signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

## 26.9.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals  $\overline{TZ1}$  to  $\overline{TZ6}$  (also collectively referred to as  $\overline{TZn}$ ) are active-low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of  $3 \cdot TBCLK$  low pulse width on  $\overline{TZn}$  inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on  $\overline{TZn}$  inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the *System Control and Interrupts* chapter.

Each  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input), respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB outputs. [Table 26-13](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] and TZCBCFLG flag bits will remain set until they are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and/or TZCBCFLG register bits are cleared, then these bits will again be immediately set.

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 26-13](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, TZOSTFLG register bit should be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

#### Note

Clear the TZFLG and TZOSTFLG flags after ensuring that the TRIPIN source of the OST has become inactive. Otherwise, if interrupts are enabled, depending on when the flags are cleared, an OST interrupt could occur and the OST flags are zero.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRISEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see [Section 26.11](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 26-13](#) lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCB register. Actions specified in TZCTLDCA and TZCTLDCB registers take effect only when ETZE bit in TZCTL2 is set.

In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCB register bit fields. Some of the possible actions, shown in [Table 26-13](#), can be taken on a trip event.

**Table 26-13. Possible Actions On a Trip Event**

TZCTL Register Bitfield Settings	EPWMxA and/or EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

### Example 26-1. Trip-Zone Configurations

#### Scenario A:

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

#### Scenario B:

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

---

#### Note

When configuring the GPIOs and INPUT X-BAR/EPWM X-BAR options, be aware that a change in the X-BAR input selections may cause an unwanted event. Therefore, ideally, the user will set up the GPIO and X-BAR input configurations before enabling the ePWM Trip-Zone. If it is a requirement to change the GPIO/X-BAR configurations while the ePWM Trip-Zone is enabled, the user can turn off the TRIPs by clearing the TZSEL register and re-configuring the TRIP selection (TZSEL) after the INPUT XBAR selection is changed.

---

### 26.9.3 Generating Trip Event Interrupts

Figure 26-43 and Figure 26-44 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 26.11.

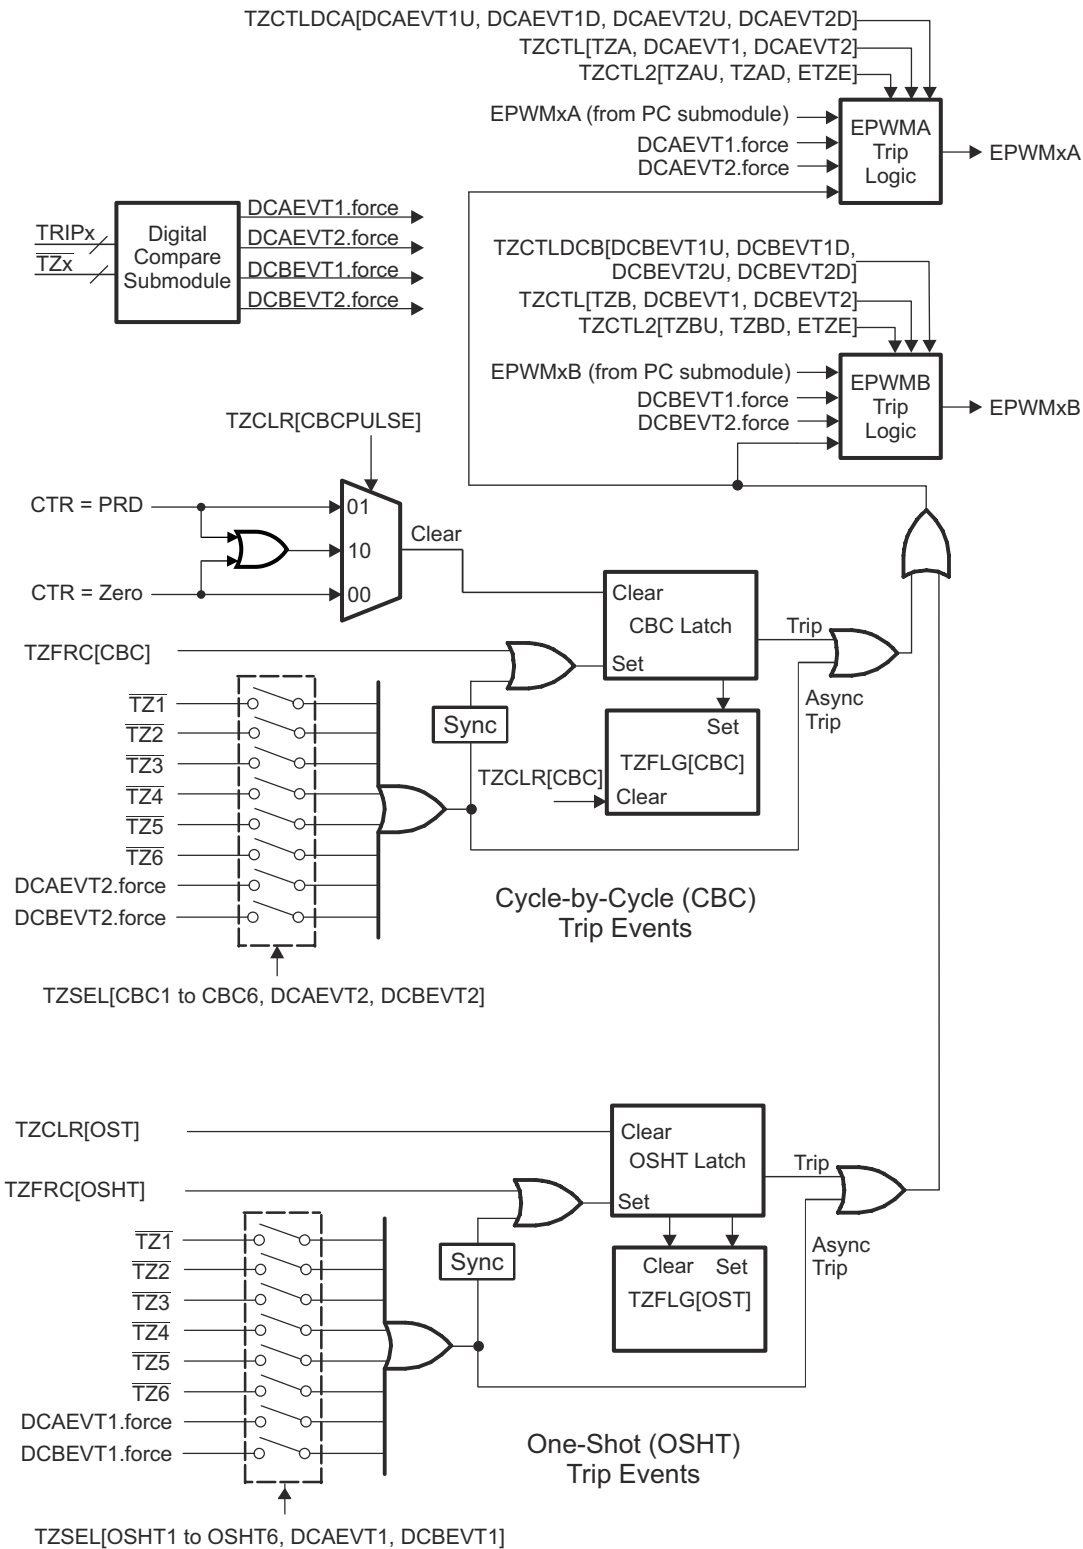

Figure 26-43. Trip-Zone Submodule Mode Control Logic

Figure 26-44. Trip-Zone Submodule Interrupt Logic

These individual flags for the CBC, OST and DCxEV<sub>Ty</sub> can be used to detect the source of the EPWMxTZINT Interrupt. When multiple sources are used to generate the EPWMxTZINT interrupt, reading and clearing the flags will user to take different actions based on the specific event.

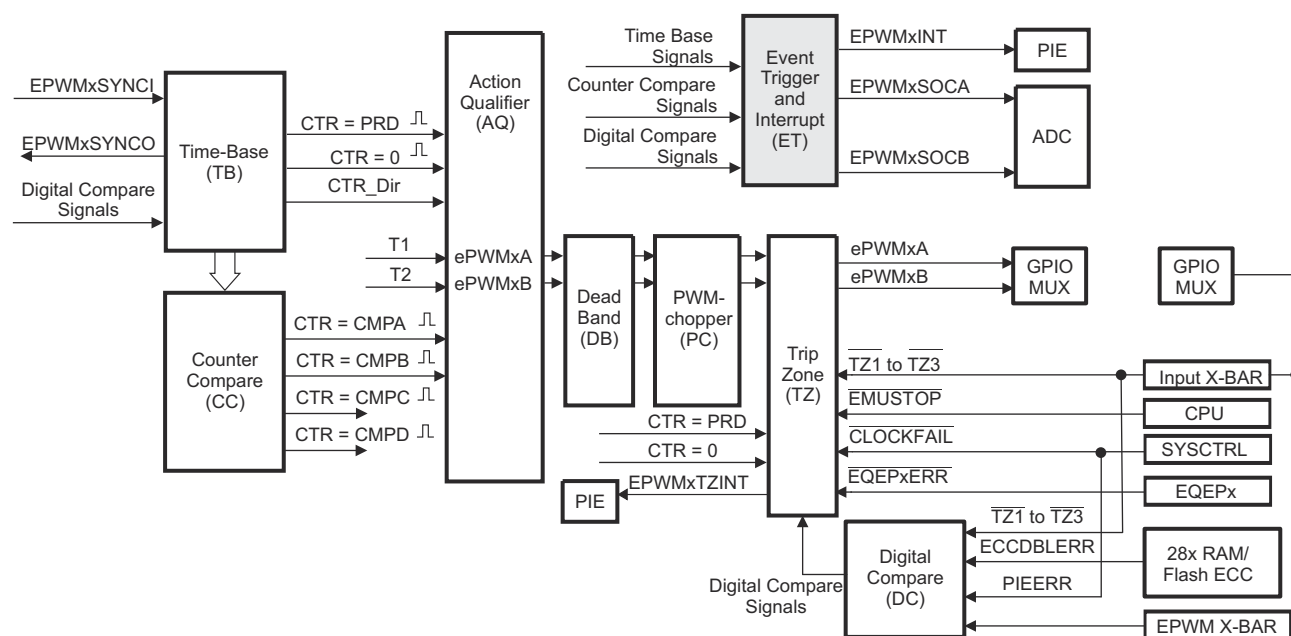

## 26.10 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs.

Figure 26-45 illustrates where the event-trigger submodule fits within the ePWM system.

**Figure 26-45. Event-Trigger Submodule**

### 26.10.1 Operational Overview of the ePWM Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of Figure 26-46) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to every fifteenth event

**Figure 26-46. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- ETSEL - This selects which of the possible events will trigger an interrupt or start an ADC conversion.
- ETPS - This programs the event prescaling options mentioned above.
- ETFLG - These are flag bits indicating status of the selected and prescaled events.
- ETCLR - These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC - These bits allow software forcing of an event. Useful for debugging or software intervention.
- ETINTPS - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- ETSOCPS - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- ETCNINITCTL - These bits enable ETCNINIT initialization via SYNC event OR via software force.
- ETCNINIT - These bits allow you to initialize INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 26-47, Figure 26-48, and Figure 26-49.

Figure 26-47 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event.
- Generate an interrupt on every second event.
- Generate an interrupt on every third event.

On ePWM type 4, in order to enable event generation capability up to 15 events the following changes have been made. The selection made on ETPS[INTPSSEL] bit determines whether ETINTPS register, INTCNT2 and INTPRD2 bit fields determine frequency of events (interrupt once every 0-15 events).

The event that can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) and (ETSEL[INTSELCMP]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x00).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x00 || TBCTR = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is incrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is decrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is incrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter ETPS[INTCNT] or ETINTPS[INTCNT2] register bits based off of the selection made using ETPS[INTPSSEL]. That is, when the specified event occurs the ETPS[INTCNT] or ETINTPS[INTCNT2] bits are incremented until they reach the value specified by ETPS[INTPRD] or ETINTPS[INTPRD2] determined again by the selection made in ETPS[INTPSSEL]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the PIE.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behavior will occur [The below behavior is also applicable to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing '0' to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored. The same applies to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event if using the INTCNT and INTPRD. You can generate an interrupt on every event up to 15 events if using the INTCNT2 and INTPRD2.

The INTCNT2 value can be initialized with the value from ETCNTINIT[INTINIT] based on the selection made in ETCNTINITCTL[INTINITEN]. When ETCNTINITCTL[INTINITEN] is set, then it enables initialization of INTCNT2 counter with contents of ETCNTINIT[INTINIT] on a SYNC event or software force determined by ETCNTINITCTL[INTINITFRC].

## 26.11 Digital Compare (DC) Submodule

Figure 26-50 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 26-51.

On this device, any of the GPIO pins can be flexibly mapped to be the trip-zone input and/or trip inputs to the trip-zone submodule and digital compare submodule. The Input X-BAR Input Select (INPUTxSELECT) register defines which GPIO pins gets assigned to be the trip-zone inputs / trip inputs.

The digital compare (DC) submodule compares signals external to the ePWM module (for instance, CMPSSx signals from the analog comparators) to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

### Note

The user is responsible for driving correct state on the selected pin before enabling clock and configuring the trip input for the respective ePWM peripheral to avoid spurious latch of TRIP signal.

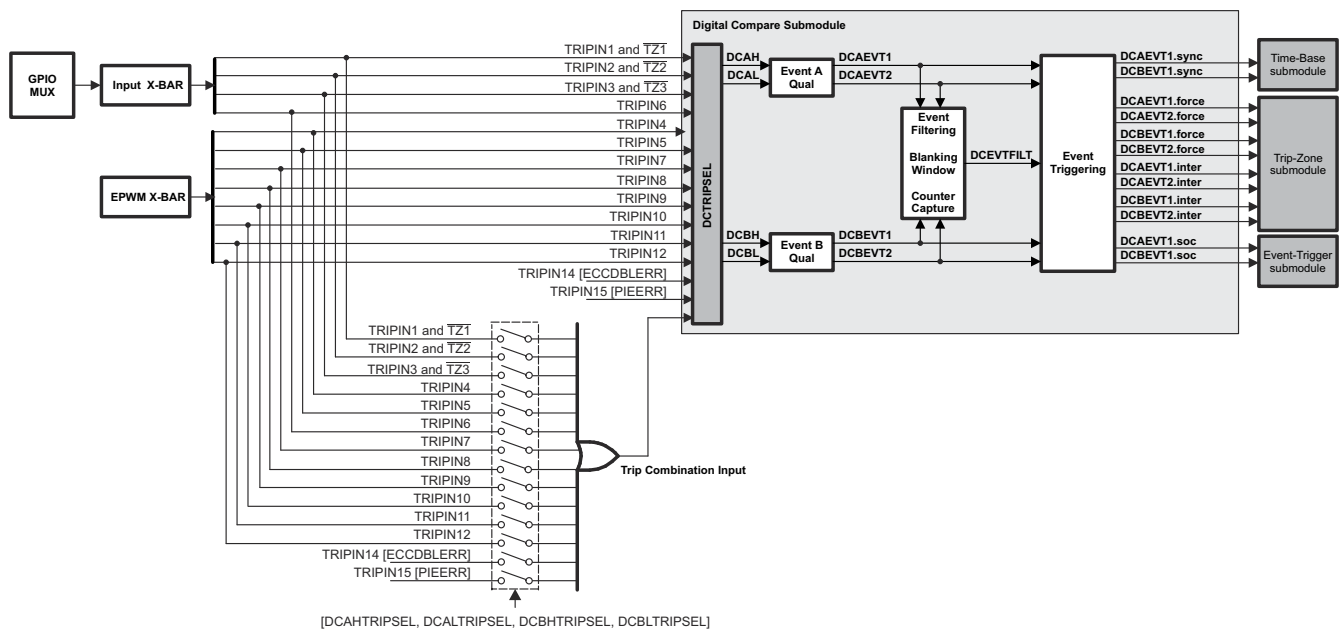

Figure 26-50. Digital-Compare Submodule High-Level Block Diagram

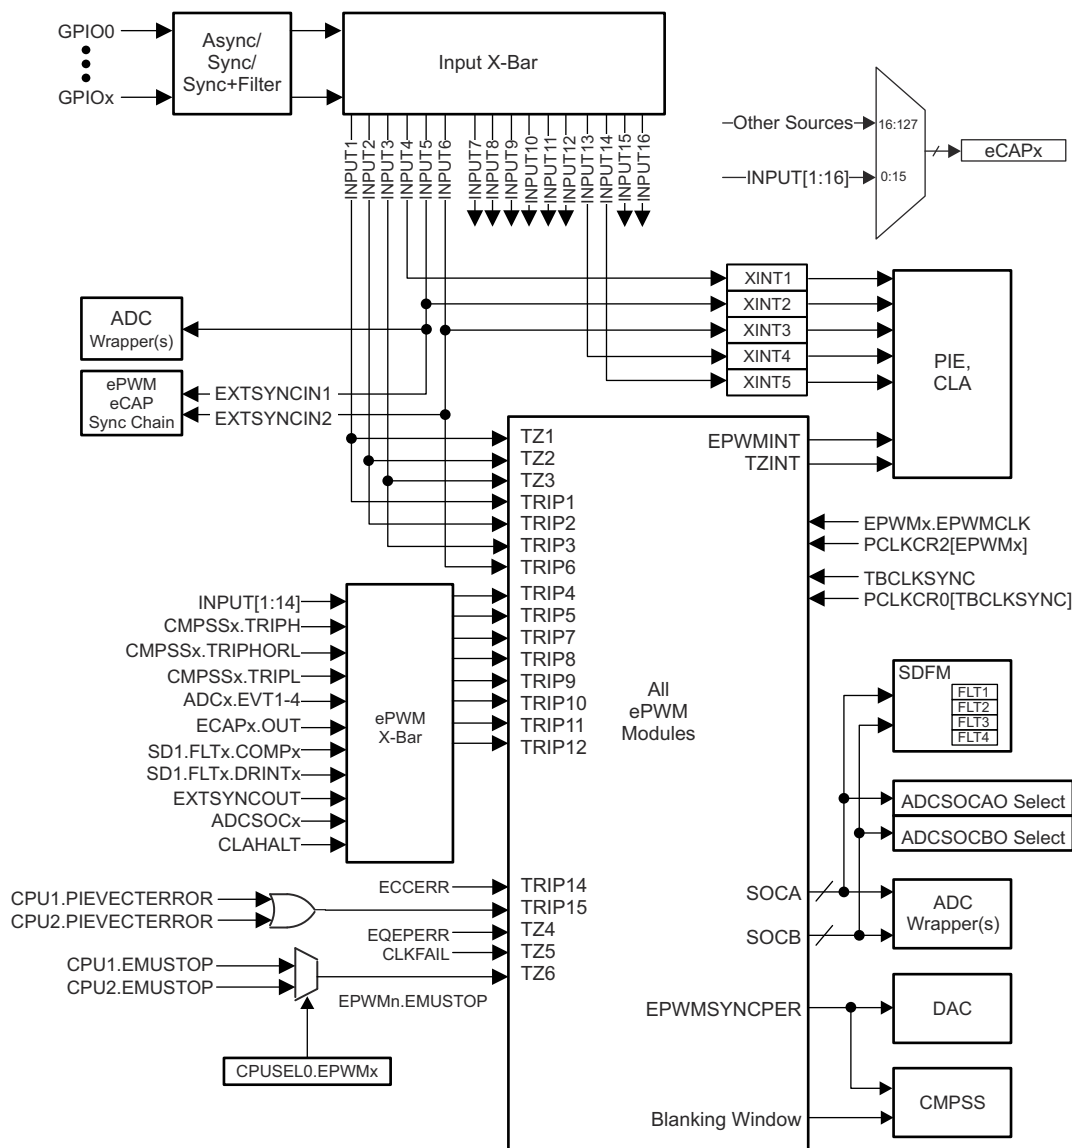

Figure 26-51. GPIO MUX-to-Trip Input Connectivity

### 26.11.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- Analog comparator (COMP) module outputs fed through the Input X-BAR logic externally using the GPIO peripheral, internal PIE, ECC error signals, TZ1, TZ2, and TZ3 inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blinking window logic) can optionally blank the input signal to remove noise.

### 26.11.2 Enhanced Trip Action Using CMPSS

In order to allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

The user has a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

### 26.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps should be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification will be introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition will remain active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition will not be cleared until after the following PWM cycle has started. Thus, the new PWM cycle will detect a trip condition as soon as it begins.

To avoid this undesired trip condition, the user application should take steps to ensure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip will not be asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal via the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (via COMPSTSCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (via HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

### 26.11.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

#### 26.11.4.1 Digital Compare Events

As described in [Section 26.11.1](#), trip zone inputs ( $\overline{TZ1}$ ,  $\overline{TZ2}$ , and  $\overline{TZ3}$ ) and CMPSSx signals from the analog comparator (COMP) module can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

### Note

The  $\overline{TZn}$  signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. ePWM outputs are asynchronously tripped when either the  $\overline{TZn}$ , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of  $3 \cdot TBCLK$  sync pulse width is required. If pulse width is  $< 3 \cdot TBCLK$  sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Section 26.11.4.2](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

Output EPWMxA:

- TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
- TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
- TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

Output EPWMxB:

- TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
- TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
- TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)

- **interrupt signal:**

DCAEVT1/2.interrupt signals generate trip zone interrupts to the PIE. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

[Figure 26-52](#) and [Figure 26-53](#) show how the DCxEVT1, DCxEVT2, or DCEVTFILT signals are processed to generate the digital compare A and B event force, interrupt, soc and sync signals.

In some of the applications like Phase Shifted Full Bridge (PSFB) Converters, it is required that different actions are taken on a CBC trip event and an OST trip event. This can be achieved using the DCxEVT1LAT.

- This latch could be cleared on CNT=0, CTR=PRD, and CNT=0 OR CTR=PRD events based on the setting of DCxCTL.EVty.LATCLRSEL setting. This is similar to CBC latch clear mechanism.
- DCxEVty.force signal could be chosen to be either the latched version or the “un-latched” version based on DCxCTL.EVtyLATSEL value.

- The status of DCxEV<sub>Ty</sub>LAT signal can be accessed by reading DCxCTL.EV<sub>Ty</sub>LAT field.

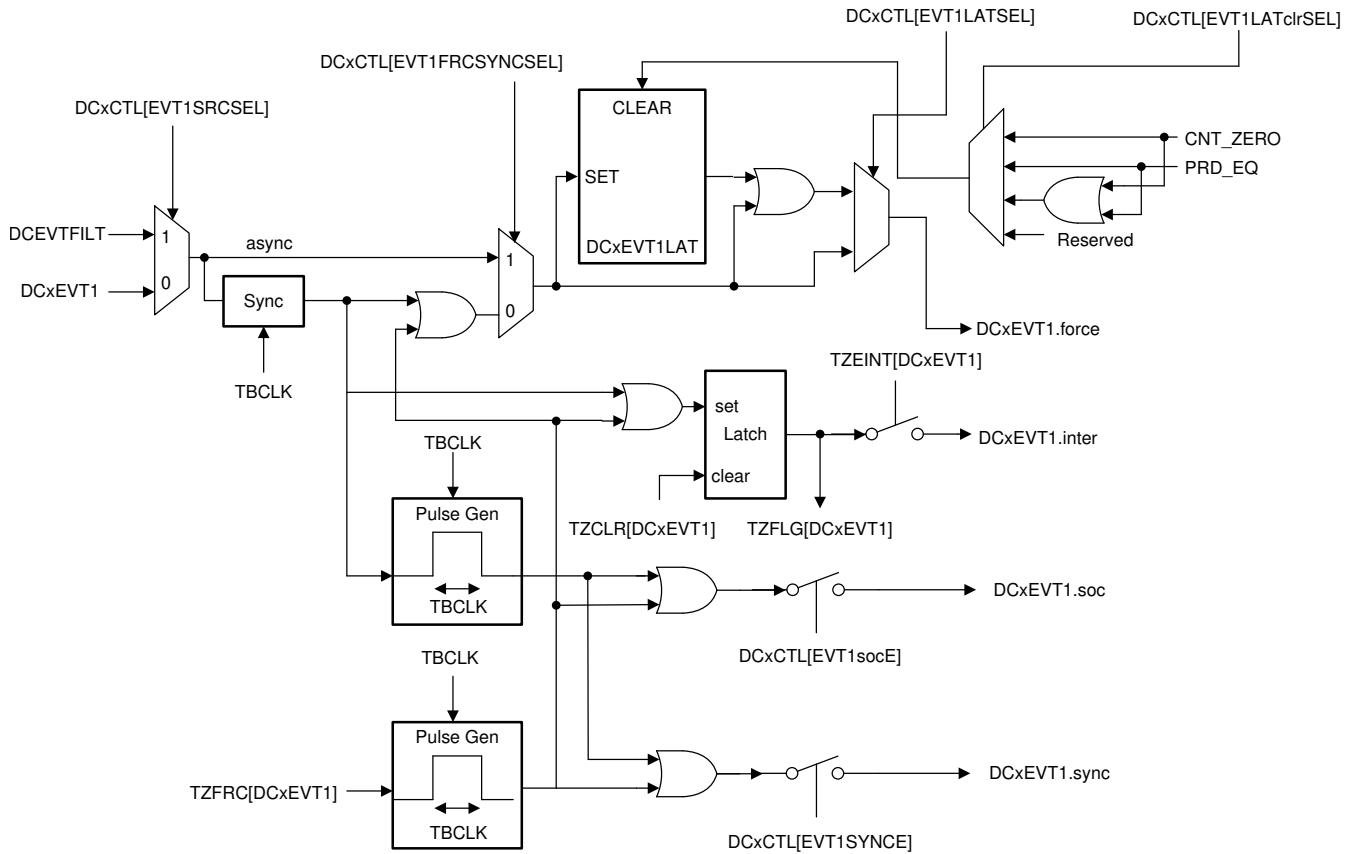

Figure 26-52. DCxEVT1 Event Triggering

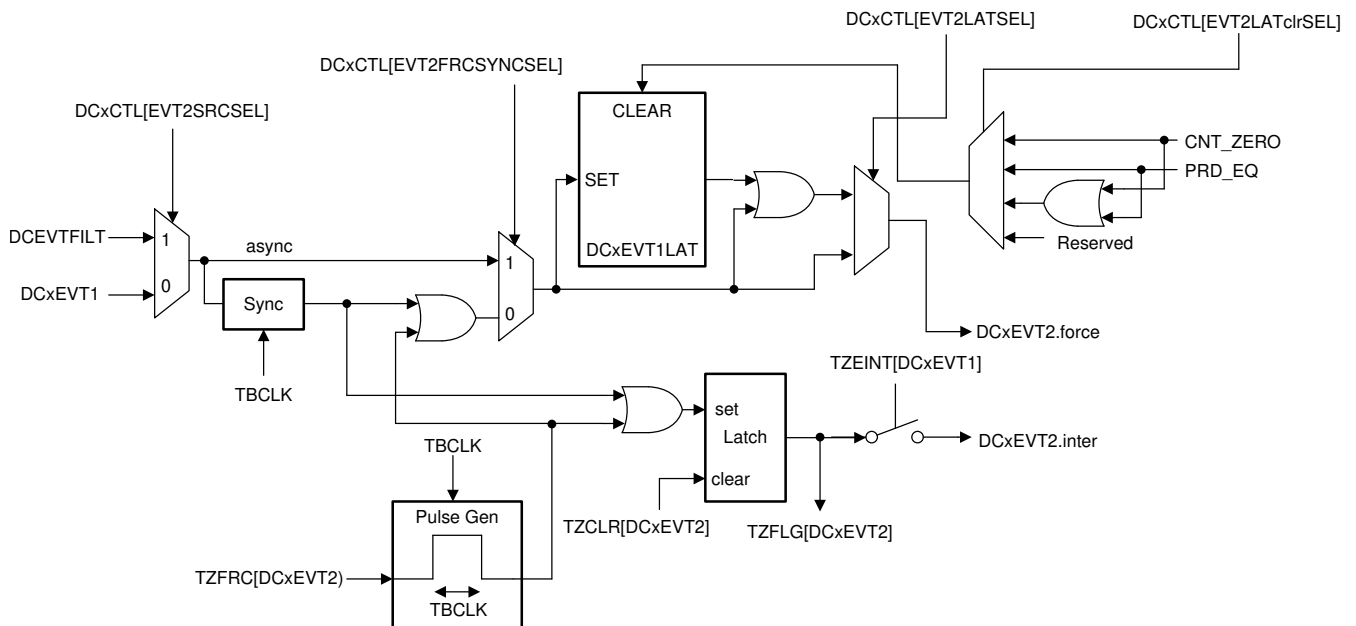

Figure 26-53. DCxEVT2 Event Triggering

### 26.11.4.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. Figure 26-54 shows the details of the event filtering logic.

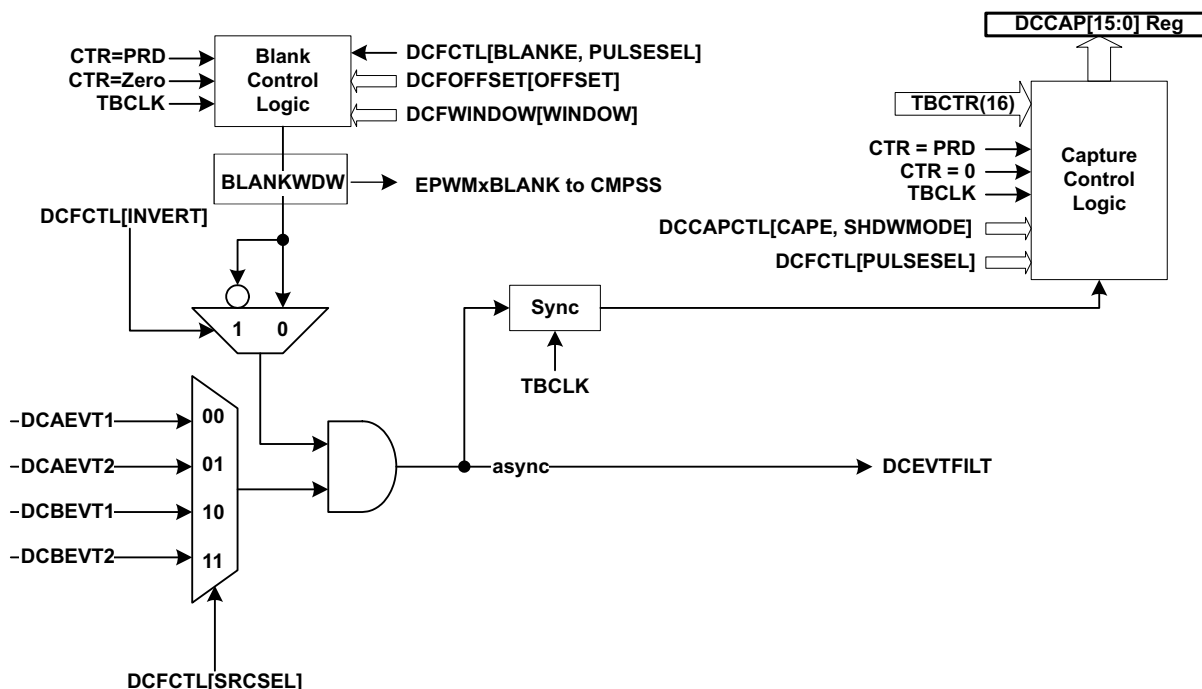

Figure 26-54. Event Filtering

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

#### Note

You must configure the ePWM blanking window appropriately so that the Trip Input stays valid for at least 3 ePWM cycles after the blanking window has expired.

Figure 26-55 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

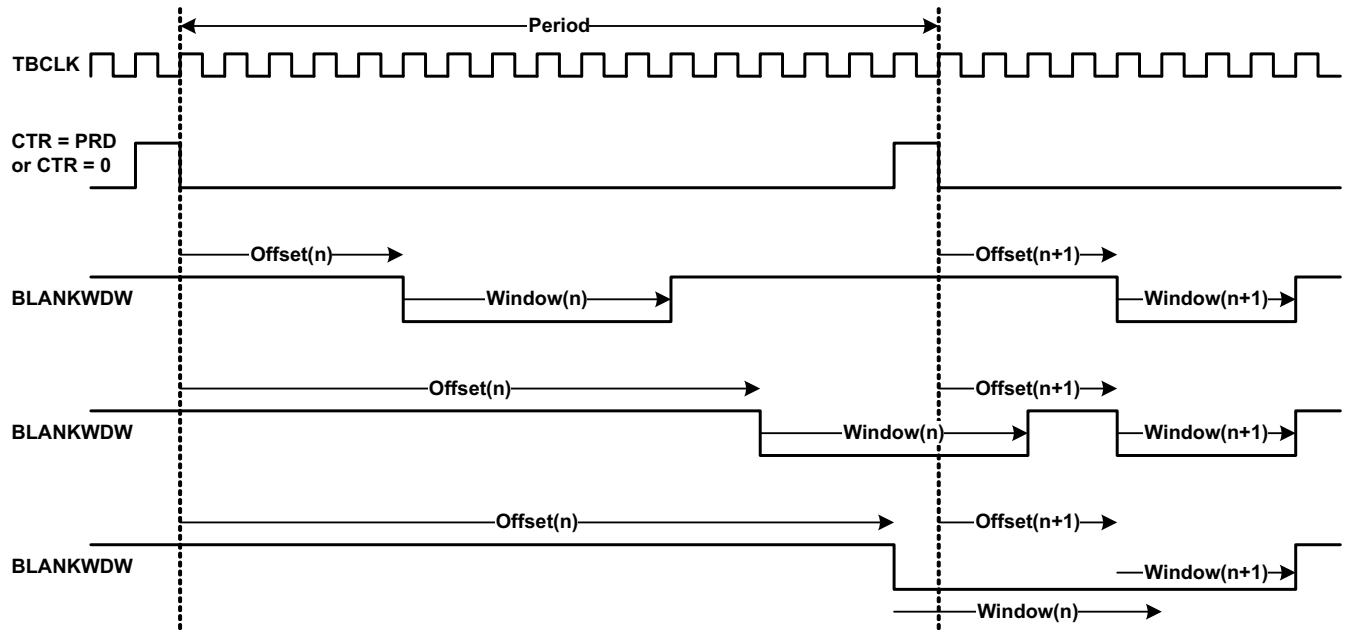

Figure 26-55. Blanking Window Timing Diagram

### 26.11.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in [Section 26.11.4.2](#). This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEV<sub>Ty</sub> signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEV<sub>Ty</sub> events as input to the valley switching block (DCFCTL[*SRCSEL*]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture 'n' rising, falling or both edges through the edge selection logic (DCFCTL[*EDGEMODE*, *EDGECOUNT*]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[*TRIGSEL*]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[*VCAPE*]).
5. Select the start edge that will indicate the start of capture for oscillation period measurement (VCNTCFG[*STARTEDGE*]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[*STOPEDGE*]) that will indicate the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
  - The *STOPEDGE* value must always be greater than *STARTEDGE* value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEV<sub>Ty</sub> signal. The CNTVAL value may be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay may be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[*VDELAYDIV*])
8. Configure VCAPCTL[*EDGEFILTDLYSEL*] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[*TRIGSEL*]. In this implementation, the software trigger is used as the source for VCAPCTL[*TRIGSEL*]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the *STARTEDGE*. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the *STARTEDGE*.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in [Figure 26-56](#).

---

#### Note

A specific application example showcasing the usage of valley switching hardware and software is available on the controlSuite.

---

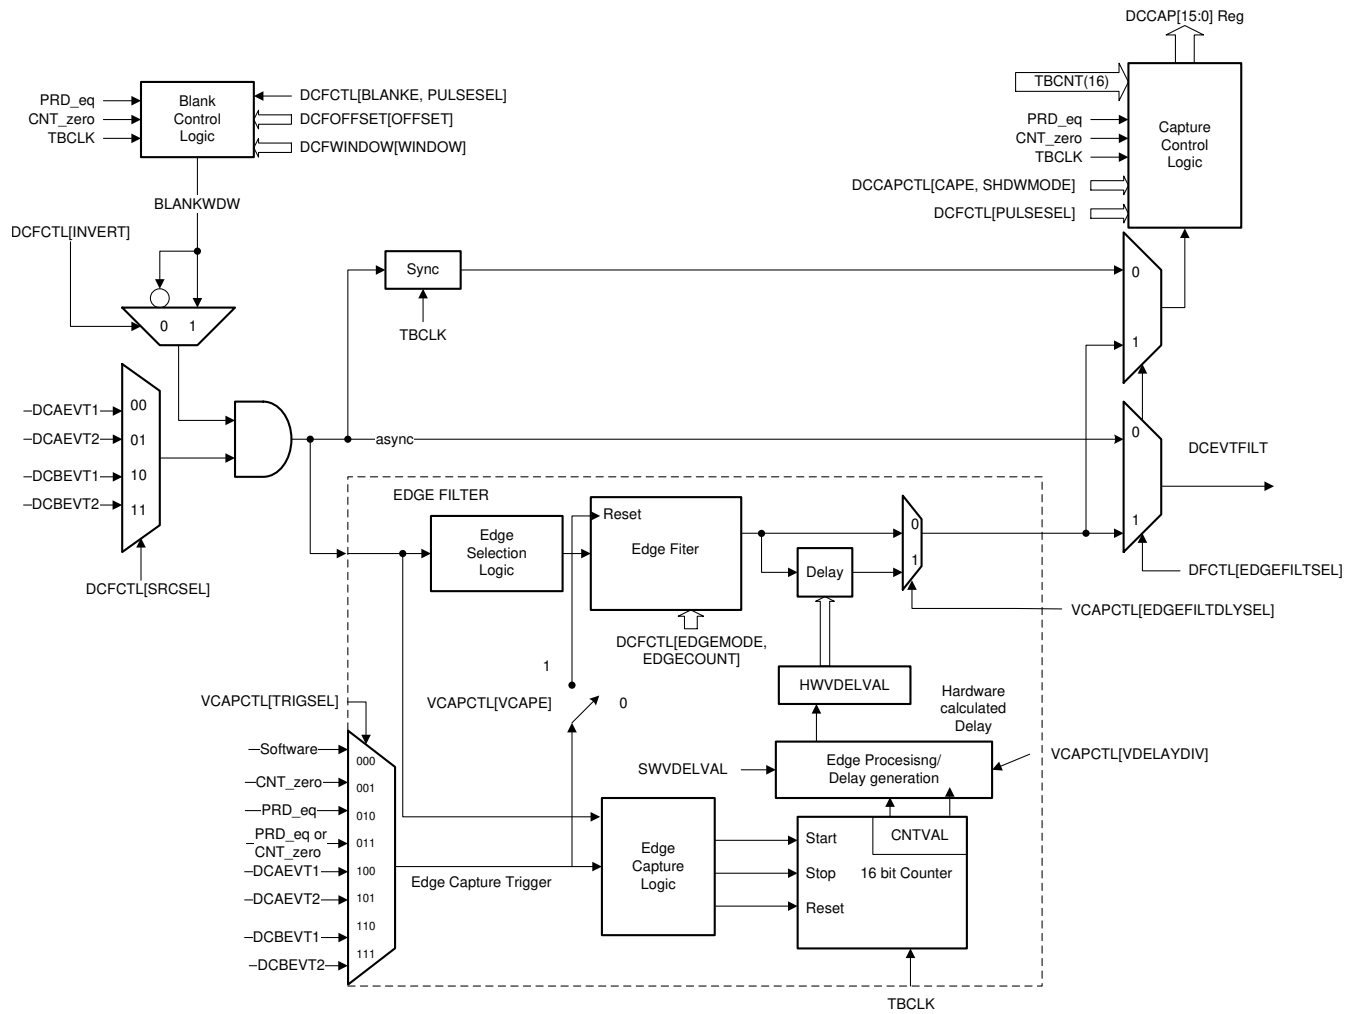

Figure 26-56. Valley Switching

### 26.12 ePWM Crossbar (X-BAR)

Figure 26-57 shows the architecture of the ePWM Crossbar (X-BAR). This module enables selection of various trigger sources into any of the eight dedicated ETWPM trips inputs, namely the TRIP4, TRIP5, TRIP7, TRIP8, TRIP9, TRIP10, TRIP11, and TRIP12.

**Note**

Refer to the *Crossbar (X-BAR)* chapter for more information on the X-BAR modules, including X-BAR flags.

Figure 26-57. ePWM X-BAR

## 26.13 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### 26.13.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 26-58. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

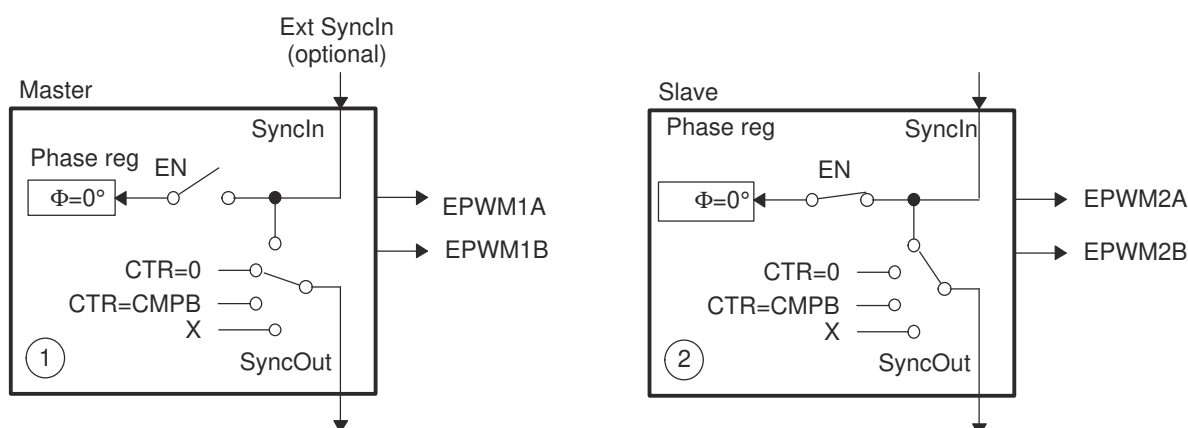

Figure 26-58. Simplified ePWM Module

### 26.13.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it (that is, by the enable switch). Although various combinations are possible, the two most common—Master module and Slave module modes—are shown in [Figure 26-59](#).

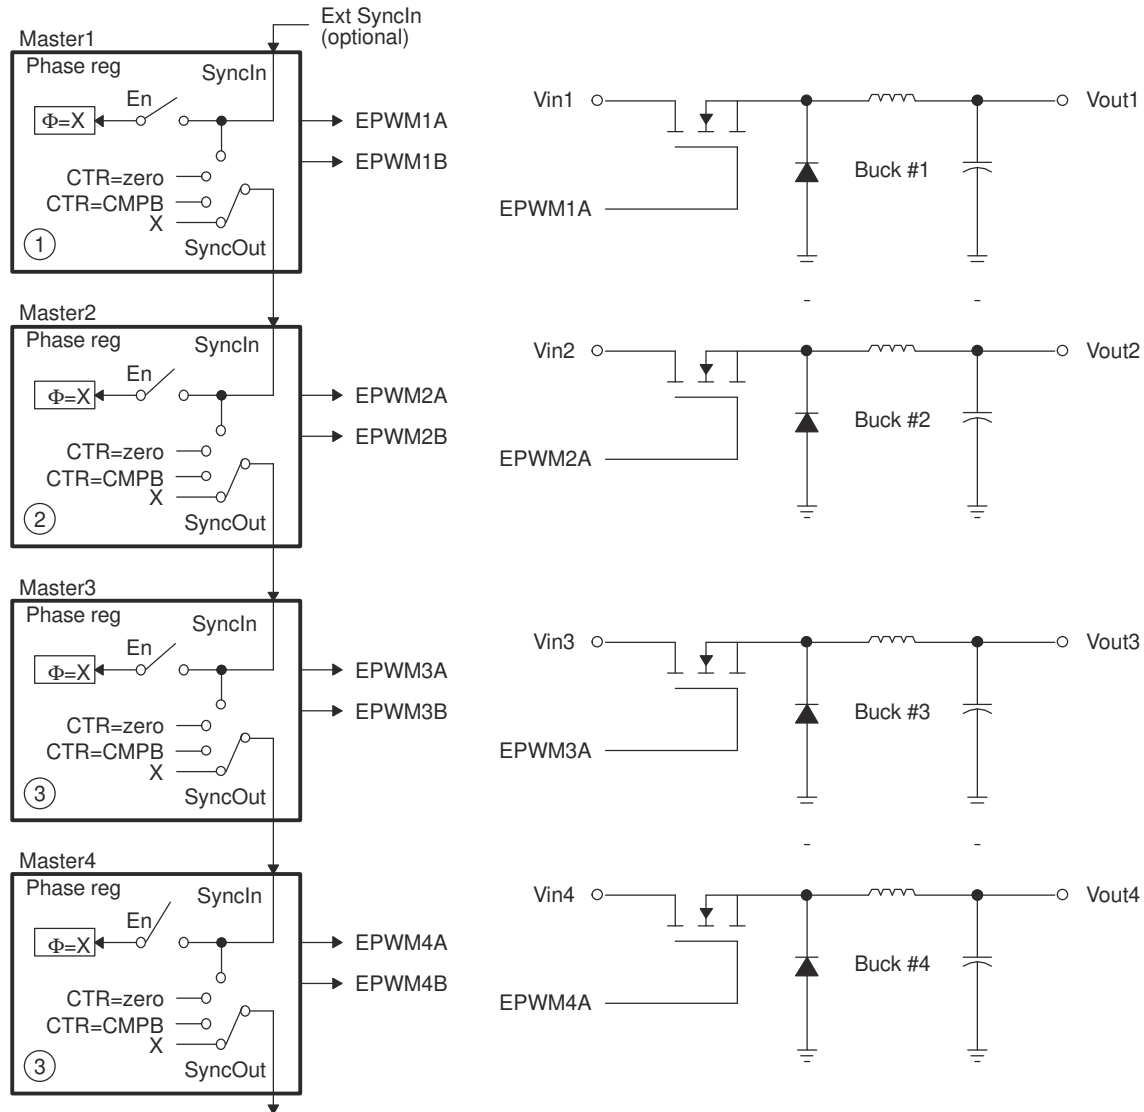

**Figure 26-59. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

### 26.13.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. [Figure 26-60](#) shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. [Figure 26-61](#) shows the waveforms generated by the setup shown in [Figure 26-60](#); note that only three waveforms are shown, although there are four stages.

A.  $\phi = X$  indicates value in phase register is a "don't care"

**Figure 26-60. Control of Four Buck Stages. Here  $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$**

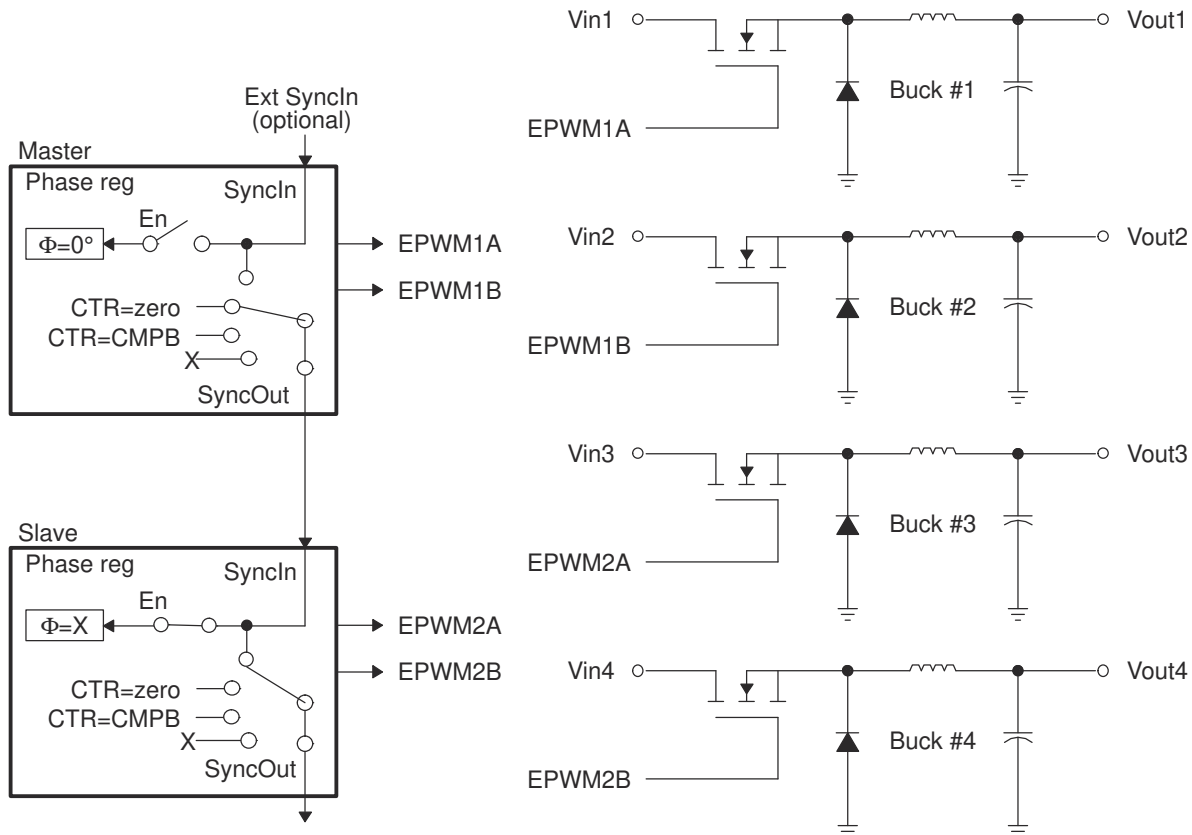

Figure 26-61. Buck Waveforms for Control of Four Buck Stages (Note: Only three bucks shown here)

### 26.13.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 is configured as a slave and operates at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 26-62 shows such a configuration; Figure 26-63 shows the waveforms generated by the configuration.

A.  $\phi = X$  indicates value in phase register is a "don't care"

**Figure 26-62. Control of Four Buck Stages. (Note:  $F_{PWM2} = N \times F_{PWM1}$ )**

A. Starts ADC conversion.

**Figure 26-63. Buck Waveforms for Control of Four Buck Stages (Note:  $F_{PWM2} = F_{PWM1}$ )**

### 26.13.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 26-64 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 26-65 shows the waveforms generated by the configuration shown in Figure 26-64.

ePWM module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by ePWM module 3 and also, most importantly, to remain in synchronization with master ePWM module 1.

Figure 26-64. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ )

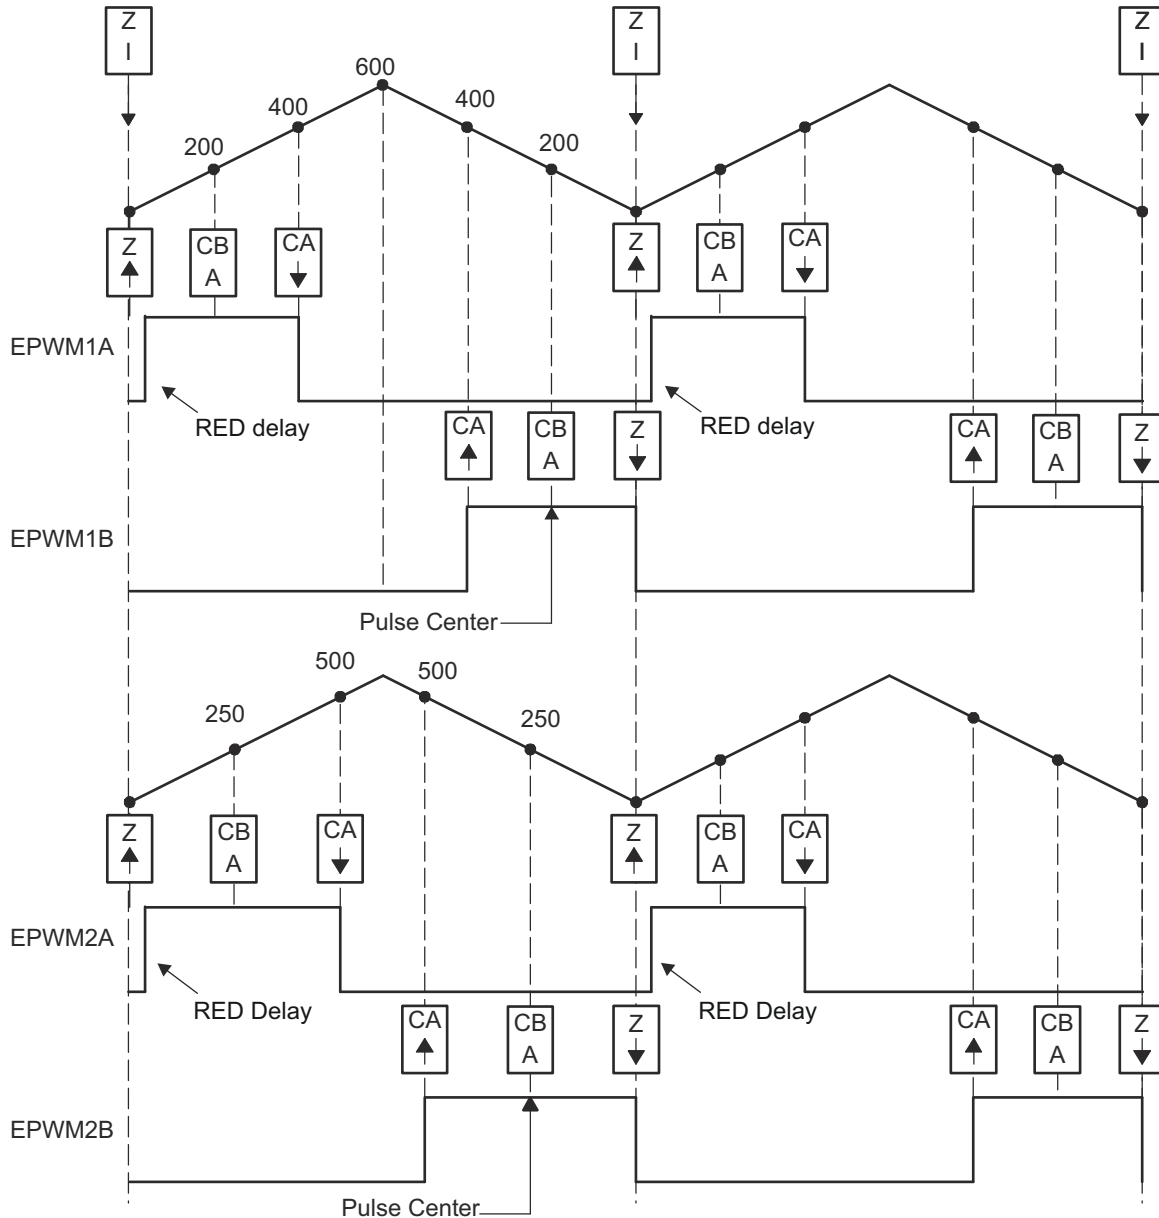

Figure 26-65. Half-H Bridge Waveforms for Control of Two Half-H Bridge Stages (Note: Here  $F_{PWM2} = F_{PWM1}$ )

Figure 26-67. 3-Phase Inverter Waveforms for Control of Dual 3-Phase Inverter Stages (Only One Inverter Shown)

**Figure 26-69. Timing Waveforms Associated With Phase Control Between Two Modules**

### 26.13.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in [Figure 26-70](#). This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be  $F = 120^\circ$ . This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master module 1.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

$$\text{TBPHS}(N,M) = (\text{TBPRD}/N) \times (M-1)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N=3), TBPRD = 600,

TBPHS(3,2) = (600/3) × (2-1) = 200 (that is, Phase value for Slave module 2)

TBPHS(3,3) = 400 (that is, Phase value for Slave module 3)

[Figure 26-71](#) shows the waveforms for the configuration in [Figure 26-70](#).

Figure 26-70. Control of a 3-Phase Interleaved DC/DC Converter

**Figure 26-71. 3-Phase Interleaved DC/DC Converter Waveforms for Control of a 3-Phase Interleaved DC/DC Converter**

### 26.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in [Figure 26-72](#) assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends itself to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge*. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. [Figure 26-73](#) shows a master and slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave phase register (TBPHS). The master phase register is not used and therefore can be initialized to zero.

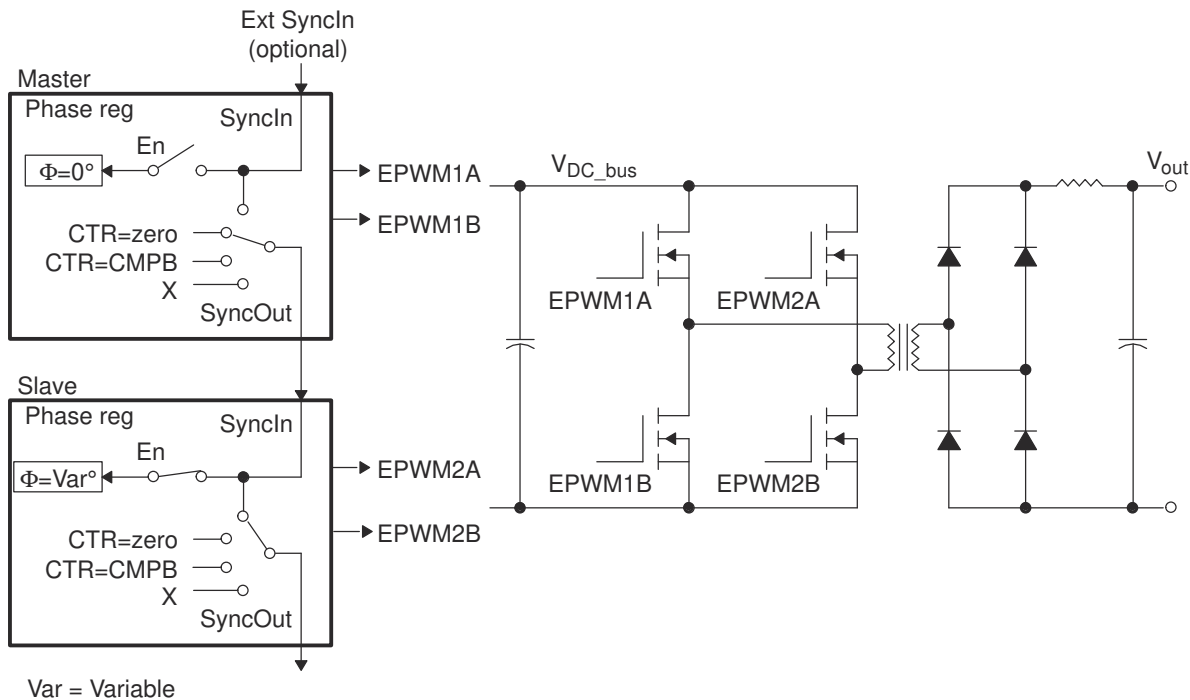

Figure 26-72. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ )

Figure 26-73. ZVS Full-H Bridge Waveforms

### 26.13.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 26-74 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 12-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference could be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 26-75 shows the waveforms generated by the configuration.

Figure 26-74. Peak Current Mode Control of a Buck Converter

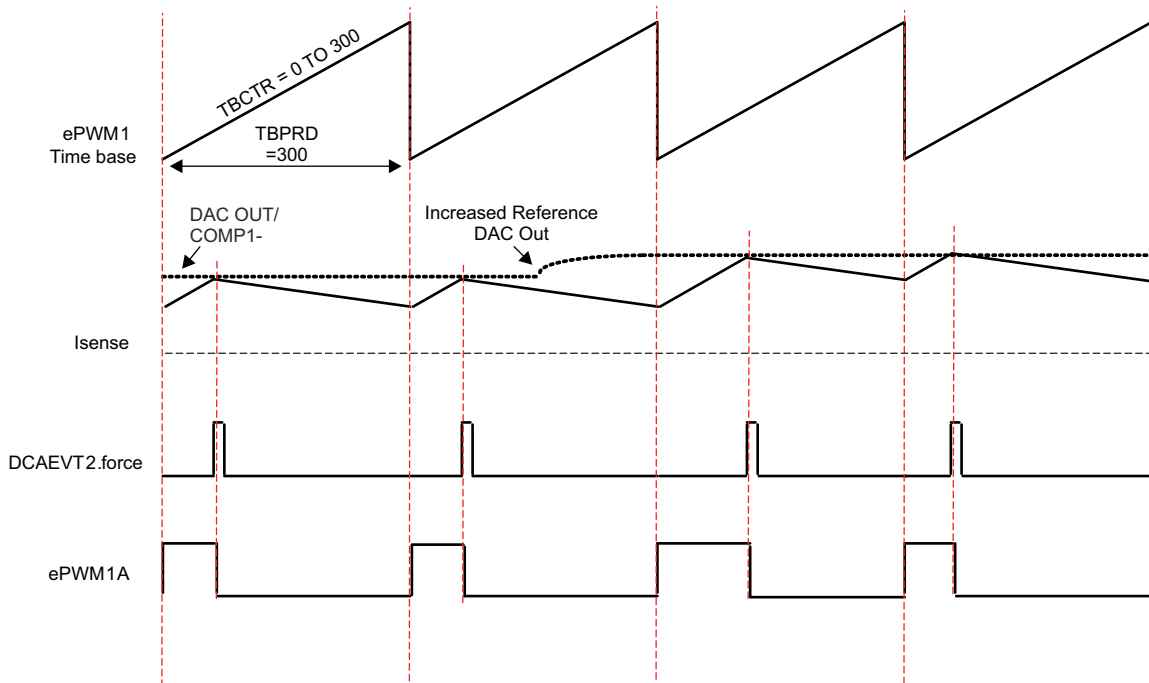

Figure 26-75. Peak Current Mode Control Waveforms for Control of a Buck Converter

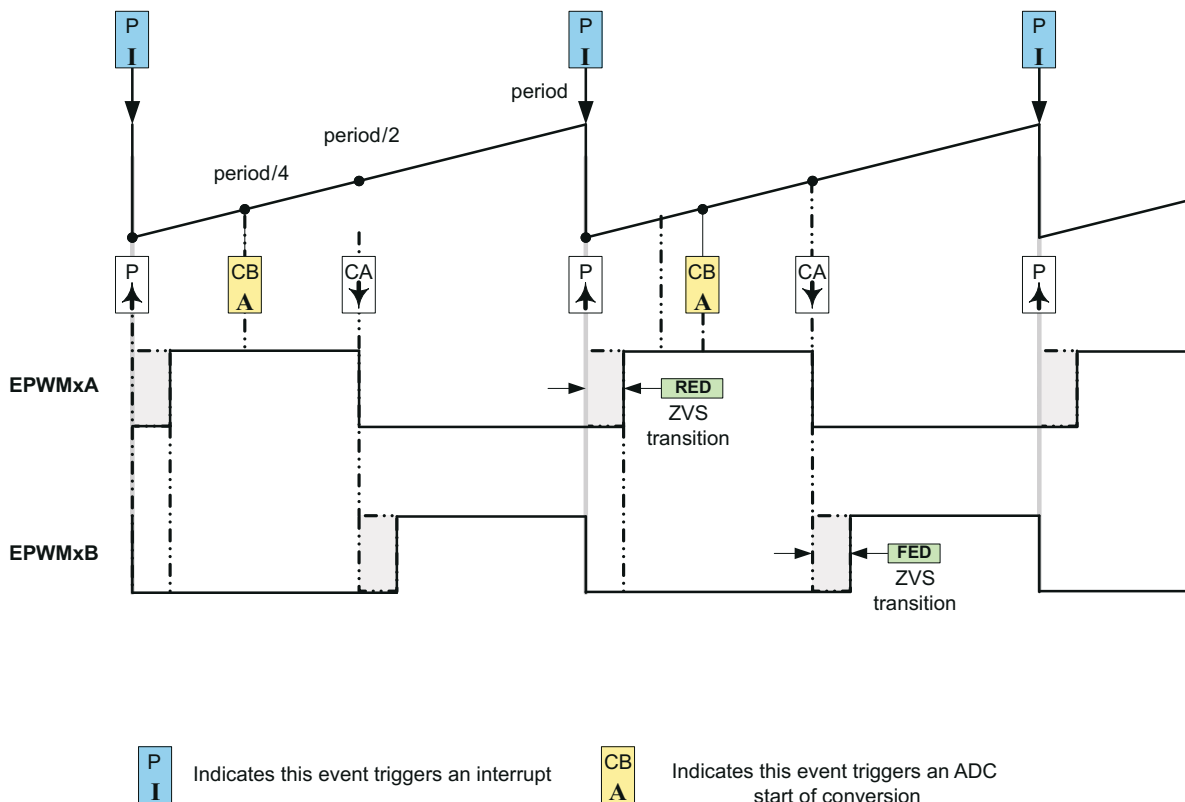

### 26.13.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example, single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multichannel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is frequency. Although the deadband is not controlled and kept constant as 300 ns (that is, 30 @100 MHz TBCLK), it is up to user to update it in real time to enhance the efficiency by adjusting enough time delay for soft switching.

NOTE:  $\Theta = X$  indicates value in phase register is 'don't care'

Figure 26-76. Control of Two Resonant Converter Stages

**P I** Indicates this event triggers an interrupt      **CB A** Indicates this event triggers an ADC start of conversion

Figure 26-77. H-Bridge LLC Resonant Converter PWM Waveforms

## 26.14 Register Lock Protection

The register lock protection mechanism is added to protect the critical ePWM registers from being corrupted by accidental writes in case of runaway code. The register EPWMLOCK contains the definition of Lock bits (Table 26-14 shows the lock bits and the corresponding registers). This register also has a KEY field; writes to this register will succeed only if the KEY field is written with a value of 0xa5a5. Refer to the register descriptions for more details.

**Table 26-14. Lock Bits and Corresponding Registers**

Bit Field	Definition	Registers Locked
HRLOCK	HRPWM Register Set Lock	HRCNFG, HRPWR, HRMSTEP, HRPCTL
GLLOCK	Global Load Register Set Lock	GLDCTL, GLDCFG
TZCFGLOCK	TripZone Register Set Lock	TZSEL, TZDCSEL, TZCTL, TZCTL2, TZCTLDCA, TZCTLDCB, TZEINT
TZCLRLOCK	TripZone Clear Register Set Lock	TZCLR, TZCBCCLR, TZOSTCLR, TZFRC
DCLOCK	Digital Compare Register Set Lock	DCTRIPSEL, DCACTL, DCBCTL, DCFCTL, DCCAPCTL, DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, DCBLTRIPSEL

### Note

Due to the presence of the KEY field in the same register, only 32-bit writes will succeed if the KEY matches. The 16-bit writes to the upper or lower half of this register will be ignored.

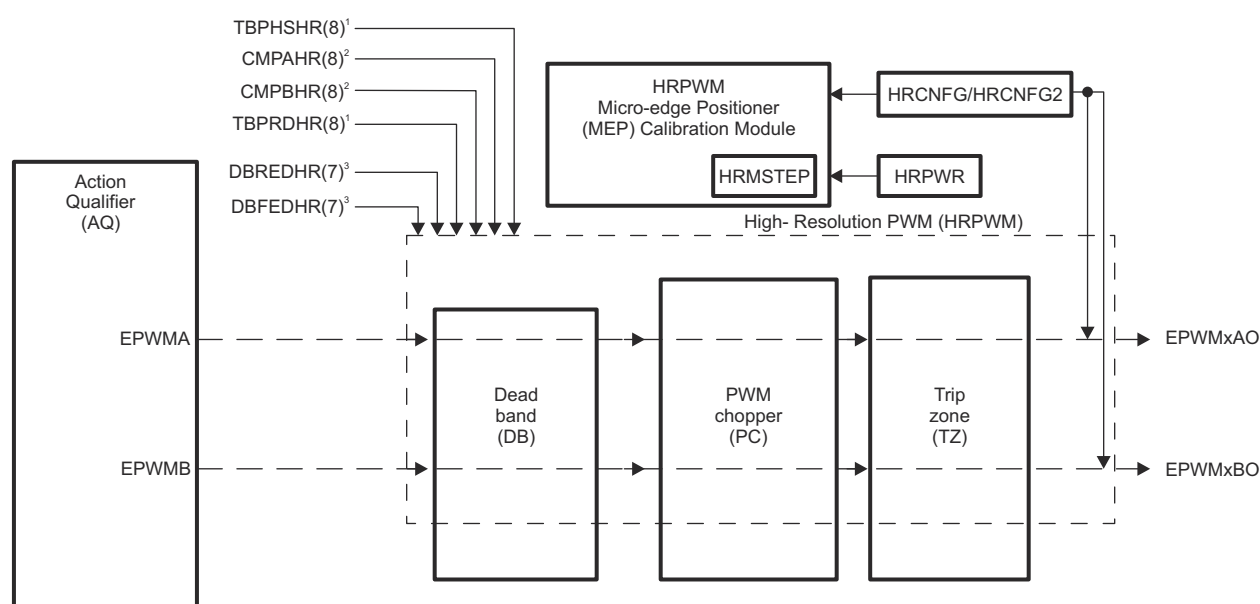

## 26.15 High-Resolution Pulse Width Modulator (HRPWM)

Figure 26-78 shows a block diagram of the HRPWM. This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~ 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A and B signal path of PWM, that is, on the EPWMxA and EPWMxB output
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running optimally
- Enables high resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output via inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module

### Note

See the device-specific datasheet to determine if your device has an ePWM module with high-resolution period support.

- A. From ePWM Time-base (TB) submodule  
 B. From ePWM counter-compare (CC) submodule  
 C. From ePWM Deadband (DB) submodule

**Figure 26-78. HRPWM Block Diagram**

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 26-79, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 26-79. Resolution Calculations for Conventionally Generated PWM**

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 26-15 shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180 ps. See the device-specific data sheet for typical and maximum performance specifications for the MEP.

**Table 26-15. Resolution for PWM and HRPWM**

PWM Frequency (kHz)	Regular Resolution (PWM) 100 MHz EPWMCLK		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.02	18.1	0.000
50	11	0.05	16.8	0.001
100	10	0.1	15.8	0.002
150	9.4	0.15	15.2	0.003
200	9	0.2	14.8	0.004
250	8.6	0.25	14.4	0.005
500	7.6	0.5	13.4	0.009
1000	6.6	1	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2	11.4	0.036

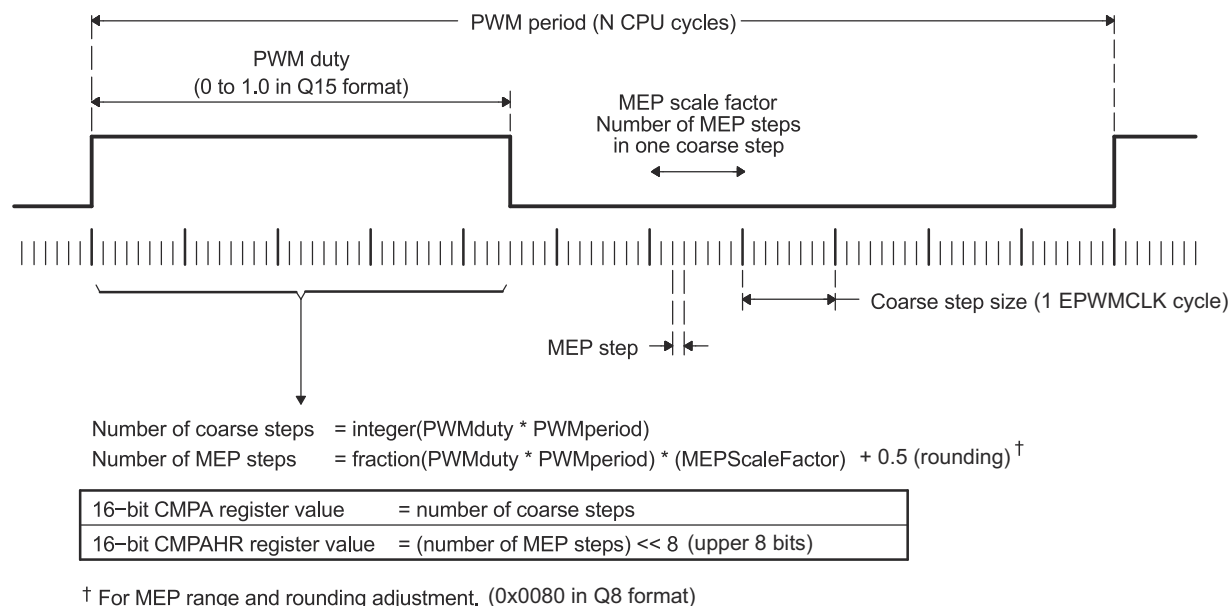

Although each application may differ, typical low frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

### 26.15.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. See the device-specific data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions. Details on software diagnostics and functions are in [Section 26.15.1.7](#).

[Figure 26-80](#) shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

**Figure 26-80. Operating Logic Using MEP**

To generate an HRPWM waveform, configure the ePWM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in [Section 26.15.1.8](#).

#### 26.15.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM, and DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Deadband Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Deadband Generator Falling Edge Delay High Resolution Register

A. Dependant upon your device, these registers may be mirrored and can be written to at two different memory locations. Check the device-specific Technical Reference Manual's *ePWM* chapter for more details on how to read and write to these locations.

**Figure 26-81. HRPWM Extension Registers and Memory Configuration**

**Note**

HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during Dead Band half cycle clocking Operation. The number of MEP steps is half in size [bits 15:9] than duty and phase high resolution registers for the same reason

HRPWM capabilities are controlled using the Channel A and B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. [Figure 26-82](#) shows how the HRPWM interfaces with the 8-bit extension registers.

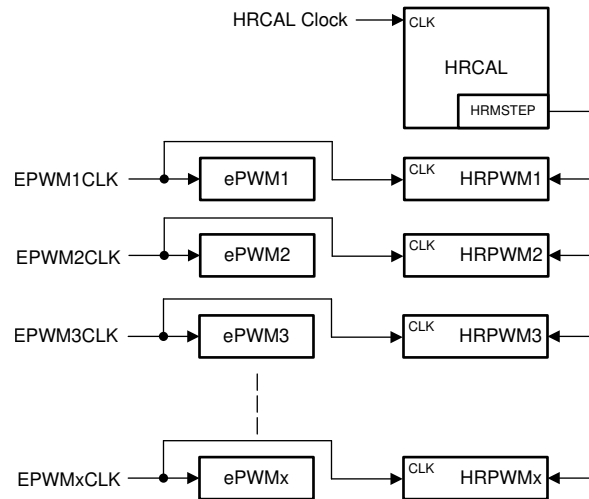

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

**Figure 26-82. HRPWM System Interface**

### 26.15.1.2 HRPWM Source Clock

Each HRPWM module is clocked from the respective EPWMxCLK. HRCAL has a separate clock. For example, HRPWM1 is sourced from EPWM1CLK while HRPWM2 is clocked from the EPWM2CLK. [Figure 26-83](#) shows the HRCAL and HRPWM modules are sourced from their respective ePWM clock source.

**Figure 26-83. HRPWM and HRCAL Source Clock**

#### Note

HRCAL registers should not be configured using CPU2 through the registers available on ePWM2 to ePWM8 modules.

### 26.15.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

- Edge Mode** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control).
- Control Mode** The MEP is programmed to be controlled either from the CMPAHR / CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR or CMPBHR register. BE control mode should be used with TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control) the duty cycle and phase can also be controlled via their respective high-resolution registers.
- Shadow Mode** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR and TBPRDHR registers and should be chosen to be the same as the regular load option for the CMPA, CMPB register. If TBPHSHR is used, then this option has no effect.
- High-Resolution B Signal Control** The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2 or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well.
- Swap ePWMxA and ePWMxB Outputs** This mode enables the swapping of the high resolution A and B outputs. The mode selection allows either A and B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A.
- Auto-conversion Mode** This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled,  $CMPAHR = \text{fraction}(PWMduty * PWMperiod) \ll 8$ . The scale factor optimization software will calculate the MEP scale factor in background code and automatically update the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module will then use the values in the HRMSTEP and CMPAHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and move the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and  $CMPAHR = (\text{fraction}(PWMduty * PWMperiod) * MEP \text{ Scale Factor} + 0.5) \ll 8$ . All calculations will need to be performed by user code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

### Note

If the HRPWM module is configured in UP-DOWN counter mode, the shadow mode for the HRPWM registers must be set to load on both ZERO AND PERIOD. New values from the user are loaded to the shadow registers only at CTR=ZERO, but the shadow mode of for the registers must be set to both ZERO AND PERIOD. The CTR=PRD event is used for specific internal logic inside the HRPWM module.

Auto-conversion Mode performs the calculation for CMPBHR , DBREDHR and DBFEDHR as well. The scale factor optimization software will calculate the MEP scale factor in background code and automatically update the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module will then use the values in the HRMSTEP and CMPBHR or DBREDHR / DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and move the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves same as CMPAHR.  $CMPBHR = (\text{fraction}(PWMduty * PWMperiod) * MEP \text{ Scale Factor} + 0.5) \ll 8$ .

You are expected to disable protection for both ePWM1 and HRPWM when the application requires access to either of these modules.

#### 26.15.1.4 Configuring Hi-Res in Deadband Rising Edge and Falling Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity and deadband enabled in half cycle clocking mode, the high resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module's register space. This register provides the following configuration options:

**Edge Mode** The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED), or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.

**Control Mode** Selects the time event that loads the shadow value in active register for DBRED and DBFED in high resolution mode. You need to select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] and DBCTL[LOADFEDMODE] bits.

#### 26.15.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see device-specific data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 26-16](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 26-16. Relationship Between MEP Steps, PWM Frequency and Resolution**

System (MHz)	MEP Steps Per EPWMCLK <sup>(1) (2) (3)</sup>	PWM Minimum (Hz) <sup>(4)</sup>	PWM Maximum (MHz)	Resolution at Maximum (Bits) <sup>(5)</sup>
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

(1) TBCLK = EPWMCLK.

(2) Table data based on a MEP time resolution of 180 ps (this is an example value. See the device-specific data sheet for MEP limits)

(3) MEP steps applied =  $T_{EPWMCLK} / 180 \text{ ps}$  in this example.

(4) PWM minimum frequency is based on a maximum period value, (TBPRD = 65535). PWM mode is asymmetrical up-count.

(5) Resolution in bits is given for the maximum PWM frequency stated.

### 26.15.1.5.1 Edge Positioning

#### Note

The following example is presented using the [CMPA:CMPAHR] register combination. The theory of operation and equations is the same if you intend to use [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 26-84, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 26-17.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 26-17 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ps.

Figure 26-84. Required PWM Waveform for a Requested Duty = 40.5%

Table 26-17. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

CMPA (count) <sup>(1) (2) (3)</sup>	Duty (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

(1) Assumed MEP step size for the above example = 180 ps. See the device-specific data manual for typical and maximum MEP values.  
 (2) TBCLK = 100 MHz, 10 ns  
 (3) For a PWM Period register value of 80 counts, PWM Period = 80 x 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

### 26.15.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

#### Assumptions for this example:

TBCLK	=	10 ns (100 MHz)
PWM frequency	=	1.25 MHz (1/800 ns)
Required PWM duty cycle, <b>PWMDuty</b>	=	0.405 (40.5%)
PWM period in terms of coarse steps, <b>PWMPeriod</b> (800 ns/10 ns)	=	80
Number of MEP steps per coarse step at 180 ps (10 n/180 ps), <b>MEP_ScaleFactor</b>	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	0.5 (0080h in Q8 format)

#### Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value	=	$\text{int}(\text{PWMDuty} * \text{PWMPeriod})$ ; int means integer part
	=	$\text{int}(0.405 * 80)$
	=	$\text{int}(32.4)$
CMPA register value	=	32 (20h)

#### Step 2: Fractional value conversion for CMPAHR register

CMPAHR	=	$(\text{frac}(\text{PWMDuty} * \text{PWMPeriod}) * \text{MEP\_ScaleFactor} + 0.5) \ll 8$ ; frac means fractional part
	=	$(\text{frac}(32.4) * 55 + 0.5) \ll 8$ ; Shifting is to move the value to the high byte of CMPAHR.
	=	$(0.4 * 55 + 0.5) \ll 8$
	=	$(22 + 0.5) \ll 8$
	=	$22.5 * 256$ ; Shifting left by 8 is the same as multiplying by 256.
	=	5760 (1680h)
CMPAHR	=	1680h CMPAHR value = 1600h (lower 8 bits will be ignored by hardware).

### Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value = frac (PWMDuty\*PWMperiod<<8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

The MEP scale factor (MEP\_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the C28x CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in [Section 26.15.1.8](#). The actual implementation takes advantage of the 32-bit CPU architecture of the C28x, and is somewhat different from the steps shown in [Section 26.15.1.5.2](#).

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

#### 26.15.1.5.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high resolution period (TBPRDHR) control is enabled via the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED and/or DBFED (the register corresponding to the edge with hi-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in [Figure 26-85](#) to [Figure 26-88](#). This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see [Table 26-18](#). When high-resolution period control is enabled (HRPCTL[HRPE]=1), the duty cycle must not fall within the restricted range. Otherwise, there may be undefined behavior on the ePWMxA output.

Figure 26-85. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Table 26-18. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles

PWM Frequency <sup>(1)</sup> (kHz)	3 Cycles Minimum Duty	3 Cycles Maximum Duty <sup>(2)</sup>
200	0.6%	99.4%
400	1.2%	98.8%
600	1.8%	98.2%
800	2.4%	97.6%
1000	3%	97%
1200	3.6%	96.4%
1400	4.2%	95.8%
1600	4.8%	95.2%
1800	5.4%	94.6%
2000	6%	94%

(1) EPWMCLK = TBCLK = 100 MHz

(2) This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in [Figure 26-86](#). In this configuration, the minimum duty cycle limitation is no longer an issue. However, there will be a maximum duty limitation with same percent numbers as given in [Table 26-18](#).

### CAUTION

If the application has enabled high-resolution period control (HRPCTL[HRPE]=1), the duty cycle must not fall within the restricted range. Otherwise, there will be undefined behavior on the ePWM output.

Figure 26-86. High % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Figure 26-87. Up-Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1)

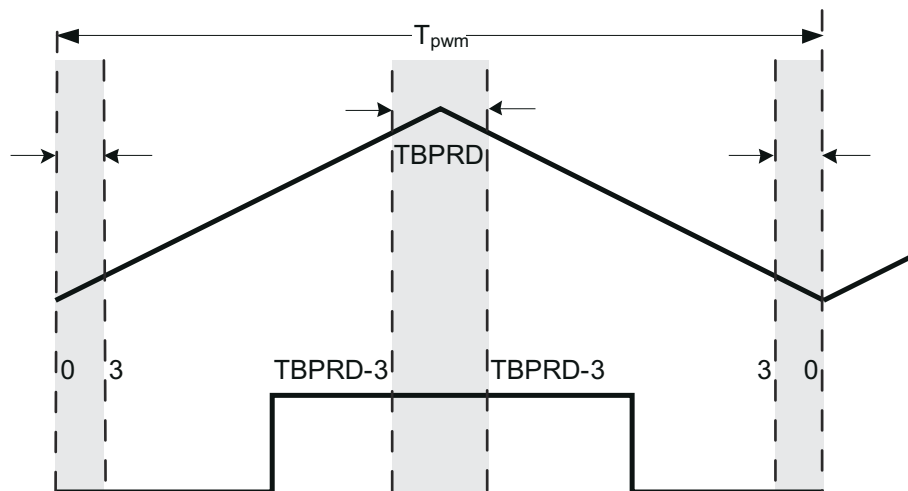

Figure 26-88. Up-Down Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1)

#### 26.15.1.5.4 High Resolution Period

High resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

#### Note

When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and vice versa, the non hi-res output will have +/- 1 TBCLK cycle jitter in up-count mode and +/- 2 TBCLK cycle jitter in up-down count mode.

The scaling procedure described for duty cycle in [Section 26.15.1.5.2](#) applies for high-resolution period as well:

#### Assumptions for this example:

TBCLK	= 10 ns (100 MHz)
Required PWM frequency	= 175 kHz (period of 571.428)
Number of MEP steps per coarse step at 180 ps (MEP_ScaleFactor)	= 55 (10 ns / 180 ps)
Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value)	= 0.5 (0080h in Q8 format)

#### Problem:

In up-count mode:

If TBPRD = 571, then PWM frequency = 174.82 kHz (period =  $(571+1) \cdot T_{TBCLK}$ ).

If TBPRD = 570, then PWM frequency = 175.13 kHz (period =  $(570+1) \cdot T_{TBCLK}$ ).

In up-down count mode:

If TBPRD = 286, then PWM frequency = 174.82 kHz (period =  $(286 \cdot 2) \cdot T_{TBCLK}$ ).

If TBPRD = 285, then PWM frequency = 175.44 kHz (period =  $(285 \cdot 2) \cdot T_{TBCLK}$ ).

#### Solution:

With 55 MEP steps per coarse step at 180 ps each:

#### Step 1: Percentage Integer Period value conversion for TBPRD register

Integer period value	= $571 \cdot T_{TBCLK}$ = $\text{int}(571.428) \cdot T_{TBCLK}$ = $\text{int}(\text{PWMperiod}) \cdot T_{TBCLK}$
----------------------	--

In up-count mode:

TBPRD	= 570 (TBPRD = period value - 1) = 023Ah
-------	---

In up-down count mode:

TBPRD	= 285 (TBPRD = period value / 2) = 011Dh
-------	---

#### Step 2: Fractional value conversion for TBPRDHR register

TBPRDHR register value	= $(\text{frac}(\text{PWMperiod}) \cdot \text{MEP\_ScaleFactor} + 0.5)$
If auto-conversion enabled and HRMSTEP = MEP_ScaleFactor value (55):	= $\text{frac}(\text{PWMperiod}) \ll 8$ (Shifting is to move the value to the high byte of TBPRDHR)
TBPRDHR register value	= $\text{frac}(571.428) \ll 8$ = $0.428 \times 256$ = 6D00h

The autoconversion will then automatically perform the calculation such that TBPRDHR MEP delay is scaled by hardware to:

$$\begin{aligned} &= ((\text{TBPRDHR}(15:0) \gg 8) \times \text{HRMSTEP} + 80\text{h}) \ll 8 \\ &= (006\text{Dh} \times 55 + 80\text{h}) \gg 8 \\ &= (17\text{EBh}) \gg 8 \\ \text{Period MEP delay} &= 0017\text{h MEP Steps} \end{aligned}$$

#### 26.15.1.5.4.1 High-Resolution Period Configuration

To use High Resolution Period, the ePWMx module must be initialized in the exact order presented.

The steps below use CMPA with shadow registers and the corresponding HRCNFG bits for hi-resolution operation on EPWMxA. For hi-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
  - ePWMx may only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
  - TBPRD and CC registers must be configured for shadow loads.
  - CMPCTL[LOADAMODE]
    - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
    - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR=0 or CTR=PRD)
5. Configure the HRCNFG register such that:
  - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
  - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
  - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired via the SFO() function described in [Section 26.15.2](#).
11. To control high-resolution period, write to the TBPRDHR(M) registers.

---

#### Note

When high-resolution period mode is enabled, an EPWMxSYNC pulse will introduce +/- 1 - 2 cycle jitter to the PWM (+/- 1 cycle in up-count mode and +/- 2 cycle in up-down count mode). For this reason, EPWMxSYNCO source should not be set to CTR = 0 or CTR = CMPB. Otherwise, the jitter will occur on every PWM cycle with the synchronization pulse.

When EPWMxSYNCl is EPWMxSYNCO source, a software synchronization pulse should be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter will appear on the PWM output at the time of the sync pulse.

---

### 26.15.1.6 Deadband High Resolution Operation

---

#### Note

In up-count mode, the deadband module is **NOT** available when any high resolution mode is enabled.

---

#### Assumptions for this example:

System clock	= 10 ns (100 MHz)
Deadband Enabled in half cycle mode, TBCLK = EPWMCLK	
Required PWM frequency	1.33 MHz (1 / 750 ns)
Required PWM duty cycle	0.5 (50%)
Required Dead band Rising Edge Delay	5% over duty
Required Dead band Rising Edge Delay in ns	(0.05 * 375 ns) = 18.75 ns

---

#### Note

Just like the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use high resolution deadband.

---

#### Deadband Delay Values as a Function of DBFED and DBRED:

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$FED = DBFED * TBCLK / 2$$

$$RED = DBRED * TBCLK / 2$$

#### DBRED and DBFED Calculated Values:

Required Dead band Rising Edge Delay in ns = 18.75 ns

$$DBRED = RED / (TBCLK / 2)$$

$$DBRED = 18.75 \text{ ns} / 5 \text{ ns}$$

$$DBRED \text{ Required} = 3.75 \text{ ns}$$

With 55 MEP steps per coarse step at 180 ps each:

#### Step 1: Integer Dead band value conversion for DBREDM register

Integer DBRED value	= int (RED / (TBCLK / 2))
	= int (3.75)
DBRED	= 3

## Step 2: Fractional value conversion for Dead band high resolution register DBREDHR

DBREDHR register value	$= (\text{frac}(\text{DBRED Required}) * \text{MEP\_ScaleFactor} + 0.5) \ll 8$ (Shifting is to move the value to the high byte of DBREDHR)
	$= (\text{frac}(3.75) * 55 + 0.5) \ll 8$
	$= (0.75 * 55 + 0.5) \ll 8$
	$= (41.75) * 256$ Shifting left by 8 is the same as multiplying by 256.
DBREDHR value	$= 29C0h$ MEP Steps
	Hardware will ignore lower 9 bits in the above calculated DBREDHR value

---

### Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED =  $\text{frac}(\text{required DB value}) \ll 8$ . The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

---

### 26.15.1.7 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150 ps (see device-specific data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature should use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO\_TI\_Build\_V8.lib software can be found in [Section 26.15.2](#).

### 26.15.1.8 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used.

[Example 26-2](#) assumes MEP step size of 150 ps and does not use the SFO library.

#### Example 26-2. #Defines for HRPWM Header Files

```
// HRPWM (High Resolution PWM) //
=====
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1 // Rising Edge position
#define HR_FEP 0x2 // Falling Edge position
#define HR_BEP 0x3 // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1 // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1 // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B 0x0 // Normal ePWMxB output
#define HR_INVERT_B 0x1 // ePWMxB is inverted ePWMxA output
```

### 26.15.1.8.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:

- PWM frequency = 1 MHz (that is, TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150 ps)

Figure 26-89 and Figure 26-90 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 26-89. Simple Buck Controlled Converter Using a Single PWM**

**Figure 26-90. PWM Waveform Generated for Simple Buck Controlled Converter**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

Example 26-3 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150 ps and does not use the SFO library.

Example 26-4 shows an assembly example of run-time code for the HRPWM buck converter.

### Example 26-3. HRPWM Buck Converter Initialization Code

```

void HrBuckDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;           // set Immediate load
EPwm1Regs.TBPRD = 100;                             // Period set for 1000 kHz PWM
hrbuck_period = 200;                                // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;           // EPWM1 is the Master

EPwm1Regs.EPWSYNCOUEN.all = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;      // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;       // optional
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;                // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;             // optional
// Now configure the HRPWM resources
EALLOW;                                           // Note these registers are protected
                                                    // and act only on ChA
EPwm1Regs.HRCNFG.all = 0x0;                       // clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;           // Control Falling Edge Position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;          // CMPAHR controls the MEP
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;      // Shadow load on CTR=Zero
EDIS;
MEP_ScaleFactor = 66*256;                         // Start with typical Scale Factor
                                                    // value for 100 MHz
                                                    // Note: Use SFO functions to update
                                                    // MEP_ScaleFactor dynamically
}

```

### Example 26-4. HRPWM Buck Converter Run-Time Code

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRBUCK_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, # HRBUCK_In
    MOVL XAR2,@_HRBUCK_In      ; Pointer to Input Q15 Duty (XAR2)
    MOVL XAR3,#CMPAHR1        ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM)
    MOV T,*XAR2 ; T <= Duty
    MPYU ACC,T,@_hrbuck_period ; Q15 to Q0 scaling based on Period
    MOV T,@_MEP_ScaleFactor   ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL              ; P <= T * AL, Optimizer scaling
    MOVH @AL,P                ; AL <= P, move result back to ACC
    ADD ACC, #0x080           ; MEP range and rounding adjustment
    MOVL *XAR3,ACC           ; CMPA: CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH         ; Store ACCH to regular CMPB

```

### 26.15.1.8.2 Implementing a DAC Function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400 kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150 ps)

Figure 26-91 and Figure 26-92 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 26-91. Simple Reconstruction Filter for a PWM-based DAC**

**Figure 26-92. PWM Waveform Generated for the PWM DAC Function**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP\_SP and does not use the SFO library.

Example 26-5 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

Example 26-6 shows an assembly example of run-time code that can execute in a high-speed ISR loop.

### Example 26-5. PWM DAC Function Initialization Code

```

void HrPwmDacDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;           // Set Immediate load
EPwm1Regs.TBPRD = 250;                             // Period set for 400 kHz PWM
hrDAC_period = 250;                                 // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;           // EPWM1 is the Master

EPwm1Regs.EPWSYNCOUTEN.all = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;    // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;     // optional

EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;              // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;           // optional
// Now configure the HRPWM resources
EALLOW;                                         // Note these registers are protected
                                                // and act only on ChA.
EPwm1Regs.HRCNFG.all = 0x0;                    // Clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;        // Control falling edge position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;        // CMPAHR controls the MEP.
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;    // Shadow load on CTR=Zero.
EDIS;
MEP_ScaleFactor = 66*256;                      // Start with typical Scale Factor
                                                // value for 100 MHz.
                                                // Use SFO functions to update MEP_ScaleFactor
                                                // dynamically.
}

```

### Example 26-6. PWM DAC Function Run-Time Code

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, # HRDAC_In
    MOVL XAR2,@_HRDAC_In           ; Pointer to input Q15 duty (XAR2)
    MOVL XAR3,#CMPAHR1           ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM)
    MOV T,*XAR2                   ; T <= duty
    MPY ACC,T,@_hrDAC_period      ; Q15 to Q0 scaling based on period
    ADD ACC,@_hrDAC_period<<15   ; Offset for bipolar operation
    MOV T,@_MEP_ScaleFactor       ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL                 ; P <= T * AL, optimizer scaling
    MOVH @AL,P                   ; AL <= P, move result back to ACC
    ADD ACC,#0x080               ; MEP range and rounding adjustment
    MOVL *XAR3,ACC               ; CMPA: CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH             ; Store ACCH to regular CMPB

```

## 26.15.2 SFO Library Software - SFO\_TI\_Build\_V8.lib

Table 26-19 lists several features of the SFO\_TI\_Build\_V8.lib library.

**Table 26-19. SFO Library Features**

	SFO_TI_Build_V8.lib	Unit
Completion-checking?	Yes	Function return value
Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts	130,000	EPWMCLK cycles

### 26.15.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100 MHz and assuming the MEP step size is 150 ps, the typical scale factor value at 100 MHz = 66 MEP steps per TBCLK unit (10 ns)

The function returns a MEP scale factor value:

MEP\_ScaleFactor = Number of MEP steps per EPWMCLK.

#### Constraints when using this function:

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50 MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50 MHz, with device process variation, the MEP step size may decrease under cold temperature and high core voltage conditions to such a point, that 255 MEP steps will not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module

#### Usage:

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated, or a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP\_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register will maintain the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3-EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see [Section 26.15.1.5.3](#)).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting CMPAHR =  $\text{fraction}(\text{PWMduty} \cdot \text{PWMperiod}) \ll 8$  or CMPBHR =  $\text{fraction}(\text{PWMduty} \cdot \text{PWMperiod}) \ll 8$  or TBPRDHR =  $\text{fraction}(\text{PWMperiod})$  while running SFO() in the background. The MEP Calibration Module will then use the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software will need to perform the necessary calculations manually so that:
  - $\text{CMPAHR} = (\text{fraction}(\text{PWMduty} \cdot \text{PWMperiod}) \cdot \text{MEP Scale Factor}) \ll 8 + 0x080$ .
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

The following snippet shows how to use the HRPWM DUTY using driverlib functions.

```
float32_t dutyFine = 85.62;
float32_t count = (dutyFine * (float32_t)(EPWM_TIMER_TBPRD << 8))/100;
uint32_t compCount = (count);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_A, compCount);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_B, compCount);
```

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore it is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution may have to be performed more frequently to match the application. Note, there is no high limit restriction on the SFO function repetition rate, hence it can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic will not be active for the first three EPWMCLK cycles of the PWM period (and the last three EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE=0]) and the CMPA/CMPB register value is less than three cycles, then its CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE=1]), the CMPA register value must not fall below three or above TBPRD-3. This would avoid any unexpected transitions on the PWM signal.

### 26.15.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP\_ScaleFactor. For example, see [Table 26-20](#).

**Table 26-20. Factor Values**

Software Function call	Functional Description	Updated Variables
SFO()	Returns MEP scale factor in the HRMSTEP register	MEP_ScaleFactor and HRMSTEP register.

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

#### Step 1. Add "Include" Files

The SFO\_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)\_Device.h and (Device)\_Epwm\_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

#### Example 26-7. A Sample of How to Add "Include" Files

```
#include "F28x7x_Device.h" // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h" // init defines
#include "SFO_V8.h" // SFO lib functions (needed for HRPWM)
```

## Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

### Example 26-8. Declaring an Element

```
int MEP_ScaleFactor = 0;    //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

## Step 3. MEP\_ScaleFactor Initialization

The SFO() function does not require a starting scale factor value in MEP\_ScaleFactor. Prior to using the MEP\_ScaleFactor variable in application code, SFO() should be called to drive the MEP calibration module to calculate an MEP\_ScaleFactor value.

As part of the one-time initialization code prior to using MEP\_ScaleFactor, include the following:

### Example 26-9. Initializing With a Scale Factor Value

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

## Step 4. Application Code

While the application is running, fluctuations in both device temperature and supply voltage may be expected. To be sure that optimal Scale Factors are used for each ePWM module, the SFO function should be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

### Note

See the HRPWM\_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

### Example 26-10. SFO Function Calls

```
main ()
{
    int status;
    // User code
    // ePWM1, 2, 3, 4 are running in HRPWM mode
    // The status variable returns 1 once a new MEP_ScaleFactor has been
    // calculated by the MEP Calibration Module running SFO
    // diagnostics.
    status = SFO();
    if(status==2) {ESTOP0;} // The function returns a 2 if MEP_ScaleFactor is greater
    // than the maximum 255 allowed (error condition)
}
```

## 26.16 Software

### 26.16.1 EPWM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/epwm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 26.16.1.1 ePWM Trip Zone

FILE: epwm\_ex1\_trip\_zone.c

This example configures ePWM1 and ePWM2 as follows

- ePWM1 has TZ1 as one shot trip source
- ePWM2 has TZ1 as cycle by cycle trip source

Initially tie TZ1 high. During the test, monitor ePWM1 or ePWM2 outputs on a scope. Pull TZ1 low to see the effect.

##### *External Connections*

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2
- TZ1 is on GPIO12

This example also makes use of the Input X-BAR. GPIO12 (the external trigger) is routed to the input X-BAR, from which it is routed to TZ1.

The TZ-Event is defined such that ePWM1A will undergo a One-Shot Trip and ePWM2A will undergo a Cycle-By-Cycle Trip.

#### 26.16.1.2 ePWM Up Down Count Action Qualifier

FILE: epwm\_ex2\_updown\_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce a waveform with independent modulation on ePWMxA and ePWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up/down count mode for this example.

View the ePWM1A/B(GPIO0 & GPIO1), ePWM2A/B(GPIO2 & GPIO3) and ePWM3A/B(GPIO4 & GPIO5) waveforms on oscilloscope.

#### 26.16.1.3 ePWM Synchronization

FILE: epwm\_ex3\_synchronization.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 without phase shift as sync source
- ePWM2 with phase shift of 300 TBCLKs
- ePWM3 with phase shift of 600 TBCLKs
- ePWM4 with phase shift of 900 TBCLKs

##### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

#### Watch Variables

- None.

#### 26.16.1.4 ePWM Digital Compare

FILE: epwm\_ex4\_digital\_compare.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TZ1, pull this pin low to trip the ePWM

#### Watch Variables

- None.

#### 26.16.1.5 ePWM Digital Compare Event Filter Blanking Window

FILE: epwm\_ex5\_digital\_compare\_event\_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the blanking window to ignore the DCBEVT1 for the duration of DC Blanking window

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1, pull this pin low to trip the ePWM

#### Watch Variables

- None.

#### 26.16.1.6 ePWM Valley Switching

FILE: epwm\_ex6\_valley\_switching.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the valley switching module to delay the

- DCFILT signal by a software defined DELAY value.

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

#### *Watch Variables*

- None.

### **26.16.1.7 ePWM Digital Compare Edge Filter**

FILE: epwm\_ex7\_edge\_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCBEVT2 forcing the ePWM output LOW as a CBC source
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCBEVT2
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- The DCBEVT2 is the source for DCFILT
- The DCFILT will count edges of the DCBEVT2 and generate a signal to trip the ePWM on the 4th edge of DCBEVT2

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

#### *Watch Variables*

- None.

### **26.16.1.8 ePWM Deadband**

FILE: epwm\_ex8\_deadband.c

This example configures ePWM1 through ePWM6 as follows

- ePWM1 with Deadband disabled (Reference)
- ePWM2 with Deadband Active High
- ePWM3 with Deadband Active Low
- ePWM4 with Deadband Active High Complimentary
- ePWM5 with Deadband Active Low Complimentary
- ePWM6 with Deadband Output Swap (switch A and B outputs)

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B
- GPIO8 EPWM5A
- GPIO9 EPWM5B
- GPIO10 EPWM6A
- GPIO11 EPWM6B

#### *Watch Variables*

- None.

### 26.16.1.9 ePWM DMA

FILE: epwm\_ex9\_dma.c

This example configures ePWM1 and DMA as follows:

- ePWM1 is set up to generate PWM waveforms
- DMA5 is set up to update the CMPAHR, CMPA, CMPBHR and CMPB every period with the next value in the configuration array. This allows the user to create a DMA enabled fifo for all the CMPx and CMPxHR registers to generate unconventional PWM waveforms.
- DMA6 is set up to update the TBPHSHR, TBPHS, TBPRDHR and TBPRD every period with the next value in the configuration array.
- Other registers such as AQCTL can be controlled through the DMA as well by following the same procedure. (Not used in this example)

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B

#### Watch Variables

- None.

### 26.16.1.10 ePWM Chopper

FILE: epwm\_ex10\_chopper.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 with Chopper disabled (Reference)
- ePWM2 with chopper enabled at 1/8 duty cycle
- ePWM3 with chopper enabled at 6/8 duty cycle
- ePWM4 with chopper enabled at 1/2 duty cycle with One-Shot Pulse enabled

#### External Connections

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

#### Watch Variables

- None.

### 26.16.1.11 EPWM Configure Signal

FILE: epwm\_ex11\_configure\_signal.c

This example configures ePWM1, ePWM2, ePWM3 to produce signal of desired frequency and duty. It also configures phase between the configured modules.

Signal of 10kHz with duty of 0.5 is configured on ePWMxA & ePWMxB with ePWMxB inverted. Also, phase of 120 degree is configured between ePWM1 to ePWM3 signals.

During the test, monitor ePWM1, ePWM2, and/or ePWM3 outputs on an oscilloscope.

- ePWM1A is on GPIO0
- ePWM1B is on GPIO1
- ePWM2A is on GPIO2
- ePWM2B is on GPIO3
- ePWM3A is on GPIO4

- ePWM3B is on GPIO5

### 26.16.1.12 Realization of Monoshot mode

FILE: epwm\_ex12\_monoshot\_mode.c

This example showcases how to generate monoshot PWM output based on external trigger, that is, generating just a single pulse output on receipt of an external trigger. And the next pulse will be generated only when the next trigger comes. The example utilizes external synchronization and T1 action qualifier event features to achieve the desired output.

ePWM1 is used to generate the monoshot output and ePWM2 is used as an external trigger for that. No external connections are required as ePWM2A is fed as the trigger using Input X-BAR automatically.

ePWM1 is configured to generate a single pulse of 0.5us when received an external trigger. This is achieved by enabling the phase synchronization feature and configuring EPWMxSYNCl as EXTSYNCIN1. And this EPWMxSYNCl is also configured as T1 event of action qualifier to set output HIGH while "CTR = PRD" action is used to set output LOW.

ePWM2 is configured to generate a 100 KHz signal with a duty of 1% (to simulate a rising edge trigger) which is routed to EXTSYNCIN1 using Input XBAR.

Observe GPIO0 (EPWM1A : Monoshot Output) and GPIO2 (EPWM2 : External Trigger) on oscilloscope.

*NOTE* : In the following example, the ePWM timer is still running in a continuous mode rather than a one-shot mode thus for more reliable implementation, refer to CLB based one shot PWM implementation demonstrated in "clb\_ex17\_one\_shot\_pwm" example

### 26.16.1.13 EPWM Action Qualifier (epwm\_up\_aq)

FILE: epwm\_ex13\_up\_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce an waveform with independent modulation on EPWMxA and EPWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up count mode for this example.

View the EPWM1A/B(GPIO0 & GPIO1), EPWM2A/B(GPIO2 & GPIO3) and EPWM3A/B(GPIO4 & GPIO5) waveforms via an oscilloscope.

## 26.16.2 HRPWM Examples

*NOTE*: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/hrpwm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

### 26.16.2.1 HRPWM Duty Control with SFO

FILE: hrpwm\_ex1\_duty\_sfo.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int* SFO();

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

#### *External Connections*

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### **26.16.2.2 HRPWM Slider**

FILE: hrpwm\_ex2\_slider.c

This example modifies the MEP control registers to show edge displacement due to HRPWM. Control blocks of the respective ePWM module channel A and B will have fine edge movement due to HRPWM logic.

Monitor ePWM1 A/B pins on an oscilloscope.

#### **26.16.2.3 HRPWM Period Control**

FILE: hrpwm\_ex3\_prd\_updown\_sfo.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

#### *External Connections*

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### **26.16.2.4 HRPWM Duty Control with UPDOWN Mode**

FILE: hrpwm\_ex4\_duty\_updown\_sfo.c

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

#### *External Connections*

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### **26.16.2.5 HRPWM Slider Test**

FILE: hrpwm\_ex5\_slider\_qformat.c

This example modifies the MEP control registers to show edge displacement due to HRPWM. Control blocks of the respective ePWM module channel A and B will have fine edge movement due to HRPWM logic. Load the hrpwm\_slider.gel file. Select the HRPWM\_eval from the GEL menu. A FineDuty slider graphics will show up in

CCS. Load the program and run. Use the Slider to and observe the EPWM edge displacement for each slider step change. This explains the MEP control on the EPwmxA channels.

Monitor ePWM1 & ePWM2 A/B pins on an oscilloscope.

### **26.16.2.6 HRPWM Duty Up Count**

FILE: hrpwm\_ex6\_duty\_sfo\_qformat.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

To run this example:

1. Run this example at maximum SYSCLKOUT
2. Activate Real time mode
3. Run the code

#### *External Connections*

- Monitor ePWM1/2 A/B pins on an oscilloscope.

#### *Watch Variables*

- status - Example run status
- updateFine - Set to 1 use HRPWM capabilities and observe in fine MEP steps(default) Set to 0 to disable HRPWM capabilities and observe in coarse SYSCLKOUT cycle steps

### **26.16.2.7 HRPWM Period Up-Down Count**

FILE: hrpwm\_ex7\_prd\_updown\_sfo\_qformat.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

To run this example:

1. Run this example at maximum SYSCLKOUT
2. Activate Real time mode
3. Run the code

### External Connections

- Monitor ePWM1/2 A/B pins on an oscilloscope.

### Watch Variables

- updateFine - Set to 1 use HRPWM capabilities and observe in fine MEP steps(default) Set to 0 to disable HRPWM capabilities and observe in coarse SYSCLKOUT cycle steps

## 26.17 ePWM Registers

This section describes the Enhanced Pulse Width Modulator registers.

### 26.17.1 EPWM Base Address Table (C28)

**Table 26-21. EPWM Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
EPwm1Regs	EPWM_REGS	EPWM1_BASE	0x0000_4000	YES	YES	YES	YES	YES

Complex bit access types are encoded to fit into small table cells. [Table 26-23](#) shows the codes that are used for access types in this section.

**Table 26-23. EPWM\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Write once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 26.17.2.1 TBCTL Register (Offset = 0h) [Reset = 83h]

TBCTL is shown in [Figure 26-90](#) and described in [Table 26-24](#).

Return to the [Summary Table](#).

Time Base Control Register

**Figure 26-93. TBCTL Register**

15	14	13	12	11	10	9	8
FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV	
R/W-0h		R/W-0h	R/W-0h			R/W-1h	
7	6	5	4	3	2	1	0
HSPCLKDIV	SWFSYNC	RESERVED		PRDL	PHSEN	CTRMODE	
R/W-1h	R-0/W1S-0h	R-0h		R/W-0h	R/W-0h	R/W-3h	

**Table 26-24. TBCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events 00: Stop after the next time-base counter increment or decrement 01: Stop when counter completes a whole cycle: - Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) - Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) - Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) 1x: Free run Reset type: SYSRSn
13	PHSDIR	R/W	0h	Phase Direction Bit This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event. In the up-count and down-count modes this bit is ignored. 0: Count down after the synchronization event. 1: Count up after the synchronization event. Reset type: SYSRSn
12-10	CLKDIV	R/W	0h	Time Base Clock Pre-Scale Bits These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV): 000: /1 (default on reset) 001: /2 010: /4 011: /8 100: /16 101: /32 110: /64 111: /128 Reset type: SYSRSn

**Table 26-24. TBCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time Base Clock Pre-Scale Bits These bits determine part of the time-base clock prescale value. $TBCLK = EPWMCLK / (HSPCLKDIV \times CLKDIV)$ . This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 000: /1 001: /2 (default on reset) 010: /4 011: /6 100: /8 101: /10 110: /12 111: /14 Reset type: SYSRSn
6	SWFSYNC	R-0/W1S	0h	Software Forced Sync Pulse 0: Writing a 0 has no effect and reads always return a 0. 1: Writing a 1 forces a one-time synchronization pulse to be generated. SWFSYNC can be enabled to affect EPWMxSYNCO by setting the EPWMSYNCOOUTEN.SWEN bit. Reset type: SYSRSn
5-4	RESERVED	R	0h	Reserved
3	PRDL	R/W	0h	Active Period Reg Load from Shadow Select 0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. A write/read to the TBPRD register accesses the shadow register. 1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register. Reset type: SYSRSn
2	PHSEN	R/W	0h	Counter Reg Load from Phase Reg Enable 0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS). 1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCl input signal occurs or a software-forced sync signal, see bit 6. Reset type: SYSRSn
1-0	CTRM	R/W	3h	Counter Mode The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 00: Up-count mode 01: Down-count mode 10: Up-down count mode 11: Freeze counter operation (default on reset) Reset type: SYSRSn

### 26.17.2.2 TBCTL2 Register (Offset = 1h) [Reset = 0h]

TBCTL2 is shown in [Figure 26-91](#) and described in [Table 26-25](#).

Return to the [Summary Table](#).

Time Base Control Register 2

3-2	LOADDMODE	R/W	0h	Active Counter-Compare D (CMPD) Load from Shadow Select Mode 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Freeze (no loads possible) Note: Has no effect in Immediate mode. Reset type: SYSRSn
1-0	LOADCMODE	R/W	0h	Active Counter-Compare C (CMPC) Load from Shadow Select Mode 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Freeze (no loads possible) Note: Has no effect in Immediate mode. Reset type: SYSRSn

### 26.17.2.10 DBCTL Register (Offset = Ch) [Reset = 0h]

DBCTL is shown in [Figure 26-99](#) and described in [Table 26-33](#).

Return to the [Summary Table](#).

Dead-Band Generator Control Register

**Figure 26-102. DBCTL Register**

15	14	13	12	11	10	9	8
HALFCYCLE	DEDB_MODE	OUTSWAP		SHDWDBFED MODE	SHDWDBRED MODE	LOADFEDMODE	
R/W-0h	R/W-0h	R/W-0h		R/W-0h	R/W-0h	R/W-0h	
7	6	5	4	3	2	1	0
LOADREDMODE		IN_MODE		POLSEL		OUT_MODE	
R/W-0h		R/W-0h		R/W-0h		R/W-0h	

**Table 26-33. DBCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit 0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2. Reset type: SYSRSn
14	DEDB_MODE	R/W	0h	Dead Band Dual-Edge B Mode Control (S8 switch) 0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only. 1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath otherwise, OutA will be invalid. Reset type: SYSRSn
13-12	OUTSWAP	R/W	0h	Dead Band Output Swap Control Bit 13 controls the S6 switch and bit 12 controls the S7 switch. 00: OutA and OutB signals are as defined by OUT-MODE bits. 01: OutA = A-path as defined by OUT-MODE bits. OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). 10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = B-path as defined by OUT-MODE bits. 11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). Reset type: SYSRSn
11	SHDWDBFEDMODE	R/W	0h	FED Dead-Band Load Mode 0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate "FED dead-band action." 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn

**Table 26-33. DBCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	SHDWDBREDMODE	R/W	0h	RED Dead-Band Load Mode 0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate "RED dead-band action." 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn
9-8	LOADFEDMODE	R/W	0h	Active DBFED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
7-6	LOADREDMODE	R/W	0h	Active DBRED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
5-4	IN_MODE	R/W	0h	Dead-Band Input Mode Control Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal. Reset type: SYSRSn
3-2	POLSEL	R/W	0h	Polarity Select Control Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes. 00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 01: Active low complementary (ALC) mode. EPWMxA is inverted. 10: Active high complementary (AHC). EPWMxB is inverted. 11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted. Reset type: SYSRSn

**Table 26-33. DBCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	OUT_MODE	R/W	0h	Dead-Band Output Mode Control Bit 1 controls the S1 switch and bit 0 controls the S0 switch. 00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect. 01: Apath = InA (delay is by-passed for A signal path) Bpath = FED (Falling Edge Delay in B signal path) 10: Apath = RED (Rising Edge Delay in A signal path) Bpath = InB (delay is by-passed for B signal path) 11: DBM is fully enabled (i.e. both RED and FED active) Reset type: SYSRSn

### 26.17.2.11 DBCTL2 Register (Offset = Dh) [Reset = 0h]

DBCTL2 is shown in [Figure 26-100](#) and described in [Table 26-34](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
15-14	RESERVED	R/W	0h	Reserved
13	RESERVED	R	0h	Reserved
12-11	HRLOADB	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPBHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Reserved Reset type: SYSRSn
10	CTLMODEB	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPBHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
9-8	EDGMODEB	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPBHR) 10: MEP control of falling edge (CMPBHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn
7	SWAPAB	R/W	0h	Swap ePWM A & B Output Signals This bit enables the swapping of the A & B signal outputs. The selection is as follows: 0: ePWMxA and ePWMxB outputs are unchanged. 1: ePWMxA signal appears on ePWMxB output and ePWMxB signal appears on ePWMxA output. Reset type: SYSRSn

**Table 26-40. HRCNFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	AUTOCONV	R/W	0h	Auto Convert Delay Line Value Selects whether the fractional duty cycle/period/phase in the CMPAHR/TBPRDHR/TBPHSHR register is automatically scaled by the MEP scale factor in the HRMSTEP register or manually scaled by calculations in application software. The SFO library function automatically updates the HRMSTEP register with the appropriate MEP scale factor. 0: Automatic HRMSTEP scaling is disabled. 1: Automatic HRMSTEP scaling is enabled. If application software is manually scaling the fractional duty cycle, or phase (i.e. software sets CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor) << 8 + 0x080 for duty cycle), then this mode must be disabled. Reset type: SYSRSn
5	SELOUTB	R/W	0h	EPWMxB Output Select Bit This bit selects which signal is output on the ePWMxB channel output. The inversion will take the high resolution mode into account and the inverted signal will contain any high resolution modification. The inversion takes place as the last step in modifying the ePWMxB signal. 0: ePWMxB output is normal. 1: ePWMxB output is inverted version of ePWMxA signal. Reset type: SYSRSn
4-3	HRLOAD	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPAHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Reserved Reset type: SYSRSn
2	CTLMODE	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPAHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
1-0	EDGMODE	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPAHR) 10: MEP control of falling edge (CMPAHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn

### 26.17.2.18 HRPWR Register (Offset = 21h) [Reset = 0h]

HRPWR is shown in [Figure 26-107](#) and described in [Table 26-41](#).

Return to the [Summary Table](#).

HRPWM Power Register

This register is only accessible on EPWM modules with HRPWM capabilities.

**Table 26-44. HRPCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-4	PWMSYNCSELX	R/W	0h	Extended selection bits for EPWMSYNCPER 000: EPWMSYNCPER is defined by PWMSYNCSEL - > default condition (compatible with previous EPWM versions) 001: Reserved 010: Reserved 011: Reserved 100: CTR = CMPC, Count direction Up 101: CTR = CMPC, Count direction Down 110: CTR = CMPD, Count direction Up 111: CTR = CMPD, Count direction Down Reset type: SYSRSn
3	RESERVED	R/W	0h	Reserved
2	TBPHSHRLOADE	R/W	0h	TBPHSHR Load Enable This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution. 0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event: 1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PHSEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature. This bit and the TBCTL[PHSEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled. Reset type: SYSRSn
1	PWMSYNCSEL	R/W	0h	PWMSYNC Source Select Bit: This bit selects the source for the EPWMSYNCPER signal that goes to the CMPSS and GPDAC: 0 CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 1 CTR = zero: Time-base counter equal to zero (TBCTR = 0x00) Reset type: SYSRSn

**Table 26-44. HRPCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	HRPE	R/W	0h	High Resolution Period Enable Bit 0: High resolution period feature disabled. In this mode the ePWM behaves as a Type 4 ePWM. 1: High resolution period enabled. In this mode the HRPWM module can control high-resolution of both the duty and frequency. When high-resolution period is enabled, TBCTL[CTRMODE] = 0,1 (down-count mode) is not supported. Reset type: SYSRSn

### 26.17.2.22 TRREM Register (Offset = 2Eh) [Reset = 0h]

TRREM is shown in [Figure 26-111](#) and described in [Table 26-45](#).

Return to the [Summary Table](#).

HRPWM High Resolution Remainder Register

This register is only accessible on EPWM modules with HRPWM capabilities.

**Figure 26-114. TRREM Register**

### 26.17.2.25 EPWMXLINK Register (Offset = 38h) [Reset = X]

EPWMXLINK is shown in [Figure 26-114](#) and described in [Table 26-48](#).

Return to the [Summary Table](#).

#### EPWMx Link Register

This register controls which EPWMs are linked to other EPWM modules. The default reset value will vary for each module. The reset value will link each EPWM module to itself to prevent unintentional linking of modules.

**Figure 26-117. EPWMXLINK Register**

### 26.17.2.36 TBPHS Register (Offset = 60h) [Reset = 0h]

TBPHS is shown in [Figure 26-125](#) and described in [Table 26-59](#).

Return to the [Summary Table](#).

Time Base Phase High

**Figure 26-128. TBPHS Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TBPHS																TBPHSHR															
R/W-0h																R/W-0h															

**Table 26-59. TBPHS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	TBPHS	R/W	0h	Phase Offset Register These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. - If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. - If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization. Reset type: SYSRSn
15-0	TBPHSHR	R/W	0h	Phase Offset (High Resolution) Register. TBPHSHR must not be used. Instead TRREM (HRPWM remainder register) must be used to mimic the functionality of TBPHSHR. The lower 8 bits in this register are ignored - writes are ignored and reads return zero Reset type: SYSRSn

**26.17.2.37 TBPRDHR Register (Offset = 62h) [Reset = 0h]**

TBPRDHR is shown in [Figure 26-126](#) and described in [Table 26-60](#).

Return to the [Summary Table](#).

TBPRDHR							
R/W-0h							
7	6	5	4	3	2	1	0
TBPRDHR							
R/W-0h							

**Table 26-60. TBPRDHR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	TBPRDHR	R/W	0h	Period High Resolution Bits The upper 8-bits contain the high-resolution portion of the period value. The TBPRDHR register is not affected by the TBCTL[PRDL] bit. Reads from this register always reflect the shadow register. Likewise writes are also to the shadow register. The TBPRDHR register is only used when the high resolution period feature is enabled. This register is only available with ePWM modules which support high-resolution period control. The lower 8 bits in this register are ignored - writes are ignored and reads return zero Reset type: SYSRSn

### 26.17.2.38 TBPRD Register (Offset = 63h) [Reset = 0h]

TBPRD is shown in [Figure 26-127](#) and described in [Table 26-61](#).

Return to the [Summary Table](#).

Time Base Period Register

**Figure 26-130. TBPRD Register**

15	14	13	12	11	10	9	8
TBPRD							
R/W-0h							
7	6	5	4	3	2	1	0
TBPRD							
R/W-0h							

**Table 26-61. TBPRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	Time Base Period Register These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDL] bit. By default this register is shadowed. - If TBCTL[PRDL] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. - If TBCTL[PRDL] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - The active and shadow registers share the same memory map address. Reset type: SYSRSn

### 26.17.2.39 CMPA Register (Offset = 6Ah) [Reset = 0h]

CMPA is shown in [Figure 26-128](#) and described in [Table 26-62](#).

Return to the [Summary Table](#).

Counter Compare A Register

**Figure 26-131. CMPA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPA																CMPAHR															
R/W-0h																R/W-0h															

**Table 26-62. CMPA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	CMPA	R/W	0h	<p>Compare A Register</p> <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>- Do nothing</li> <li>the event is ignored.</li> <li>- Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>- Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>- Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>- If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.</li> <li>- Before a write, the CMPCTL[SHDWFULL] bit can be read to determine if the shadow register is currently full.</li> <li>- If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>- In either mode, the active and shadow registers share the same memory map address.</li> </ul> <p>Reset type: SYSRSn</p>
15-0	CMPAHR	R/W	0h	<p>Compare A HRPWM Extension Register</p> <p>The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register.</p> <p>The lower 8 bits in this register are ignored</p> <p>Reset type: SYSRSn</p>

### 26.17.2.40 CMPB Register (Offset = 6Ch) [Reset = 0h]

CMPB is shown in [Figure 26-129](#) and described in [Table 26-63](#).

Return to the [Summary Table](#).

Compare B Register

**Figure 26-132. CMPB Register**

RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED						GFRCLD	OSHTLD
R-0h						R-0/W1S-0h	R-0/W1S-0h

**Table 26-66. GLDCTL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	GFRCLD	R-0/W1S	0h	Force Load Event in One Shot Mode 0: Writing of 0 will be ignored. Always reads back a 0. 1: Force one load event at the input of the event pre-scale counter as shown in the diagram below. This bit is intended to be used for testing and/or software force loading of the events in global load mode. Reset type: SYSRSn
0	OSHTLD	R-0/W1S	0h	Enable Reload Event in One Shot Mode 0: Writing of 0 will be ignored. Always reads back a 0. 1: Turns the one shot latch condition ON. Upon occurrence of a chosen load strobe, one shadow to active reload occurs and the latch will be cleared. Hence writing 1 to this bit would allow one load strobe event to pass through and block further strobe events. Reset type: SYSRSn

#### 26.17.2.44 SWVDELVAL Register (Offset = 77h) [Reset = 0h]

SWVDELVAL is shown in [Figure 26-133](#) and described in [Table 26-67](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	DCBEVT2	R	0h	Latched Status Flag for Digital Compare Output B Event 2 0: Indicates no trip event has occurred on DCBEVT2 1: Indicates a trip event has occurred for the event defined for DCBEVT2 Reset type: SYSRSn
5	DCBEVT1	R	0h	Latched Status Flag for Digital Compare Output B Event 1 0: Indicates no trip event has occurred on DCBEVT1 1: Indicates a trip event has occurred for the event defined for DCBEVT1 Reset type: SYSRSn
4	DCAEVT2	R	0h	Latched Status Flag for Digital Compare Output A Event 2 0: Indicates no trip event has occurred on DCAEVT2 1: Indicates a trip event has occurred for the event defined for DCAEVT2 Reset type: SYSRSn
3	DCAEVT1	R	0h	Latched Status Flag for Digital Compare Output A Event 1 0: Indicates no trip event has occurred on DCAEVT1 1: Indicates a trip event has occurred for the event defined for DCAEVT1 Reset type: SYSRSn
2	OST	R	0h	Latched Status Flag for A One-Shot Trip Event 0: No one-shot trip event has occurred. 1: Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn
1	CBC	R	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0: No cycle-by-cycle trip event has occurred. 1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

**Table 26-75. TZFLG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	INT	R	0h	Latched Trip Interrupt Status Flag 0: Indicates no interrupt has been generated. 1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition. No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

### 26.17.2.53 TZCBCFLG Register (Offset = 94h) [Reset = 0h]

TZCBCFLG is shown in [Figure 26-142](#) and described in [Table 26-76](#).

Return to the [Summary Table](#).

RESERVED												SHDWMODE		CAPE	
R-0h												R/W-0h		R/W-0h	

**Table 26-95. DCCAPCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	CAPMODE	R/W	0h	<p>Counter Capture Mode</p> <p>0: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs, further trip (capture) events are ignored until the next PRD_eq or CNT_zero event (as selected by the PULSESEL bit in the DCFCTL register) re-triggers the capture mechanism.</p> <p>If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value.</p> <p>If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value.</p> <p>1: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs - it will set the CAPSTS flag and further trip (capture) events are ignored until this bit is cleared. CAPSTS can be cleared by writing to CAPCLR bit in DCCAPCTL register and it re-triggers the capture mechanism.</p> <p>If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value.</p> <p>If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value.</p> <p>Reset type: SYSRSn</p>
14	CAPCLR	R-0/W1S	0h	<p>DC Capture Latched Status Clear Flag</p> <p>0: Writing a 0 has no effect.</p> <p>1: Writing a 1 will clear this CAPSTS (set) condition.</p> <p>Reset type: SYSRSn</p>
13	CAPSTS	R	0h	<p>Latched Status Flag for Capture Event</p> <p>0: No DC capture event occurred.</p> <p>1: A DC capture event has occurred.</p> <p>Reset type: SYSRSn</p>
12-2	RESERVED	R	0h	Reserved

**Table 26-95. DCCAPCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	SHDWMODE	R/W	0h	TBCTR Counter Capture Shadow Select Mode 0: Enable shadow mode. The DCCAP active register is copied to shadow register on a TBCTR = TBPRD or TBCTR = zero event as defined by the DCFCTL[PULSESEL] bit. CPU reads of the DCCAP register will return the shadow register contents. 1: Active Mode. In this mode the shadow register is disabled. CPU reads from the DCCAP register will always return the active register contents. Reset type: SYSRSn
0	CAPE	R/W	0h	TBCTR Counter Capture Enable/Disable 0: Disable the time-base counter capture. 1: Enable the time-base counter capture. Reset type: SYSRSn

### 26.17.2.73 DCFOFFSET Register (Offset = C9h) [Reset = 0h]

DCFOFFSET is shown in [Figure 26-162](#) and described in [Table 26-96](#).

Return to the [Summary Table](#).

Digital Compare Filter Offset Register

**Figure 26-165. DCFOFFSET Register**

15	14	13	12	11	10	9	8
DCFOFFSET							
R/W-0h							
7	6	5	4	3	2	1	0
DCFOFFSET

**Table 26-96. DCFOFFSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DCFOFFSET	R/W	0h	<p>Blanking Window Offset</p> <p>These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted.</p> <p>Reset type: SYSRSn</p>

### 26.17.2.74 DCFOFFSETCNT Register (Offset = CAh) [Reset = 0h]

DCFOFFSETCNT is shown in [Figure 26-163](#) and described in [Table 26-97](#).

Return to the [Summary Table](#).

Digital Compare Filter Offset Counter Register

**Figure 26-166. DCFOFFSETCNT Register**

15	14	13	12	11	10	9	8
DCFOFFSETCNT							
R-0h							
7	6	5	4	3	2	1	0
DCFOFFSETCNT							
R-0h							

**Table 26-97. DCFOFFSETCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DCFOFFSETCNT	R	0h	Blanking Offset Counter These 16-bits are read only and indicate the current value of the offset counter. The counter counts down to zero and then stops until it is re-loaded on the next period or zero event as defined by the DCCTL[PULSESEL] bit. The offset counter is not affected by the free/soft emulation bits. That is, it will always continue to count down if the device is halted by a emulation stop. Reset type: SYSRSn

### 26.17.2.75 DCFWINDOW Register (Offset = CBh) [Reset = 0h]

DCFWINDOW is shown in [Figure 26-164](#) and described in [Table 26-98](#).

Return to the [Summary Table](#).

Digital Compare Filter Window Register

**Figure 26-167. DCFWINDOW Register**

**Table 26-107. VCNTVAL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	VCNTVAL	R	0h	Valley Time Base Counter Register This register reflects the captured VCNT value upon occurrence of STOPENGE selected in VCNTCFG register. Reset type: SYSRSn

### 26.17.3 SYNC\_SOC\_REGS Registers

Table 26-108 lists the memory-mapped registers for the SYNC\_SOC\_REGS registers. All register offset addresses not listed in Table 26-108 should be considered as reserved locations and the register contents should not be modified.

**Table 26-108. SYNC\_SOC\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SYNCSELECT	Sync Input and Output Select Register	EALLOW	<a href="#">Go</a>
2h	ADCSOCOUTSELECT	External ADC (Off Chip) SOC Select Register	EALLOW	<a href="#">Go</a>
4h	SYNCSOCLOCK	SYNCSEL and EXTADCSOC Select Lock register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 26-109 shows the codes that are used for access types in this section.

**Table 26-109. SYNC\_SOC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 26.17.3.1 SYNCSELECT Register (Offset = 0h) [Reset = 0h]

SYNCSELECT is shown in [Figure 26-174](#) and described in [Table 26-110](#).

## Enhanced Quadrature Encoder Pulse (eQEP)

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type 2 eQEP. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

## 27.1 Introduction

An incremental encoder disk is patterned with a track of slots along its periphery, as shown in Figure 27-1. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

Figure 27-1. Optical Encoder Disk

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and conversely, as shown in Figure 27-2.

Figure 27-2. QEP Encoder Output Signal for Forward/Reverse Movement

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 kHz, so

by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 27-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 27-3. Index Pulse Example

Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \quad (12)$$

$$v(k) \approx \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (13)$$

where:

- $v(k)$  = Velocity at time instant  $k$
- $x(k)$  = Position at time instant  $k$
- $x(k-1)$  = Position at time instant  $k-1$
- $T$  = Fixed unit time or inverse of velocity calculation rate
- $\Delta X$  = Incremental position movement in unit time
- $t(k)$  = Time instant " $k$ "
- $t(k-1)$  = Time instant " $k-1$ "
- $X$  = Fixed unit position
- $\Delta T$  = Incremental time elapsed for unit position movement

Equation 12 is the conventional approach to velocity estimation and it requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on [Equation 12](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 13](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 13](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does [Equation 12](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 13](#) at low speed and have the DSP software switch over to [Equation 12](#) when the motor speed rises above some specified threshold.

## 27.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured via the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode should not be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 27.3 Description

This section provides the eQEP inputs, memory map, and functional description.

### 27.3.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYSCLK prior to entering the module. The application code should enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- **QEPA/XCLK and QEPB/XDIR**

These two pins can be used in quadrature-clock mode or direction-count mode.

- Quadrature-clock Mode

The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase.

This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and conversely. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

- Direction-count Mode

In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- **QEPI: Index or Zero Marker**

The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- **QEPS: Strobe Input**

This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

Input signals to the eQEP (QEPA, QEPB, QEPI and QEPS) can come from multiple sources; that is, device pin, CMPSSx, or PWMXBARx. One typical used case is if SinCos transducers are used in the motor control system to estimate the position of motor shaft and Index signal is coming from traditional rotary encoder, source of the eQEP signals (QEPA, QEPB and QEPI) can be configured as output of CMPSSx which decodes the Sin, Cos and Index signals. [Figure 27-4](#) illustrates the use case.

Selection of the source of Input signals (QEPA, QEPB, and QEPI) is user-configurable through the QEPSRCSEL register as shown in [Table 27-1](#).

Figure 27-4. Using eQEP to Decode Signals from SinCos Transducer

**Table 27-1. eQEP Input Source Select Table**

QEPSRCSEL. QEPASEL	Source for QEPA	QEPSRCSEL. QEPBSEL	Source for QEPB	QEPSRCSEL. QEPISEL	Source for QEPI
0	Device Pin	0	Device Pin	0	Device Pin
1	CMPSS1.CTRIPH	1	CMPSS1.CTRIPH	1	CMPSS1.CTRIPH
2	CMPSS2.CTRIPH	2	CMPSS2.CTRIPH	2	CMPSS2.CTRIPH
3	CMPSS3.CTRIPH	3	CMPSS3.CTRIPH	3	CMPSS3.CTRIPH
4	CMPSS4.CTRIPH	4	CMPSS4.CTRIPH	4	CMPSS4.CTRIPH

12	PWMXBAR.4	12	PWMXBAR.4	12	PWMXBAR.4
13	PWMXBAR.5	13	PWMXBAR.5	13	PWMXBAR.5
14	PWMXBAR.6	14	PWMXBAR.6	14	PWMXBAR.6
15	PWMXBAR.7	15	PWMXBAR.7	15	PWMXBAR.7

**Note**

Configuration of QEPSRCSEL register to select the source of QEPA, QEPB, and QEPI signals can lead to unexpected transition on these signals, which can cause an undesirable outcome if eQEP is already running. You need to make sure that the eQEP is disabled before configuring the QEPSRCSEL register for input signals.

### 27.3.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 27-5):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)
- Quadrature Mode Adapter (QMA)

## 27.4 Quadrature Decoder Unit (QDU)

Figure 27-6 shows a functional block diagram of the QDU.

Figure 27-6. Functional Block Diagram of Decoder Unit

### 27.4.1 Position Counter Input Modes

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode

- DOWN-count mode

**27.4.1.1 Quadrature Count Mode**

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

**Direction Decoding**

The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. Table 27-3 and Figure 27-7 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 27-8 shows the direction decoding and clock generation from the eQEP input signals.

**Table 27-3. Quadrature Decoder Truth Table**

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment
	QB↓	DOWN	Decrement
	QA↓	TOGGLE	Increment or Decrement
QA↓	QB↓	UP	Increment
	QB↑	DOWN	Decrement
	QA↑	TOGGLE	Increment or Decrement
QB↑	QA↑	DOWN	Decrement
	QA↓	UP	Increment
	QB↓	TOGGLE	Increment or Decrement
QB↓	QA↓	DOWN	Decrement
	QA↑	UP	Increment
	QB↑	TOGGLE	Increment or Decrement

**Figure 27-7. Quadrature Decoder State Machine**

**Figure 27-8. Quadrature-clock and Direction Decoding**

**Phase Error Flag** In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOSCNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 27-7](#) are invalid transitions that generate a phase error.

**Count Multiplication** The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 27-8](#).

**Reverse Count** In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder, thereby reversing the counting direction.

#### 27.4.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for the position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

### 27.4.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by a factor of 2x. In up-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

### 27.4.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

### 27.4.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit will invert the index input.

### 27.4.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

## 27.5 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

### 27.5.1 Position Counter Operating Modes

Position-counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after "0". The Interrupt flag is set to indicate overflow/underflow in QFLG register.

### 27.5.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM]=00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOS MAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in [Figure 27-9](#).

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to '00' or '11' when pcr=0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOS LAT register on every index marker.

**Figure 27-9. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or 0xF9F)**

#### Note

In case of a boundary condition where the time period between the Index Event and the previous QCLK edge is less than SYSCLK period, then QPOSCNT gets reset to zero or QPOS MAX in the same SYSCLK cycle and does not wait for the next QCLK edge to occur.

### 27.5.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 27-10 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

Figure 27-10. Position Counter Underflow/Overflow (QPOSMAX = 4)

### 27.5.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 27.5.1.2.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

#### **27.5.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)**

In this mode, QPOSCNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

#### **27.5.2 Position Counter Latch**

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

##### **27.5.2.1 Index Event Latch**

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

##### **Latch on Rising Edge (QEPCTL[IEL]=01)**

The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

##### **Latch on Falling Edge (QEPCTL[IEL] = 10)**

The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

##### **Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)**

The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

Figure 27-11 shows the position counter latch using an index event marker.

Figure 27-11. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)

### 27.5.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction, and on the falling edge of the strobe input for reverse direction as shown in Figure 27-12.

The strobe event latch interrupt flag (QLFG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

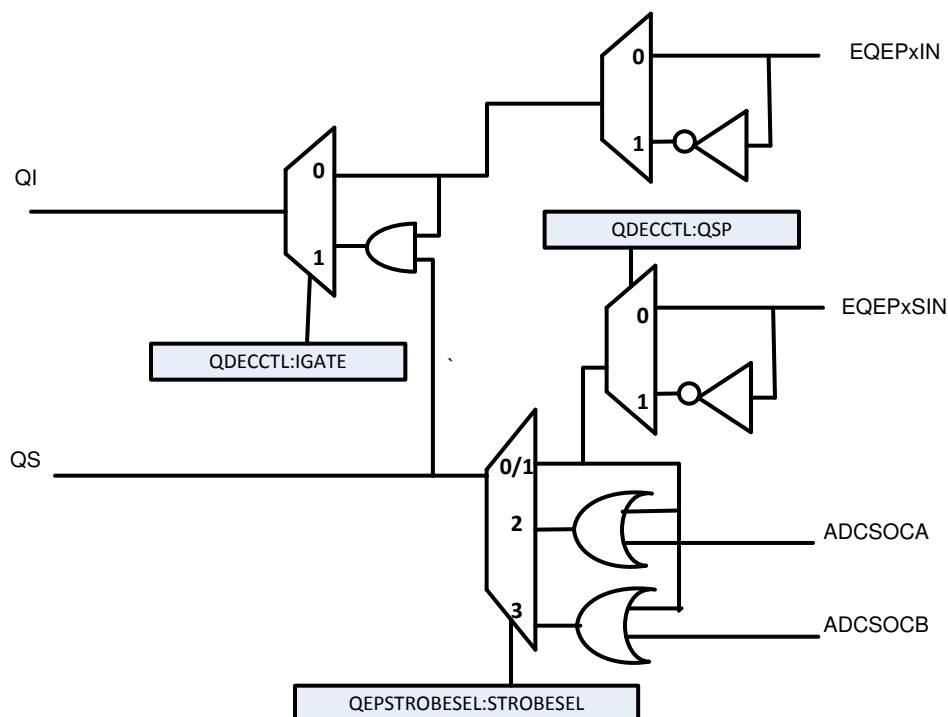

Figure 27-12. Strobe Event Latch (QEPCTL[SEL] = 1)

There is an added feature on Type 2.0 eQEP where position-counter value can also be latched on ADCSOCA and ADCSOCB events by configuring the register QEPSTROBESEL.STROBESEL as shown in figure [Figure 27-13](#)

**Figure 27-13. Latching Position Counter on ADCSOCA/ADCSOCB event**

### 27.5.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

#### Index Event Initialization (IEI)

The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization will be on the falling edge of the index input.

#### Strobe Event Initialization (SEI)

If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

#### Software Initialization (SWI)

The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to it again, the position counter will be re-initialized.

### 27.5.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 27-14 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

**Figure 27-14. eQEP Position-compare Unit**

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

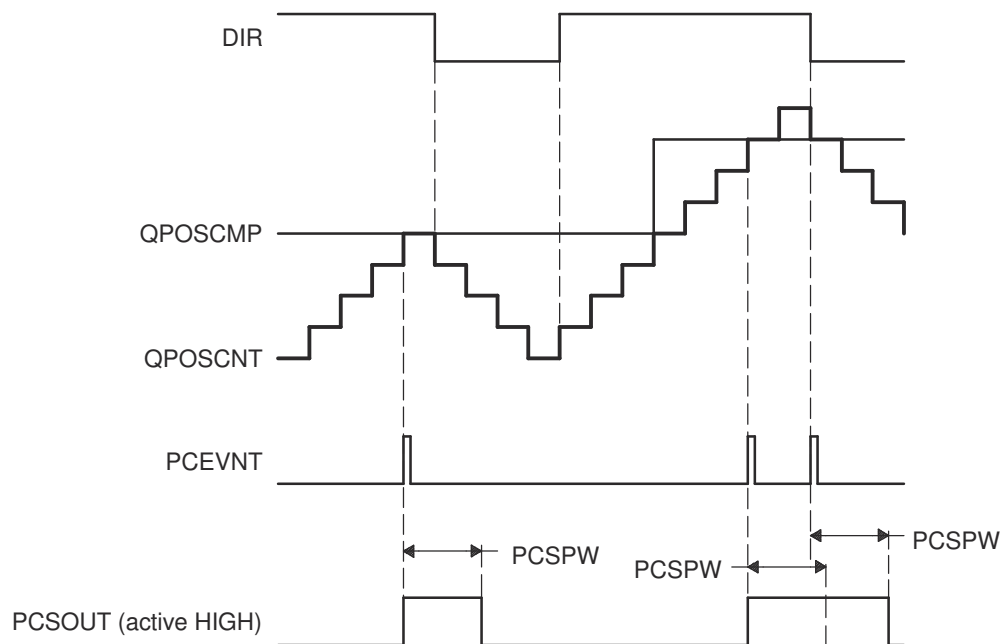

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 27-15).

See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

**Figure 27-15. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 27-16](#).

**Figure 27-16. eQEP Position-compare Sync Output Pulse Stretcher**

## 27.6 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 27-17](#). This feature is typically used for low-speed measurement using the following formula:

$$v(k) = \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (14)$$

where:

- X = Unit position is defined by integer multiple of quadrature edges (see [Figure 27-18](#))
- ΔT = Elapsed time between unit position events
- v(k) = Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

If the QEP capture timer overflows between unit position events, then it sets the QEP capture overflow flag (QEPSTS[COEF]) in the status register and the QCPRDLAT register is set to 0xFFFF. If direction change occurs between the unit position events, then the error flag is set in the status register (QEPSTS[CDEF]) and the QCPRDLAT register is set to 0xFFFF.

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 27-19](#) shows the capture unit operation along with the position counter.

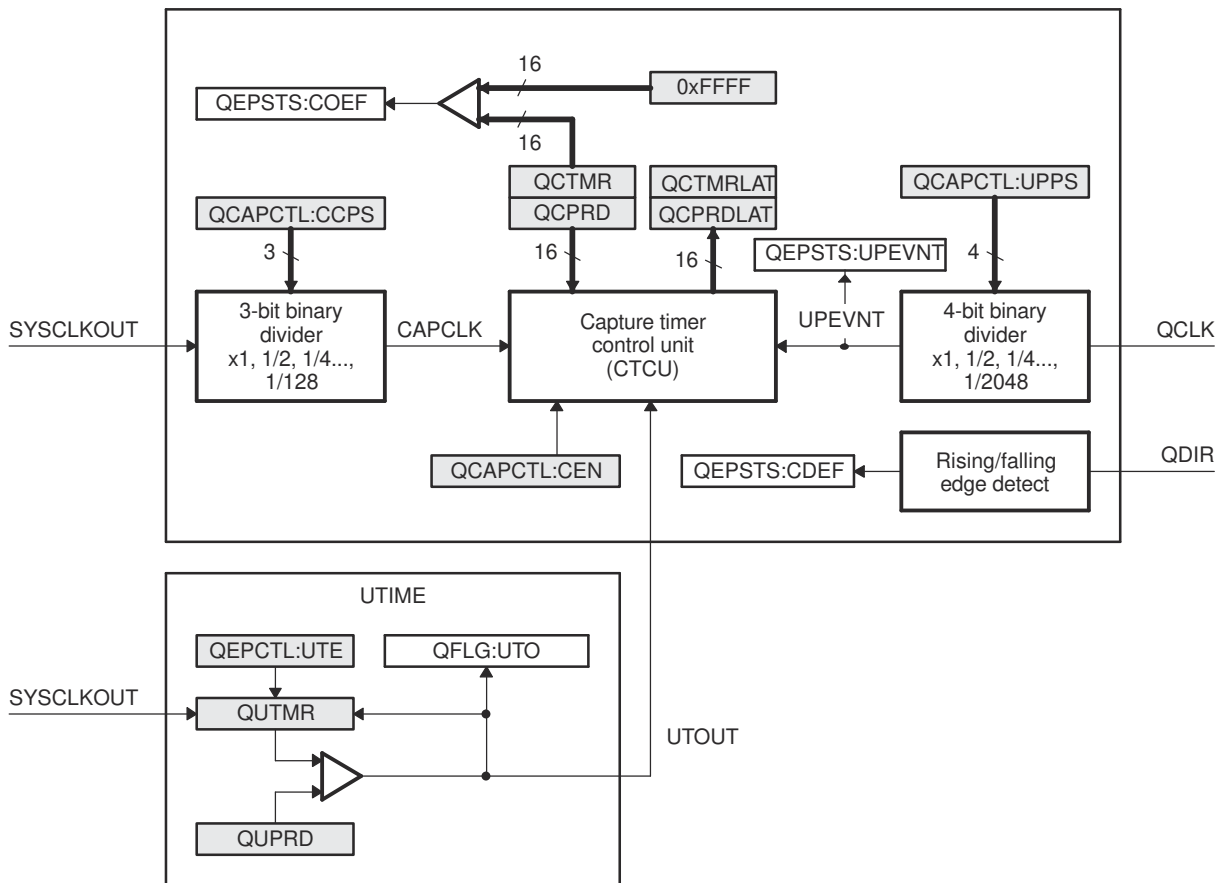

Figure 27-17. eQEP Edge Capture Unit

**Note**

The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CCPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

Figure 27-18. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

Figure 27-19. eQEP Edge Capture Unit - Timing Details

Velocity calculation equation:

$$v(k) = \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \quad (15)$$

where:

- $v(k)$  = Velocity at time instant  $k$
- $x(k)$  = Position at time instant  $k$
- $x(k-1)$  = Position at time instant  $k-1$
- $T$  = Fixed unit time or inverse of velocity calculation rate
- $\Delta X$  = Incremental position movement in unit time
- $X$  = Fixed unit position
- $\Delta T$  = Incremental time elapsed for unit position movement
- $t(k)$  = Time instant "k"
- $t(k-1)$  = Time instant "k-1"

Unit time ( $T$ ) and unit period ( $X$ ) are configured using the QUPRD and QCAPCTL[Upps] registers. Incremental position output and incremental time output is available in the QOSLAT and QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
$T$	Unit Period Register (QUPRD)
$\Delta X$	Incremental Position = QOSLAT( $k$ ) - QOSLAT( $k-1$ )
$X$	Fixed unit position defined by sensor resolution and ZCAPCTL[Upps] bits
$\Delta T$	Capture Period Latch (QCPRDLAT)

## 27.7 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer (Figure 27-20) that monitors the quadrature clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature clock event is detected until a period match ( $QWDPRD = QWDTMR$ ), then the watchdog timer times out and the watchdog interrupt flag is set ( $QFLG[WTO]$ ). The time-out value is programmable through the watchdog period register ( $QWDPRD$ ).

Figure 27-20. eQEP Watchdog Timer

## 27.8 eQEP Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYCLKOUT to generate periodic interrupts for velocity calculations, see Figure 27-21. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), it resets the unit timer (QUTMR) and also generates the unit time out interrupt flag ( $QFLG[UTO]$ ). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 27.6.

Figure 27-21. eQEP Unit Timer Base

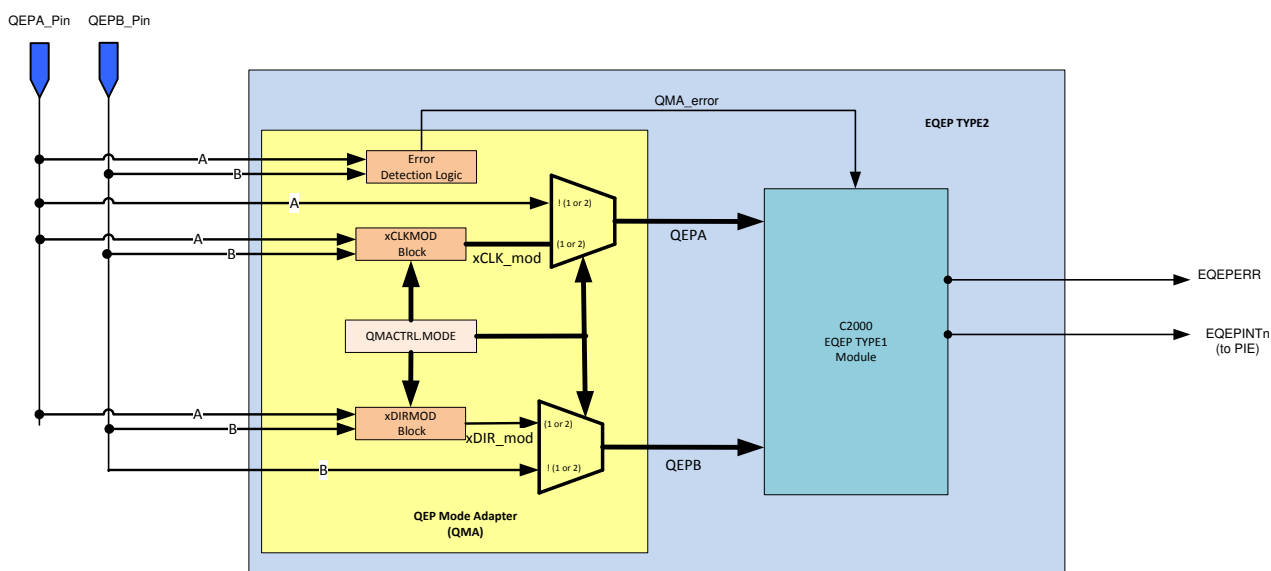

## 27.9 QMA Module

The QEP Mode Adapter (QMA) is designed to extend the C2000™ eQEP module capabilities to support the additional modes described. [Figure 27-22](#) depicts how the QMA module is integrated into the eQEP module.

At reset, by default QMA logic is bypassed and the EQEPA and EQEPB inputs from the pins go directly into the eQEP module. When QMA module is enabled by configuring the QMACTRL[MODE] register, the EQEPA and EQEPB input are processed by this module and modified version of EQEPA and EQEPB signals are sent to the eQEP module. The QMA module requires the eQEP module to be configured in the Direction-Count mode and generates a clock signal on EQEPA input and direction signal on EQEPB input as needed for the proper operation of the intended mode.

- The xCLKMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the clock signal on the EQEPA input to the eQEP module.
- The xDIRMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the direction signal on the EQEPB input to the eQEP module.

The QMA module has error detection logic to detect illegal transitions on EQEPA and EQEPB input signals. The QMA module's error and interrupt are integrated inside the eQEP module as described in [Section 27.10](#). In addition, the QMACTRL register configuration can be locked using the QMALOCK register. Refer to the register description for more details.

**Figure 27-22. QMA Module Block Diagram**

### 27.9.1 Modes of Operation

The QMA module can be operated in the following modes by configuring the QMACTRL register:

- QMA Mode-1 (QMACTRL[MODE]=1)
- QMA Mode-2 (QMACTRL[MODE]=2)

#### 27.9.1.1 QMA Mode-1 (QMACTRL[MODE]=1)

This mode is used when the default state of EQEPA and EQEPB inputs is high. In this mode, outputs of QMA correspond to the following as shown in Figure 27-23:

- EQEPA Output of QMA is the AND of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is the direction signal generated by QMA based on EQEPA and EQEPB inputs

Figure 27-23. QMA Mode-1

### 27.9.1.2 QMA Mode-2 (QMACTRL[MODE]=2)

This mode is used when the default state of EQEPA and EQEPB inputs is low. In this mode, outputs of QMA correspond to the following as shown in Figure 27-24:

- EQEPA Output of QMA is the OR of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is the direction signal generated by QMA based on EQEPA and EQEPB inputs

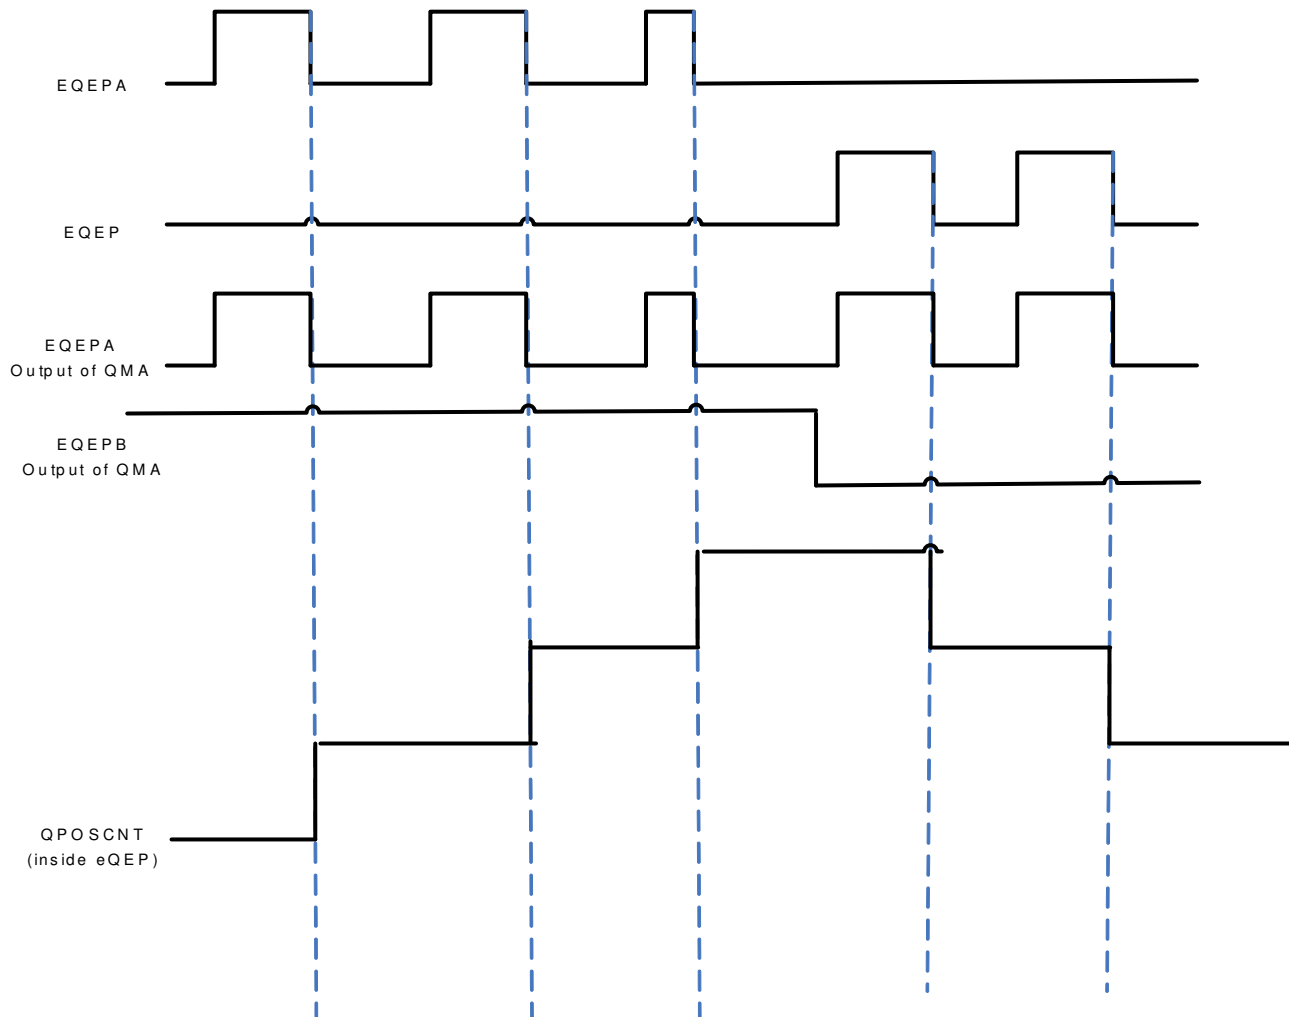

Figure 27-24. QMA Mode-2

### 27.9.2 Interrupt and Error Generation

The error detection logic detects illegal transitions on EQEPA and EQEPB signals and generates an error signal. This error signal can be used to generate eQEP interrupt and error output. Refer to Section 27.10 for details.

## 27.10 eQEP Interrupt Structure

Figure 27-25 shows how the interrupt mechanism works in the eQEP module.

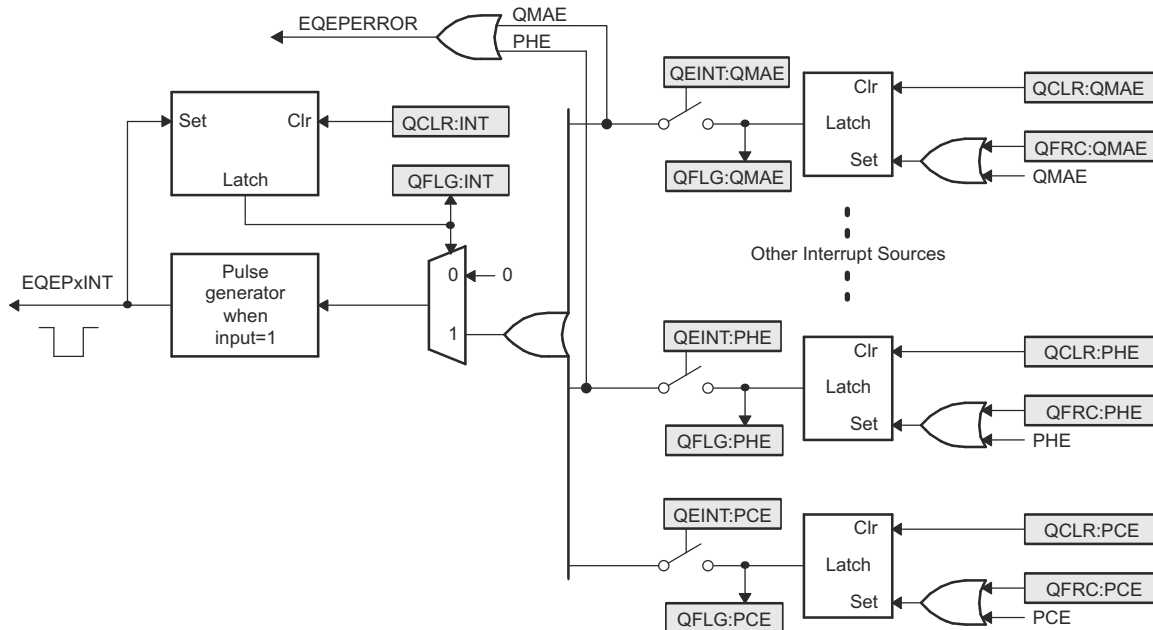

Figure 27-25. eQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT).

An interrupt pulse is generated to PIE when:

1. Interrupt is enabled for eQEP event inside QEINT register
2. Interrupt flag for eQEP event inside QFLG register is set, and
3. Global interrupt status flag bit QFLG[INT] had been cleared for previously generated interrupt event. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, by way of the interrupt clear register (QCLR), before any other interrupt pulses are generated. If either flags inside the QFLG register are not cleared, further interrupt events will not generate an interrupt to PIE. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

## 27.11 Software

### 27.11.1 EQEP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/eqep

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 27.11.1.1 Frequency Measurement Using eQEP

FILE: eqep\_ex1\_freq\_cal.c

This example will calculate the frequency of an input signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. It will interrupt once every period and call the frequency calculation function. This example uses the IQMath library to simplify high-precision calculations.

In addition to the main example file, the following files must be included in this project:

- *eqep\_ex1\_calculation.c* - contains frequency calculation function
- *eqep\_ex1\_calculation.h* - includes initialization values for frequency structure

The configuration for this example is as follows

- Maximum frequency is configured to 10KHz (baseFreq)
- Minimum frequency is assumed at 50Hz for capture pre-scaler selection

*SPEED\_FR*: High Frequency Measurement is obtained by counting the external input pulses for 10ms (unit timer set to 100Hz).  $\lfloor \text{SPEED\_FR} = \frac{\text{Count} \Delta}{10\text{ms}} \rfloor$

*SPEED\_PR*: Low Frequency Measurement is obtained by measuring time period of input edges. Time measurement is averaged over 64 edges for better results and the capture unit performs the time measurement using pre-scaled SYSCLK.

Note that the pre-scaler for capture unit clock is selected such that the capture timer does not overflow at the required minimum frequency. This example runs indefinitely until the user stops it.

For more information about the frequency calculation see the comments at the beginning of eqep\_ex1\_calculation.c and the XLS file provided with the project, eqep\_ex1\_calculation.xls.

#### 27.11.1.2 Position and Speed Measurement Using eQEP

FILE: eqep\_ex2\_pos\_speed.c

This example provides position and speed measurement using the capture unit and speed measurement using unit time out of the eQEP module. ePWM1 and a GPIO are configured to generate simulated eQEP signals. The ePWM module will interrupt once every period and call the position/speed calculation function. This example uses the IQMath library to simplify high-precision calculations.

In addition to the main example file, the following files must be included in this project:

- *eqep\_ex2\_calculation.c* - contains position/speed calculation function
- *eqep\_ex2\_calculation.h* - includes initialization values for position/speed structure

The configuration for this example is as follows

- Maximum speed is configured to 6000rpm (baseRPM)
- Minimum speed is assumed at 10rpm for capture pre-scaler selection
- Pole pair is configured to 2 (polePairs)
- Encoder resolution is configured to 4000 counts/revolution (mechScaler)
- Which means:  $4000 / 4 = 1000$  line/revolution quadrature encoder (simulated by ePWM1)
- ePWM1 (simulating QEP encoder signals) is configured for a 5kHz frequency or 300 rpm ( $= 4 * 5000 \text{ cnts/sec} * 60 \text{ sec/min} / 4000 \text{ cnts/rev}$ )

*SPEEDRPM\_FR*: High Speed Measurement is obtained by counting the QEP input pulses for 10ms (unit timer set to 100Hz).

$SPEEDRPM\_FR = (\text{Position Delta} / 10\text{ms}) * 60 \text{ rpm}$

**SPEEDRPM\_PR:** Low Speed Measurement is obtained by measuring time period of QEP edges. Time measurement is averaged over 64 edges for better results and the capture unit performs the time measurement using pre-scaled SYSCLK.

Note that the pre-scaler for capture unit clock is selected such that the capture timer does not overflow at the required minimum frequency. This example runs indefinitely until the user stops it.

For more information about the position/speed calculation see the comments at the beginning of eqep\_ex2\_calculation.c and the XLS file provided with the project, eqep\_ex2\_calculation.xls.

#### External Connections

- Connect GPIO20/eQEP1A to GPIO0/ePWM1A (simulates eQEP Phase A signal)
- Connect GPIO21/eQEP1B to GPIO1/ePWM1B (simulates eQEP Phase B signal)
- Connect GPIO23/eQEP1I to GPIO2 (simulates eQEP Index Signal)

#### Watch Variables

- *posSpeed.speedRPMFR* - Speed meas. in rpm using QEP position counter
- *posSpeed.speedRPMFR* - Speed meas. in rpm using capture unit
- *posSpeed.thetaMech* - Motor mechanical angle (Q15)
- *posSpeed.thetaElec* - Motor electrical angle (Q15)

### 27.11.1.3 ePWM frequency Measurement Using eQEP via xbar connection

FILE: eqep\_ex3\_epwm\_xbar.c

This example will calculate the frequency of an PWM signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. This ePWM signal is connected to input of eQEP using Input CrossBar and EPWM XBAR. ePWM module will interrupt once every period and call the frequency calculation function. This example uses the IQMath library to simplify high-precision calculations.

In addition to the main example file, the following files must be included in this project:

- *eqep\_ex1\_calculation.c* - contains frequency calculation function
- *eqep\_ex1\_calculation.h* - includes initialization values for frequency structure

The configuration for this example is as follows

- Maximum frequency is configured to 10KHz (baseFreq)
- Minimum frequency is assumed at 50Hz for capture pre-scalar selection
- GPIO0 is connected to output of INPUT\_XBAR1
- INPUT\_XBAR1 is connected to output of PWMXBAR at TRIP4
- eQEPA source is configured as PWMXBAR.1 output (TRIP4)

**SPEED\_FR:** High Frequency Measurement is obtained by counting the external input pulses for 10ms (unit timer set to 100Hz).  $\lfloor \text{SPEED\_FR} = \frac{\text{Count} \Delta}{10\text{ms}} \rfloor$

**SPEED\_PR:** Low Frequency Measurement is obtained by measuring time period of input edges. Time measurement is averaged over 64 edges for better results and the capture unit performs the time measurement using pre-scaled SYSCLK.

Note that the pre-scaler for capture unit clock is selected such that the capture timer does not overflow at the required minimum frequency. This example runs indefinitely until the user stops it.

For more information about the frequency calculation see the comments at the beginning of eqep\_ex1\_calculation.c and the XLS file provided with the project, eqep\_ex1\_calculation.xls.

#### Watch Variables

- *freq.freqHzFR* - Frequency measurement using position counter/unit time out
- *freq.freqHzPR* - Frequency measurement using capture unit

### 27.11.1.4 Frequency Measurement Using eQEP via unit timeout interrupt

FILE: eqep\_ex4\_freq\_cal\_interrupt.c

This example will calculate the frequency of an input signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. EQEP unit timeout is set which will generate an interrupt every *UNIT\_PERIOD* microseconds and frequency calculation occurs continuously

The configuration for this example is as follows

- PWM frequency is specified as 5000 Hz
- UNIT\_PERIOD is specified as 10000  $\mu$ s
- Min frequency is  $(1/(2*10\text{ms}))$ , that is, 50 Hz
- Highest frequency can be  $(2^{32})/((2*10\text{ ms}))$
- Resolution of frequency measurement is 50 Hz

*freq* : Frequency Measurement is obtained by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms).

#### ExternalConnections

- Connect GPIO20/eQEP1A to GPIO0/ePWM1A

#### Watch Variables

- *freq* - Frequency measurement using position counter/unit time out
- *pass* - If measured frequency matches with PWM frequency then pass = 1 else 0

### 27.11.1.5 Motor speed and direction measurement using eQEP via unit timeout interrupt

FILE: eqep\_ex5\_speed\_dir\_motor.c

This example can be used to sense the speed and direction of motor using eQEP in quadrature encoder mode. ePWM1A is configured to simulate motor encoder signals with frequency of 5 kHz on both A and B pins with 90 degree phase shift (so as to run this example without motor). EQEP unit timeout is set which will generate an interrupt every *UNIT\_PERIOD* microseconds and speed calculation occurs continuously based on the direction of motor

The configuration for this example is as follows

- PWM frequency is specified as 5000 Hz
- UNIT\_PERIOD is specified as 10000  $\mu$ s
- Simulated quadrature signal frequency is 20000 Hz (4 \* 5000)
- Encoder holes assumed as 1000
- Thus Simulated motor speed is 300rpm (5000 \* (60 / 1000))

*freq* : Simulated quadrature signal frequency measured by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms). *speed* : Measure motor speed in rpm *dir* : Indicates clockwise (1) or anticlockwise (-1)

*External Connections* (if motor encoder signals are simulated by ePWM)

- Connect GPIO20/eQEP1A to GPIO0/ePWM1A
- Connect GPIO21/eQEP1B to GPIO1/ePWM1B With motor
- Connect GPIO20/eQEP1A to encoder A output
- Connect GPIO21/eQEP1B to encoder B output

#### Watch Variables

- *freq* : Simulated motor frequency measurement is obtained by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms).
- *speed* : Measure motor speed in rpm
- *dir* : Indicates clockwise (1) or anticlockwise (-1)
- *pass* - If measured quadrature frequency matches with input quadrature frequency (4 \* PWM frequency) then pass = 1 else fail = 1 (\*\* only when "MOTOR" is commented out)

## 27.12 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

### 27.12.1 EQEP Base Address Table (C28)

**Table 27-4. EQEP Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
EQep1Regs	EQEP_REGS	EQEP1_BASE	0x0000_5100	YES	YES	YES	YES	YES
EQep2Regs	EQEP_REGS	EQEP2_BASE	0x0000_5140	YES	YES	YES	YES	YES
EQep3Regs	EQEP_REGS	EQEP3_BASE	0x0000_5180	YES	YES	YES	YES	YES

## 27.12.2 EQEP\_REGS Registers

Table 27-5 lists the memory-mapped registers for the EQEP\_REGS registers. All register offset addresses not listed in Table 27-5 should be considered as reserved locations and the register contents should not be modified.

**Table 27-5. EQEP\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	QPOSCNT	Position Counter		<a href="#">Go</a>
2h	QPOSINIT	Position Counter Init		<a href="#">Go</a>
4h	QPOSMAX	Maximum Position Count		<a href="#">Go</a>
6h	QPOSCMP	Position Compare		<a href="#">Go</a>
8h	QPOSILAT	Index Position Latch		<a href="#">Go</a>
Ah	QPOSSLAT	Strobe Position Latch		<a href="#">Go</a>
Ch	QPOSLAT	Position Latch		<a href="#">Go</a>
Eh	QUTMR	QEP Unit Timer		<a href="#">Go</a>
10h	QUPRD	QEP Unit Period		<a href="#">Go</a>
12h	QWDTMR	QEP Watchdog Timer		<a href="#">Go</a>
13h	QWDPRD	QEP Watchdog Period		<a href="#">Go</a>

36h	QEPSRCSEL	QEP Source Select Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 27-6 shows the codes that are used for access types in this section.

**Table 27-6. EQEP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear

**Table 27-6. EQEP\_REGS Access Type Codes  
(continued)**

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 27.12.2.1 QPOSCNT Register (Offset = 0h) [Reset = 0h]

QPOSCNT is shown in [Figure 27-25](#) and described in [Table 27-7](#).

Return to the [Summary Table](#).

Position Counter

**Figure 27-26. QPOSCNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSCNT																															
R/W-0h																															

**Table 27-7. QPOSCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSCNT	R/W	0h	Position Counter This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point. This Register acts as a Read ONLY register while counter is counting up/down. Note: It is recommended to only write to the position counter register (QPOSCNT) during initialization, i.e. when the eQEP position counter is disabled (QPEN bit of QEPCTL is zero). Once the position counter is enabled (QPEN bit is one), writing to the eQEP position counter register (QPOSCNT) may cause unexpected results. Reset type: SYSRSn

### 27.12.2.2 QPOSINIT Register (Offset = 2h) [Reset = 0h]

QPOSINIT is shown in [Figure 27-26](#) and described in [Table 27-8](#).

Return to the [Summary Table](#).

Position Counter Init

**Figure 27-27. QPOSINIT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSINIT																															
R/W-0h																															

**Table 27-8. QPOSINIT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSINIT	R/W	0h	Position Counter Init This register contains the position value that is used to initialize the position counter based on external strobe or index event. The position counter can be initialized through software. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 27.12.2.3 QPOSMAX Register (Offset = 4h) [Reset = 0h]

QPOSMAX is shown in [Figure 27-27](#) and described in [Table 27-9](#).

Return to the [Summary Table](#).

Maximum Position Count

**Figure 27-28. QPOSMAX Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSMAX																															
R/W-0h																															

**Table 27-9. QPOSMAX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSMAX	R/W	0h	Maximum Position Count This register contains the maximum position counter value. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 27.12.2.4 QPOSCMP Register (Offset = 6h) [Reset = 0h]

QPOSCMP is shown in [Figure 27-28](#) and described in [Table 27-10](#).

Return to the [Summary Table](#).

Position Compare

**Figure 27-29. QPOSCMP Register**

**Table 27-10. QPOSCMP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSCMP	R/W	0h	Position Compare The position-compare value in this register is compared with the position counter (QPOSCNT) to generate sync output and/or interrupt on compare match. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 27.12.2.5 QPOSILAT Register (Offset = 8h) [Reset = 0h]

QPOSILAT is shown in [Figure 27-29](#) and described in [Table 27-11](#).

Return to the [Summary Table](#).

Index Position Latch

**Figure 27-30. QPOSILAT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSILAT																															
R-0h																															

**Table 27-11. QPOSILAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSILAT	R	0h	Index Position Latch The position-counter value is latched into this register on an index event as defined by the QEPCTL[IEL] bits. Reset type: SYSRSn

### 27.12.2.6 QPOSSLAT Register (Offset = Ah) [Reset = 0h]

QPOSSLAT is shown in [Figure 27-30](#) and described in [Table 27-12](#).

Return to the [Summary Table](#).

Strobe Position Latch

**Figure 27-31. QPOSSLAT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSSLAT

Bit	Field	Type	Reset	Description
31-0	QPOSSLAT	R	0h	Strobe Position Latch The position-counter value is latched into this register on a strobe event as defined by the QEPCTL[SEL] bits. Reset type: SYSRSn

### 27.12.2.7 QPOSLAT Register (Offset = Ch) [Reset = 0h]

QPOSLAT is shown in [Figure 27-31](#) and described in [Table 27-13](#).

Return to the [Summary Table](#).

Position Latch

**Figure 27-32. QPOSLAT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSLAT																															
R-0h																															

**Table 27-13. QPOSLAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSLAT	R	0h	Position Latch The position-counter value is latched into this register on a unit time out event. Reset type: SYSRSn

### 27.12.2.8 QUTMR Register (Offset = Eh) [Reset = 0h]

QUTMR is shown in [Figure 27-32](#) and described in [Table 27-14](#).

Return to the [Summary Table](#).

QEP Unit Timer

**Figure 27-33. QUTMR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QUTMR																															
R/W-0h																															

**Table 27-14. QUTMR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QUTMR	R/W	0h	QEP Unit Timer This register acts as time base for unit time event generation. When this timer value matches the unit time period value a unit time event is generated. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 27.12.2.9 QUPRD Register (Offset = 10h) [Reset = 0h]

QUPRD is shown in [Figure 27-33](#) and described in [Table 27-15](#).

Return to the [Summary Table](#).

QEP Unit Period

**Figure 27-34. QUPRD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QUPRD																															
R/W-0h																															

**Table 27-15. QUPRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QUPRD	R/W	0h	QEP Unit Period This register contains the period count for the unit timer to generate periodic unit time events. These events latch the eQEP position information at periodic intervals and optionally generate an interrupt. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

**27.12.2.10 QWDTMR Register (Offset = 12h) [Reset = 0h]**

QWDTMR is shown in [Figure 27-34](#) and described in [Table 27-16](#).

Return to the [Summary Table](#).

QEP Watchdog Timer

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation mode Reset type: SYSRSn 0h (R/W) = QPOSCNT behavior Position counter stops immediately on emulation suspend 0h (R/W) = QWDTMR behavior Watchdog counter stops immediately 0h (R/W) = QUTMR behavior Unit timer stops immediately 0h (R/W) = QCTMR behavior Capture Timer stops immediately 1h (R/W) = QPOSCNT behavior Position counter continues to count until the rollover 1h (R/W) = QWDTMR behavior Watchdog counter counts until WD period match roll over 1h (R/W) = QUTMR behavior Unit timer counts until period rollover 1h (R/W) = QCTMR behavior Capture Timer counts until next unit period event 2h (R/W) = QPOSCNT behavior Position counter is unaffected by emulation suspend 2h (R/W) = QWDTMR behavior Watchdog counter is unaffected by emulation suspend 2h (R/W) = QUTMR behavior Unit timer is unaffected by emulation suspend 2h (R/W) = QCTMR behavior Capture Timer is unaffected by emulation suspend 3h (R/W) = Same as FREE_SOFT_2
13-12	PCRM	R/W	0h	Position counter reset Reset type: SYSRSn 0h (R/W) = Position counter reset on an index event 1h (R/W) = Position counter reset on the maximum position 2h (R/W) = Position counter reset on the first index event 3h (R/W) = Position counter reset on a unit time event
11-10	SEI	R/W	0h	Strobe event initialization of position counter Reset type: SYSRSn 0h (R/W) = Does nothing (action disabled) 1h (R/W) = Does nothing (action disabled) 2h (R/W) = Initializes the position counter on rising edge of the QEPS signal 3h (R/W) = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe

**Table 27-19. QEPCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9-8	IEI	R/W	0h	Index event init of position count Reset type: SYSRSn 0h (R/W) = Do nothing (action disabled) 1h (R/W) = Do nothing (action disabled) 2h (R/W) = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 3h (R/W) = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)
7	SWI	R/W	0h	Software init position counter Reset type: SYSRSn 0h (R/W) = Do nothing (action disabled) 1h (R/W) = Initialize position counter (QPOSCNT=QPOSINIT). This bit is not cleared automatically
6	SEL	R/W	0h	Strobe event latch of position counter Reset type: SYSRSn 0h (R/W) = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the QDECCTL register 1h (R/W) = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe
5-4	IEL	R/W	0h	Index event latch of position counter (software index marker) Reset type: SYSRSn 0h (R/W) = Reserved 1h (R/W) = Latches position counter on rising edge of the index signal 2h (R/W) = Latches position counter on falling edge of the index signal 3h (R/W) = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the QPOSILAT register and the direction flag is latched in the QEPSTS[QDLF] bit. This mode is useful for software index marking.
3	QPEN	R/W	0h	Quadrature position counter enable/software reset Reset type: SYSRSn 0h (R/W) = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. When QPEN is disabled, some flags in the QFLG register do not get reset or cleared and show the actual state of that flag. 1h (R/W) = eQEP position counter is enabled
2	QCLM	R/W	0h	QEP capture latch mode Reset type: SYSRSn 0h (R/W) = Latch on position counter read by CPU. Capture timer and capture period values are latched into QCTMRLAT and QCPRDLAT registers when CPU reads the QPOSCNT register. 1h (R/W) = Latch on unit time out. Position counter, capture timer and capture period values are latched into QPOSLAT, QCTMRLAT and QCPRDLAT registers on unit time out.
1	UTE	R/W	0h	QEP unit timer enable Reset type: SYSRSn 0h (R/W) = Disable eQEP unit timer 1h (R/W) = Enable unit timer
0	WDE	R/W	0h	QEP watchdog enable Reset type: SYSRSn 0h (R/W) = Disable the eQEP watchdog timer 1h (R/W) = Enable the eQEP watchdog timer

### 27.12.2.14 QCAPCTL Register (Offset = 16h) [Reset = 0h]

QCAPCTL is shown in [Figure 27-38](#) and described in [Table 27-20](#).

Return to the [Summary Table](#).

The sigma delta filter module (SDFM) is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma ( $\Delta\Sigma$ ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

### 28.1.2 Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Different configurable modulator clock modes supported:
  - Mode 0: Modulator clock rate equals the modulator data rate.
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
    1. Two independent Higher Threshold comparators (used to detect over-value condition)
    2. Two independent Lower Threshold comparators (used to detect under-value condition)
    3. One independent Threshold-Crossing comparator (used to measure duty cycle/frequency with eCAP)
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32
- Four independent configurable primary filter (data filter) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - OSR value for data filter unit (DOSR) programmable from 1 to 256
  - Ability to enable or disable (or both) individual filter module
  - Ability to synchronize all four independent filters of an SDFM module by using the Master Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- Data filter unit has a programmable mode FIFO to reduce interrupt overhead. The FIFO has the following features:
  - The primary filter (data filter) has a 16-deep x 32-bit FIFO.
  - The FIFO can interrupt the CPU after programmable number of data-ready events.
  - FIFO Wait-for-Sync feature: Ability to ignore data-ready events until the PWM synchronization signal (SDSYNC) is received. Once the SDSYNC event is received, the FIFO is populated on every data-ready event.
  - Data filter output can be represented in either 16 bits or 32 bits.
- PWMx.SOCA/SOCB can be configured to serve as SDSYNC source on a per-data-filter-channel basis.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.
- Configurable Input Qualification available for both SD-Cx and SD-Dx
- Ability to use one filter channel clock (SD-C1) to provide clock to other filter clock channels.
- Configurable digital filter available on comparator filter events to blankout comparator events caused by spurious noise

### 28.1.3 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

Figure 28-2 shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in Section 28.12.

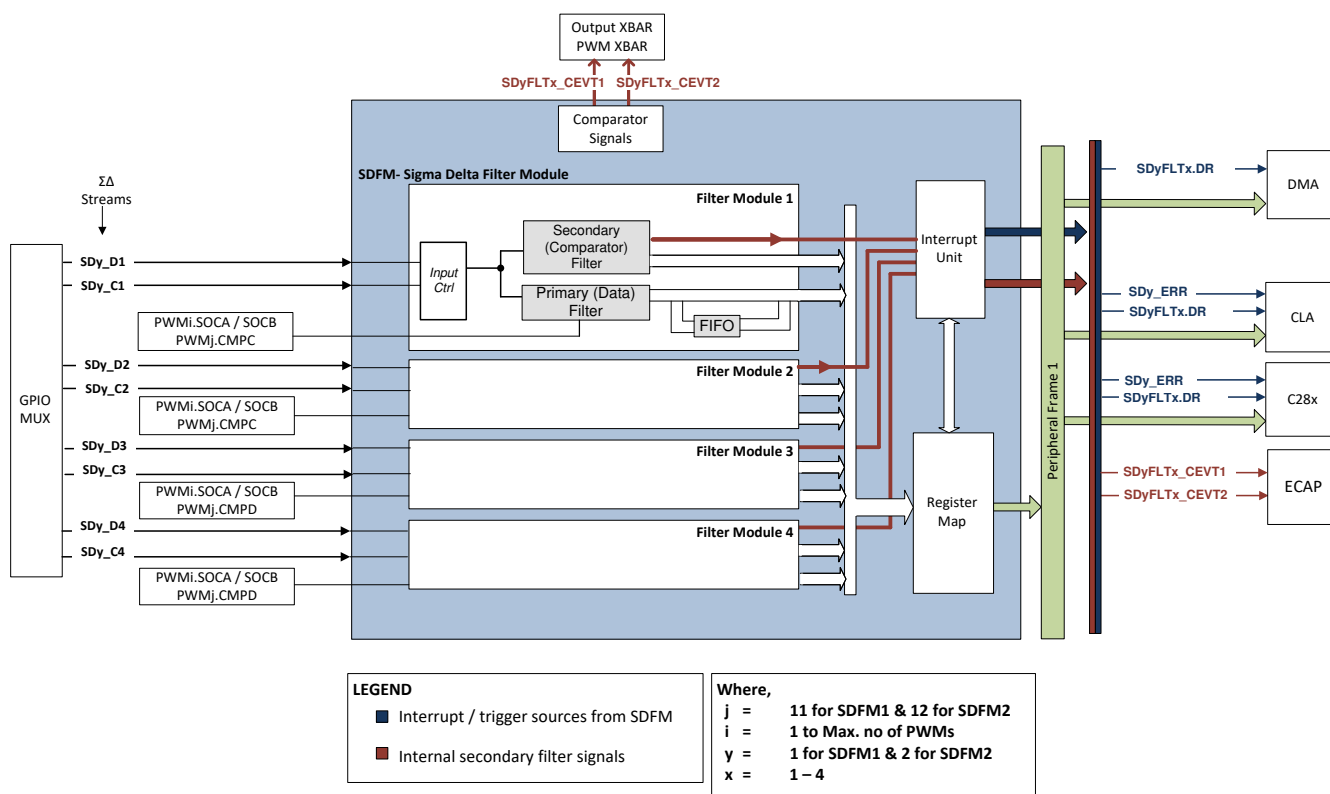

Figure 28-2. Sigma Delta Filter Module (SDFM) Block Diagram

Each filter module shown in Figure 28-3 has a primary (data) filter and a secondary (comparator) filter pair that receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

Figure 28-3. Block Diagram of One Filter Module

## 28.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, the following GPIO input qualification can be used. Other GPIO qualifications are not supported.

- If GPIO Input qualification is ASYNC, make sure to check the SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware of the following caution message.

### CAUTION

The SDFM clock inputs (SDx\_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions should be taken on these signals to ensure a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

### Note

The SDFM module expects SD-Dx to change on the falling edge of SD-Cx and strobes for SD-Dx on the rising edge. But some SD-modulators in the market change SD-Dx on the rising edge and expect SDFM to strobe for data on the falling edge. In such cases, the GPIO inversion feature (GPxINV) is used on SD-Cx pin to change polarity and make it compatible with the SDFM.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

### 28.3 Input Qualification

Impulse noise sources such as EMI, crosstalk, and so on, has the possibility of corrupting SDCLK and SDDATA bit streams, resulting in corrupted SDFM filtered data. This impulse noise effects could be mitigated when using the input qualification feature which synchronizes SDCLK / SDDATA signals with PLLCLK. By default, both SDCLK and SDDATA bit stream are not synchronized. SDCLK can be synchronized to PLLCLK by setting SDCTLPARAMx.SDCLKSYNC = 1 and SDDATA can be synchronized to PLLCLK by setting SDCTLPARAMx.SDDATASYNC = 1. [Figure 28-4](#) shows optional Input Qualification option on SDCLK and SDDATA lines.

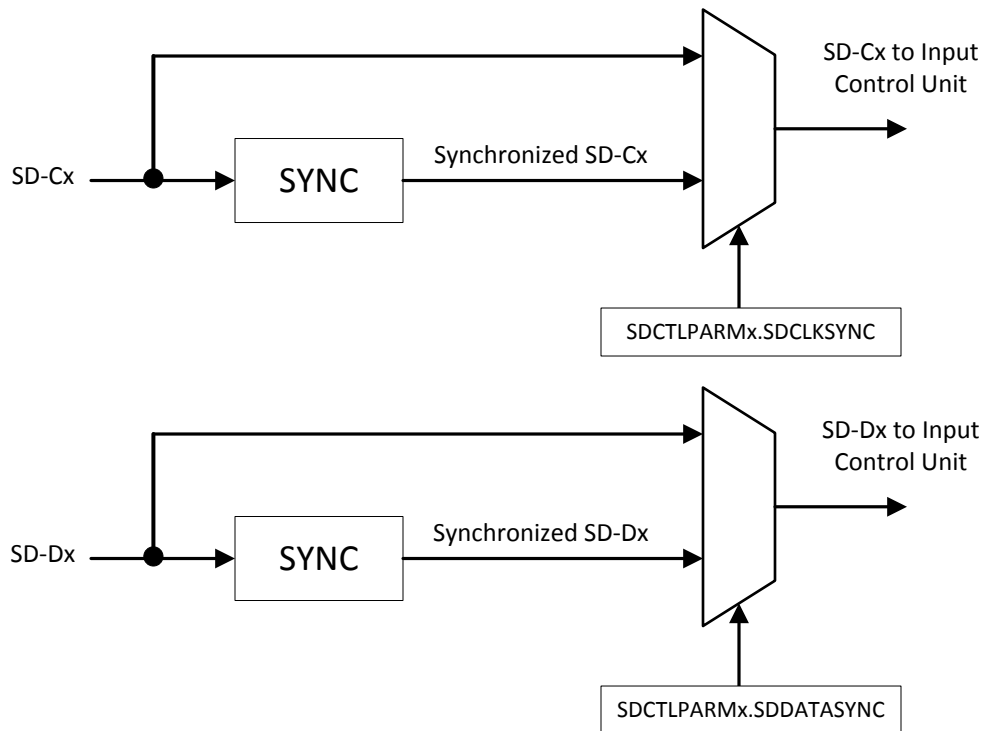

Figure 28-4. Input Qualification on SD-Cx and SD-Dx

## 28.4 Input Control Unit

The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in Mode 0. [Table 28-1](#) and [Figure 28-5](#) show how SDCTLPARMx.MOD bits can be configured in Mode 0.

**Table 28-1. Modulator Clock Modes**

Modulator Mode [MOD]	Description
0	The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock.
1	Reserved
2	Reserved
3	Reserved

### Note

In order to achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

Mode 0 Operation

**Figure 28-5. Different Modulator Modes Supported**

## 28.5 SDFM Clock Control

In systems, the modulator clock could be generated using PWMs. Assuming all the SD-CLKs see the same delay on board traces, you could potentially use just one clock to clock multiple filters, thereby saving on the number of pins used for SDFM. In order to enable this Filter1 SDCLK (SD-C1) can possibly be fed to other filter channels if required. SDCTLPARAMx.SDCLKSEL register bit field can be configured to select filter channel SDCLK. See [Figure 28-6](#) to view this feature.

Figure 28-6. SDFM Clock Control

### 28.6 Sinc Filter

Both comparator filter and data filter available in SDFM have the Sinc<sup>N</sup> filter as its core. The Sinc<sup>N</sup> filter is essentially a low-pass filter that converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc<sup>N</sup> architecture consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 28-7. The Z-transfer function of the Sinc filter of order N is shown in Figure 28-8.

Figure 28-7. Simplified Sinc Filter Architecture

$$H(Z) = \left[ \frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^N$$

**N** = Order of Sinc filter  
**OSR** = Over Sampling Ratio

**Figure 28-8. Z-Transform of Sinc Filter of Order N**

Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution (or) ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator datasheet to determine the effective resolution for a given Sinc filter configuration. [Figure 28-9](#) shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10 MHz.

**Figure 28-9. Frequency Response of Different Sinc Filters**

The order of different sinc filter is shown in [Table 28-2](#).

**Table 28-2. Order of Sinc Filter**

Filter Type	Order of Sinc Filter
Sinc1	1
Sinc2	2
Sinc3	3
SincFast	3

### 28.6.1 Data Rate and Latency of the Sinc Filter

The data rate of the sinc filter (filter throughput) represented in samples/sec is calculated by the following formula:

$$\text{Data rate of Sinc filter} = \frac{\text{Modulator data rate}}{\text{OSR}} \quad (16)$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency is calculated by the following formula:

$$\text{Latency of Sinc filter} = \frac{\text{Order of Sinc filter}}{\text{Data rate of Sinc filter}} \quad (17)$$

#### Example configuration:

Sinc filter type	= sinc3
Modulator data rate	= 10 MHz
OSR	= 256
Data rate of Sinc Filter	= 10 MHz / 256 = 39.1 K samples / sec
Sinc filter latency	= 76.8 $\mu$ s
Sinc filter type	= sinc2
Modulator data rate	= 10 MHz
OSR	= 256
Data rate of Sinc Filter	= 10 MHz / 256 = 39.1 K samples / sec
Sinc filter latency	= 51.2 $\mu$ s

### 28.7 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDFPARMx.FEN = 1 enables the data filter. The data filter output is represented in 26-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. [Table 28-3](#) shows the different full scale values that the data filter can store using different OSRs.

See [Section 28.6.1](#) to understand how to calculate data rate and latency of data filter.

**Table 28-3. Peak Data Values for Different DOSR/Filter Combinations**

DOSR	Sinc1	Sinc2	Sinc3	SincFast
x	x	x <sup>2</sup>	x <sup>3</sup>	2x <sup>2</sup>
4	-4 to 4	-16 to 16	-64 to 64	-32 to 32
8	-8 to 8	-64 to 64	-512 to 512	-128 to 128
16	-16 to 16	-256 to 256	-4096 to 4096	-512 to 512
32	-32 to 32	-1024 to 1024	-32,768 to 32,768	-2048 to 2048
64	-64 to 64	-4096 to 4096	-262,144 to 262,144	-8192 to 8192
128	-128 to 128	-16,384 to 16,384	-2,097,152 to 2,097,152	-32,768 to 32,768
256	-256 to 256	-65,536 to 65,536	-16,777,216 to 16,777,216	-131,072 to 131,072

### 28.7.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

#### 32-bit data filter representation:

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits do not have any bearing on the output of the data filter in this configuration.

#### 16-bit data filter representation:

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

For example, for the data filter configuration below:

- Filter type = Sinc3
- OSR = 128
- SDDPARMx.DR = 0

The data filter with a 26-bit signed output value can be in the range of  $-16,777,216$  to  $16,777,216$ . But, 16-bit signed output supports values only from  $-32,768$  to  $32,767$ . Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. [Table 28-4](#) shows the configuration settings of shift control bits for different OSR and filter types.

**Table 28-4. Shift Control Bit Configuration Settings**

OSR	Sinc1	Sinc2	SincFast	Sinc3
1 to 31	0	0	0	0
32 to 40	0	0	0	1
41 to 50	0	0	0	2
51 to 63	0	0	0	3
64 to 80	0	0	0	4
81 to 101	0	0	0	5
102 to 127	0	0	0	6
128 to 161	0	0	1	7
162 to 181	0	0	1	8
182 to 203	0	1	2	8
204 to 255	0	1	2	9
256	0	2	3	10

#### CAUTION

Configuring shift control bits incorrectly will result in getting incorrect 16-bit data filter output.

### 28.7.2 Data FIFO

Each primary (data) filter channel has a 16-level deep, 32-bit FIFO.

FIFOs can be configured to collect a programmable number of data filter samples before issuing data-ready interrupt. This reduces the number of data-ready interrupts generated and resulting interrupt overhead for managed data flow.

By default, FIFO operation is disabled. FIFOs can be enabled by setting SDFIFOCTLx.FFEN = 1. When FIFO is enabled, each data-ready event from the data filter will populate the FIFO, and the status of the FIFO at any given time is updated in the SDFIFOCTLx.SDFFST bit field.

### Setting up FIFO to interrupt after receiving programmable number of data ready events:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Configure SDFIFOCTLx.SDFFIL bit field to any value between 0 to 16
- Configure SDFM data ready event to interrupt on FIFO interrupt (SDFFINT) (Set SDFFINTx = 1)
- Select data-ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

When the SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met, the SDIFLG.SDFFINTx bit is set and an interrupt is generated on the DRINTx. SDIFLG.SDFFINTx flag can be cleared by setting the SDIFLGCLR.SDFFINTx bit field.

### Wait for Sync feature:

The FIFO wait for sync feature can be used to ignore data-ready events from the data filter until the SDSYNC (from PWM) event is triggered.

By default, the Wait for Sync feature is disabled. This feature can be enabled by setting SDSYNcx.WTSYNcEN = 1

### When the wait for sync feature is disabled:

FIFOs get populated on every data ready event until the FIFO gets full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL.

### When the wait for sync feature enabled:

FIFOs will not be get populated on every data ready event until it receives a SDSYNC event. On a SYSYNC event, it sets SDSYNcx.WTSYNFLG = 1 and data ready events from primary filter will start populating FIFO until either the FIFOs get full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL. WTSYNFLG can be cleared either automatically (or) manually.

When WTSYNFLG = 0, FIFOs contents are frozen and subsequent data ready events don't get populate FIFO until next SDSYNC event.

### WTSYNFLG automatic clear mode:

By default, this mode is enabled. When SDSYNcx.WTSClREN = 1, WTSYNFLG is automatically cleared on SDFFINT event.

### WTSYNFLG manual clear mode:

Setting SDSYNcx.WTSYNCLR = 1 can be used to clear WTSYNFLG manually.

### Clearing FIFO contents:

FIFO contents can be cleared by any of the following methods:-

- Disabling FIFO clear FIFO contents. This can be done by clearing SDFIFOCTLx.FFEN = 0.
- Disabling Primary filter clear FIFO contents. This can be done by either clearing SDDFPARMx.FEN = 0 (or) by clearing SDMFILEN.MFE = 0.
- FIFO contents can also be automatically cleared upon receiving the SDSYNC event. By default, this feature is disabled and this feature can be enabled by setting FIFO Clear-on-SDSYNC enable (SDSYNcx.FFSYNCLREN = 1).

**Note:** The above feature is only enabled when wait for sync feature is enabled (SDSYNcx.WTSYNcEN = 1).

### FIFO debug access behavior:

Debug access of SDDATFIFOx registers does not affect FIFO pointers. On a CPU / CLA / DMA access to SDDATFIFOx register, FIFO read pointers would be advanced to next available entry in FIFO.

### 28.7.3 SDSYNC Event

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting SDDFPARMx.SDSYNCEN = 1. Each primary filter can be synchronized from any of the available PWMx. SOCA / SOCB signals (see [Table 28-5](#)). Additionally, PWM11.CMPC/CMPD can be used to reset SDFM1 filter modules and PWM12.CMPC/CMPD can be used to reset SDFM2 filter modules. The SDSYNcx.SDSYNcSEL bits allow the user to configure which PWM signal provides the SDSYNC pulse to the primary filter. [Figure 28-10](#) shows how the PWM signals are connected to SDFM.

**Table 28-5. SDSYNcx.SYNcSEL**

SYNCSEL[5:2]	SDSYNcx.SYNcSEL[1:0]			
	0	1	2	3
0	PWM1.SOCA	PWM1.SOCB	Rsvd	Rsvd
1	PWM2.SOCA	PWM2.SOCB	Rsvd	Rsvd
2	PWM3.SOCA	PWM3.SOCB	Rsvd	Rsvd
3	PWM4.SOCA	PWM4.SOCB	Rsvd	Rsvd
4	PWM5.SOCA	PWM5.SOCB	Rsvd	Rsvd
5	PWM6.SOCA	PWM6.SOCB	Rsvd	Rsvd
6	PWM7.SOCA	PWM7.SOCB	Rsvd	Rsvd
7	PWM8.SOCA	PWM8.SOCB	Rsvd	Rsvd
8	PWM9.SOCA	PWM9.SOCB	Rsvd	Rsvd
9	PWM10.SOCA	PWM10.SOCB	Rsvd	Rsvd
10	PWM11.SOCA	PWM11.SOCB	Rsvd	Rsvd
11	PWM12.SOCA	PWM12.SOCB	Rsvd	Rsvd
12	PWM13.SOCA	PWM13.SOCB	Rsvd	Rsvd
13	PWM14.SOCA	PWM14.SOCB	Rsvd	Rsvd
14	PWM15.SOCA	PWM15.SOCB	Rsvd	Rsvd
15	PWM16.SOCA	PWM16.SOCB	Rsvd	SDFM1.SDSYNC1 - PWM11.CMPC SDFM1.SDSYNC2 - PWM11.CMPC SDFM1.SDSYNC3 - PWM11.CMPD SDFM1.SDSYNC4 - PWM11.CMPD SDFM2.SDSYNC1 - PWM12.CMPC SDFM2.SDSYNC2 - PWM12.CMPC SDFM2.SDSYNC3 - PWM12.CMPD SDFM2.SDSYNC4 - PWM12.CMPD

Figure 28-10. SDSYNC Event

**Note**

Ensure that ONLY ONE SDSYNC event will be generated per PWM timer period. Using PWM in up-count or down-count mode would automatically ensure that you get ONLY SDSYNC event. But, if up-down count mode is used, then make sure that only one SDSYNC event per PWM cycle is generated; otherwise, the filter synchronizer will corrupt SDFM timing by providing two pulses per PWM cycle.

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type will be incorrect. Table 28-6 shows the number of incorrect samples on the following conditions:

- When Sinc filter is enabled / configured for first time.
- When Sinc filter is disabled / re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

**Table 28-6. Number of Incorrect Samples Tabulated**

Filter Type	Number of Incorrect Samples After the Filter is Enabled and Configured
Sinc1	No incorrect sample
Sinc2	The first sample of the Sinc2 filter is incorrect
SincFast	The first two samples of the SincFast filter are incorrect
Sinc3	The first two samples of the Sinc3 filter are incorrect

**CAUTION**

SDFM comparator interrupts should be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (CEVT1 and CEVT2) should be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and five SD-Cx clock cycles.

## 28.8 Comparator (Secondary) Filter Unit

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

### Note

The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

The comparator filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is disabled and setting SDCPARMx.CEN = 1 enables the comparator filter. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as '0' and a high input signal as '1'. The resulting calculations give only positive values for the output of the comparator filter. [Table 28-7](#) shows the different full-scale values that the comparator filter can store using different OSRs.

**Table 28-7. Peak Data Values for Different OSR/Filter Combinations**

OSR	Sinc1	Sinc2	Sinc3	SincFast
x	0 to x	0 to x2	0 to x3	0 to 2x2
4	0 to 4	0 to 16	0 to 64	0 to 32
8	0 to 8	0 to 64	0 to 512	0 to 128
16	0 to 16	0 to 256	0 to 4096	0 to 512
32	0 to 32	0 to 1024	0 to 32,768	0 to 2048

See [Section 28.6.1](#) to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is memory-mapped and can be read in the SDCDATAx register. This register, SDCDATAx, is updated every COSR number of SD-Cx cycles. The comparator filter digital output is connected to digital comparators explained below.

Figure 28-11. Comparator Unit Structure

### 28.8.1 Higher Threshold (HLT) Comparators

- High threshold comparator can be used to detect over-value condition.
- When comparator data  $\geq$  higher threshold register, a high threshold event is generated.
- Higher threshold comparator events except for COMPHZx can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has three High Threshold comparators:
  - **Higher Threshold 1 (HLT1) Comparator :**
    - When comparator data  $\geq$  (SDFLTxCMPH1.HLT), HLT1 comparator generates COMPH1 event.
    - The COMPH1 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold 2 (HLT2) Comparator**
    - When comparator data  $\geq$  (SDFLTxCMPH2.HLT), HLT2 comparator generates COMPH2 event.
    - The COMPH2 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold (HTLZ) Comparator**
    - When comparator data  $\geq$  (SDFLT1CMPHZ.CMPHZ), it can generate a Higher Threshold (B) event (COMPHZx) and sets the corresponding SDSTATUS.HZx flag. But, this event cannot be configured to generate SDFM interrupt (SDx\_ERR). The COMPHZ signals from HTLZ comparator are connected to CLB XBAR.

### 28.8.2 Lower Threshold (LLT) Comparators

- The low threshold comparator can be used to detect under-value condition.
- When comparator data  $\leq$  Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events : CPU interrupt, CLA task, PWM trip.
- Lower threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of Threshold crossing
- This device has two low threshold comparators. .
  - **Lower Threshold 1 (LLT1) Comparator**
    - When comparator data  $\leq$  (SDFLTxCMPL1.LLT), the LLT1 comparator generates COMPL1 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.
  - **Lower Threshold 2 (LLT2) Comparator**
    - When comparator data  $\leq$  (SDFLTxCMPL2.LLT), LLT2 comparator generates COMPL2 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.

### 28.8.3 Digital Filter

The digital filter works on a window of FIFO samples ( $SAMPWIN + 1$ ) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold ( $THRESH$ ) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of  $THRESH$  must be greater than  $SAMPWIN / 2$ .

A prescale function ( $CLKPRESCALE$ ) determines the filter sampling rate, where the filter FIFO captures one sample every  $CLKPRESCALE$  system clocks. Old data from the FIFO is discarded.

A conceptual model of the digital filter is shown in [Figure 28-12](#).

Figure 28-12. Digital Filter

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}

```

### Filter Initialization Sequence

To ensure proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure the digital filter parameters for operation:
  - Set  $SAMPWIN$  for the number of samples to monitor in the FIFO window.
  - Set  $THRESH$  for the threshold required for majority qualification.
  - Set  $CLKPRESCALE$  for the digital filter clock prescale value.
2. Initialize the sample values in the digital FIFO window by setting  $FILINIT = 1$ .

## 28.9 Theoretical SDFM Filter Output

The following equations can be used to derive a theoretical filter output of an SDFM filter output for both a comparator filter and a data filter.

$$\text{Density of ones in bitstream} = \frac{\text{Input Voltage} + V_{\text{clipping}}}{2 \times V_{\text{clipping}}} \quad (18)$$

Where:

- $V_{\text{clipping}}$  = maximum differential voltage input range of modulator
- Input voltage = Differential input voltage applied to the modulator

$$\begin{aligned} \text{Comparator Filter Output (Theoretical)} = \\ \text{Density of ones in bitstream} \times \text{Maximum Filter Output (FilterType, COSR)} \end{aligned} \quad (19)$$

$$\text{FilterOutput} = \left\{ \frac{\text{absolute}(\text{Input voltage})}{V_{\text{clipping}}} \right\} \times \text{Maximum Filter Output (FilterType, DOSR)} \quad (20)$$

$$\text{Data Filter Output}_{32\text{bit}}(\text{Theoretical}) = \begin{cases} \text{FilterOutput} & \text{if Input Voltage is +ve voltage} \\ 2\text{'s complement} & \text{if input voltage is -ve voltage} \\ \text{of FilterOutput} & \end{cases} \quad (21)$$

$$\begin{aligned} \text{Data Filter Output}_{16\text{bit}}(\text{Theoretical}) = \\ \text{Data Filter Output}_{32\text{bit}}(\text{Theoretical}) \gg \text{Shift value}(\text{FilterType, OSR}) \end{aligned} \quad (22)$$

For example, when using the AMC1306x25 modulator:

AMC1306x25	Vclipping = Input voltage (AINP - AINN) =	320 mV 100 mV
SDFM filter settings	Filter type = Comparator OSR (COSR) = Data filter OSR (DOSR) =	3 32 100

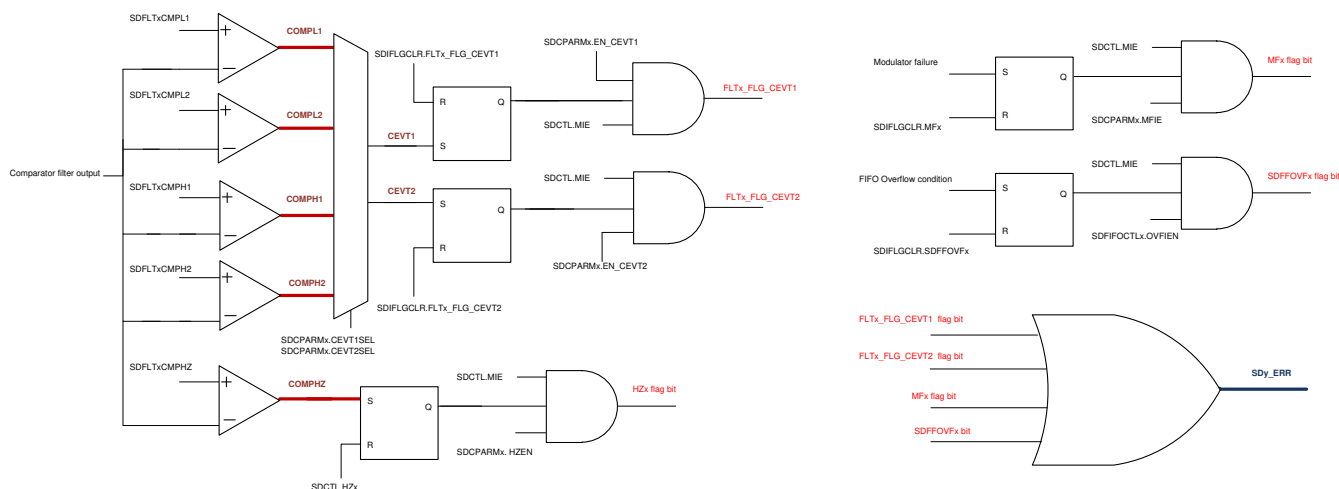

Density of ones in bitstream	Using <a href="#">Equation 18</a>	0.65625
Comparator filter output Filter type = Sinc3 COSR = 32	Using <a href="#">Equation 19</a>	21504
Data filter output (32-bit) Filter type = Sinc3 DOSR = 100	Using <a href="#">Equation 20</a> and <a href="#">Equation 21</a>	312500
Data filter output (32-bit) Filter type = Sinc3 DOSR = 100 (Right shift by 5)	Using <a href="#">Equation 22</a>	9765

## 28.10 Interrupt Unit

Each SDFM can generate five CPU interrupts such as SDFM Error (SDy\_ERR) and SDFM data ready (SDy\_DRINT1 / SDy\_DRINT2, SDy\_DRINT3, SDy\_DRINT4) interrupts for each filter module.

### 28.10.1 SDFM (SDyERR) Interrupt Sources

Figure 28-13 shows the structure of SDy\_ERR interrupt. SDy\_ERR interrupt can be triggered by any of these 16 events.

**Figure 28-13. SDFM Error (SD\_ERR) Interrupt Sources**

#### 1. Comparator Event1 (CEVT1)

CEVT1 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator Event1 interrupt (SDCPARMx.EN\_CEVT1 = 1)

On a CEVT1 event, SDIFLG.FLTx\_FLG\_CEVT1 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 2. Comparator Event2 (CEVT2)

CEVT2 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator event1 interrupt (SDCPARMx.EN\_CEVT2 = 1)

On a CEVT2 event, SDIFLG.FLTx\_FLG\_CEVT2 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

### 3. Modulator Failure (MFx) event

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

### 4. FIFO overflow (SDFFOVx) event

The number of filter data available in FIFO at any given point can be tracked in SDFIFOCTLx.SDFFST. If the number of words received in FIFO is greater than Max FIFO depth (16), SDFFOVx event is generated. SDFFOVx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt, only if below configurations are made:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO overflow interrupt (Set SDFIFOCTLx.OVFIEN = 1) and
- Enable Main interrupt enable (Set SDCTL.MIE = 1)

On a SDFFOVx event, all subsequent data (primary) filter data is lost and is not stored in FIFO. SDIFLG.SDFFOVx flag bit is set on a FIFO overflow event and this bit can be cleared if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 28.10.2 Data Ready (DRINT) Interrupt Sources

Figure 28-14 shows the structure of interrupt SDy\_DRINTx interrupt. Each SDy\_DRINTx interrupt is triggered by corresponding Data Filter channel.

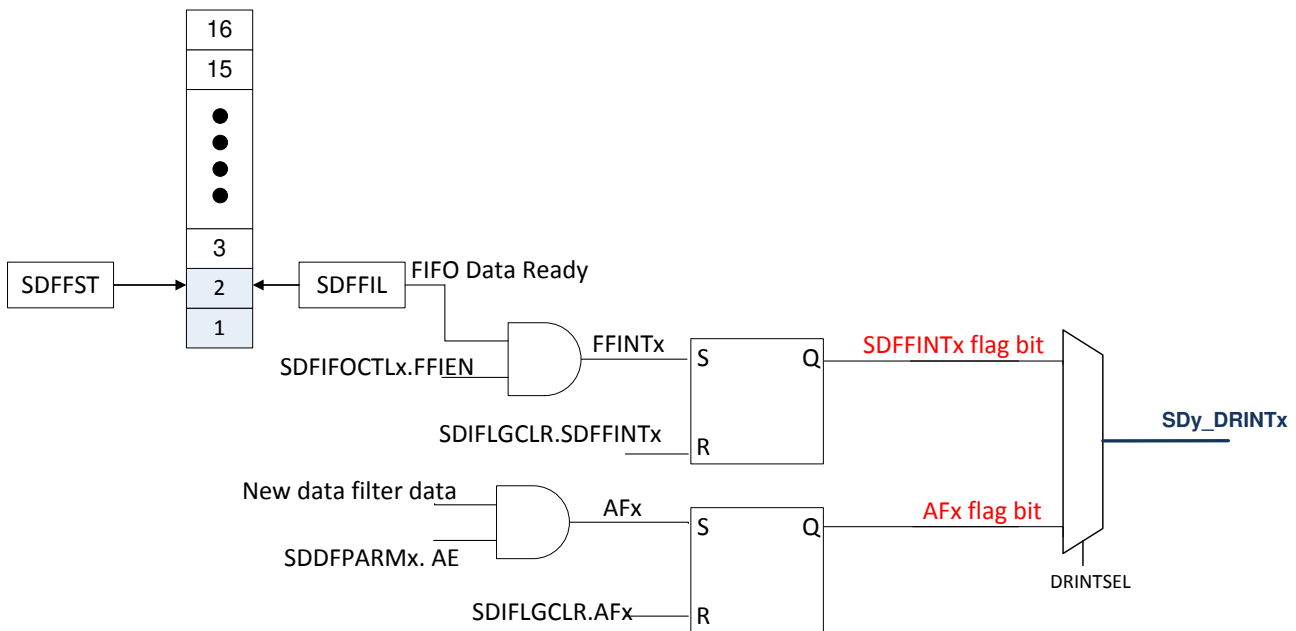

Figure 28-14. SDFM Data Ready (SDy\_DRINTx) Interrupt

## 1. Data Acknowledge (AFx)

When the primary filter is ready with a new filter data, AFx event is generated. AFx events from each filter can generate its own SDy\_DRINTx interrupt. This event can be configured to trigger SDy\_DRINTx interrupt only if below configurations are made:

- Enable individual filter interrupts (SDDFPARMx.AE = 1)
- Select data-ready interrupt source AFx (DRINTx = AFx) (SDFIFOCTLx.DRINTSEL = 0)

On an AFx event, the SDIFLG.AFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 2. Four FIFO Data ready interrupt (SDFFINTx)

FIFO Data Ready event is generated whenever SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met. FIFO data ready events from each filter can generate its own SDy\_DRINTx interrupt. This event can be configured to trigger SDy\_DRINTx interrupt only if below configurations are made:

Table 28-8 shows how the DRINTx output is selected.

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1) and
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Select data-Ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

**Table 28-8. SDFM Data-Ready Interrupt (SDy\_DRINTx) Output Selection**

DRINTSEL	AE	FFIEN	FFEN	DRINTx
0	0	x	X	0
0	1	x	X	AFx
1	x	0	X	0
1	x	x	0	0
1	x	1	1	SDFFINTx

## 28.11 Software

### 28.11.1 SDFM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/sdfm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 28.11.1.1 SDFM Filter Sync CPU

FILE: sdfm\_ex1\_filter\_sync\_cpuread.c

In this example, SDFM filter data is read by CPU in SDFM ISR routine. The SDFM configuration is shown below:

- SDFM used in this example - SDFM1
- Input control mode selected - MODE0
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - HLT = 0x7FFF (Higher threshold setting)
  - LLT = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 128
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 7 bits for Sinc3 filter with OSR = 128
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available.

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 28.11.1.2 SDFM Filter Sync CLA

FILE: sdfm\_ex2\_filter\_sync\_claread.c

In this example, SDFM filter data is read by CLA in Cla1Task1. The SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32

- hlt = 0x7FFF (Higher threshold setting)
- llt = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### *External Connections*

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### *Watch Variables*

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

### **28.11.1.3 SDFM Filter Sync DMA**

FILE: `sdm_ex3_filter_sync_dmaread.c`

In this example, SDFM filter data is read by DMA. The SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### *External Connections*

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 28.11.1.4 SDFM PWM Sync

FILE: `sdfm_ex4_pwm_sync_cpuread.c`

In this example, SDFM filter data is read by CPU in SDFM ISR routine. The SDFM configuration is shown below:

- SDFM1 is used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000(Lower threshold setting)

#### Data filter settings

- All the 4 filter modules enabled
- Sinc3 filter selected
- OSR = 256
- All the 4 filters are synchronized by using PWM (Master Filter enable bit)
- Filter output represented in 16 bit format
- In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256

#### Interrupt module settings for SDFM filter

- All the 4 higher threshold comparator interrupts disabled
- All the 4 lower threshold comparator interrupts disabled
- All the 4 modulator failure interrupts disabled
- All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 28.11.1.5 SDFM Type 1 Filter FIFO

FILE: `sdfm_ex5_type1_filter_fifo_cpuread.c`

This example configures SDFM1 filter in type 1 to demonstrate data read through CPU in FIFO & non-FIFO mode. Data filter is configured in mode 0 to select SINC3 filter with OSR of 256. Filter output is configured for 16-bit format and data shift of 10 is used.

This example demonstrates the FIFO usage if enabled. FIFO length is set at 16 and data ready interrupt is configured to be triggered when FIFO is full. In this example, SDFM filter data is read by CPU in SDFM Data Ready ISR routine.

#### *External Connections*

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO16, GPIO17)
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO48, GPIO49)
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO122, GPIO123)

#### *Watch Variables*

- *filter1Result* - Output of filter 1

### **28.11.1.6 SDFM Filter Sync CLA**

FILE: `sdfm_ex6_FIFO_freeze_claread.c`

In this example, SDFM FIFO will not be filled until a SDSYNC event. On a SDSYNC event, SDFM data filter output will start filling FIFO and stop filling after programmable number 'N' of FIFO is filled.

SDy-C1 (Filter1 channel clock) is internally configured to connected SDy-C2 / SDy-C3 / SDy-C4 SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000 (Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### *External Connections*

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO122-GPIO137

#### *Watch Variables*

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3

- *filter4Result* - Output of filter 4

## 28.12 SDFM Registers

This section describes the Sigma Delta Filter Module registers.

### 28.12.1 SDFM Base Address Table (C28)

**Table 28-9. SDFM Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
Sdfm1Regs	SDFM_REGS	SDFM1_BASE	0x0000_5E00	YES	YES	YES	YES	YES
Sdfm2Regs	SDFM_REGS	SDFM2_BASE	0x0000_5E80	YES	YES	YES	YES	YES

## 28.12.2 SDFM\_REGS Registers

Table 28-10 lists the memory-mapped registers for the SDFM\_REGS registers. All register offset addresses not listed in Table 28-10 should be considered as reserved locations and the register contents should not be modified.

**Table 28-10. SDFM\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SDIFLG	SD Interrupt Flag Register		<a href="#">Go</a>
2h	SDIFLGCLR	SD Interrupt Flag Clear Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 28-11](#) shows the codes that are used for access types in this section.

**Table 28-11. SDFM\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 28.12.2.1 SDIFLG Register (Offset = 0h) [Reset = 0h]

SDIFLG is shown in [Figure 28-15](#) and described in [Table 28-12](#).

Return to the [Summary Table](#).

0	FLT1_FLG_CEVT1	R	0h	CEVT1 Interrupt flag for filter1 0: CEVT1 event has not occurred 1: CEVT1 event has occurred Reset type: SYSRSn

### 28.12.2.2 SDIFLGCLR Register (Offset = 2h) [Reset = 0h]

SDIFLGCLR is shown in [Figure 28-16](#) and described in [Table 28-13](#).

Return to the [Summary Table](#).

SD Module Interrupt Flag Clear Bits:

Writing a "1" will clear the respective flag bit in the SDIFLG register.

Writes of "0" are ignored.

Note: If user writes a "1" to clear a bit on the same cycle that the hardware is trying to set the bit to "1", then hardware has priority and the bit will not be cleared.

The following chapters describe the communication peripherals.

## 29.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown in [Figure 29-1](#). This Technical Reference Manual is organized into five major sections:

- **C28x SYSTEM RESOURCES**

These chapters describe the C28x CPU subsystem, C28x Boot ROM, device configuration, and other system peripherals.

- **ANALOG PERIPHERALS**

These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.

- **CONTROL PERIPHERALS**

These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- **COMMUNICATION PERIPHERALS**

These chapters describe the communication peripherals available to the C28x subsystem such as the I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.

- **CONNECTIVITY MANAGER (CM)**

These chapters describe the Connectivity Manager (CM) subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Figure 29-1. F2838x Block Diagram

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

## 30.1 Introduction

This device uses the CAN IP known as DCAN.

### 30.1.2 Features

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1 Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably), each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard (11-bit) or extended (29-bit) identifier
  - Supports programmable identifier receive mask
  - Supports data and remote frames
  - Holds 0 to 8 bytes of data
  - Parity-checked configuration and data RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Message-RAM parity-check mechanism
- Two interrupt lines
- DMA support

---

#### Note

For a CAN bit clock of 200 MHz, the smallest bit rate possible is 7.8125 kbps.

Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data manual) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

---

### 30.1.3 Block Diagram

Figure 30-1 shows a block diagram of the CAN module. Following is a description of some of the main blocks.

Figure 30-1. CAN Block Diagram

### 30.1.3.1 CAN Core

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. It handles all ISO 118981 protocol functions.

### 30.1.3.2 Message Handler

The message handler is a state machine which controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. It also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

### 30.1.3.3 Message RAM

The CAN message RAM enables the storage of 32 CAN messages.

### 30.1.3.4 Registers and Message Object Access (IFx)

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through Interface registers.

Three Interface register sets control the CPU read and write accesses to the Message RAM. There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also [Section 30.13](#). The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

## 30.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests as well as the generation of interrupts or DMA requests.

The register set of the CAN may be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

### 30.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

### 30.2.2 Address/Data Bus Bridge

The CAN module uses a special addressing scheme to support byte accesses. It is recommended to only use 32-bit accesses to the CAN registers using the *HWREG\_BP()* macro that uses the *\_\_byte\_peripheral\_32()* intrinsic. If 16-bit accesses are to be used, the lower 16 bits should be written to the register's address, and the upper 16 bits should be written to the register's address, plus 2.

Because of the bus bridge, the view of the CAN module's register space through the Code Composer Studio™ (CCS) IDE memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses should be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view; odd addresses from the module are not displayed.

**Table 30-1. CAN Register Access from Software**

CAN Register Space			C28x 8-Bit		C28x 16-Bit		C28x 32-Bit	
Address	Name	Data	Access	Data	Access	Data	Address	Data

## 30.3 Operating Modes

### 30.3.1 Initialization

The initialization mode is entered either by software (by setting the **Init** bit in the CAN\_CTL register), by hardware reset, or by going bus-off. While the **Init** bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN\_TX output is recessive (high). The CAN error counters are not updated. Setting the **Init** bit does not change any other configuration register.

To initialize the CAN Controller, the CPU has to configure the CAN Bit timing and those message objects which have to be used for CAN communication. Message objects which are not needed, can be deactivated with their **MsgVal** bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and **CCE** bits in the CAN Control register are set.

Clearing the **Init** bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before it can take part in bus activities and start the message transfer. For more details, see [Section 30.12](#).

The initialization of the message objects is independent of the **Init** bit; however, all message objects should be configured to particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering will be applied to it when the modified message object number is same or smaller than the previously found message object. This assures data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

### 30.3.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for communication.

Received messages are stored into their appropriate message objects if they pass acceptance filtering. The whole message (MSGID, DLC, and up to eight data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits which are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority. Messages may be updated or set to 'not valid' at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

#### 30.3.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting the DAR bit in the CAN Control register. Further details to this mode are provided in [Section 30.11.3](#).

#### 30.3.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module will stay in bus-off state.

The CAN provides an automatic auto-bus-on feature which is enabled by the ABO bit. If set, the CAN will automatically start the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

---

#### Note

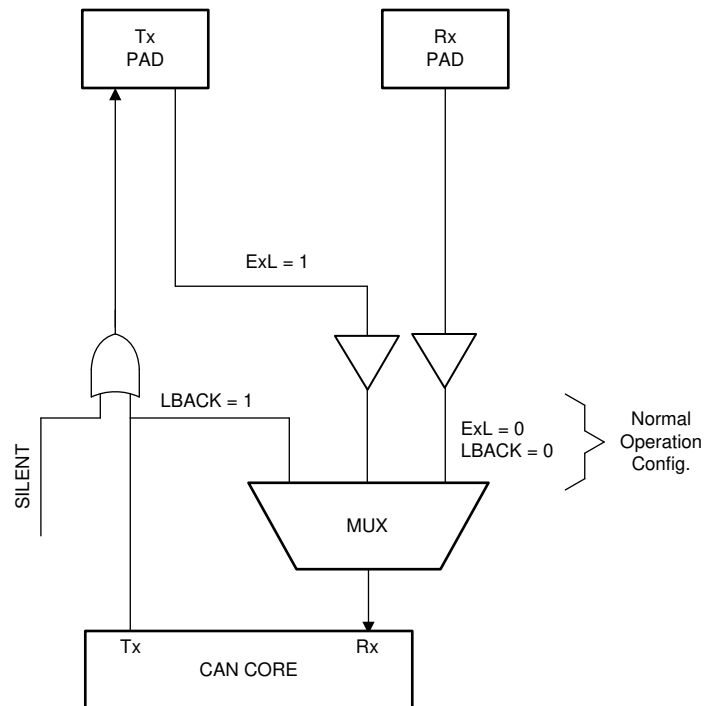

If the CAN module goes Bus-Off due to multiple CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit is cleared by the application (or due to the auto-bus-on feature), the device will wait for 129 occurrences of Bus Idle (equal to 129 \* 11 consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the Init bit. At the end of the bus-off recovery sequence, the error counters will be reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

---

### 30.3.3 Test Modes

The CAN module provides several test modes which are mainly intended for self-test purposes. Figure 30-2 aids in understanding the various test modes. It should be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. For the sake of brevity, this diagram does not include the GPIO muxing or the I/O buffers.

For all test modes, the Test bit in the CAN Control register needs to be set to 1 to enable write access to the CAN\_TEST register.

**Figure 30-2. CAN\_MUX**

### 30.3.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The CAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, the received frames are internally routed to the CAN Core.

Figure 30-3 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in test register (CAN\_TEST), to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 30-3. CAN Core in Silent Mode

### 30.3.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN\_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN\_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 30-4 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in loopback mode. Loopback mode can be activated by setting the LBack bit in the CAN\_TEST register to 1.

---

#### Note

In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see [Section 30.3.3.3](#).

---

**Figure 30-4. CAN Core in Loopback Mode**

### 30.3.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to the CAN Core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the ExL bit in Test Register to 1.

Figure 30-5 shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in external loopback mode.

**Note**

When loopback mode is active (LBack bit set), the ExL bit will be ignored.

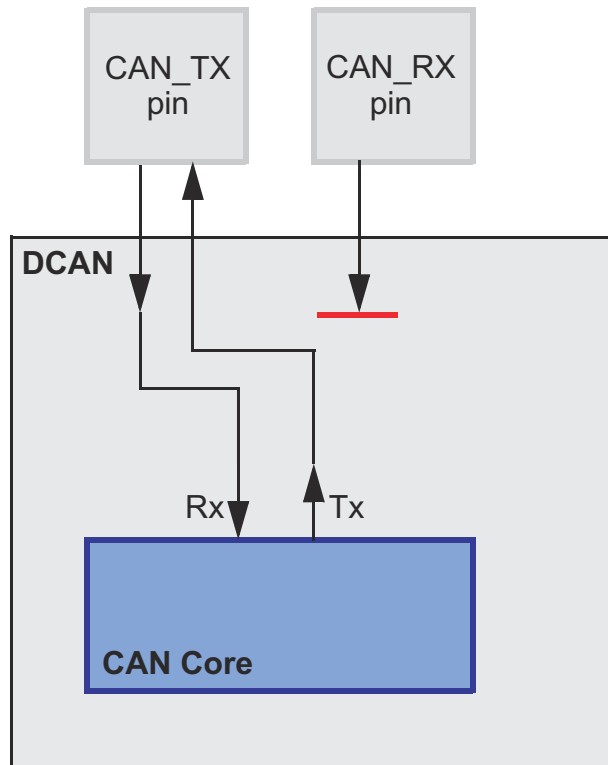

Figure 30-5. CAN Core in External Loopback Mode

### 30.3.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN\_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN\_TX pin.

Figure 30-6 shows the connection of the signals CAN\_TX and CAN\_RX to the CAN Core in case of the combination of loopback mode with silent mode.

**Figure 30-6. CAN Core in Loopback Combined with Silent Mode**

## 30.4 Multiple Clock Source

The CAN bit timing clock is normally derived from the system clock (SYSCLK). If desired, the bit clock can be derived directly from the external clock source (XTAL).

The *System Control* chapter and the device data sheet provide for more information on how to configure the relevant clock source registers in the system module.

### Note

The CAN core has to be programmed to at least eight clock cycles per bit time. To achieve a transfer rate of 1 Mbps an oscillator frequency of 8 MHz or higher has to be used.

## 30.5 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt register. When no interrupt is pending, the register will hold the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk and LEC by reading the Error and Status Register, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID / INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine which reads the message from the interrupt source, may also read the message and reset the message object's IntPnd at the same time (CIntPnd bit in the IF1/IF2 Command register). When IntPnd is cleared, the Interrupt register will point to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN\_GLB\_INT\_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt via CAN\_GLB\_INT\_CLR and PIEACK.

### 30.5.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in [Section 30.14.1](#). Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

Note that writing to the IntPnd bit in the CAN\_IFnMCTL registers can force an interrupt.

### 30.5.2 Status Change Interrupts

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN\_CTL Register.

### 30.5.3 Error Interrupts

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT, which has to be enabled by setting IE0 in the CAN\_CTL register.

### 30.5.4 PIE Nomenclature for DCAN Interrupts

[Table 30-3](#) shows the PIE nomenclature for the interrupts.

**Table 30-3. PIE Nomenclature for Interrupts**

Interrupt	CANA	CANB
CANINT0	CANA_0	CANB_0
CANINT1	CANA_1	CANB_1

### 30.5.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in Figure 30-7 and Figure 30-8. Mailbox interrupts for transmit and receive operations can be routed to both CANINT0 and CANINT1. However, error and status interrupts can only be routed to CANINT0.

Figure 30-7. CAN Interrupt Topology 1

Figure 30-8. CAN Interrupt Topology 2

## 30.6 DMA Functionality

The CAN module provides three DMA trigger outputs, one for each of the three Interface Registers IF1, IF2 and IF3. These can be enabled using the DE1, DE2, and DE3 bits in the CAN\_CTL register.

The Update of IF1 and IF2 registers will be initiated by a write access to the IF1 and IF2 Command registers, respectively. Once enabled, setting the DMAActive bit in the IF1CMD or IF2CMD registers will cause a DMA request the next time the corresponding interface becomes available.

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update. That is, when IF3 DMA requests are enabled, all IF3 updates will trigger a DMA request.

When a DCAN internal IFx update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers; that is, DMA requests are cleared after the first read or write access to an IF register set.

## 30.7 Parity Check Mechanism

The CAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in Message RAM, one parity bit will be calculated.

Parity information is stored in the Message RAM on write accesses and will be checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN Control register. In case of a disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the CAN. A parity bit will be set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

### 30.7.1 Behavior on Parity Error

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object will be checked. If a parity error is detected, the PER bit in the Error and Status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

## 30.8 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit will wait until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect. Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization (see [Section 30.14.3](#)).

---

### Note

During debug mode, the Message RAM cannot be accessed via the IFx register sets.

Writing to control registers in Debug mode may influence the CAN state machine and further message handling.

---

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers (clear of DMA Active flag by read/write)

## 30.9 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects should be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see [Section 30.10](#).

For the configuration of the Bit Timing, see [Section 30.12.2](#).

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to '0' by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted via the CAN bus.

The CPU may enable the interrupt lines (setting IE0 and IE1 to '1') at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication may be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with IntPnd = '1'. It is updated even if the interrupt lines to the CPU are disabled (IE0 / IE1 are zero).

The CPU may poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData registers and the Transmission Request registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers; all Receive Objects are grouped at the high numbers.

## 30.10 Configuration of Message Objects

The entire Message RAM should be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

### 30.10.1 Configuration of a Transmit Object for Data Frames

Figure 30-9 shows how a transmit object can be initialized.

**Figure 30-9. Initialization of a Transmit Object**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.
- The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.
- If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.
- If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.
- The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see [Section 30.11.8](#). Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

### 30.10.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object will cause the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

### 30.10.3 Configuration of a Single Receive Object for Data Frames

Figure 30-10 shows how a receive object for data frames can be initialized.

**Figure 30-10. Initialization of a Single Receive Object for Data Frames**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- When the message handler stores a data frame in the message object, it will store the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.
- The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored data frame.
- If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = '1') for acceptance filtering.

### 30.10.4 Configuration of a Single Receive Object for Remote Frames

Figure 30-11 shows how a receive object for remote frames can be initialized.

**Figure 30-11. Initialization of a Single Receive Object for Remote Frames**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

- Receive objects for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer, see [Section 30.10.5](#).
- UMask must be set to '1'. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see [Section 30.11.8](#).
- The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.
- If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

### 30.10.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to zero. The EoB bits of the last message object of a FIFO buffer is set to one, configuring it as the end of the block.

## 30.11 Message Handling

When initialization is finished, the CAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages that are received and accepted. Messages that are not read before the next messages are accepted for the same message object will be overwritten. Messages may be read interrupt-driven or after polling of NewDat.

### 30.11.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).
- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

### 30.11.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 30.11.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN Control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching Transmit Object the RmtEn bit is set.

#### 30.11.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MsgVal nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see [Section 30.11.3](#).

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

#### 30.11.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

---

#### Note

After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

---

### 30.11.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

### 30.11.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

### 30.11.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

1. Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'  
The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'  
The remote frame is ignored, this message object remains unchanged.
3. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'  
The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

### 30.11.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface registers, the data consistency is guaranteed by the message handler state machine.

Typically the CPU will write 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

### 30.11.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

### 30.11.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is '1'.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is '0' the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to '0', all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = '1') and therefore overwrite previous messages in this message object.

### 30.11.12 Reading from a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer. A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared. A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in [Figure 30-12](#).

---

#### Note

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality cannot be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

---

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

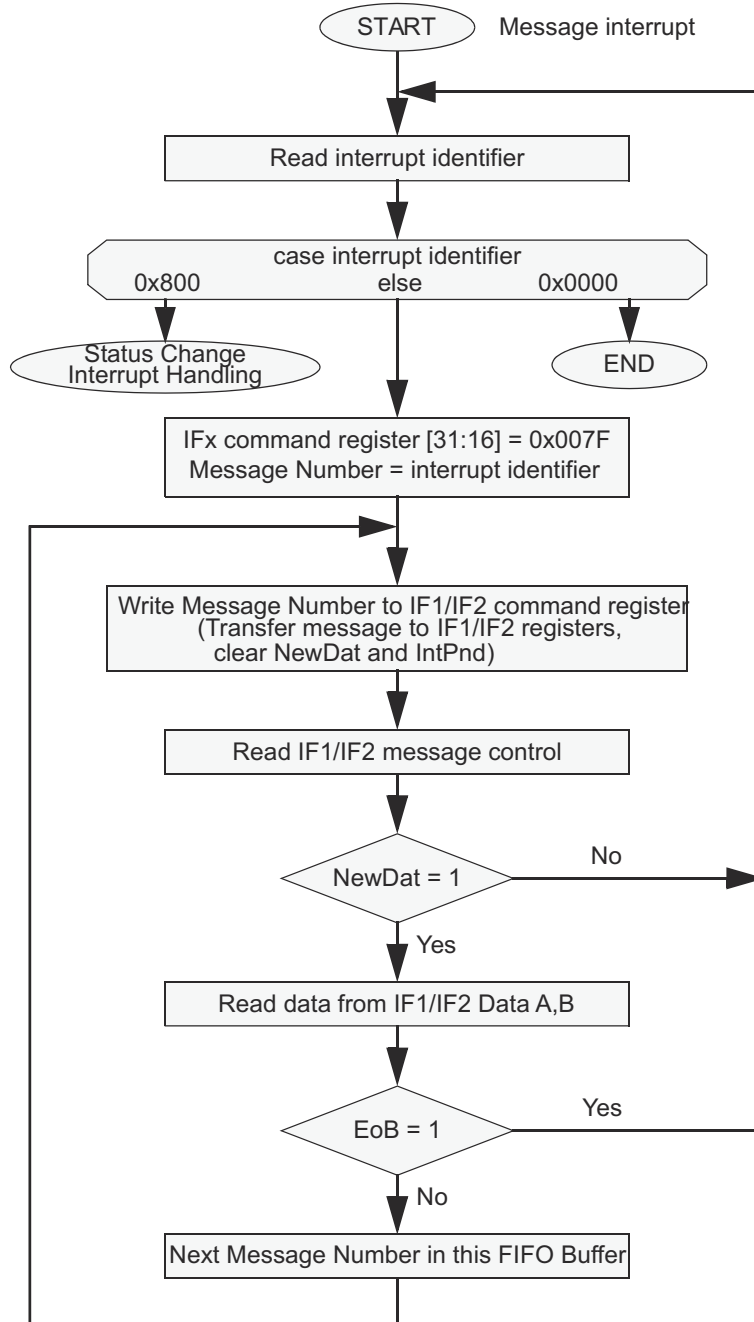

Figure 30-12. CPU Handling of a FIFO Buffer (Interrupt Driven)

## 30.12 CAN Bit Timing

The CAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods ( $F_{osc}$ ) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range ( $df$ ), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

### 30.12.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see [Figure 30-13](#)):

- Synchronization Segment (Sync\_Seg)
- Propagation Time Segment (Prop\_Seg)
- Phase Buffer Segment 1 (Phase\_Seg1)
- Phase Buffer Segment 2 (Phase\_Seg2)

**Figure 30-13. Bit Timing**

Each segment consists of a specific number of time quanta. The length of one time quantum ( $t_q$ ), which is the basic time unit of the bit time, is given by the CAN\_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate Prescaler} / \text{CAN\_CLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. [Table 30-4](#) describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

**Table 30-4. Programmable Ranges Required by CAN Protocol**

Parameter	Range	Remark
Sync_Seg	1 $t_q$ (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 ... 8] $t_q$	Compensates for the physical delay times
Phase_Seg1	[1 ... 8] $t_q$	May be lengthened temporarily by synchronization
Phase_Seg2	[1 ... 8] $t_q$	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 ... 4] $t_q$	May not be longer than either phase buffer segment

**Note**

For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

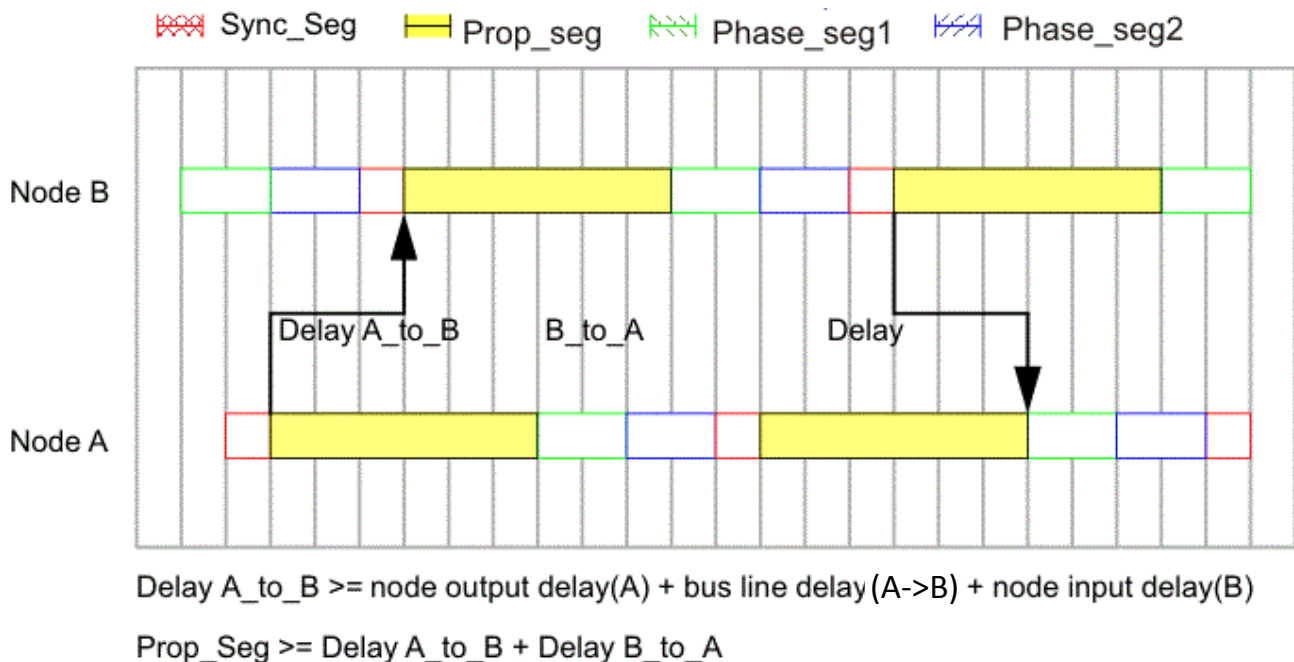

**30.12.1.1 Synchronization Segment**

The Synchronization Segment (Sync\_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync\_Seg, its distance to the Sync\_Seg is called the phase error of this edge.

**30.12.1.2 Propagation Time Segment**

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 30-14 shows the phase shift and propagation times between two CAN nodes.

**Figure 30-14. The Propagation Time Segment**

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A\_to\_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay(B\_to\_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase\_Seg1. This condition defines the length of Prop\_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase\_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the Bit timing configuration (Prop\_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of  $1 t_q$ , requiring a longer Prop\_Seg.

### 30.12.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase\_Seg1 and Phase\_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync\_Seg, otherwise its distance to the Sync\_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync\_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame only resynchronizing is possible.

- Hard Synchronization

After a hard synchronization, the bit time is restarted with the end of Sync\_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge which causes resynchronization is positive, Phase\_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase\_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

When the phase error of the edge which causes resynchronization is negative, Phase\_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase\_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

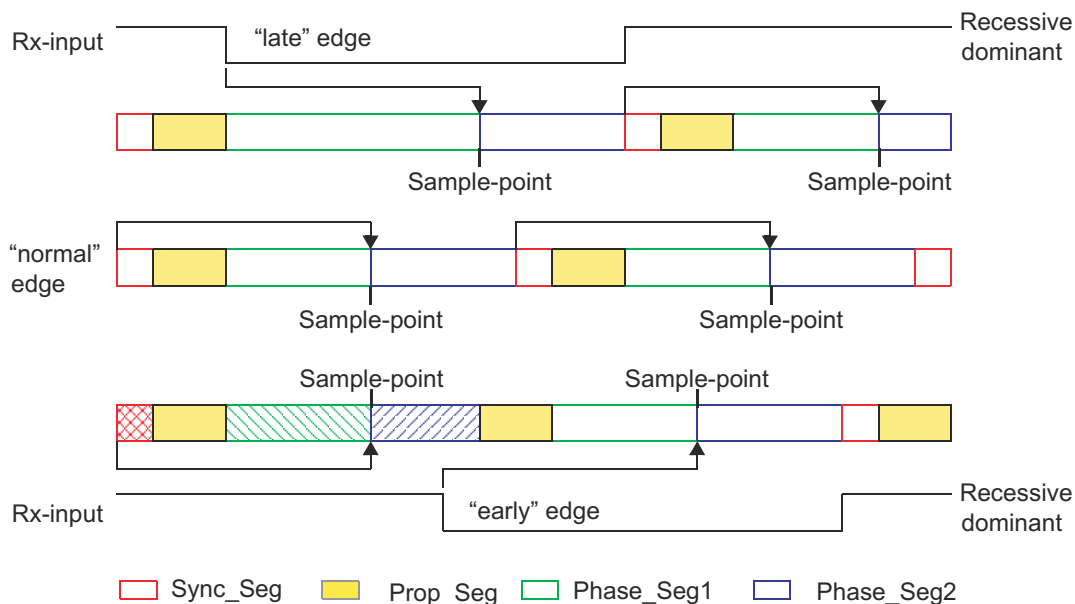

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop\_Seg + Phase\_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The "leading" transmitter does not necessarily win the arbitration, therefore the receivers have to synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator's tolerance range.

The examples in Figure 30-15 show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

**Figure 30-15. Synchronization on Late and Early Edges**

In the first example, an edge from recessive to dominant occurs at the end of Prop\_Seg. The edge is "late" since it occurs after the Sync\_Seg. Reacting to the "late" edge, Phase\_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync\_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync\_Seg.

In the second example, an edge from recessive to dominant occurs during Phase\_Seg2. The edge is "early" since it occurs before a Sync\_Seg. Reacting to the "early" edge, Phase\_Seg2 is shortened and Sync\_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync\_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

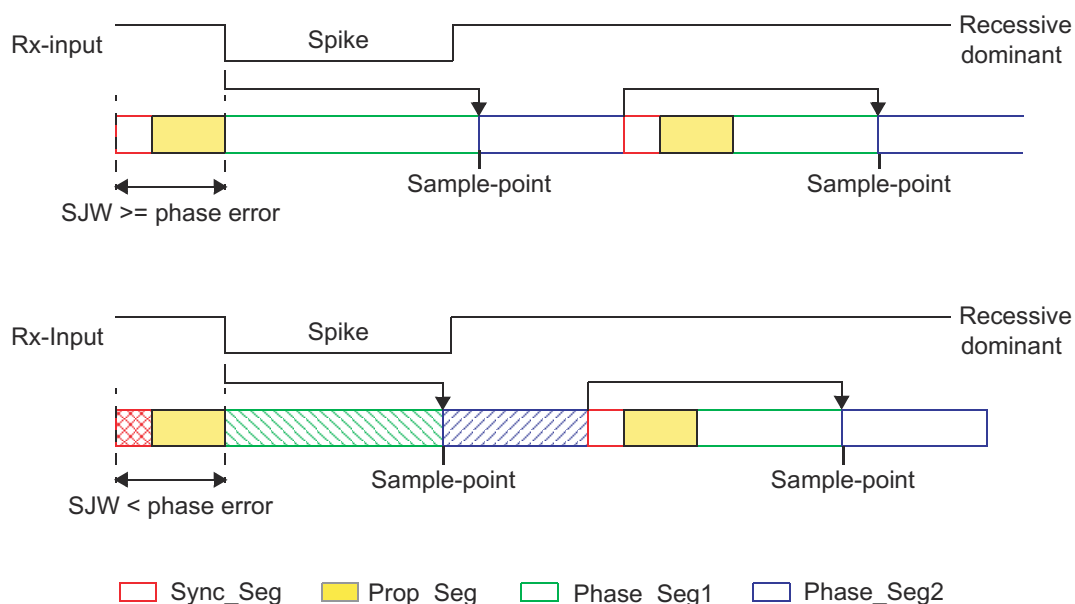

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync\_Seg when synchronizing on an "early" edge because it cannot subsequently redefine that time quantum of Phase\_Seg2 where the edge occurs to be the Sync\_Seg.

The examples in Figure 30-16 show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop\_Seg and has the length of (Prop\_Seg + Phase\_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

**Figure 30-16. Filtering of Short Dominant Spikes**

### 30.12.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range  $df$  for an oscillator's frequency  $f_{osc}$  around the nominal frequency  $f_{nom}$  with:

$$(1 - df) \cdot f_{nom} \leq f_{osc} \leq (1 + df) \cdot f_{nom} \quad (23)$$

depends on the proportions of Phase\_Seg1, Phase\_Seg2, SJW, and the bit time. The maximum tolerance  $df$  is defined by two conditions (both shall be met):

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit\_time} \quad (24)$$

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop\_Seg = 1 and Phase\_Seg1 = Phase\_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8  $\mu$ s) with a bus length of 40 m.

### 30.12.2 Configuration of the CAN Bit Timing

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop\_Seg and Phase\_Seg1 (as TSEG1) is combined with Phase\_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see [Figure 30-17](#)).

In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1...n], values in the range of [0...n-1] are programmed. That way, for example, SJW (functional range of [1...4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values) [TSEG1 + TSEG2 + 3]  $t_q$  or (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2]  $t_q$ .

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP.

The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is  $0 t_q$  for the CAN.

Generally, the IPT is CAN controller specific, but may not be longer than  $2 t_q$ . The IPT length is the lower limit of the programmed length of Phase\_Seg2. In case of a synchronization, Phase\_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

Figure 30-17. Structure of the CAN Core's CAN Protocol Controller

### 30.12.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time ( $1 / \text{Bit rate}$ ) must be an integer multiple of the CAN clock period.

---

#### Note

8 MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1 MBit/s.

---

The bit time may consist of 8 to 25 time quanta. The length of the time quantum  $t_q$  is defined by the Baud Rate Prescaler with  $t_q = (\text{Baud Rate Prescaler}) / \text{CAN\_CLK}$ . Several combinations may lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop\_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop\_Seg is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The Sync\_Seg is  $1 t_q$  long (fixed), leaving  $(\text{bit time} - \text{Prop\_Seg} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length,  $\text{Phase\_Seg2} = \text{Phase\_Seg1}$ , else  $\text{Phase\_Seg2} = \text{Phase\_Seg1} + 1$ .

The minimum nominal length of Phase\_Seg2 has to be regarded as well. Phase\_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of  $[0 \dots 2] t_q$ .

The length of the synchronization jump width is set to its maximum value, which is the minimum of 4 and Phase\_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in [Section 30.12.1.4](#).

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

$(\text{Phase\_Seg2}-1) \& (\text{Phase\_Seg1} + \text{Prop\_Seg} - 1) \&$

$(\text{SynchronizationJumpWidth}-1) \& (\text{Prescaler}-1)$

### 30.12.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN\_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

$t_q$	100 ns	=	$t_{CAN\_CLK}$
delay of bus driver	90 ns	=	
delay of receiver circuit	40 ns	=	
delay of bus line (40m)	220 ns	=	
$t_{Prop}$	700 ns	=	$2 \cdot \text{delays} = 7 \cdot t_q$
$t_{SJW}$	100 ns	=	$1 \cdot t_q$
$t_{TSeg1}$	800 ns	=	$t_{Prop} + t_{SJW}$
$t_{TSeg2}$	100 ns	=	Information Processing Time + $1 \cdot t_q$
$t_{Sync-Seg}$	100 ns	=	$1 \cdot t_q$
bit time	1000 ns	=	$t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	0.35 %	=	$\frac{\min(Tseg1, Tseg2)}{2((13 \times \text{bit time}) - Tseg2)}$
			$= \frac{0.1 \mu s}{2((13 \times 1 \mu s) - 0.1 \mu s)}$

In this example, the concatenated bit time parameters are  $(1-1)_3 \& (8-1)_4 \& (1-1)_2 \& (1-1)_6$ , so the Bit Timing Register is programmed to = 0x00000700.

### 30.12.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN\_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

$t_q$	1 $\mu s$	=	$2 \cdot t_{CAN\_CLK}$
delay of bus driver	200 ns	=	
delay of receiver circuit	80 ns	=	
delay of bus line (40m)	220 ns	=	
$t_{Prop}$	1 $\mu s$	=	$1 \cdot t_q$
$t_{SJW}$	4 $\mu s$	=	$4 \cdot t_q$
$t_{TSeg1}$	5 $\mu s$	=	$t_{Prop} + t_{SJW}$
$t_{TSeg2}$	4 $\mu s$	=	Information Processing Time + $4 \cdot t_q$
$t_{Sync-Seg}$	1 $\mu s$	=	$1 \cdot t_q$
bit time	10 $\mu s$	=	$t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	1.58 %	=	$\frac{\min(Tseg1, Tseg2)}{2((13 \times \text{bit time}) - Tseg2)}$
			$= \frac{4 \mu s}{2((13 \times 10 \mu s) - 4 \mu s)}$

In this example, the concatenated bit time parameters are  $(4-1)_3 \& (5-1)_4 \& (4-1)_2 \& (2-1)_6$ , so the Bit Timing register is programmed to = 0x000034C1.

### 30.13 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modify-write cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see [Section 30.14.1](#)) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

That being said, there is one condition that can cause a write access to the message RAM to be lost. If `MsgVal = 1` for the message object which is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM may be lost. The reason for this is that it might happen that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when it is in the process of receiving a message for the same message object.

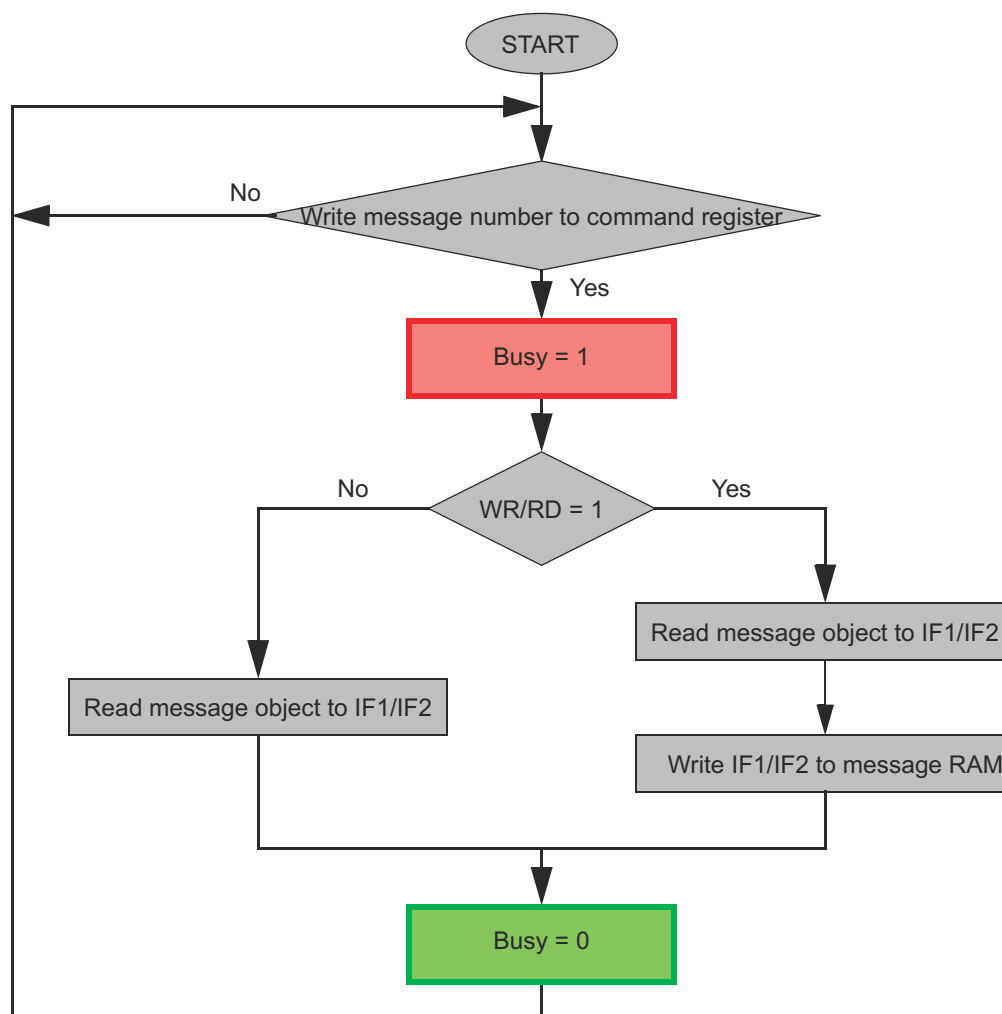

To avoid this issue with receive mail boxes, reset `MsgVal` before changing any of the following: `Id28-0`, `Xtd`, `Dir`, `DLC3-0`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`.

To avoid this issue with transmit mail boxes, reset `MsgVal` before changing any of the following: `Dir`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`. Other fields not listed above, like `Data`, may be changed without fear of losing a write to the message RAM.

#### 30.13.1 Message Interface Register Sets 1 and 2 (IF1 and IF2)

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register will be overwritten by values taken from the other IFx registers. If the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register will be copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see [Figure 30-18](#)).

**Figure 30-18. Data Transfer Between IF1 / IF2 Registers and Message RAM**

### 30.13.2 Message Interface Register Set 3 (IF3)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA will be requested. The DMA request stays active until the first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in the CAN Control register.

#### Note

The IF3 register set can not be used for transferring data into message objects.

### 30.14 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed via the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

#### 30.14.1 Structure of Message Objects

Figure 30-19 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Figure 30-19. Structure of a Message Object**

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

**Table 30-5. Message Object Field Descriptions**

Name	Value	Description
MsgVal	0	Message valid The message object is ignored by the message handler.
	1	The message object is to be used by the message handler. Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code DLC[3:0] are changed.
UMask	0	Use Acceptance Mask Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering. Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]	ID[28:0]	Message Identifier 29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits

**Table 30-5. Message Object Field Descriptions (continued)**

Name	Value	Description
Msk[28:0]	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering. Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28xx devices, where a "1" means the corresponding bit is NOT used for filtering, and "0" means it is used.
Xtd	0	The 11-bit ("standard") identifier will be used for this message object.
	1	The 29-bit ("extended") identifier will be used for this message object.
MXtd	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering. Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
MDir	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority.

**Table 30-5. Message Object Field Descriptions (continued)**

Name	Value	Description
RmtEn	0	Remote Enable At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set. Note: See <a href="#">Section 30.11.8</a> for details on the setup of RmtEn and UMask for remote frames.
TxRqst	0	Transmit Request This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]	0-8	Data length code Data frame has 0-8 data bytes.
	9-15	Data frame has 8 data bytes. Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

### 30.14.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) \* 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

#### Note

'0' is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

Message Object number 1 has the highest priority.

**Table 30-6. Message RAM Addressing in Debug Mode**

Message Object Number	Offset From Base Address	Word Number	Debug Mode <sup>(1)</sup>
last implemented (here:32)	0x0000	1	Parity
	0x0004	2	MXtd,MDir,Mask
	0x0008	3	Xtd,Dir,ID
	0x000C	4	Ctrl
	0x0010	5	Data Bytes 3-0
	0x0014	6	Data Bytes 7-4
1	0x0020	1	Parity
	0x0024	2	MXtd,MDir,Mask
	0x0028	3	Xtd,Dir,ID
	0x002C	4	Ctrl
	0x0030	5	Data Bytes 3-0
	0x0034	6	Data Bytes 7-4
2	0x0040	1	Parity
	0x0044	2	MXtd,MDir,Mask
	0x0048	3	Xtd,Dir,ID
	0x004C	4	Ctrl
	0x0050	5	Data Bytes 3-0
	0x0054	6	Data Bytes 7-4
... 31	...	...	...
	0x03E0	1	Parity
	0x03E4	2	MXtd,MDir,Mask
	0x03E8	3	Xtd,Dir,ID
	0x03EC	4	Ctrl
	0x03F0	5	Data Bytes 3-0
0x03F4	6	Data Bytes 7-4	

(1) See [Section 30.14.3](#).

### 30.14.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

#### Note

During debug mode, the Message RAM cannot be accessed via the IFx register sets.

**Figure 30-20. Message RAM Representation in Debug Mode**

## 30.15 Software

### 30.15.1 CAN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/can

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 30.15.1.1 CAN External Loopback

FILE: can\_ex1\_loopback.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 2 byte message that contains an incrementing pattern.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for information about this example.

##### External Connections

- None.

##### Watch Variables

- msgCount - A counter for the number of successful messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### 30.15.1.2 CAN Loopback - CM

FILE: can\_ex1\_polling.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. The message that is sent is a 2 byte message that contains an incrementing pattern.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual.

Before running this example, please run the can\_config\_c28x example from the c28x folder. It will initialize the clock, configure the GPIOs and allocate CAN A to CM.

##### External Connections

- None.

##### Watch Variables

- msgCount - A counter for the number of successful messages received.
- rxMsgData - An array with the data that was received.
- txMsgData - An array with the data being sent.

#### 30.15.1.3 CAN External Loopback with Interrupts

FILE: can\_ex2\_loopback\_interrupts.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 4 byte message that contains an incrementing pattern. A CAN interrupt handler is used to confirm message transmission and count the number of messages that have been sent.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for information about this example.

#### External Connections

- None.

#### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- errorFlag - A flag that indicates an error has occurred

### 30.15.1.4 CAN External Loopback with Interrupts - CM

FILE: can\_ex2\_loopback\_interrupts.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 4 byte message that contains an incrementing pattern. A CAN interrupt handler is used to confirm message transmission and count the number of messages that have been sent.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual.

Before running this example, please run the can\_config\_c28x example from the c28x folder. It will initialize the clock, configure the GPIOs and allocate CAN A to CM.

#### External Connections

- None.

#### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- errorFlag - A flag that indicates an error has occurred

### 30.15.1.5 CAN-A to CAN-B External Transmit

FILE: can\_ex3\_external\_transmit.c

This example initializes CAN module A and CAN module B for external communication. CAN-A module is setup to transmit incrementing data for "n" number of times to the CAN-B module, where "n" is the value of TXCOUNT. CAN-B module is setup to trigger an interrupt service routine (ISR) when data is received. An error flag will be set if the transmitted data doesn't match the received data.

Both CAN modules on the device need to be connected to each other via CAN transceivers. *Hardware Required*

- A C2000 board with two CAN transceivers

#### External Connections

- ControlCARD CANA is on DEVICE\_GPIO\_PIN\_CANTXA (CANTXA)
- and DEVICE\_GPIO\_PIN\_CANRXA (CANRXA)
- ControlCARD CANB is on DEVICE\_GPIO\_PIN\_CANTXB (CANTXB)
- and DEVICE\_GPIO\_PIN\_CANRXB (CANRXB)

#### Watch Variables

- TXCOUNT - Adjust to set the number of messages to be transmitted
- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- errorFlag - A flag that indicates an error has occurred

### 30.15.1.6 CAN-A to CAN-B External Transmit - CM

FILE: can\_ex3\_external\_transmit.c

This example initializes CAN module A and CAN module B for external communication. CAN-A module is setup to transmit incrementing data for "n" number of times to the CAN-B module, where "n" is the value of TXCOUNT. CAN-B module is setup to trigger an interrupt service routine (ISR) when data is received. An error flag will be set if the transmitted data doesn't match the received data.

Before running this example, please run the can\_config\_c28x example from the c28x folder. It will initialize the clock, configure the GPIOs and allocate CAN A and CAN B to CM.

Both CAN modules on the device need to be connected to each other via CAN transceivers. *Hardware Required*

- A C2000 board with two CAN transceivers

#### External Connections

- ControlCARD CANA is on GPIO37 (CANTXA) and GPIO36 (CANRXA)
- ControlCARD CANB is on GPIO12 (CANTXB) and GPIO10 (CANRXB)

#### Watch Variables

- TXCOUNT - Adjust to set the number of messages to be transmitted
- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- errorFlag - A flag that indicates an error has occurred

### 30.15.1.7 CAN External Loopback with DMA

FILE: can\_ex4\_loopback\_dma.c

This example sets up the CAN module to transmit and receive messages on the CAN bus. The CAN module is set to transmit a 4 byte message internally. An interrupt is used to assert the DMA request line which then triggers the DMA to transfer the received data from the CAN interface register to the receive buffer array. A data check is performed once the transfer is complete.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for information about this example.

#### External Connections

- None.

#### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

### 30.15.1.8 CAN Transmit and Receive Configurations - CM

FILE: can\_ex4\_transmit\_receive.c

This example shows the basic setup of CAN in order to transmit or receive messages on the CAN bus with a specific Message ID. The CAN Controller is configured according to the selection of the define.

When the TRANSMIT define is selected, the CAN Controller acts as a Transmitter and sends data to the second CAN Controller connected externally. If TRANSMIT is not defined the CAN Controller acts as a Receiver and waits for message to be transmitted by the External CAN Controller.

Before running this example, please run the can\_config\_c28x example from the c28x folder. It will initialize the clock, configure the GPIOs and allocate CAN A to CM.

CAN modules on the device need to be connected to via CAN transceivers. *Hardware Required*

- A C2000 board with CAN transceiver.

#### *External Connections*

- ControlCARD CANA is on GPIO37 (CANTXA) and GPIO36 (CANRXA)

#### *Watch Variables Transmit \Configuration*

- MSGCOUNT - Adjust to set the number of messages
- txMsgCount - A counter for the number of messages sent
- txMsgData - An array with the data being sent
- errorFlag - A flag that indicates an error has occurred
- rxMsgCount - Has the initial value as No. of Messages to be received and decrements with each message.

### **30.15.1.9 CAN Transmit and Receive Configurations**

FILE: can\_ex5\_transmit\_receive.c

This example shows the basic setup of CAN in order to transmit or receive messages on the CAN bus with a specific Message ID. The CAN Controller is configured according to the selection of the define.

When the TRANSMIT define is selected, the CAN Controller acts as a Transmitter and sends data to the second CAN Controller connected externally. If TRANSMIT is not defined the CAN Controller acts as a Receiver and waits for message to be transmitted by the External CAN Controller. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for information about this example.

CAN modules on the device need to be connected to via CAN transceivers. *Hardware Required*

- A C2000 board with CAN transceiver.

#### *External Connections*

- ControlCARD CANA is on DEVICE\_GPIO\_PIN\_CANTXA (CANTXA)
- and DEVICE\_GPIO\_PIN\_CANRXA (CANRXA)

#### *Watch Variables Transmit \Configuration*

- MSGCOUNT - Adjust to set the number of messages
- txMsgCount - A counter for the number of messages sent
- txMsgData - An array with the data being sent
- errorFlag - A flag that indicates an error has occurred
- rxMsgCount - Has the initial value as No. of Messages to be received and decrements with each message.

### **30.15.1.10 CAN Error Generation Example**

FILE: can\_ex6\_error\_generation.c

This example demonstrates the ways of handling CAN Error conditions. It generates the CAN Packets and sends them over GPIO. It is looped back externally to be received in CAN module. The CAN Interrupt service routine reads the Error status and demonstrates how different Error conditions can be detected.

Change ERR\_CFG define to the different Error Scenarios and run the example. The corresponding Error Flag will be set in status variable of canalSR() routine. Uses a CPU Timer (Timer 0) for periodic timer interrupt of CANBITRATE uSec. On the Timer interrupt it sends the required CAN Frame type with the specified error conditions. CAN modules on the device need to be connected to via CAN transceivers. Please refer to the

application note titled "Configurable Error Generator for Controller Area Network" at [www.ti.com/lit/pdf/spracq3](http://www.ti.com/lit/pdf/spracq3) for further details on this example

#### *External Connections*

- ControlCARD GPIOTX\_PIN should be connected to
- DEVICE\_GPIO\_PIN\_CANRXA(CANRXA)

#### *Watch Variables Transmit \Configuration*

- status - variable in canISR for checking error Status

#### **30.15.1.11 CAN Remote Request Loopback**

FILE: can\_ex7\_loopback\_tx\_rx\_remote\_frame.c

This example shows the basic setup of CAN in order to transmit a remote frame and get a response for the remote frame and store it in a receive Object. The CAN peripheral is configured to transmit remote request frame and a remote answer frame messages with a specific CAN ID. Message object 3 is configured to transmit a remote request. Message object 2 is configured as a remote answer object with filter mask such that it accepts remote frame with any message ID and transmits remote answer with message ID 7 and data length 8. Message object 1 is configured as a received object with filter message ID 7 so as to store the remote answer data transmitted by message object 2.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual.

#### *External Connections*

- None.

#### *Watch Variables*

- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### **30.15.1.12 CAN example that illustrates the usage of Mask registers**

FILE: can\_ex8\_mask.c

This example initializes CAN module A for Reception. When a frame with a matching filter criterion is received, the data will be copied in mailbox 1 and LED will be toggled a few times and the code gets ready for the next frame. If a message of any other MSGID is received, an ACK will be provided. Completion of reception is determined by polling CAN\_NDAT\_21 register. No interrupts are used. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for information about this example.

#### *Hardware Required*

- An external CAN node that transmits to CAN-A on the C2000 MCU

#### *Watch Variables*

- rxMsgCount - A counter for the number of messages received
- rxMsgData - An array with the data that was received

## 30.16 CAN Registers

This section describes the Controller Area Network registers.

### 30.16.1 CAN Base Address Table (C28)

**Table 30-7. CAN Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
CanaRegs	CAN_REGS	CANA_BASE	0x0004_8000	YES	YES	YES	-	YES
CanbRegs	CAN_REGS	CANB_BASE	0x0004_A000	YES	YES	YES	-	YES

### 30.16.2 CM CAN Base Address Table (CM)

**Table 30-8. CM CAN Base Address Table (CM)**

DriverLib Name	Base Address	$\mu$ DMA Access	Ethernet DMA Access
CANA_BASE	0x4007_0000	-	-
CANB_BASE	0x4007_4000	-	-

### 30.16.3 CAN\_REGS Registers

Table 30-9 lists the memory-mapped registers for the CAN\_REGS registers. All register offset addresses not listed in Table 30-9 should be considered as reserved locations and the register contents should not be modified.

**Table 30-9. CAN\_REGS Registers**

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	CAN_CTL	CAN Control Register		<a href="#">Go</a>
8h	4h	CAN_ES	Error and Status Register		<a href="#">Go</a>
10h	8h	CAN_ERRC	Error Counter Register		<a href="#">Go</a>
18h	Ch	CAN_BTR	Bit Timing Register		<a href="#">Go</a>
20h	10h	CAN_INT	Interrupt Register		<a href="#">Go</a>

228h	114h	CAN_IF1DATB	IF1 Data B Register		<a href="#">Go</a>
240h	120h	CAN_IF2CMD	IF2 Command Register		<a href="#">Go</a>
248h	124h	CAN_IF2MSK	IF2 Mask Register		<a href="#">Go</a>
250h	128h	CAN_IF2ARB	IF2 Arbitration Register		<a href="#">Go</a>
258h	12Ch	CAN_IF2MCTL	IF2 Message Control Register		<a href="#">Go</a>
260h	130h	CAN_IF2DATA	IF2 Data A Register		<a href="#">Go</a>
268h	134h	CAN_IF2DATB	IF2 Data B Register		<a href="#">Go</a>
280h	140h	CAN_IF3OBS	IF3 Observation Register		<a href="#">Go</a>
288h	144h	CAN_IF3MSK	IF3 Mask Register		<a href="#">Go</a>
290h	148h	CAN_IF3ARB	IF3 Arbitration Register		<a href="#">Go</a>
298h	14Ch	CAN_IF3MCTL	IF3 Message Control Register		<a href="#">Go</a>
2A0h	150h	CAN_IF3DATA	IF3 Data A Register		<a href="#">Go</a>
2A8h	154h	CAN_IF3DATB	IF3 Data B Register		<a href="#">Go</a>
2C0h	160h	CAN_IF3UPD	IF3 Update Enable Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 30-10](#) shows the codes that are used for access types in this section.

**Table 30-10. CAN\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 30.16.3.1 CAN\_CTL Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 1401h]

CAN\_CTL is shown in [Figure 30-21](#) and described in [Table 30-11](#).

Return to the [Summary Table](#).

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

**Figure 30-21. CAN\_CTL Register**

24	RESERVED	R/W	0h	Reserved
23-21	RESERVED	R	0h	Reserved
20	DE3	R/W	0h	Enable DMA request line for IF3 0 Disabled 1 Enabled Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. Reset type: SYSRSn
19	DE2	R/W	0h	Enable DMA request line for IF2 0 Disabled 1 Enabled Note: A pending DMA request for IF1 remains active until first access to one of the IF2 registers. Reset type: SYSRSn
18	DE1	R/W	0h	Enable DMA request line for IF1 0 Disabled 1 Enabled Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. Reset type: SYSRSn
17	IE1	R/W	0h	Interrupt line 1 Enable 0 CANINT1 is disabled. 1 CANINT1 is enabled. Interrupts will assert CANINT1 line to 1 line remains active until pending interrupts are processed. Reset type: SYSRSn
16	INITDBG	R	0h	Debug Mode Status Bit: This bit indicates the internal init state for a debug access 0 Not in debug mode, or debug mode requested but not entered. 1 Debug mode requested and internally entered the CAN module is ready for debug accesses. Reset type: SYSRSn

**Table 30-11. CAN\_CTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15	SWR	R-0/W1C	0h	Software Reset Enable Bit: This bit activates the software reset. 0 Normal Operation. 1 Module is forced to reset state. This bit will get cleared automatically one clock cycle after execution of software reset. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR bit. Note: This bit is write-protected by Init bit. If module is reset using the SWR bit, no user configuration is lost. Only status bits get reset along with logic which needs to be reset for the next CAN transaction. If module is reset using SOFTPRES register, entire module will get reset, including configuration registers. Reset type: SYSRSn
14	RESERVED	R	0h	Reserved
13-10	PMD	R/W	5h	Parity on/off 0101 Parity function disabled Any other value - Parity function enabled Reset type: SYSRSn

8	IDS	R/W	0h	Interrupt Debug Support Enable 0 When Debug mode is requested, the CAN module will wait for a started transmission or reception to be completed before entering Debug mode 1 When Debug mode is requested, the CAN module will interrupt any transmission or reception, and enter Debug mode immediately. Reset type: SYSRSn
7	Test	R/W	0h	Test Mode Enable 0 Disable Test Mode (Normal operation) 1 Enable Test Mode Reset type: SYSRSn
6	CCE	R/W	0h	Configuration Change Enable 0 The CPU has no write access to the configuration registers. 1 The CPU has write access to the configuration registers (when Init bit is set). Reset type: SYSRSn
5	DAR	R/W	0h	Disable Automatic Retransmission 0 Automatic Retransmission of "not successful" messages enabled. 1 Automatic Retransmission disabled. Reset type: SYSRSn
4	RESERVED	R	0h	Reserved
3	EIE	R/W	0h	Error Interrupt Enable 0 Disabled - PER, BOff and EWarn bits cannot generate an interrupt. 1 Enabled - PER, BOff and EWarn bits can generate an interrupt at CANINT0 line and affect the Interrupt Register. Reset type: SYSRSn
2	SIE	R/W	0h	Status Change Interrupt Enable 0 Disabled - RxOk, TxOk and LEC bits cannot generate an interrupt. 1 Enabled - RxOk, TxOk and LEC can generate an interrupt on the CANINT0 line Reset type: SYSRSn
1	IE0	R/W	0h	Interrupt line 0 Enable 0 CANINT0 is disabled. 1 CANINT0 is enabled. Interrupts will assert CANINT0 line to 1 line remains active until pending interrupts are processed. Reset type: SYSRSn

**Table 30-11. CAN\_CTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	Init	R/W	1h	Initialization Mode This bit is used to keep the CAN module inactive during bit timing configuration and message RAM initialization. It is set automatically during a bus off event. Clearing this bit will not shorten the bus recovery time. 0 CAN module processes messages normally 1 CAN module ignores bus activity Reset type: SYSRSn

### 30.16.3.2 CAN\_ES Register (Offset (x8) = 8h, Offset (x16) = 4h) [Reset = 7h]

CAN\_ES is shown in [Figure 30-22](#) and described in [Table 30-12](#).

Return to the [Summary Table](#).

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

9	RESERVED	R	0h	Reserved
8	PER	R	0h	Parity Error Detected: This bit will be reset after the CPU reads the register. 0 No parity error has been detected since last read access. 1 The parity check mechanism has detected a parity error in the Message RAM. Reset type: SYSRSn
7	BOff	R	0h	Bus-off Status Bit: 0 The CAN module is not in Bus-Off state. 1 The CAN module is in Bus-Off state. Reset type: SYSRSn
6	EWarn	R	0h	Warning State Bit: 0 Both error counters are below the error warning limit of 96. 1 At least one of the error counters has reached the error warning limit of 96. Reset type: SYSRSn
5	EPass	R	0h	Error Passive State 0 On CAN Bus error, the CAN could send active error frames. 1 The CAN Core is in the error passive state as defined in the CAN Specification. Reset type: SYSRSn

**Table 30-12. CAN\_ES Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	RxOk	R	0h	<p>Reception status Bit: This bit indicates the status of reception. The bit will be reset after the CPU reads the register.</p> <p>0 No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.</p> <p>1 A message has been successfully received since the last time when this bit was reset by a read access of the CPU. This bit will be set independent of the result of acceptance filtering.</p> <p>Reset type: SYSRSn</p>
3	TxOk	R	0h	<p>Transmission status Bit: This bit indicates the status of transmission. The bit will be reset after the CPU reads the register.</p> <p>0 No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.</p> <p>1 A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was cleared by a read access of the CPU.</p> <p>Reset type: SYSRSn</p>
2-0	LEC	R	7h	<p>Last Error Code</p> <p>The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register.</p> <p>0 No Error</p> <p>1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.</p> <p>2 Form Error: A fixed format part of a received frame has the wrong format.</p> <p>3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node.</p> <p>4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).</p> <p>7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'.</p> <p>Reset type: SYSRSn</p>

### 30.16.3.3 CAN\_ERRC Register (Offset (x8) = 10h, Offset (x16) = 8h) [Reset = 0h]

CAN\_ERRC is shown in [Figure 30-23](#) and described in [Table 30-13](#).

Return to the [Summary Table](#).

This register reflects the value of the Transmit and Receive error counters

**Figure 30-23. CAN\_ERRC Register**

7-0	TEC	R	0h	Transmit Error Counter Actual state of the Transmit Error Counter. (values from 0 to 255). Reset type: SYSRSn

### 30.16.3.4 CAN\_BTR Register (Offset (x8) = 18h, Offset (x16) = Ch) [Reset = 2301h]

CAN\_BTR is shown in [Figure 30-24](#) and described in [Table 30-14](#).

Return to the [Summary Table](#).

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to 1024 CAN\_CLK periods.

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	Reserved
19-16	BRPE	R/W	0h	Baud Rate Prescaler Extension Valid programmed values are 0 to 15. By programming BRPE the Baud Rate Prescaler can be extended to values up to 1024. Note: This bit is Write Protected by CCE bit. Reset type: SYSRSn
15	RESERVED	R	0h	Reserved
14-12	TSEG2	R/W	2h	Time segment after the sample point Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the Bit Timing will be the programmed TSeg2 value + 1. Note: This bit is Write Protected by CCE bit. Reset type: SYSRSn
11-8	TSEG1	R/W	3h	Time segment before the sample point Valid programmed values are 1 to 15. The actual TSeg1 value interpreted for the Bit Timing will be the programmed TSeg1 value + 1. Note: This bit is Write Protected by CCE bit. Reset type: SYSRSn
7-6	SJW	R/W	0h	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the Synchronization will be the programmed SJW value + 1. Note: This bit is Write Protected by CCE bit. Reset type: SYSRSn

**Table 30-14. CAN\_BTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5-0	BRP	R/W	1h	Baud Rate Prescaler- Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the Bit Timing will be the programmed BRP value + 1. Note: This bit is Write Protected by CCE bit. Reset type: SYSRSn

### 30.16.3.5 CAN\_INT Register (Offset (x8) = 20h, Offset (x16) = 10h) [Reset = 0h]

CAN\_INT is shown in [Figure 30-25](#) and described in [Table 30-15](#).

Return to the [Summary Table](#).

This register is used to identify the source of the interrupt(s).

**Figure 30-25. CAN\_INT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								INT1ID								INT0ID															
R-0h								R-0h								R-0h															

**Table 30-15. CAN\_INT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	INT1ID	R	0h	Interrupt 1 Cause 0x00 No interrupt is pending. 0x01-0x20 Number of message object (mailbox) which caused the interrupt. 0x21-0xFF Unused. If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. Note: The CANINT1 interrupt line remains active until INT1ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. A message interrupt is cleared by clearing the mailbox's IntPnd bit. Among the message interrupts, the mailbox's interrupt priority decreases with increasing message number. Reset type: SYSRSn
15-0	INT0ID	R	0h	Interrupt 0 Cause 0x0000 - No interrupt is pending. 0x0001 - 0x0020 - Number of message object which caused the interrupt. 0x0021 - 0x7FFF - Unused. 0x8000 - Error and Status Register value is not 0x07. 0x8001 - 0xFFFF - Unused. If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. Note: The CANINT0 interrupt line remains active until INT0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. Reset type: SYSRSn

### 30.16.3.6 CAN\_TEST Register (Offset (x8) = 28h, Offset (x16) = 14h) [Reset = 0h]

CAN\_TEST is shown in [Figure 30-26](#) and described in [Table 30-16](#).

Return to the [Summary Table](#).

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

Note: Setting Tx[1:0] other than '00' will disturb message transfer.

Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

### 30.16.3.7 CAN\_PERR Register (Offset (x8) = 38h, Offset (x16) = 1Ch) [Reset = 100h]

CAN\_PERR is shown in [Figure 30-27](#) and described in [Table 30-17](#).

Return to the [Summary Table](#).

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism

it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

**Figure 30-27. CAN\_PERR Register**

Bit	Field	Type	Reset	Description
31-0	ABO_Time	R/W	0h	Auto-Bus-On Timer Number of clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. "Clock" refers to the input clock to the CAN module. This function has to be enabled by setting bit ABO in CAN Control Register. The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO Time register after this phase. NOTE: On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted. NOTE: During Debug mode, running Auto-Bus-On timer will be paused. Reset type: SYSRSn

### 30.16.3.13 CAN\_TXRQ\_X Register (Offset (x8) = 108h, Offset (x16) = 84h) [Reset = 0h]

CAN\_TXRQ\_X is shown in [Figure 30-33](#) and described in [Table 30-23](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN\_TXRQ\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

Bit 1 represents byte 1 of CAN_TXRQ_21 Register. If one or more bits in that byte are set, then bit 1 will be set. Reset type: SYSRSn

### 30.16.3.14 CAN\_TXRQ\_21 Register (Offset (x8) = 110h, Offset (x16) = 88h) [Reset = 0h]

CAN\_TXRQ\_21 is shown in [Figure 30-34](#) and described in [Table 30-24](#).

Return to the [Summary Table](#).

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

**Figure 30-34. CAN\_TXRQ\_21 Register**

### 30.16.3.18 CAN\_IPEN\_21 Register (Offset (x8) = 160h, Offset (x16) = B0h) [Reset = 0h]

CAN\_IPEN\_21 is shown in [Figure 30-38](#) and described in [Table 30-28](#).

Return to the [Summary Table](#).

This register holds the IntPnd bits of the mailboxes. By reading out these bits, the CPU can check for pending interrupts in the mailboxes. The IntPnd bit of a specific mailbox can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

### 30.16.3.19 CAN\_MVAL\_X Register (Offset (x8) = 180h, Offset (x16) = C0h) [Reset = 0h]

CAN\_MVAL\_X is shown in [Figure 30-39](#) and described in [Table 30-29](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Message Valid 2\_1 Register (CAN\_MVAL\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the MsgVal bits of these mailboxes are set, the corresponding bit in this register will be set.

### 30.16.3.20 CAN\_MVAL\_21 Register (Offset (x8) = 188h, Offset (x16) = C4h) [Reset = 0h]

CAN\_MVAL\_21 is shown in [Figure 30-40](#) and described in [Table 30-30](#).

Return to the [Summary Table](#).

This registers hold the MsgVal bits of all mailboxes. By reading out the MsgVal bits, the CPU can check which mailbox is valid. The MsgVal bit of a specific mailbox can be set/reset by the CPU via the IF1/2 "Message Interface" Registers.

**Figure 30-40. CAN\_MVAL\_21 Register**

### 30.16.3.21 CAN\_IP\_MUX21 Register (Offset (x8) = 1B0h, Offset (x16) = D8h) [Reset = 0h]

CAN\_IP\_MUX21 is shown in [Figure 30-41](#) and described in [Table 30-31](#).

Return to the [Summary Table](#).

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

**Figure 30-41. CAN\_IP\_MUX21 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 30.16.3.22 CAN\_IF1CMD Register (Offset (x8) = 200h, Offset (x16) = 100h) [Reset = 1h]

CAN\_IF1CMD is shown in [Figure 30-42](#) and described in [Table 30-32](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16-bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

Note: This bit is write protected by Busy bit. Reset type: SYSRSn

### 30.16.3.24 CAN\_IF1ARB Register (Offset (x8) = 210h, Offset (x16) = 108h) [Reset = 0h]

CAN\_IF1ARB is shown in [Figure 30-44](#) and described in [Table 30-34](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 30.16.3.26 CAN\_IF1DATA Register (Offset (x8) = 220h, Offset (x16) = 110h) [Reset = 0h]

CAN\_IF1DATA is shown in [Figure 30-46](#) and described in [Table 30-36](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

**Figure 30-46. CAN\_IF1DATA Register**

### 30.16.3.27 CAN\_IF1DATB Register (Offset (x8) = 228h, Offset (x16) = 114h) [Reset = 0h]

CAN\_IF1DATB is shown in [Figure 30-47](#) and described in [Table 30-37](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 30.16.3.28 CAN\_IF2CMD Register (Offset (x8) = 240h, Offset (x16) = 120h) [Reset = 1h]

CAN\_IF2CMD is shown in [Figure 30-48](#) and described in [Table 30-38](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 30.16.3.30 CAN\_IF2ARB Register (Offset (x8) = 250h, Offset (x16) = 128h) [Reset = 0h]

CAN\_IF2ARB is shown in [Figure 30-50](#) and described in [Table 30-40](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 30.16.3.34 CAN\_IF3OBS Register (Offset (x8) = 280h, Offset (x16) = 140h) [Reset = 0h]

CAN\_IF3OBS is shown in [Figure 30-54](#) and described in [Table 30-44](#).

Return to the [Summary Table](#).

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

### 30.16.3.40 CAN\_IF3UPD Register (Offset (x8) = 2C0h, Offset (x16) = 160h) [Reset = 0h]

CAN\_IF3UPD is shown in [Figure 30-60](#) and described in [Table 30-50](#).

Return to the [Summary Table](#).

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set. Note: IF3 Update enable should not be set for transmit objects.

**Figure 30-60. CAN\_IF3UPD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

This chapter describes the implementation and integration of the EtherCAT™ Slave Controller (ESC). The EtherCAT peripheral can be mapped to either CM or CPU1 subsystems (default access mapped to CPU1 subsystem), and thus either of these subsystems can run the EtherCAT slave stack and application software to implement an EtherCAT slave node.

On this device, the CPU1 is the master subsystem. If the intention is to use the CM subsystem as the owner of ESC, then certain ESC subsystem configurations can only be done by the CPU1 during initialization before allocating the ownership of the ESC peripheral to the CM subsystem. These details are explained in this chapter.

Information about the EtherCAT standards and working principles can be in found these documents:

- EtherCAT ET1100 Datasheet
- EtherCAT ESC Hardware Datasheet (Section I)
- EtherCAT IP Core for Xilinx FPGAs

Refer to [Section 31.1.11](#) for details on EtherCAT IP errata provided from Beckhoff Automation™.

<b>31.1 Introduction</b> .....	<b>3430</b>

## 31.1 Introduction

Ethernet for Control Automation Technology (EtherCAT™) is an Ethernet-based fieldbus system, invented by Beckhoff Automation™ and is standardized in IEC 61158. All the slave nodes connected to the bus interpret, process, and modify the data addressed to them "on the fly", without having to buffer the frame inside the node. This real-time behavior, frame processing and forwarding requirements are implemented by the EtherCAT slave controller hardware. EtherCAT does not require software interaction for data transmission inside the slaves. EtherCAT only defines the MAC layer while the higher layer protocols and stack are implemented in software on the microcontrollers connected to the ESC.

- Involves master and slave(s) setup where slave nodes are physically connected daisy-chain style but logically operate on a loop
- Specializes in precise, low jitter synchronization across slave nodes
- Uses IEEE 802.3 Ethernet physical layer and standard Ethernet frames

A list of relevant terms and definitions are listed in [Table 31-1](#).

**Table 31-1. Abbreviations**

Name	Definition
CM	Connectivity Manager (referring to Cortex®-M4 subsystem on this MCU)
CPU1	Master C28 CPU1 subsystem on this MCU
DIGIO	Digital IO profile
ENI	EtherCAT Network Information
ESC	EtherCAT Slave Controller
ESCSS or SS	Subsystem (specifically referring to EtherCAT Subsystem on this device)
ESI	EtherCAT Slave Information
ET1100	Beckhoff EtherCAT slave controller
ETG	EtherCAT Technical Group
EtherCAT	Ethernet for Control Automation Technology
FMMU	Fieldbus Memory Management Units
HAL	Hardware Abstraction Layer
MII	Medium Independent Interface
NMIWDRS	NMI Watchdog Reset
PDI	Processor Data Interface
POR	Power-on-Reset
SSC	EtherCAT Slave Stack Code
WDRS	Watchdog Reset
XRS	External Reset

### 31.1.2 ESC Features

The ESC on this MCU provides the following functionality.

- Up to 2 MII ports to connect to EtherCAT PHYs
- Process data interface (PDI) through 16-bit asynchronous interface (ASYNC16)
- 64-bit distributed clocking.
  - Sync output signals to synchronize device events and latch input signals supporting time stamping for events.
  - Distributed clock features of SYNC0/1 (o/ps) and LATCH0/1 able to synchronize GPIOs and allow inputs from any GPIOs as well as other muxing options for internal device events.
- 8 FMMUs
  - Supports all native types of RD/ WR/ RDWR and built-in features of bit/byte addressing
- 8 Sync Managers
- I2C EEPROM interface
- Up-to 32 general-purpose inputs and 32 general-purpose outputs
- 2 SYNC and 2 LATCH signals connected to GPIOs as well as critical signals internal to the chip
- 16 KB Process Data RAM with parity

### 31.1.3 ESC Subsystem Integrated Features

In addition to the ESC features, the following are the device-specific features provided by the integration of the ESC to the MCU:

- ESC access allocation to either CM (Cortex®-M4) subsystem or CPU1 subsystem during initialization
- EtherCAT reset request from master can be routed to NMI or general Interrupt controller on MCU
- RAM Parity error routed to NMI on MCU
- DMA access to EtherCAT RAM
- Up to 32 GPI (general purpose inputs) and up to 32 GPO (general purpose outputs) feature integrated in addition to 16bit ASYNC PDI interface
- Interface to CLB
- Distributed clock feature of SYNC0/1 able to synchronize PWMs, generate interrupt/DMA requests, trigger ECAP capture, or allow external component action through GPIO access.
- EtherCAT SYNC0/1 pulse can trigger a CLA task.
- Distributed clock feature of LATCH0/1 allowing inputs from any GPIO or PWM crossbar triggers

### 31.1.4 F2838x ESC versus Beckhoff ET1100

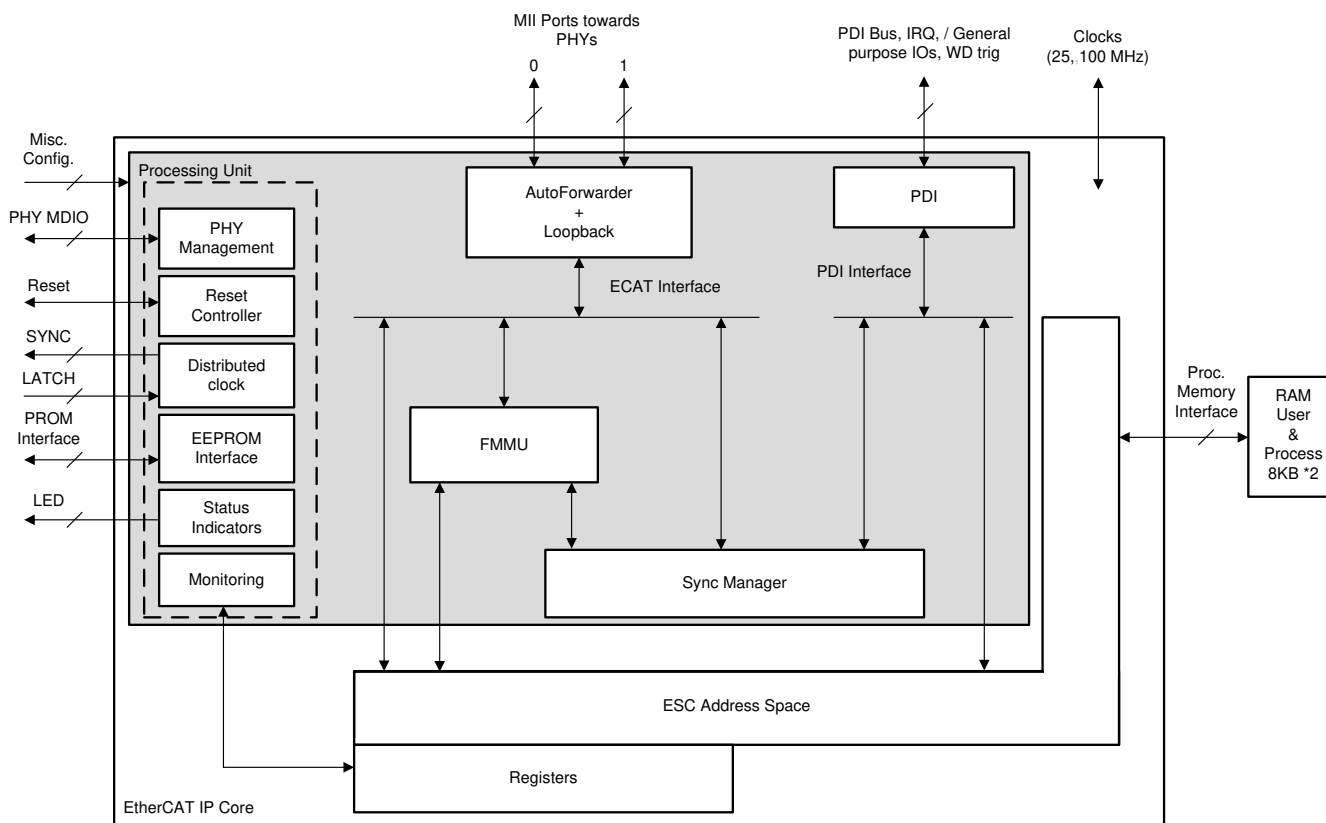

Table 31-2 details a comparison between the F2838x ESC IP Core implementation and the Beckhoff's ET1100 ESC.

**Table 31-2. F2838x ESC versus Beckhoff ET1100**

Feature	F2838x ESC	Beckhoff ET1100
Transmission Speed	100 Mbit/s	100 Mbit/s
Number of Ports	2 (MII Only)	4 (MII or EBUS)
FMMUs	8	8
SyncManagers	8	8
RAM (KByte)	16 KB	8 KB
Distributed Clocks	Yes, 64-bit	Yes, 64-bit
EBUS Support	No	Yes
Process Data Interfaces (PDI)	16-bit ASYNC	Digital I/O SPI 8-bit ASYNC/SYNC 16-bit ASYNC/SYNC

### 31.1.5 EtherCAT IP Block Diagram

Figure 31-1 shows the general functionality of etherCAT IP from Beckhoff and later on this chapter we will see how this is integrated into the MCU.

**Figure 31-1. EtherCAT IP Block Diagram**

### 31.1.6 ESC Functional Blocks

The following introduces each of the sub-blocks. For more details, refer to the Beckhoff EtherCAT documentation.

#### 31.1.6.1 Interface to EtherCAT Master

The EtherCAT master is a remote entity normally implemented through the device with ethernet switch capability. Beckhoff suggests using either standard ethernet physical layer interface through MII or RMII protocol, or using low-voltage differential pair signaling with EBUS protocol. Per Beckhoff specification, up to 4 PHY ports can be supported. In this MCU implementation of ESC:

- Only MII supported for Ethernet PHY interface
- ESC supports only 2 PHY ports

#### 31.1.6.2 Process Data Interface

Process data interface (PDI) is a connection from ESC IP to the micro-controller and slave application. The implementation of ESC on this MCU supports:

- 16-bit asynchronous interface (ASYNC16) to local host only

#### 31.1.6.3 General Purpose Inputs and Outputs

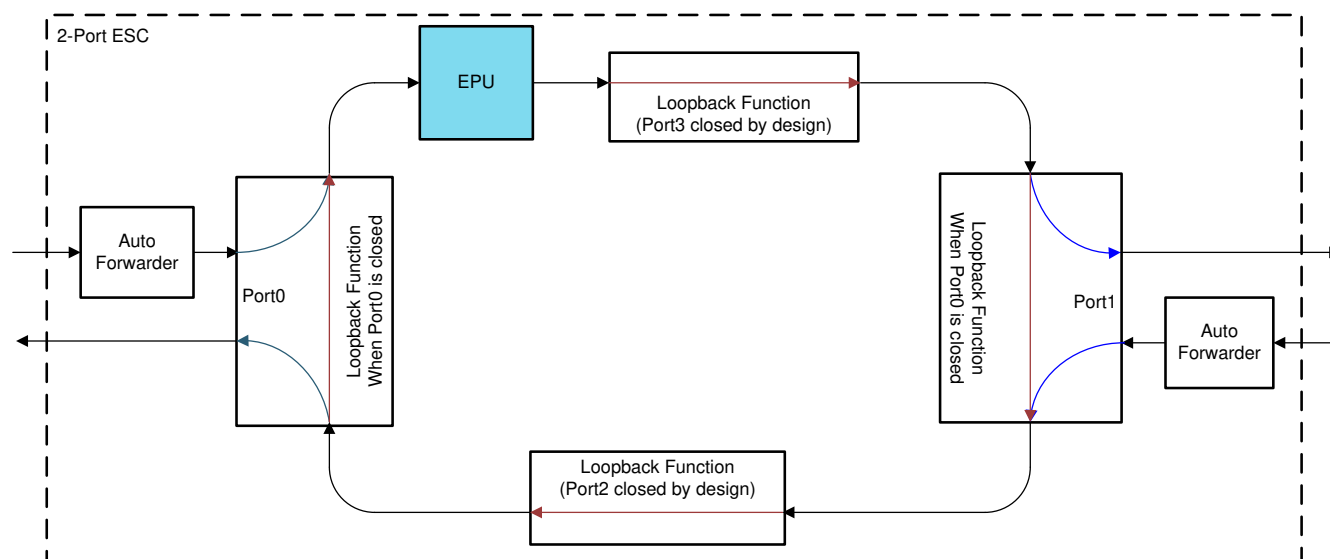

Since this MCU does not support Digital I/O PDI interface, the ESC supports general purpose I/O which allows 32 GPI and 32 GPO signals. These EtherCAT GPI/GPO's can be programmed to either be driven by (or drive) device I/O pins or can be driven by (or drive) the same I/O pins after qualifying them using internal events.

- Refer to [Section 31.2.9](#) for more details.

#### 31.1.6.4 EtherCAT Processing Unit

The EtherCAT Processing Unit (EPU) receives, analyses and processes the EtherCAT data stream. It is logically located between port 0 and port 1. The main purpose of the EtherCAT Processing Unit is to enable and coordinate access to the internal registers and the memory space of the ESC, which can be addressed both from the EtherCAT master and from the local application via the PDI. Data exchange between master and slave application is comparable to a dual-ported memory (process memory), enhanced by special functions; for example, for consistency checking (SyncManager) and data mapping (FMMU). The EtherCAT Processing Units contain the main function blocks of EtherCAT slaves besides Auto-Forwarding, Loop-back function, and PDI.

- **Auto-Forwarder:**
  - The Auto-forwarder's functions included receiving EtherCAT frame, checksum computation and verification, timestamp capture for received frames, and forwarding to Loop-back component.
- **Loop-back Function:**
  - For the two-port implementation on this device, port 3 and port 2 are looped back by design, as shown in [Figure 31-2](#).
  - Port-0 is a special port that is always connected to the master while designing the topology. At egress it acts as a terminal point for network connected downstream, hence, any circulating packets shall get dropped at port-0 in the event of port-0 being looped-back.
  - In event of a network or link loss downstream to the ESC port-1, the packets will end in loopback.

**Figure 31-2. Two-port ESC Description**

**Figure 31-3. Two-port Block Diagram in EtherCAT Topology**

### 31.1.6.5 Fieldbus Memory Management Unit

The fieldbus memory management unit (FMMU) maps the logical addresses of the memory elements in ESC to physical address that allows the remote EtherCAT master to address registers and process ram as one memory map that can be accessed across the EtherCAT network. Mapping can be done up-to bit-wise mapping.

### 31.1.6.6 Sync Manager

The integrity and security of the data in dual port memory across Master & local application is maintained by the Sync Manager. Sync Manager allows data be accessed as buffered or mailbox, where either there is definite read/write space or sequence defined for both of the master entities.

### 31.1.6.7 Monitoring

The monitoring unit contains error counters and watchdogs. The watchdogs are used for observing communication and returning to a safe state in case of an error. Error counters are used for error detection and analysis.

### 31.1.6.8 Reset Controller

The reset controller aggregates the internal/external resets as well as asserts the reset to external pin, which can be connected to device pin to reset companion devices on the board.

### 31.1.6.9 PHY Management

The PHY control is maintained through the MDIO interface which allows the configuration of the PHYs and enabling advanced features of link detection, if present, be enabled.

### 31.1.6.10 Distributed Clock (DC)

Distributed clocks (DC) allows the tracked time at ESC be synchronized across the EtherCAT network, which in turn makes precisely timed event possible throughout the network. Events could be realized with triggers from ESC outputs which are programmed to create a toggle at certain absolute time tracked by the ESC or through sampling of timestamp of certain system event inputs to ESC which can further be used for synchronizing the time.

- Refer to [Section 31.2.10](#) for more details.

### 31.1.6.11 EEPROM

Every ESC requires non-volatile memory to store the configuration contents of the ESI (EtherCAT Slave Information) which are accessed by the Master normally before enabling the ESC in the network. Size of the memory is configurable with a minimum of 1Kbit up to 4Mbit are supported depending on the ESC. This non-volatile memory is supported in simplest form by ESC IP core as serial access EEPROM.

- For ESI EEPROM Layout and mandatory information, refer to the **ESC Hardware Datasheet Section I - Technology (ethercat\_esc\_datasheet\_sec1\_technology)** document provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com).
- EEPROM is supported using the I2C interface on this device and is further explained in [Section 31.2.8](#).

### 31.1.6.12 Status / LEDs

ESC supports the status indication of application activity, link status and link errors which can be utilized for visual status indication through LEDs.

### 31.1.7 EtherCAT Physical Layer

EtherCAT slave devices with Ethernet Physical Layer are able to support MII interfaces, RMII interfaces, and EBUS interfaces. Since RMII PHYs include TX FIFO's, they increase the packet forwarding delay of an EtherCAT slave device as well as the jitter. RMII as an Ethernet Physical Layer is not supported on this device due to these reasons and therefore only the MII interface is supported.

- On this device, only MII is supported (RMII and EBUS are not supported)
- Refer to the **ESC Application Note - PHY Selection Guide (an\_phy\_selection\_guide)** provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com) for additional PHY selection details.

Table 31-3 depicts the number of pins needed for MII interface for two ports.

**Table 31-3. EtherCAT Physical Layer Signals**

Pin	Number of Pins for 2 Ports	MII	Direction	Description
nMII_Link	2	Yes	IN	Input signal provided by the PHY, if a 100 Mbits/s (full duplex) link is established
RX_CLK	2	Yes	IN	Receive Clock
RX_DV	2	Yes	IN	Receive Data valid
RX_DATA[1:0]	4	Yes	IN	Receive Data
RX_DATA[3:2]	4	Yes	IN	Receive Data
RX_ERR	2	Yes	IN	Receive error
TX_CLK <sup>(1)</sup>	2	Optional	IN	Transmit Clock
TX_ENA	2	Yes	OUT	Transmit Enable
TX_DATA[1:0]	4	Yes	OUT	Transmit Data
TX_DATA[3:2]	4	Yes	OUT	Transmit Data
MCLK	1	Yes	OUT	MII Interface clock
MDIO	1	Yes	BI-Directional	MII Interface Data
<b>Total Pins:</b>	28 (required) + 2 (optional)			

- (1) The TX\_CLK though optional with TX\_SHIFT compensation, from the integration on this MCU point of view it is strongly recommended to route the TX\_CLK port whenever the MII port interface is selected.

#### 31.1.7.1 MII Interface

Ethernet IEEE802.3 specified MII interface is supported with possible minor variation in clocking to optimize the clock delay to operate the Tx FIFO. Unlike regular integration of Tx Clock being sourced by the PHY, the ESC implementation allows the common source clock between PHY and ESC be used for Tx logic. The option is selected by manual Tx shift compensation which allows Tx-Data and Tx-En be compensated in steps of 10ns to meet the timing requirements of data sampling at the PHY.

The following signals are used by the ESC to connect to an Ethernet PHY. The MDIO pins are not shown in Figure 31-4, as these pins are covered in the next section.

The MII signals TX\_ERR, COL and CRS are not used by the ESC. These are not available on the MCU for EtherCAT.

Note: The PHY reset signal is also not shown in the diagram.

**Figure 31-4. ESC PHY Interface Diagram**

If an ESC MII interface is not used, LINK\_MII has to be tied to the logic value high which indicates no link. RX\_CLK, RXD, RX\_ER, and especially RX\_DV have to be tied to GND and this is taken care of by design internally when the functional IO mux for the RX pins is not configured when the IP is out of reset. The TX outputs can be left unconnected, by not configuring the Functional IO mux for respective EtherCAT functionality, unless they are used for ESC configuration.

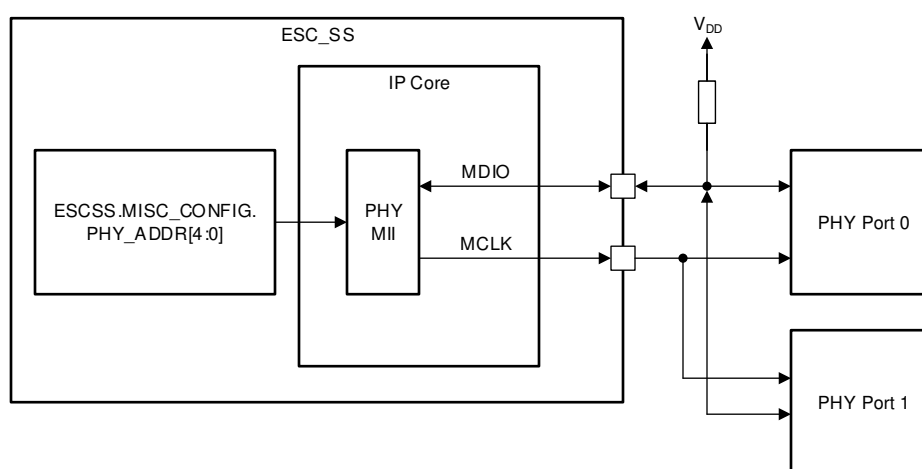

### 31.1.7.2 PHY Management Interface

Most EtherCAT slave controllers with MII/RMII ports use the MII management interface for communication with the Ethernet PHYs. Most ESCs do not use the management interface for link detection or configuration of link modes. For link detection, it is recommended that the ESC use a separate signal (LINK\_MII). The MII management interface can be used by the EtherCAT master – or the local MCU. Enhanced MII link detection uses the management interface for restarting auto-negotiation after communication errors occurred.

On this ESC, it is possible to make use of the MII management interface for link detection and PHY configuration.

#### Note

Note that the EtherCAT link status through the MII Management Interface option should only be enabled if only a Gigabit PHY is to be supported, and should not be enabled if needing to support both 10/100 and Gigabit PHY. For this reason, the Link Status through MII Management Interface is disabled on this ESC. Instead, use the LINKACT or PHY MII\_LINK signals for link status purposes.

A. Note that MDIO must have a pull-up resistor (4.7 kOhm recommended) externally. MCLK is driven rail-to-rail, idle value is high.

**Figure 31-5. PHY Management Interface Connectivity**

#### 31.1.7.2.1 PHY Address Configuration

The ESC addresses the Ethernet PHYs typically using the logical port number plus the PHY address offset. Ideally, the Ethernet PHY addresses should correspond with the logical port number, so PHY addresses 0 and 1 are used.

A PHY address offset of 0 to 31 can be applied which moves the PHY addresses to any consecutive address range. The ESC module expects logical port 0 to have PHY address 0 plus the PHY address offset. The PHY address offset can be selected in register ESCSS\_MISC\_CONFIG.PHY\_ADDR[4:0].

#### 31.1.7.2.2 PHY Reset Signal

The PHY reset signal is generated out of the ESC module. If it is required to release both, the PHY and ESC module synchronous out of reset, this signal can be used. Since there are no pull devices active on the MCU during and after reset, a pull down resistor must be added on this signal on the board level.

In some case, PHYs may be released from reset after releasing the ESC module. To generate a delay, the pin for nPHY\_RESET can be used as an I/O and shall be switched later to the alternate output function.

### 31.1.7.2.3 PHY Clock

The PHY Clock connectivity is shown in [Figure 31-4](#). On this MCU, the user has option to clock the PHY using the ESCSS\_PHY\_CLK signal if needed otherwise user can chose to provide an external 25 MHz source to the PHY and ESC (both must be clocked from the same source). For more details regarding providing PHY clock, refer to [Section 31.2.6.2](#) and see the EtherCAT data sheet from Beckhoff.

---

#### Note

Beckhoff documents strict accuracy (ppm) requirements for the shared 25 MHz ESC and PHY clock. Special care should be taken within a design to ensure EtherCAT clocking requirements are met. Relying on external components (oscillator and clock buffer) for the 25 MHz source are recommended. Validation of a design during normal operating conditions may be necessary to confirm clocking requirements are adequately met, especially if using the ESCSS\_PHY\_CLK signal.

---

### 31.1.8 EtherCAT Protocol

EtherCAT uses standard IEEE 802.3 Ethernet frames, thus a standard network controller can be used and no special hardware is required on master side. EtherCAT has a reserved EtherType of 0x88A4 that distinguishes it from other Ethernet frames. Thus, EtherCAT can run in parallel to other Ethernet protocols.

- EtherCAT does not need the IP protocol, however it can be encapsulated in IP/UDP.
- The EtherCAT Slave Controller processes the frame in hardware, therefore, communication performance is independent from processor power.

An EtherCAT frame is subdivided into the EtherCAT frame header followed by one or more EtherCAT datagrams. At least one EtherCAT datagram has to be in the frame. Only EtherCAT frames with Type 1 in the EtherCAT Header are currently processed by the ESCs. The ESCs also support IEEE802.1Q VLAN Tags, although the VLAN Tag contents are not evaluated by the ESC.

- If the minimum Ethernet frame size requirement is not fulfilled, padding bytes have to be added. Otherwise, the EtherCAT frame is exactly as large as the sum of all EtherCAT datagrams plus EtherCAT frame header.
- For further reading, including details on network time or network propagation delay, refer to the **ESC Hardware Datasheet Section I - Technology (ethercat\_esc\_datasheet\_sec1\_technology)** document provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com).

### 31.1.9 EtherCAT State Machine

The EtherCAT State Machine (ESM) is responsible for the coordination of master and slave applications at start up and during operation. State changes are typically initiated by requests of the master. They are acknowledged by the local application after the associated operations have been executed. Unsolicited state changes of the local application are also possible.

There are four states (see [Figure 31-6](#)) an EtherCAT slave shall support, plus one optional state:

- Init
- Pre-Operational
- Safe-Operational
- Operational
- Bootstrap (Optional)

**Figure 31-6. EtherCAT State Machine**

### Note

Not all state changes are possible, for example, the transition from "Init" to "Operational" requires the following sequence: Init → Pre-Operational → Safe-Operational → Operational.

### 31.1.10 More Information on EtherCAT

- For further information on EtherCAT, refer to the EtherCAT specifications, available from the EtherCAT Technology Group (ETG, [www.ethercat.org](http://www.ethercat.org)).
- Refer to the IEC standard “Digital data communications for measurement and control – Fieldbus for use in industrial control systems”, IEC 61158 Type 12: EtherCAT, available from the IEC ([www.iec.ch](http://www.iec.ch)).
- Documentation on Beckhoff Automation EtherCAT Slave Controllers are available at the Beckhoff website ([www.beckhoff.com](http://www.beckhoff.com)), for example, data sheets, application notes, and ASIC pinout configuration tools.

### 31.1.11 Beckhoff Automation™ EtherCAT IP Errata

Table 31-4 details the Beckhoff Automation™ errata of the EtherCAT IP integrated onto this device.

**Table 31-4. EtherCAT IP Errata**

Errata Number	Description
ER#156	WKC increment for reading reserved FMMU registers (+0xD+0xF)
ER#158	WKC increment for writing 0x0914-0x0917
ER#162	ESC DL Control (0x0101) loop setting Auto-Close (01): if port waits for write access to be opened, the temporary loop bit (0x0100[1]) is not taken into account when a write command to ESC DL Control occurs.
ER#164	EEPROM FSM cannot accept another command within 1680 ns after finishing a previous command
ER#165	EtherCAT reset register 0x0040 cannot be written using VLAN tagged frames, because state is reset due to double ECAT_CLEAR. VLAN tagged frames are rarely used for EtherCAT.
ER#168	Changing SyncSignal cycle times during activation can lead to extremely long cycle times, resulting from (intermediate) violation of the minimum delay between two consecutive pulses. For example, changing Sync1 from a few ns before Sync0 to a few ns after Sync0 results in a missed Sync1 time, which could take up to several 32/64 bit turn-arounds until the next pulse occurs. Changing cycle time from PDI can result in usage of intermediate, inconsistent values, which could result in unwanted cycle times or extremely long delays as above.

## 31.2 ESC and ESCSS Description

This section details the aspects of the ESC integration in the MCU. On this MCU, the ESC is integrated such that the ESC peripheral is accessed by either the CM subsystem or the CPU1 (master) subsystem. The MCU with the ESC functions as an EtherCAT slave device.

Figure 31-7 shows the ESC on this MCU.

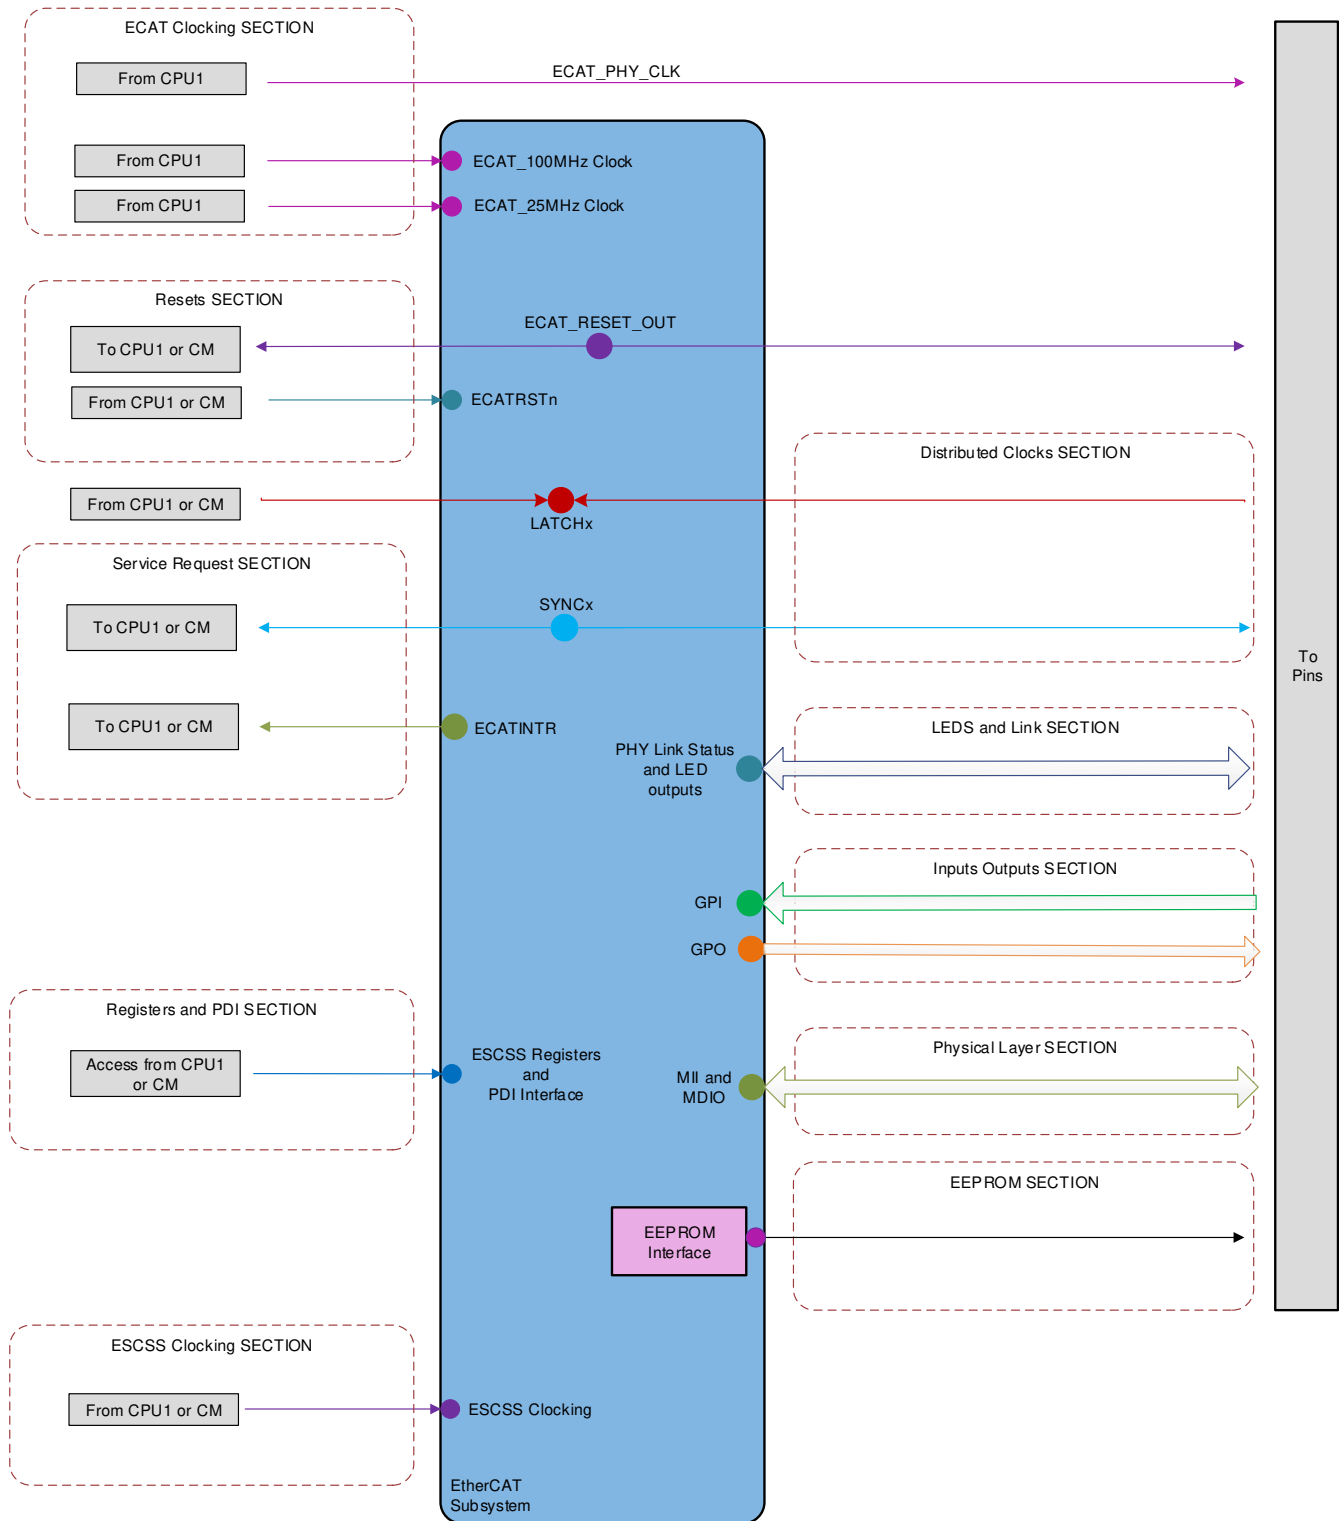

Figure 31-7. ESC Integration on MCU

**Table 31-5. ESC Integration Figure Sections**

ESC Figure Sections	More Information Links
ECAT/ESCSS Clocking	<a href="#">ESC Clocking</a>
Resets	<a href="#">ESCSS Resets</a>
Service Request	<a href="#">SYNC Signals</a> <a href="#">Interrupts and Interrupt Mapping</a>
Registers and PDI	<a href="#">ESC SubSystem</a>
Distributed Clocks	<a href="#">Distributed Clocks - Sync and Latch</a>
LEDS and Link	<a href="#">LED Controls</a>
Inputs Outputs	<a href="#">General Purpose Inputs and Outputs</a>
Physical Layer	<a href="#">EtherCAT Physical Layer</a>
EEPROM	<a href="#">Slave Node Configuration and EEPROM</a>

There are various actions that the controlling processor (CPU1/CM) needs to perform in response to actions initiated by the EtherCAT Master meant for this particular slave. All these interactions take place through one of the following:

- The 16-bit Asynchronous interface through which registers and RAM of the EtherCAT IP are read/written.
- An interrupt request going from the ESC to the Local Host (CM or CPU1).
- SYNC0 and SYNC1 pulses generated by the ESC which can be used as triggers for initiating further action.
- LATCH0 and LATCH1 which will be sampled by the ESC.
- EtherCAT general purpose inputs and outputs.

### 31.2.1 ESC RAM Parity and Memory Maps

This section details the CPU1 and CM ESC RAM parity logic and ESC memory maps.

#### 31.2.1.1 ESC RAM Parity Logic

The ESC RAM has Parity logic to ensure the data integrity of the contents. The byte wide parity is implemented as PDI accesses to RAM could be done byte wide. To ensure that errors in parity logic itself do not mask the memory error, redundant parity generation logic will be used. The parity generated by both logics is compared to ensure safe operation of the memory accesses.

- Use **INITIATE\_MEM\_INIT** bit from the ESCSS register to trigger the memory initialization.

#### 31.2.1.2 CPU1 ESC Memory Address Map

When the ESC is allocated to CPU1, [Table 31-6](#) is the memory map and associated details.

**Table 31-6. ESC Address Map On CPU1**

Memory Map Region	Memory Region	Accessed Through	Parity Scheme	DMA Access	CLA Access	CPU2 Access	Security	Access/ Bus
DPRAM memory map (16 KB)	0x00050800 - 0x000527FF	PDI interface of ESC	1 parity bit for 8 bits of data	Yes	No	No	No	Async
ESC Registers	0x00050000 - 0x000507FF	PDI Interface of ESC	No	No	No	No	No	Async
ESCSS Registers <sup>(1)</sup>	0x00057E00 - 0x00057FFF	Direct Access	No	No	No	No	No	VBUS32

(1) When register access protection is enabled, all write accesses are blocked; however, a violation interrupt is not generated in the event of an attempted write access.

### 31.2.1.3 CM ESC Memory Address Map

When ESC is allocated to CM, [Table 31-7](#) is the memory map and features.

**Table 31-7. ESC Address Map on CM**

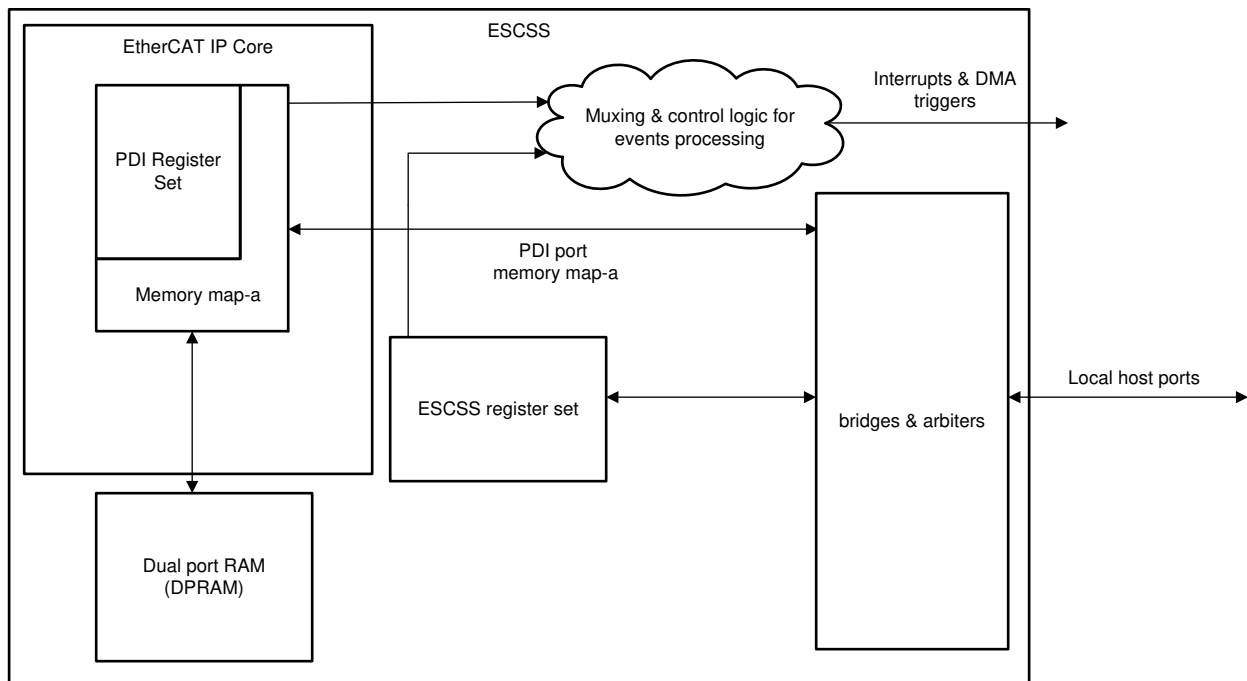

Memory Map Region	Memory Region	Accessed Through	Parity Scheme	μDMA Access	Bus/Protocol	Security
ESC RAM memory map (16 KB)	0x400A1000 - 0x400A4FFF	PDI interface of ESC	1 parity bit for 8 bits of data	Yes	System/PDI	No
ESC Registers	0x400A0000 – 0x400A0FFF	PDI	No	No	System/PDI	No
ESC_SS Registers	0x400AFC00 – 0x400AFFFF	Direct Access	No	No	System/VBUSB	No

### 31.2.2 Local Host Communication

[Figure 31-8](#) shows how the ESC and ESC subsystem connects to the Local host subsystem. Local host subsystem can include the CPU (CPU1 or CM) of the device and DMA engine as bus masters accessing the EtherCAT IP. This local host subsystem will be acting upon the commands which are sent to it by the EtherCAT Master in the form of EtherCAT datagrams.

The 16-bit Asynchronous interface and the interrupt request line are the main channels through which the Local host subsystem interacts with the EtherCAT IP. The interrupt request line can be used to trigger actions based on EtherCAT IP internal events, exception conditions or time synchronized events. DMA engine is used to transfer the contents from the process data memory to system RAM on any of these events. The user application needs to select the events that will act as interrupts or DMA requests. The mask and clear events for the interrupt causes are configured to be accessed by the CPU/Co-processor that is mastering the EtherCAT IP.

**Figure 31-8. Interaction of ESCSS with the CPU Subsystem**

### 31.2.2.1 Byte Accessibility Through PDI

The ESC has a few registers which need byte wide access to affect the functionality. The EtherCAT implementation on this MCU is as follows:

- CPU1 supports 16-bit accesses only
- CM supports byte accesses

### 31.2.2.2 Software Details for Operation Across Clock Domains

The registers accessible from the CPU would be in the system clock domain and hence those will be synchronized to the PDI clock before being used within the EtherCAT IP. Given the frequency ratios and different styles of synchronization schemes, the application needs to assume there is a delay in getting the values transferred from one domain to other. Such a delay could vary based on the frequency of system clock and/or type of synchronizer used in the path.

For example, a system clock of 200 MHz and ESCSS running at 100 MHz would require at least 10 clock-system clock cycles delay before values are affected on the other side. If a write occurs to the PDI and some other action is performed elsewhere (not involving the PDI) then the software should perform a simple read to ensure that the write is complete.

### 31.2.3 Debug Emulation Mode Operation

There are two aspects of the EtherCAT IP operation that need to be considered from a debug emulation stand point.

- **CPU Halted Condition:**
  - **CPU1:** For any operation from the EtherCAT IP which is based off an interrupt request, it is quite important that this interrupt is marked as a realtime interrupt and the debugger must be halted in RealTime mode. If the CPU is halted without taking the above precaution, then the EtherCAT IP can only be active for those parts where servicing the interrupt is not required (For example, GPIO and SYNC0/1 output triggers can all function unaffected).
  - **CM:** Does not apply. CM doesn't have Real time debug and will remain in halt mode until released by the run command again regardless of interrupt request assertions.
- **Debugger Writes/Reads of EtherCAT IP registers/memories Condition:** The EtherCAT IP does not have any mechanism to identify a debug initiated read/write. Debug accesses to the registers or the ESC RAM can affect the state of the EtherCAT IP. This is addressed by the following:
  - **CPU1/CM:** The "enable debug access" bit must be set in the ESCSS Access Control Register in order to enable user access to the ESC RAM and EtherCAT registers for the purpose of debug. By default, this is disabled.

### 31.2.4 ESC SubSystem

The EtherCAT Slave Controller SubSystem (ESSC) wraps the ESC core with required register configurations and required logic for different functions of the EtherCAT and RAM (ESC RAM). This section covers the ESSC integration aspects. [Figure 31-9](#) shows the EtherCAT subsystem Integration.

- **ESSC Configuration registers slave interface** is the port for accessing the critical device level configurations which are a must have for the ESSC to function.
- **ESSC register slave interface** has control and status registers including SYNC, LATCH configurations, interrupt related controls, and GPI/GPO related controls.
- **PDI Async slave interface** is a 16 bit wide data interface that allows the local application to access the registers internal to the EtherCAT IP Core as well as the dual port memory (ESC RAM) through the SyncManager and the FMMUs.

Figure 31-9. ESCSS Wrapper

### 31.2.4.1 CPU1 Bus Interface

Interface to the CPU1 core is retained at the ESCSS boundary as a native mem32 interface which connects the RD and WR ports independently to all the slave entities within the ESCSS.

- CPU1 MEM32 RD/WR ports are: Configuration Registers, Control/Status Registers, PDI
- CPU1 DMA MEM32 RD/WR ports are: PDI (access to ESC RAM only)

### 31.2.4.2 CM Bus Interface

The CM interface involves the AHB bus that is arbitrated between the CM and  $\mu$ DMA accesses to the PDI .

- CM System bus ports are: Configuration Registers, Control/Status Registers, PDI
- $\mu$ DMA ports are: PDI (access to ESC RAM only)

### 31.2.5 Interrupts and Interrupt Mapping

The ESC has one interrupt line that can be connected to the local host (CPU1 or CM) which is called PDI IRQ from the ESC. Besides this, there are other interrupt causes generated within the ESCSS. These are aggregated to a total of 4 interrupt lines that are connected to the local host core.

**Table 31-8** summarizes these exceptions and their mapping. There are 4 interrupt lines provided for ESCSS which are: ECATSS\_Intr, RESET\_OUT\_Intr, SYNC0\_Intr and SYNC1\_Intr. Each of these causes have an independent set of mask/clear/set controls and raw/masked interrupt status flags. This allows independent cause servicing on the exception event with flexibility to mask or service the desired set of causes. All these interrupts are mapped onto NVIC on CM and PIE on CPU1. Please refer to the System Control chapter of the TRM for details on the interrupt numbers.

In event that the same exception is available to the multiple bus master cores of the local host CPU then it is expected that the application software ensures clearing of the RIS is a software synchronized event between those masters and there is no stale exceptions pending for one master while the other clears the RIS. In other words, there is no separate exception cause (RIS/MIS) copy per master but are common interrupt registers for the local host across masters.

**Table 31-8. Service Request Generation Map**

Source	Description	Master				
		CPU1	CLA	CPU1 DMA	CM	μDMA
EtherCAT IRQ	AL Event Request of the ESC	ECATSS_ intr	ECATSS_ intr	Not Available	ECATSS_ intr	Not Available
PDI Interface Timeout Error	PDI Interface WatchDog timeout error	ECATSS_ intr	ECATSS_ intr	Not Available	ECATSS_ intr	Not Available
μDMA Done <sup>(1)</sup>	This event indicates to CM or CPU1 that μDMA transfer by earlier event is over	ECATSS_ intr	Not Available	Not Available	ECATSS_ intr	Not Available
EtherCAT RESET_OUT Event	RESET_OUT can be programmed as interrupt to the CPU to either complete the reset sequence with required pre-steps if an or acknowledge the reset request in some other way. Given the high priority nature of the signal independent interrupt line is allocated	RESET_OUT_ Intr	RESET_OUT_ Intr	Not Available	RESET_OUT_ Intr	Not Available
SYNC0 Event	Precise time event 2, can be used to start routine SYNC1_Intr on cores or data transfer using DMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC0_ Intr	SYNC0_ Intr	SYNC_ DMAReq	SYNC0_ Intr	SYNC_ DMAReq
SYNC1 Event	Precise time event 1, can be used to start routine on cores or data transfer using DMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC1_ Intr	SYNC1_ Intr	SYNC_ DMAReq	SYNC1_ Intr	SYNC_ DMAReq

- (1) Only μDMA has the DMA\_DONE qualifier. This is not applicable to the CPU1 DMA. The DMA\_DONE cause is specific to μDMA integration in the systems and it is routed to the CPU that is master of the EtherCAT. While μDMA configuration will be limited by the CM core, in cases where μDMA request is linked to time precise SYNC triggers, the EtherCAT master should be able to clear the DMA\_DONE RIS (RAW Interrupt Status) to re-arm the μDMA request generation in ESCSS. If unused, this interrupt cause should be kept masked by the EtherCAT master CPU.

### 31.2.6 Power, Clocks, and Resets

This section details the ESCSS power requirements, clocking, and resets. The EtherCAT IP has 2 clock ports and one reset output. Since the PLLs, dividers, and gating is implemented as part of system control, this setup is always handled by CPU1 during the initialization sequence.

### 31.2.6.1 Power

The ESC module is inside the main power domain like other peripherals and there are no special considerations about the power up or power down sequences that need to be taken. Please refer to system control chapter for different power modes.

### 31.2.6.2 Clocking

Two functional clock inputs are defined for the ESC: CLK25 (25 MHz) and CLK100 (100 MHz).

EtherCAT functional clock inputs CLK25 and CLK100 are sourced by the MCU clocking module either using SYSPLL or AUXPLL. At the SoC level, you have multiple options to choose from regarding what inputs are used for the SYSPLL or AUXPLL.

- Due to the 25 ppm requirement for EtherCAT, an external oscillator of 25 MHz is suggested to be used as the main clock source.
- A less accurate clock than 25 ppm limits the ability of the ESC to act as the network reference clock. For practical reasons, clock accuracy must be the same or better than the Ethernet clock source that is 50 ppm.

#### Note

- CLK25 and CLK100 are used for the ESC core operation. These two clocks and the clocks to the PHY **must have a common source**, which establishes a deterministic phase relationship between PHY clocks and ESC clocks.
- In MII mode, 25 MHz RX clock is sourced by the PHY while the TX clock from PHY is optional (which effectively saves a pin). The phase differential between the PHY TX clock and CLK25 can be compensated to the TX data and TX EN using the manual compensation mode in increments of 10 ns.

Figure 31-10 shows the clocks connectivity. Refer to the *System Control and Interrupts* chapter for additional details of the PLL source selections and clock dividers.

Figure 31-10. Clocking of ESC

As it may not always be feasible to have a clock accuracy of 25 ppm, in the case of a low accuracy clock (up to 100 ppm) being used, then the following restrictions apply:

- RX FIFO size can not be reduced lower than 7 (default for 100 ppm), which in turn affects the latency of the transfer as the transfer starts after half of the FIFO full threshold, thus resulting in a RX Delay.
- This ECS cannot be used as the first slave from the master in the network, as typically the first slave from the master is treated as the reference clock for the distributed clocks functionality.
- The number of iterations required for synchronizing clocks (specially the drift computation) increases.

### 31.2.6.3 Resets

This section describes the ESCSS sources of reset. There are other conditional reset sources which may impact ESCSS and those include all the device level reset sources including: device pin reset “XRSN” or software initiated device level reset “SYSRSn”.

---

#### Note

Whenever the device comes out of reset, software must execute the following sequence to ensure that PHY can see the full stretching of its reset:

1. Configure the EtherCAT GPIOs
2. Put the ESCSS into soft reset
3. Bring the ESCSS out of soft reset

Refer to [Section 31.3](#) more information on proper software procedure.

---

#### 31.2.6.3.1 Chip Level Reset

Chip level resets (such as POR, XRS, WDRS, or NMIWDRS) is a master reset that resets the entire device including EtherCAT IP.

#### 31.2.6.3.2 EtherCAT Soft Resets

ESCSS can be reset by three soft reset mechanisms, including:

- System control level software programmable (SOFTPRES23) which is reset only by chip level and EtherCAT resets. Default keeps the IP in reset which is released by local application after setting EtherCAT ready for operation.
- Reset by a particular command sequence from Remote EtherCAT master.
- Reset by a particular command sequence from the local host application. (CM core only)

#### 31.2.6.3.3 Reset Out (RESET\_OUT)

Multiple reset sources of ESCSS are combined to make the reset vector that drives the EtherCAT and companion devices (PHYs) on this MCU. The RESET\_OUT is asserted only when it is configured to be a reset. If configured as an interrupt or NMI, it is expected that the local host will complete the reset.

By default, RESET\_OUT performs no action and must be setup to cause the reset to IP core and PHY. The input events to RESET\_OUT include the remote EtherCAT Master, local host application, and EtherCAT soft reset.

When the intent is to perform a reset to the ESCSS and the device, the following options are available to reset the device after software has given a reset to the ESCSS:

- Use the system control SIMRESET register to generate a device reset.
- Use the watchdog or NMIWD to generate a device reset.

### 31.2.7 LED Controls

There are four LED outputs from the ESC that can be routed out of GPIO to indicate different status of the ESC. [Table 31-9](#) is the recommendation for applications on the usage, especially for the pin sensitive systems that can support this and still meet the intent. All the LED functions are routed to the peripheral pin mux and it is up to the user to configure the LEDs as per the available pins.

**Table 31-9. Status LED Options and Priority**

LED	Priority Order	Function	Recommendation	Usage Priority
RUN	5	Shows the status of ESC state machine with different blinking patterns.	In the case where color LEDs are not supported then this needs to be supported.	Must
ERR <sup>(1)</sup>	4	Indicates the Error in ESC operation.	In the case where color LEDs are not supported then at least the Error status needs to be reported.	Must
STATE	2	Combination of the RUN and ERR LED.	Not supported on this device.	-
LINKACT0 (ESC_LED_LINK0_ACTIVE)	3	Link Active Status for link towards Master.	Link Status on Master side (Port0) is important to know if the ESC and network downstream is part of network or not. The prior ESC will loopback if this node fails hence the frame would reach. The status on this LED eases the debug.	Desired
LINKACT1 (ESC_LED_LINK1_ACTIVE)	1	Link Active status for link towards Network side.	The Link status on the network side (Port 1) is critical from continuity through the ESC point hence this is kept highest priority status reporting.	Must

(1) Driven by software, not ESC IP on this device.

The PHY MII\_LINK (ESC\_PHYx\_LINKSTATUS) indication is a gross indication from PHY and may not really indicate if the established link meets the characteristics including auto-negotiation as required by EtherCAT. Hence it may not be a true status indication; however, it is critical to shorten reaction time in the event of link loss that is crucial for redundancy operation. Using LINKACT LEDs (LED\_LINKx\_ACTIVE) for the status output and MII\_LINK (ESC\_PHYx\_LINKSTATUS) for the status input is the most ideal usage; however, they may not be practical to sacrifice 4 pins. The tradeoff of whether MII\_LINK itself is used as a crude Link status LED or LINKACT is used depends on link loss reaction time requirements and available number of GPIOs for the system.

---

#### Note

Note that the EtherCAT link status through the MII Management Interface option should only be enabled if only a Gigabit PHY is to be supported, and should not be enabled if needing to support both 10/100 and Gigabit PHY. For this reason, the Link Status through MII Management Interface is disabled on this ESC. Instead, use the LINKACT or PHY MII\_LINK signals for link status purposes.

---

### 31.2.8 Slave Node Configuration and EEPROM

The ESC requires non-volatile memory (for example, an EEPROM with I2C interface), which is referred to as the Slave Information Interface (SII) memory, to store the EtherCAT Slave Information (ESI) data.

The ESI data contains information about the slave device identification, supported features, and other network accessible properties.

---

#### Note

The ESI XML file is generated from Beckhoff's Slave Stack Code (SSC) tool.

---

- **EtherCAT Slave**
  - Uses the SII upon power-on or reset to load configuration data into the EtherCAT slave configuration registers.
- **EtherCAT Master**
  - During development, master is used to program the device SII memory with the ESI data.

- When the ESI file isn't provided to the master, the master reads the device SII memory upon boot-up to determine the slave device properties such as the process data and their mapping options, the supported mailbox protocols including optional features, as well as the supported modes of synchronization.

### 31.2.9 General Purpose Inputs and Outputs

The ESC subsystem implementation on this MCU supports 32 General Purpose Inputs (GPI) and 32 General Purpose Outputs (GPO) in addition to the PDI.

These GPI/GPOs provide an advantage for embedded applications over discrete components in that they can selectively drive or sense GPIOs in a time controlled manner. For example, it could be a sensor/actuator control, status read, LED status update, and so on. The following section describes the integration and usage of this feature.

#### 31.2.9.1 General Purpose Inputs

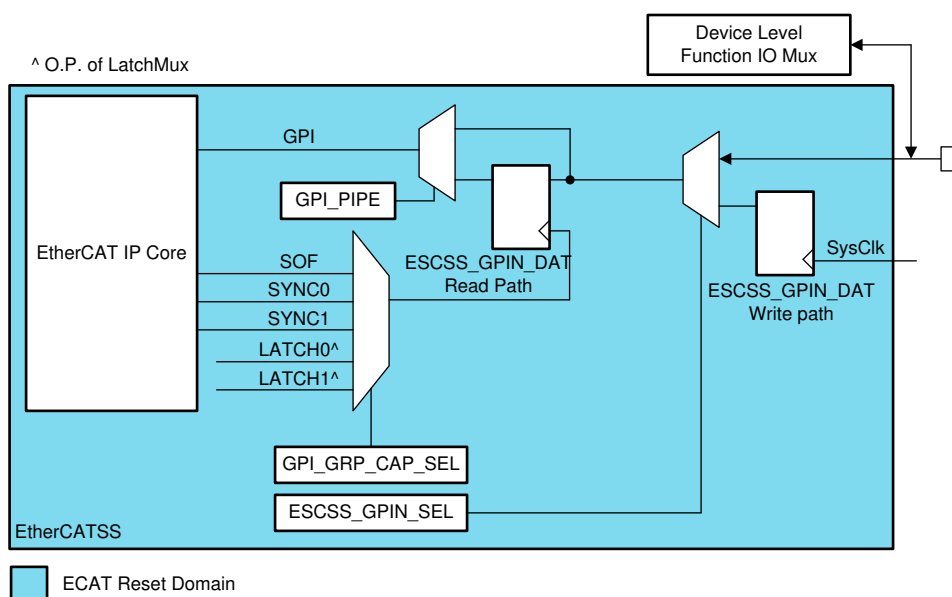

General purpose inputs are connected to the device GPIO pin mux through an input buffer with an option to directly connect the asynchronous input flowing directly into the IP or through a ESCSS register pipeline which can hold the value stable while it is captured within the ESC. The state of the GPI can be captured based on the following events:

- **Start-of-Frame (SOF):** Contents can be ready for capture in the frame if requested by master
- **SYNC0/1:** Contents captured on a precise time tick
- **LATCH0/1:** Contents synchronized with LATCHIN read (allows simultaneous input and timestamp capture)

The ESCSS\_GPIN\_DAT register, containing the contents of the GPIN data, is available for reading from host CPU to allow debug access. Additionally, ESCSS\_GPIN\_DAT allows CPU writes for being used GPIN override purposes such as in place of using GPIOs.

GPIs are divided in 4 sets of GPIO:7, GPI8:15, GPI16:23, and GPI24:31 for clocking the capture trigger, which means the same capture trigger has to be used for the IOs within a set. Thus either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs. Selection of which Inputs (ESCSS\_GPIN\_SEL) and outputs (ESCSS\_GPOUT\_SEL) can be connected to GPIO is possible at each single IO level.

Figure 31-11 illustrates the integration of the GPI feature.

**Figure 31-11. ESC SS General Purpose Inputs Integration**

**Note**

For Software: The write data will get reflected on the ESCSS\_GPIN\_DAT read path only when one of the configured events like SOF, SYNC0/1, etc is seen as configured after a few cycles of that event getting generated. Additionally, the copy of ESCSS\_GPIN\_DAT register readable by the CPU is provided without synchronization, therefore multiple reads should be performed to confirm a stable value before using it.

**31.2.9.2 General Purpose Output**

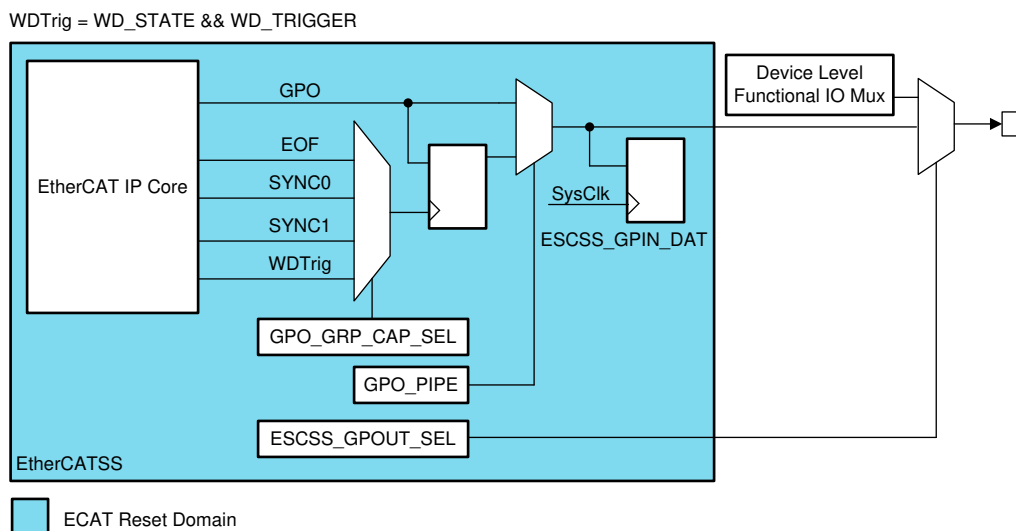

General purpose outputs are connected to the device GPIO pin mux through an output buffer with an option to directly connect from the ESC IP core registers to the external world or through a ESCSS register pipeline which can hold the output value stable. The state of the GPO can be set based on the following events:

- **End-of-Frame:** Contents can be updated by the master from the last received frame
- **SYNC0/1:** Contents can be updated based on a precise time tick
- **Watchdog Trigger:** Contents can be updated based on the last successful access to process data memory

The ESCSS\_GPOUT\_DAT register, containing the contents of the GPO data, is available for reading from host CPU to allow debug access or to read in place of GPIOs.

GPOs are divided in 4 sets of GPIO0:7, GPI8:15, GPI16:23, and GPI24:31 for clocking the output trigger, which means the same output trigger has to be used for the IOs within a set. Thus either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs. Selection of which Inputs (ESCSS\_GPIN\_SEL) and outputs (ESCSS\_GPOUT\_SEL) can be connected to GPIO is possible at each single IO level.

Figure 31-12 illustrates the integration of the GPO feature.

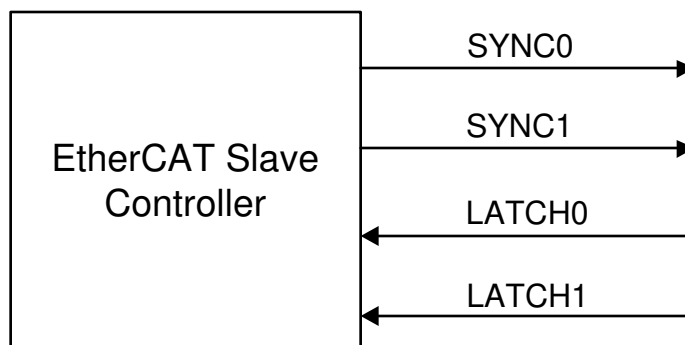

**Figure 31-12. ESC SS General Purpose Output Integration**

**Note**

In Figure 31-12, the synchronisation between CLK100 or CLK25 with respect to SysClk is not shown and it is implicit by design. Local host shall adjust for the synchronisation delays as required while processing the data in either direction.

### 31.2.10 Distributed Clocks – Sync and Latch

Distributed clocks (DC) is a differentiating feature of the EtherCAT network. Distributed clocks allows all the slave nodes in the EtherCAT network to be bound in tight margin of time to synchronize the events and EtherCAT master command.

**Figure 31-13. ESC SYNC and LATCH**

This feature has sub-features as listed below. To enable the utility of these features at the application level, the related signals of DC are integrated tightly with the C2000 control loop logic, as well as, an external component which could be a possible implementation to trigger/latch other components on the board. This section explains the integration of these signals and related nuances of usage.

#### Distributed clock features:

- Clock Synchronization
- Sync Signal Generation
- Latch Signal event capture

Apart from usage for Control loop synchronizations, these features are also used to synchronize the system and network time. These include the following:

- **System Time PDI Controlled:** Synchronize system time between two different EtherCAT networks.
- **Communication Timing:** To synchronize slave communication with Sync signals, output or input events, and so on.

For further reading, including details on network time or network propagation delay, refer to the **ESC Hardware Datasheet Section I - Technology (ethercat\_esc\_datasheet\_sec1\_technology)** document provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com).

#### 31.2.10.1 Clock Synchronization

DC clock synchronization is the ability and procedure of the ESC to maintain the copy of reference clock based on local clock (internal 64 bit time base) and other adjustment as derived by the procedure. The reference clock is the most accurate clock in the system and is typically held by one of the slaves (Topologically first one after master is preferred). This time-base has higher accuracy requirement and it needs to periodically synchronize with an absolute time source like GPS or any other maintained time-base as in IEEE1588 network.

The synchronization order is as follows:

1. The master maintains its own Master clock which is either the absolute time synchronized or it controls the reference clock itself.
2. The master queries the ESC time-base based on topology information and timestamps to determine the drift of the local clock for each ESC with regards to the reference clock.
3. The master programs the clock drift adjustments in each respective ESC.
4. With further periodic queries of the local clock, the master determines the drift of the local clock and keeps adjusting it so as to maintain the copies of the reference clocks on each ESCs in a tight limit.

While the IP requires two clocks of 25 MHz and 100 MHz, the 100 MHz clock is used for the internal time-base and supports the best accuracy possible. Refer to [Section 31.2.6.2](#) section for more details on clocking.

### 31.2.10.2 SYNC Signals

Sync signals are precise time controlled signals and are able to trigger time synchronized action(s) of the device master(s). CPU core and DMA engine triggers are configured independently for every end point. The following sections describe ESC signal integration and various control triggers in the device.

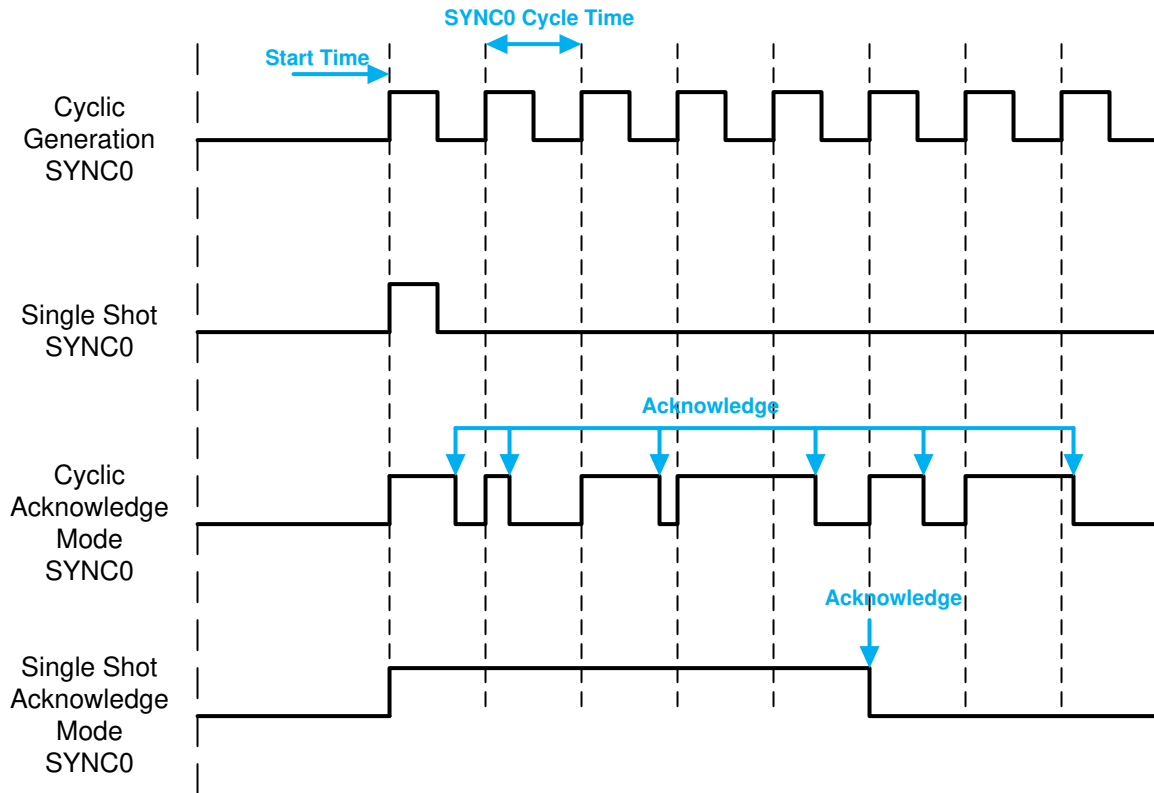

Figure 31-14. SYNC0 Signal Modes

- **SYNC0:** SYNC0 is the primary trigger and can be generated in either a cyclic (periodic event generation like rise edge at every x period) or one shot mode. Furthermore, these modes can be either with or without acknowledge, such that when enabled with acknowledge mode, the next event won't be generated until the acknowledgment is received from the controlling master. If the acknowledgment is delayed, the event will be skipped and the next periodic event is generated. Remember that the acknowledgment could be part of the interrupt servicing from the PDI and thus such a delay in triggering the next event is acceptable since the servicing routine can accordingly take action for the period elapsed. These modes are shown in Figure 31-14
- **SYNC1:** The SYNC1 generation follows the SYNC0 generation with a programmable delay and depending upon the delay time defined, it may or may not generate the pulse since the predefined delay from SYNC0 event is newly measured only after the SYNC1 event (except for the start).

#### Note

- The SYNC0/1 when used in a system clock domain is stretched to at least 3 clock wide pulse.
- When ESC goes through a reset, the SYNC outputs triggering external device events need to be kept at a safe value. At reset, the output values are '0' and this could be an active state when the reset occurs therefore the corresponding care of usage from the remote device should be taken.

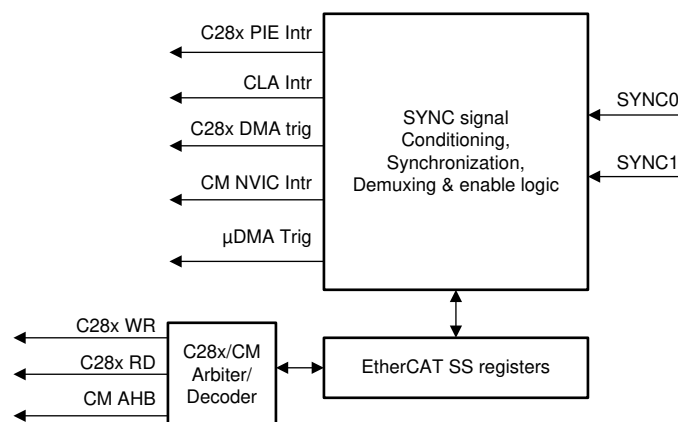

### 31.2.10.2.1 Seeking Host Intervention

SYNC can be used to initiate the action from the local host or related DMA engine which can respond with control action or data transfers from the ESC IP.

These actions can be selectively initiated in terms of:

- Interrupts to CPU cores (CPU1, CLA or CM)
- DMA requests to DMA cores (CPU1 DMA and CM  $\mu$ DMA)

Figure 31-15 depicts the SYNC connection diagram to the CPU subsystems.

**Figure 31-15. SYNC Integration for the HOST Intervention**

Table 31-10 shows the Host Intervention selections, control and information that helps applications to route and handle the SYNC signals for respective Host intervention.

**Table 31-10. ESC SYNC Integration Map**

Destination	Source	Enable	Mask	Clear	Source Clock	Destination Clock	Destination Signaling
C28x PIE Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[0]	ESCSS_INTR_MASK[0]	ESCSS_INTR_CLR[0]	ECAT.100MHz	C28x.SysClk	Pulse
C28x PIE Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[0]	ESCSS_INTR_MASK[1]	ESCSS_INTR_CLR[1]	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C28x DMA Trigger	SYNC0	ESCSS_SYNC0_CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C28x DMA Trigger	SYNC1	ESCSS_SYNC1_CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
CM NVIC Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[3]	ESCSS_INTR_MASK[0]	ESCSS_INTR_CLR[0]	ECAT.100MHz	CM.SysClk	Pulse/Level
CM NVIC Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[3]	ESCSS_INTR_MASK[1]	ESCSS_INTR_CLR[1]	ECAT.100MHz	CM.SysClk	Pulse/Level
$\mu$ DMA Trigger	SYNC0	ESCSS_SYNC0_CONFIG[4]	NA	NA	ECAT.100MHz	CM.SysClk	Pulse/Level
$\mu$ DMA Trigger	SYNC1	ESCSS_SYNC1_CONFIG[4]	NA	NA	ECAT.100MHz	CM.SysClk	Pulse/Level

The difference between Enable and Mask is that Enable allows the conditioned and synchronized interrupt to be routed to the raw interrupt/trigger cause register, while Mask is a software control to allow raising an interrupt or not. Disabling the SYNC0/1 on a respective trigger would lose any events that happen until it is enabled again.

**Regarding the CLA:**

- The CLA does not have access to EtherCAT hence it does not have the MASK/Clear controls, however, the trigger would start the action on the CLA processing which upon completion should be acknowledged by CPU1 to clear the cause.

**Regarding the DMA:**

- The DMA triggers do not have Mask and Clear capabilities as typically there is no feedback mechanism from the DMA to clear the trigger cause.
- The expectation is that DMA Done is routed to ESCSS and it raises an interrupt to CPU for acknowledgment. CPU1 upon clearing the trigger cause, acknowledges the SYNC through PDI.
- [Figure 31-16](#) is the symbolic view of DMA request source select. If a given source event triggers multiple events across different masters then the software has to ensure there is a status exchange before cause is cleared.

**Figure 31-16. SYNC Event Muxing for Different Host DMA Triggers**

### 31.2.10.3 LATCH Signals

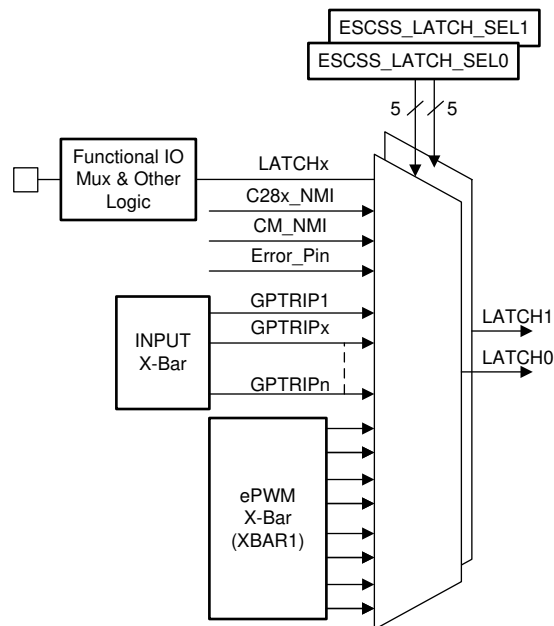

Latch inputs to the ESC can be used to capture the time-stamp or register the GPI inputs. Two latch inputs are available. Latch enables external events:

- To take a system time snapshot of the EtherCAT network, measure time, or schedule further operations.
- To capture the status of the GPI inputs either as the status of connected external components or as part of control flow.

Both the Latch inputs can be independently configured to operate on either rising or falling edge of the signal. The LATCH events can be individually assigned either for the PDI control or EtherCAT master control. Additionally it supports the one shot or continuous mode.

- In **one shot mode**, the next capture of the timestamp is done on qualifying LATCH event only after the previous one is acknowledged.
- In **continuous mode**, time-stamps are successively captured on a qualifying event, regardless of a preceding one being read or not.

Figure 31-17 depicts the different sources for the LATCH0/1 so as to full-fill the application requirements. These are subsequently explained thereafter for possible use.

**Figure 31-17. ESC Latch Input Integration**

The details of connections and mux select to these muxes is shown in [Table 31-11](#) and selection is possible individually for each of the LATCH0 or LATCH1 signal.

**Table 31-11. ESC LATCH0/1 Trigger Table**

ESCSS_LATCH_SELx	Signal Hookup
0	ESCSS_LATCH0 (From Pin)
1	ESCSS_LATCH1 (From Pin)

### 31.2.10.3.1 Timestamping

Timestamping allows the local application or remote EtherCAT master to measure the time events and plan the subsequent controls.

#### Timestamping: Device Internal Events

- Enable timestamping and logging of internal device events coming from control logic
- The same outputs of the EPWM crossbar that connect to the 8 EPWMs can be used as 8 input signals (PWMXBAROUT0-PWMXBAROUT7) for time stamping
- Note that there is no independent option for Latch muxing as far as EPWM cross-bar inputs are concerned; unless one of the TRIP outputs are not used in control loop and such a crossbar output is dedicated for LATCH0/1 toggle

#### Timestamping: External Events

- Enable external board components apart from the MCU to trigger timestamp capture
- For example, timestamp a periodic event or pulse/edge event from a sensor when the sensor data is read or accessed
- Connecting the LATCH0/1 controls through the input crossbar allows timestamp capture based on any selected GPIO toggle (such as GPTRIP15 or GPTRIP16)
  - Two GPTRIPs are provided for independent GPIO choice for LATCH0 and LATCH1
  - GPTRIP1,2,3 allow the same functionality however those could be utilized for EPWM trip zone functions where pins may or may not need to match. In the case a trip zone based on GPTRIP is to be latched, one of these inputs can be used

#### Timestamping: Device Exception Events

- Log and timestamp exception events within the device (ex: NMI exceptions) and/or periodically collect information to find out systemic issues in the system
- Could be used by local application and/or remote master to diagnose or debug the system
- On CPU1, ERAD can be used to analyze particular accesses or data patterns/counts on the CPU bus. Refer to the ERAD chapter for further information

### 31.2.10.4 Device Control and Synchronization

The primary advantage of DC functionality is when used in conjunction with device control functions. The precisely timed pulse/edge nature of the SYNC allows the ESC to synchronize the internal resources like PWMs, ECAPs (for capture as well as PWM) with remote system components. The following are the connections which are available for applications to program for allowing this synchronization.

#### 31.2.10.4.1 Synchronization of PWM

The PWM Sync-chain on the MCU can be triggered either by the device external inputs from the GPIO via input cross-bar or the PWM internal events when the chain is programmed appropriately. The SYNC0/1 inputs in this implementation also act as the external sync inputs to the PWM sync-chain. The integration is shown in [Figure 31-18](#).

The additional select register added to the trigger crossbar register allows independent programming of the EXTSYNcx from either GPTRIP or SYNC0/1.

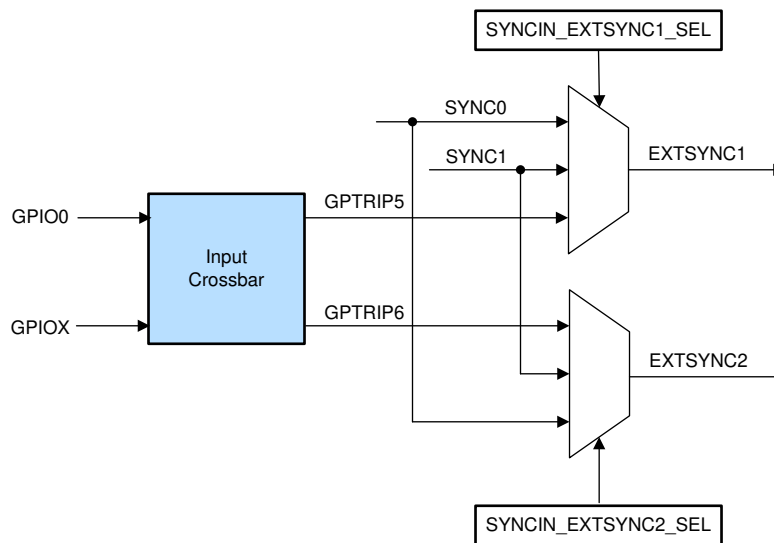

Figure 31-18. SYNC Integration for Control Functions - PWM SYNC

#### 31.2.10.4.2 ECAP SYNC Inputs

ECAP supports accurate time capture of events that can be relatively checked against the series of events in vicinity and used for the control loop action. Additionally, ECAP has inbuilt capability of limited PWM action that can be triggered based on the selected input. Hence, the SYNC0/1 are also connected to ECAP input mux. The exact select value/vector for SYNC0/1 is defined in the ECAP chapter.

Figure 31-19. SYNC Integration for Control Functions – ECAP

### 31.2.10.4.3 SYNC Signal Conditioning and Rerouting

SYNC0/SYNC1 generation modes can generate various waveform patterns to create different trigger conditions. The SYNC0/1 signals are routed to the CLB, which can make conditional and/or delay based waveforms. Using the CLB, these signals can be processed for additional uses based on the application.

Additionally, this integration also allows routing SYNC0/1 signals with or without processing to other destinations within the device which are not explicitly connected. Details of the CLB input mux selects are explained in the CLB chapter.

**Figure 31-20. SYNC Integration for Signal Conditioning – CLB**

## 31.3 Software Initialization Sequence and Allocating Ownership

This section details the software initialization sequence when configuring CPU1 or CM as ESC owner. The CM sequence includes details on allocating ownership of the EtherCAT peripheral.

**Table 31-12. CPU1 Software Initialization Sequence**

Step	Action
1	General device initialization (Configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	Configure Aux Clock for EtherCAT (if using Aux clock as source)
3	Configure GPIOs for EtherCAT (set Pin Configurations, set GPIO qualification mode, set Pad Configuration)
4	Initialize interrupts and register ISR handlers
5	Set EtherCAT clock source and divider. Then configure whether or not EtherCAT PHY will be clocked from device or external PHY clock.
6	Configure the EEPROM size
7	Bring EtherCAT peripheral out of reset via system control register
8	Perform EtherCAT memory initialization and wait until memory initialization is complete
9	(Optional) Enable debug access to the EtherCAT registers
10	(Optional) Check that EEPROM loaded successfully
11	EtherCAT subsystem configurations for interrupt masking, SYNCx connections, and so on <sup>(1)</sup>

(1) Applications should ensure that ESC outputs are in safe state until EEPROM is loaded and that SYNC/LATCH is configured only after EEPROM is loaded.

**Table 31-13. CM Software Initialization Sequence**

Step	Core	Action
1	CPU1	General device initialization (Configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	CPU1	Configure GPIOs for EtherCAT (set Pin Configurations, set GPIO qualification mode, set Pad Configuration)
3	CPU1	Allocate EtherCAT peripheral to CM
4	CPU1	Configure CM clocks and release CM from reset to wait mode
5	CPU1	Configure Aux Clock for EtherCAT (if using Aux clock as source)
6	CPU1	Set EtherCAT clock source and divider. Then configure whether or not EtherCAT PHY will be clocked from device or external PHY clock.
7	CPU1	Set CM boot mode and boot CM to start application
8	CPU1	General Device Initialization
9	CM	Initialize interrupts and register ISR handlers
10	CM	Configure EtherCAT EEPROM size
11	CM	Bring EtherCAT peripheral out of reset via system control register
12	CM	Perform EtherCAT memory initialization and wait until memory initialization is complete
13	CM	(Optional) Enable debug access to the EtherCAT registers
14	CM	(Optional) Check that EEPROM loaded successfully
15	CM	EtherCAT subsystem configurations for interrupt masking, SYNCx connections, and so on <sup>(1)</sup>

- (1) Applications should ensure that ESC outputs are in safe state until EEPROM is loaded and that SYNC/LATCH is configured only after EEPROM is loaded.

## 31.4 ESC Configuration Constants

The following is EtherCAT IP core configurations that are static by design.

**Table 31-14. ESC Configuration Constants Table**

Name	Value
ESC Type	0x91
Revision	0x0
Build	0x0
FMMU Supported	0x8
SyncManagers	0x8
RAM Size	0x10
Port Descriptor	0xF
ESC Features Supported	0x1CC
Product ID	0x0
Vendor ID	0x0

**Table 31-15. ESC IP Register Constants Table**

EtherCAT IP Register	Offset Address	Value <sup>(1)</sup>
PDI 8/16Bit asynchronous Microcontroller configuration	0x0150	0x00
Sync/Latch PDI configuration	0x0151	0x66
Pulse Length of SyncSignals	0x0982/0x0983	0x000A

- (1) These values will not be changed or overwritten by EEPROM contents.

## 31.5 EtherCAT IP Registers

The EtherCAT IP (IP core) register details are included as part of Beckhoff documentation.

**Table 31-16. EtherCAT IP Register Documentation**

Document	Beckhoff ESC Type	Link
EtherCAT Slave Controller Hardware Data Sheet - Section II - Register Description (ethercat_esc_datasheet_sec2_registers)	EtherCAT IP Core	<a href="http://www.beckhoff.com">www.beckhoff.com</a>

### 31.5.1 ECAT Base Address Table (C28)

**Table 31-17. ECAT Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
EscssRegs	ESCSS_REGS	ESC_SS_BASE	0x0005_7E00	YES	-	-	-	YES
EscssConfigRegs	ESCSS_CONFIG_REGS	ESC_SS_CONFIG_BASE	0x0005_7F00	YES	-	-	-	YES

### 31.5.2 ESCSS\_REGS Registers

Table 31-18 lists the memory-mapped registers for the ESCSS\_REGS registers. All register offset addresses not listed in Table 31-18 should be considered as reserved locations and the register contents should not be modified.

**Table 31-18. ESCSS\_REGS Registers**

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	ESCSS_IPRENUM	IP Revision Number		<a href="#">Go</a>
4h	2h	ESCSS_INTR_RIS	EtherCATSS Interrupt Raw Status		<a href="#">Go</a>
8h	4h	ESCSS_INTR_MASK	EtherCATSS Interrupt Mask		<a href="#">Go</a>
Ch	6h	ESCSS_INTR_MIS	EtherCATSS Masked Interrupt Status		<a href="#">Go</a>
10h	8h	ESCSS_INTR_CLR	EtherCATSS Interrupt Clear		<a href="#">Go</a>
14h	Ah	ESCSS_INTR_SET	EtherCATSS Interrupt Set to emulate		<a href="#">Go</a>
18h	Ch	ESCSS_LATCH_SEL	Select for Latch0/1 inputs and LATCHIN input		<a href="#">Go</a>
1Ch	Eh	ESCSS_ACCESS_CTRL	PDI interface access control config.		<a href="#">Go</a>
20h	10h	ESCSS_GPIN_DAT	GPIN data capture for debug & override		<a href="#">Go</a>
24h	12h	ESCSS_GPIN_PIPE	GPIN pipeline select		<a href="#">Go</a>
28h	14h	ESCSS_GPIN_GRP_CAP_SEL	GPIN pipe group capture trigger		<a href="#">Go</a>
2Ch	16h	ESCSS_GPOUT_DAT	GPOUT data capture for debug & override		<a href="#">Go</a>
30h	18h	ESCSS_GPOUT_PIPE	GPOUT pipeline select		<a href="#">Go</a>
34h	1Ah	ESCSS_GPOUT_GRP_CAP_SEL	GPOUT pipe group capture trigger		<a href="#">Go</a>
38h	1Ch	ESCSS_MEM_TEST	Memory Test Control		<a href="#">Go</a>
3Ch	1Eh	ESCSS_RESET_DEST_CONFIG	ResetOut impact or destination config	LOCK	<a href="#">Go</a>
40h	20h	ESCSS_SYNC0_CONFIG	SYNC0 Configuration for various triggers	LOCK	<a href="#">Go</a>
44h	22h	ESCSS_SYNC1_CONFIG	SYNC1 Configuration for various triggers	LOCK	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 31-19](#) shows the codes that are used for access types in this section.

**Table 31-19. ESCSS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 31.5.2.1 ESCSS\_IPRENUM Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 0h]

ESSC\_IPRENUM is shown in [Figure 31-20](#) and described in [Table 31-20](#).

Return to the [Summary Table](#).

IP Revision number showing the Major & Minor IP versions 4 bit each

**Figure 31-21. ESCSS\_IPRENUM Register**

**Table 31-21. ESCSS\_INTR\_RIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	MASTER_RESET_RIS	R	0h	Indicates Raw Status of the EtherCAT Master Reset event , until cleared by ESCSS_INTR_CLR 0: EtherCAT Master Reset Event did not happen since last IP reset or last clear of this bit and ECAT Master reset programmed to be Interrupt to local host. 1: EtherCAT Master Reset Event has occurred. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Information of this event is lost if ECAT Master event is programmed to be reset IP. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_RIS	R	0h	Indicates Raw Status of the past event on PDI access timeout Error, until cleared by ESCSS_INTR_CLR 0: PDI Access Timeout Error Event did not happen since reset or last clear of this bit. 1: PDI Access Timeout Error Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask as long as Timeout is enabled, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn

**Table 31-21. ESCSS\_INTR\_RIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	DMA_DONE_RIS	R	0h	Indicates Raw Status of the past event on DMA Done, until cleared by ESCSS_INTR_CLR 0: DMA Done Event did not happen since reset or last clear of this bit. 1: DMA Done Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
2	IRQ_RIS	R	0h	Indicates Raw Status of the past event on EtherCATSS IRQ, until cleared by ESCSS_INTR_CLR 0: EtherCATSS IRQ Event did not happen since reset or last clear of this bit. 1: EtherCATSS IRQ Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
1	SYNC1_RIS	R	0h	Indicates Raw Status of the past event on SYNC1, until cleared by ESCSS_INTR_CLR 0: SYNC1 Event did not happen since reset or last clear of this bit. 1: SYNC1 Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
0	SYNC0_RIS	R	0h	Indicates Raw Status of the past event on SYNC0, until cleared by ESCSS_INTR_CLR 0: SYNC0 Event did not happen since reset or last clear of this bit. 1: SYNC0 Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn

### 31.5.2.3 ESCSS\_INTR\_MASK Register (Offset (x8) = 8h, Offset (x16) = 4h) [Reset = 0h]

ESSCSS\_INTR\_MASK is shown in [Figure 31-22](#) and described in [Table 31-22](#).

Return to the [Summary Table](#).

Allows to mask individual interrupt cause impacting the interrupt

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	MASTER_RESET_MASK	R/W	0h	Masks EtherCAT Master reset event against any effect on interrupts or other CPU Interrupts. 1: EtherCAT Master Reset affects the interrupt/DMA trigger. 0: EtherCAT Master Reset masked and does not affect Interrupt. Reset type: ECAT.IPRS <sub>n</sub>
4	TIMEOUT_ERR_MASK	R/W	0h	Masks PDI access timeout Error to have effect on interrupts or other CPU Interrupts. 1: PDI Access Timeout Errors affects the interrupt/DMA trigger. 0: PDI Access Timeout Errors masked and does not affect Interrupt. Reset type: ECAT.IPRS <sub>n</sub>
3	DMA_DONE_MASK	R/W	0h	Masks DMA Done status update to have effect on interrupts or other CPU Interrupts. 1: DMA Done affects the interrupt/DMA trigger. 0: DMA Done masked and does not affect Interrupt. Raw DMA Done status is updated regardless of this setting. Reset type: ECAT.IPRS <sub>n</sub>
2	IRQ_MASK	R/W	0h	Masks EtherCATSS IRQ to have effect on interrupts or other CPU/DMA triggers. 1: EtherCATSS IRQ affects the interrupt/DMA trigger. 0: EtherCATSS IRQ masked and does not affect Interrupt/DMA trigger. Raw EtherCATSS IRQ status is updated regardless of this setting. Reset type: ECAT.IPRS <sub>n</sub>
1	SYNC1_MASK	R/W	0h	Masks SYNC1 to have effect on interrupts or other CPU/DMA triggers as programmed in HOST_TRIG_MAP registers. 1: SYNC1 affects the interrupt/DMA trigger. 0: SYNC1 masked and does not affect Interrupt/DMA trigger. Raw SYNC1 status is updated regardless of this setting. Reset type: ECAT.IPRS <sub>n</sub>

**Table 31-22. ESCSS\_INTR\_MASK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SYNC0_MASK	R/W	0h	Masks SYNC0 to have effect on interrupts or other CPU/DMA triggers as programmed in HOST_TRIG_MAP registers. 1: SYNC0 affects the interrupt/DMA trigger. 0: SYNC0 masked and does not affect Interrupt/DMA trigger. Raw SYNC0 status is updated regardless of this setting. Reset type: ECAT.IPRSn

### 31.5.2.4 ESCSS\_INTR\_MIS Register (Offset (x8) = Ch, Offset (x16) = 6h) [Reset = 0h]

ESSCS\_INTR\_MIS is shown in [Figure 31-23](#) and described in [Table 31-23](#).

Return to the [Summary Table](#).

Registers the Masked Interrupt status of different interrupt triggers. This is AND of RIS & MASK of respective fields

**Table 31-23. ESCSS\_INTR\_MIS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	MASTER_RESET_MIS	R	0h	Indicates Masked Interrupt status of the past event on EtherCAT Master Reset, until RIS cleared by ESCSS_INTR_CLR or by Reset. 0: No pending EtherCAT Master Reset interrupt, if configured and unmasked. 1: EtherCAT Master Reset Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_MIS	R	0h	Indicates Masked Interrupt status of the past event on PDI Access Timeout Error, until RIS cleared by ESCSS_INTR_CLR 0: No pending PDI Access Timeout Error interrupt. 1: PDI Access Timeout Error Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
3	DMA_DONE_MIS	R	0h	Indicates Masked Interrupt status of the past event on DMA Done, until RIS is cleared by ESCSS_INTR_CLR 0: No pending DMA Done interrupt. 1: DMA Done Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn

**Table 31-23. ESCSS\_INTR\_MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	IRQ_MIS	R	0h	Indicates Masked Interrupt status of the past event on EtherCATSS IRQ, until RIS is cleared by ESCSS_INTR_CLR 0: No pending EtherCATSS IRQ interrupt. 1: EtherCATSS IRQ Event has triggered the interrupt and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
1	SYNC1_MIS	R	0h	Indicates Masked Interrupt status of the past event on SYNC0, until RIS is cleared by ESCSS_INTR_CLR 0: No pending SYNC1 interrupt. 1: SYNC1 Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
0	SYNC0_MIS	R	0h	Indicates Masked Interrupt status of the past event on SYNC0, until RIS is cleared by ESCSS_INTR_CLR 0: No pending SYNC0 interrupt. 1: SYNC0 Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn

### 31.5.2.5 ESCSS\_INTR\_CLR Register (Offset (x8) = 10h, Offset (x16) = 8h) [Reset = 0h]

ESSCS\_INTR\_CLR is shown in [Figure 31-24](#) and described in [Table 31-24](#).

Return to the [Summary Table](#).

### 31.5.3 ESCSS\_CONFIG\_REGS Registers

Table 31-38 lists the memory-mapped registers for the ESCSS\_CONFIG\_REGS registers. All register offset addresses not listed in Table 31-38 should be considered as reserved locations and the register contents should not be modified.

**Table 31-38. ESCSS\_CONFIG\_REGS Registers**

Offset (x8)	Offset (x16)	Acronym	Register Name	Write Protection	Section
0h	0h	ESCSS_CONFIG_LOCK	EtherCATSS Configuration Lock		<a href="#">Go</a>
4h	2h	ESCSS_MISC_IO_CONFIG	RESET_IN, EEPROM IO connections select	LOCK	<a href="#">Go</a>
8h	4h	ESCSS_PHY_IO_CONFIG	Control Register of ESCSS		<a href="#">Go</a>
Ch	6h	ESCSS_SYNC_IO_CONFIG	SYNC Signals IO configurations	LOCK	<a href="#">Go</a>
10h	8h	ESCSS_LATCH_IO_CONFIG	LATCH inputs IO pad select	LOCK	<a href="#">Go</a>
14h	Ah	ESCSS_GPIN_SEL	GPIN Select between IO PAD & tieoff	LOCK	<a href="#">Go</a>
18h	Ch	ESCSS_GPIN_IOPAD_SEL	GPIN IO pad Select	LOCK	<a href="#">Go</a>
1Ch	Eh	ESCSS_GPOUT_SEL	GPOUT IO pad connect select	LOCK	<a href="#">Go</a>
20h	10h	ESCSS_GPOUT_IOPAD_SEL	GPOUT IO pad select	LOCK	<a href="#">Go</a>
24h	12h	ESCSS_LED_CONFIG	Selection of LED o/p connect to IO pad	LOCK	<a href="#">Go</a>
28h	14h	ESCSS_MISC_CONFIG	Miscellaneous Configuration	LOCK	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 31-39 shows the codes that are used for access types in this section.

**Table 31-39. ESCSS\_CONFIG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 31.5.3.1 ESCSS\_CONFIG\_LOCK Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 0h]

ESSCS\_CONFIG\_LOCK is shown in [Figure 31-38](#) and described in [Table 31-40](#).

Return to the [Summary Table](#).

Lock bit for EtherCAT configuration registers

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-8	WRITE_KEY	R-0/W	0h	The key value should be 0xa5 for the writes to bit 0 take effect. Writes of other values will be ignored. Reset type: ECAT.XRSn
7-5	RESERVED	R	0h	Reserved
4	IO_CONFIG_ENABLE	R/W	0h	This bit enables the IO configurations allowing the EtherCAT ports to take effect. Till this bit is written EtherCAT ports are not connected to the IO pad. Enable takes effect when this bit is set to 1. Changing IO selections or IO configurations after this bit is set can have unpredictable IO behavior on the device IOs. Reset type: ECAT.XRSn
3-1	RESERVED	R	0h	Reserved
0	LOCK_ENABLE	R/WOnce	0h	This bit enables locking the contents of all the EtherCAT configuration registers. The lock takes effect when this bit is set to 1. This bit can be set only once after ecatXRSN and gets reset after the next ecatXRSN. Reset type: ECAT.XRSn

### 31.5.3.2 ESCSS\_MISC\_IO\_CONFIG Register (Offset (x8) = 4h, Offset (x16) = 2h) [Reset = 2h]

ESSC\_MISC\_IO\_CONFIG is shown in [Figure 31-39](#) and described in [Table 31-41](#).

Return to the [Summary Table](#).

2	RESERVED	R	0h	Reserved
1-0	LATCH0_IOPAD_SEL	R/W	0h	Selects the LATCH0 position for IO PAD selection. IOPADposition can be targeted to suit the device edge or other IO function tradeoffs. While 4 options possible in there could be less than 4 options supported in device, writing mux combination that is not supported defaults to IO pad sets of option"00". Refer to device specifications for IOPAD details for each mapping. Reset type: ECAT.XRSn

### 31.5.3.6 ESCSS\_GPIN\_SEL Register (Offset (x8) = 14h, Offset (x16) = Ah) [Reset = 0h]

ESSCS\_GPIN\_SEL is shown in [Figure 31-43](#) and described in [Table 31-45](#).

Return to the [Summary Table](#).

Register to configure each GPI input is connected to IO-pad or not.

**Figure 31-44. ESCSS\_GPIN\_SEL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPIN_SEL																															
R/W-0h																															

**Table 31-45. ESCSS\_GPIN\_SEL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	GPIN_SEL	R/W	0h	Allows bit-wise selection of the GPIN be connected from GPIO PAD. Once those are not driven by GPIO, will be driven from register writable from local Host. 0: No connection to GPIO PAD, but connects to ESCSS_GPIN_DAT. 1: Mux Select the GPIN from the dedicated IO PAD. This acts as Mux select for input from GPIO over tieoff. Reset type: ECAT.XRSn

### 31.5.3.7 ESCSS\_GPIN\_IOPAD\_SEL Register (Offset (x8) = 18h, Offset (x16) = Ch) [Reset = 0h]

ESSCS\_GPIN\_IOPAD\_SEL is shown in [Figure 31-44](#) and described in [Table 31-46](#).

Return to the [Summary Table](#).

Register to configure each GPI input is connected to IO-pad or not.

**Figure 31-45. ESCSS\_GPIN\_IOPAD\_SEL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPIN_IOPAD_SEL																															
R/W-0h																															

**Table 31-46. ESCSS\_GPIN\_IOPAD\_SEL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	GPIN_IOPAD_SEL	R/W	0h	This is to allow the EtherCAT GPIN input be taken from either of the two IO-pads allocated. The details of which IOs are allocated will be listed in device spec. In case only one IOPAD is allocated, the corresponding bit of the GPIN does not have the effect. Reset type: ECAT.XRSn

### 31.5.3.8 ESCSS\_GPOUT\_SEL Register (Offset (x8) = 1Ch, Offset (x16) = Eh) [Reset = 0h]

ESSCS\_GPOUT\_SEL is shown in [Figure 31-45](#) and described in [Table 31-47](#).

Return to the [Summary Table](#).

Register to configure each GPO to be connected to IO-pad or not.

**Figure 31-46. ESCSS\_GPOUT\_SEL Register**

<b>32.6 FSI Registers</b> .....	<b>3552</b>

## 32.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, they can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to ensure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, refer to the [Fast Serial Interface \(FSI\) Skew Compensation Application Report](#).

### 32.1.1 FSI Related Collateral

### 32.1.2 FSI Features

The FSI module includes the following features:

- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- FSI-SPI compatibility mode (limited features available)
- Tag match notifications

### 32.2 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features may require additional configuration of modules that are not within the scope of this chapter, the details can be found elsewhere in this TRM.

#### 32.2.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.

A. The signals connected to the trigger muxes are described in [Section 32.2.6](#).

**Figure 32-1. FSI Transmitter (FSITX) CPU Interface**

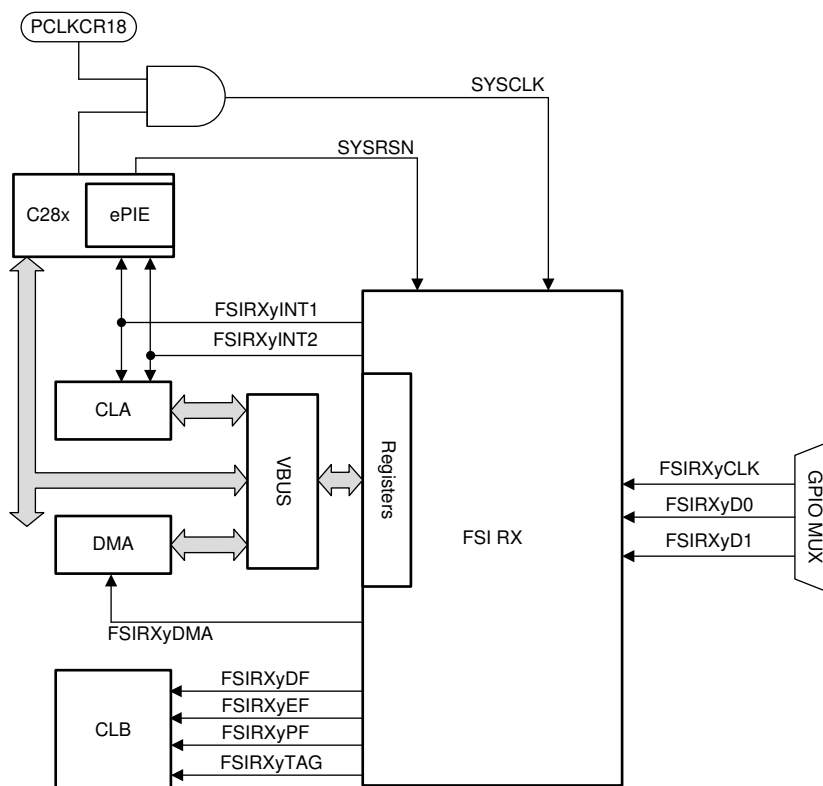

Figure 32-2. FSI Receiver (FSIRX) CPU Interface with CLB

### 32.2.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core will communicate directly to a single FSI receiver core. Similarly, an FSI receiver core will receive data from a single FSI transmitter core.

Each FSI core has three signals associated with it: one clock and two data signals. Data is always transmitted or received with the most significant bit of each frame field being first. If multi-lane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and their GPIOs repurposed for other application needs. [Table 32-1](#) and [Table 32-2](#) describe the various signals that can be selected by the PADCONFIG register to be brought out to device pins.

**CAUTION**  
The maximum RXCLK rate is SYSCLK/2 and should not exceed this limit.

Table 32-1. FSI Receiver Core Signals

Signal Name	Direction	Description	Inactive Level <sup>(1)</sup>
RXCLK	Input	This is the receive clock input signal for the FSI receive module. This must should be connected to TXCLK of the transmitting FSI module.	Logic High
RXD0	Input	This is the primary data input line for reception. This should be connected to the TXD0 of the transmitting FSI module.	Logic High
RXD1	Input	This is an additional data input line for reception. This signal should be connected to the TXD1 of the transmitting FSI module if multi-lane transmission is used.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively receiving data.

**Table 32-2. FSI Transmitter Core Signals**

Signal Name	Direction	Description	Inactive Level <sup>(1)</sup>
TXCLK	Output	<p>This is the transmit clock. It is driven by the FSI transmit module.</p> <p>During a transmission, four clock edges will be transmitted before the start of frame phase (preamble) and four clock edges will follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock.</p> <p>In FSI-SPI compatibility mode, the preamble and the post frame clock edges will not be transmitted. Data is transmitted only on one edge of the clock. Data will transmit on rising edge and received on falling edge of the clock.</p>	Logic High
TXD0	Output	<p>This is the primary data output line for transmission. This signal is driven by the FSI transmit module.</p> <p>When the FSI is configured for multi-lane transmission, TXD0 will contain all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame will be transmitted in full.</p>	Logic High
TXD1	Output	<p>This is an additional data output line for transmission if the FSI is configured for multi-lane transmission. This signal is driven by the FSI transmit module.</p> <p>During transmission, the data bits are split between TXD0 and TXD1. TXD1 will contain all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line will be identical to TXD0.</p>	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

### 32.2.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See the *General Purpose Input-Output (GPIO)* chapter for more details on the GPIO mux and settings.

### 32.2.3 FSI Interrupts

Each FSI module contains multiple interrupt sources which can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT\_STS, EVT\_FRC, and the EVT\_CLR registers, respectively.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX\_INT\_CTRL register. The receiver events are assigned an interrupt vector using RX\_INT1\_CTRL and RX\_INT2\_CTRL registers. If an interrupt is not required, ensure the bit is not set in the respective INT\_CTRL register.

#### 32.2.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME\_DONE):** This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF\_UNDERRUN):** This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet been written to by the CLA, CPU, or DMA.
- **Buffer Overrun (BUF\_OVERRUN):** The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun may occur if a piece of data is overwritten before it has been transmitted.
- **Ping Frame Triggered (PING\_TRIGGERED):** The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit will be set when the ping counter has timed out or an external ping trigger event has occurred.

### 32.2.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events:

- **Ping Watchdog Timeout (PING\_WD\_TO):** This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX\_PING\_WD\_REF register.
- **Frame Watchdog Timeout (FRAME\_WD\_TO):** This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX\_FRAME\_WD\_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter will start counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog will time out and this event will be generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **CRC Error (CRC\_ERR):** This error indicates that a CRC error has occurred. A CRC error will be generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE\_ERR):** This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **End-of-Frame Error (EOF\_ERR):** This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **Receive Buffer Overrun (BUF\_OVERRUN):** This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF\_UNDERRUN):** This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads the buffer while it is empty.
- **Frame Done (FRAME\_DONE):** This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR\_FRAME):** This event indicates that an error frame has been received.
- **Ping Frame Received (PING\_FRAME):** This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME\_OVERRUN):** This event indicates that a new frame has been received while the FRAME\_DONE flag was still set.
- **Data Frame Received (DATA\_FRAME):** This event indicates that a data frame has been received.
- **Ping Tag Matched (PING\_TAG\_MATCH):** This event indicates that a ping frame with a matching tag has been received.
- **Data Tag Matched (DATA\_TAG\_MATCH):** This event indicates that a data frame with a matching tag has been received.
- **Error Tag Matched (ERROR\_TAG\_MATCH):** This event indicates that an error frame with a matching tag has been received.

### 32.2.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application should select the interrupt vector for each desired event using the TX\_INT\_CTRL register for the transmitter, and RX\_INT1\_CTRL and RX\_INT2\_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

---

#### Note

If an event is registered for both interrupt vectors, both interrupts will fire. There are no hardware checks for overlapping interrupt vector assignments.

---

### 32.2.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user should clear the event flag using the EVT\_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt will be generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This may cause the application to miss events that may be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine will be similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX\_EVT\_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events that require action.
- Perform the necessary actions for each of the events seen in the snapshot.
- Write to the receive event and error clear register (RX\_EVT\_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag may still be set at the end of the ISR. As soon as the ISR completes, a new interrupt will be generated and this flag will still be set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR may cause race conditions which will cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both are handled within the same interrupt line, the software may only respond to one of the events if they both occur close in time.

### 32.2.4 CLA Task Triggering

In addition to generating interrupt vectors to the PIE, both interrupt lines for each module TX\_INT1, TX\_INT2, RX\_INT1, and RX\_INT2 can be assigned to trigger CLA tasks. Refer to the Configuration options table for the list of all sources capable of CLA task triggering. The configuration and use of CLA tasks are described in [Section 8.2.4](#). The CLA has access to the entire FSI register map. This allows the CLA to manage the FSI independently from the CPU, freeing it up for other tasks.

### 32.2.5 DMA Interface

Both the transmitter and receiver are capable of using the DMA for automatic data transfers. The DMA trigger is independent from the interrupt signals. DMA events are only triggered on the completion of a data frame.

The transmitter DMA trigger is enabled by setting TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. The transmitter must also set TX\_OPER\_CTRL\_LO.START\_MODE to 0x2 to allow either a write to the TX\_FRAME\_CTRL.START bit or to the TX\_FRAME\_TAG\_UDATA register to start the transmission.

The receiver DMA trigger is enabled by setting RX\_DMA\_CTRL.DMA\_EVT\_EN to 1.

Refer to [Section 32.3.2](#) and [Section 32.3.3](#) for more DMA information specific to each FSI Module.

### 32.2.6 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and/or generic frames. These muxes are independently configured for each type of frame. The application may select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX\_PING\_CTRL.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_PING\_CTRL.EXT\_TRIG\_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX\_OPER\_CTRL\_HI.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x1 in order for a frame to be transmitted by an external trigger.

---

#### Note

Triggers generated by the CLB are asynchronous and must be at least 3 SYSCLKs wide.

---

## 32.3 FSI Functional Description

### 32.3.1 FSI Functional Description

The Fast Serial Interface Transmitter and Receiver modules (FSI\_TX/FSI\_RX) are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

### 32.3.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU, CLA, and the DMA.

The transmitter has the following features:

- Automated ping frame generation
- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data
- DMA support
- CLA task triggering

Figure 32-3 shows the high-level block diagram of the FSI transmitter. Figure 32-4 shows the block diagram of the transmitter core submodule.

The following sections describe the various aspects of the FSI transmitter in detail.

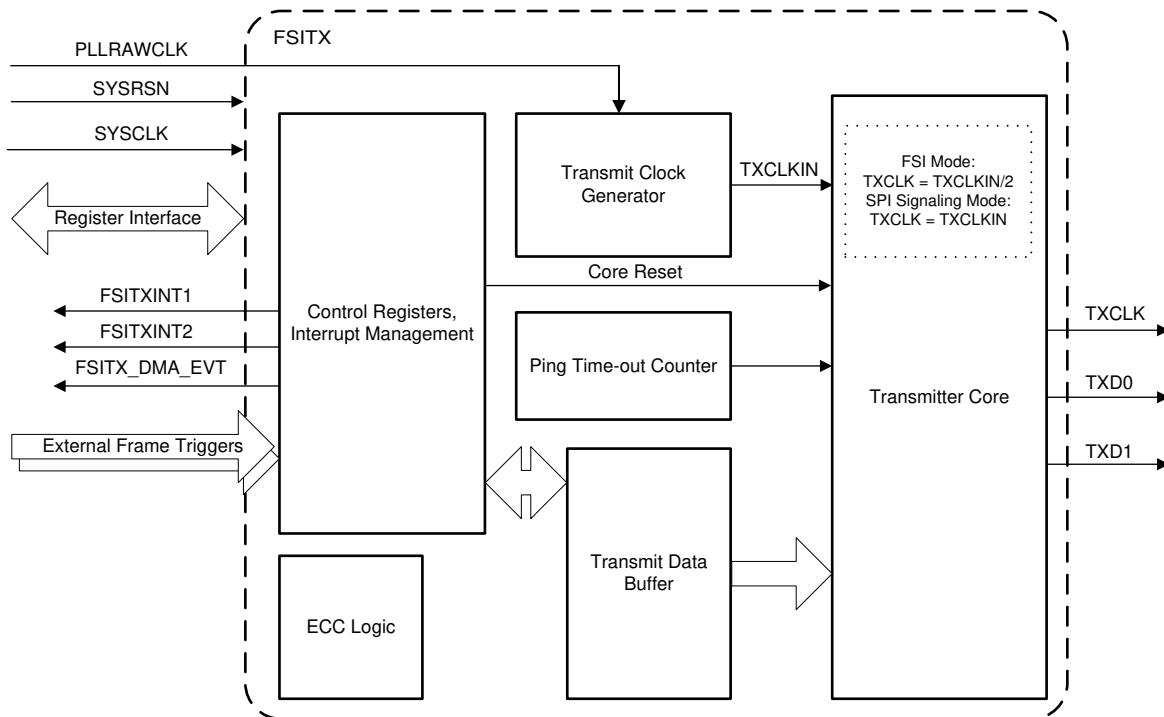

Figure 32-3. FSI Transmitter Block Diagram

**Figure 32-4. FSI Transmitter Core Block Diagram**

### 32.3.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module should execute the following initialization sequence in order to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX\_CLK\_CTRL.CLK\_RST to 1 and subsequently clearing it.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX\_OPER\_CTRL\_LO.SEL\_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX\_CLK\_CTRL.PRESCALE\_VAL.
4. Enable the transmitter clock divider by setting TX\_CLK\_CTRL.CLK\_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX\_MASTER\_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX\_MASTER\_CTRL.

After initialization and configuration, the transmitter module should synchronize with receiver module before transmitting. The synchronization sequence is described in [Section 32.4.1](#).

#### **CAUTION**

Do not change TX\_CLK\_CTRL.PRESCALE\_VAL while the clock is enabled (TX\_CLK\_CTRL.CLK\_EN = 1). Doing so may cause undefined behavior.

### 32.3.2.2 FSI\_TX Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX\_CLK\_CTRL.PRESCALE\_VAL) then setting the clock divider enable bit (TX\_CLK\_CTRL.CLK\_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0x0 or 0x1) through 255 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

#### CAUTION

TXCLK should never be configured to be faster than SYSCLK/2.

### 32.3.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps may be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
  - Set the user data
  - Write to the data buffer
  - Set the word length if the frame is a software defined frame length
4. Set the start condition

---

#### Note

Transmit Frame Start Restriction:

A new frame transmission can be initiated by one of the methods selected in the TX\_OPER\_CTRL\_LO.START\_MODE bits. If there is already a PING frame transmission taking place, due to a hardware initiated PING timer, the new frame transmission will begin as soon as the on-going PING transmission is completed.

Once a START of frame has been initiated, the next START of frame will be recognized when the first frame has started transmitting the End-of-Frame (EOF) field. If a new START trigger arrives before the current transmission has reached the EOF field, the trigger will be lost without a notification.

---

#### Note

There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior will be as follows:

- The transmitted frame structure will be exactly like an NWORD data frame. The size of the data frame will be determined by the value in the TX\_FRAME\_CTRL.N\_WORDS register.
- The frame type field of the transmitted data frame will be transmitted as programmed. If this is received by an FSI receiver, it will generate a Type error.

This mechanism can be used to force a Type error in a received frame for testing purposes.

---

The following sections describe the specific configuration for each frame type and start condition.

### 32.3.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps should be executed. Steps 1-6 may be executed in any order before setting TX\_FRAME\_CTRL.START. Some fields may not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and will be re-transmitted in the subsequent frame unless they are modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX\_FRAME\_CTRL.FRAME\_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX\_FRAME\_CTRL.N\_WORDS to 1 less than the number of words to be transmitted if TX\_FRAME\_CTRL.FRAME\_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words will be transmitted, N = 16, set TX\_FRAME\_CTRL.N\_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware will calculate the CRC to be transmitted. If TX\_OPER\_CTRL\_LO.SW\_CRC is 1, the application may calculate a custom CRC value and then set TX\_USER\_CRC to the result.
5. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired tag.
6. Set TX\_FRAME\_TAG\_UDATA.USER\_DATA to the desired user data.
7. Set TX\_FRAME\_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

### 32.3.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See [Section 32.2.6](#) for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in [Section 32.3.2.3.1](#). The only difference is that in Step 7, the start condition will be automatically set when the external trigger condition is met rather than by software.

It is important to note that by externally triggering frames, the frame information to be sent will be pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX will take the data as is, and the application software should ensure that this data has been updated as necessary.

Using TX\_EVT\_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

### 32.3.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

#### 32.3.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX\_PING\_CTRL.CNT\_RST.
2. Set the desired ping tag to TX\_PING\_TAG.TAG.
3. Set the ping timer reference value to TX\_PING\_TO\_REF.TO\_REF.
4. Enable the ping timer by writing 1 to TX\_PING\_CTRL.TIMER\_EN.

The ping timer is a free-running counter which will count up from 0. The current value of the ping timer counter is found in TX\_PING\_TO\_CNT. When the current value of TX\_PING\_TO\_CNT matches the reference value TX\_PING\_TO\_REF.TO\_REF, TX\_EVT\_STS.PING\_TRIGGERED will be set. TX\_PING\_TO\_CNT will reset to 0 and resume counting until the next match has occurred or the ping timer is halted by software (TX\_PING\_CTRL.TIMER\_EN is set to 0).

### 32.3.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX\_FRAME\_CTRL.FRAME\_TYPE to 0000'b to denote that the frame being sent will be a Ping Frame.
2. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired value.
3. Write 1 to TX\_FRAME\_CTRL.START. This will start the transmission.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

### 32.3.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers may be selected. See [Section 32.2.6](#) for the list of input sources.

#### CAUTION

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX\_PING\_CTRL.EXT\_TRIG\_EN is set to 1, it will take precedence and the ping timer will be ignored.

### 32.3.2.3.4 Transmitting Frames with DMA

The FSI transmitter can send data which is continuously fed with the DMA. A DMA trigger will be generated every time a data frame transmission is completed. This is concurrent with the FRAME\_DONE signal that sets the TX\_EVT\_STS.FRAME\_DONE flag.

In order to transmit continuous data with the DMA, some configurations need to be made on the transmitter:

First, set TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This will allow the DMA trigger to propagate to the DMA module. Next, TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX\_FRAME\_CTRL.START or TX\_FRAME\_TAG\_UDATA..

The DMA must also be configured properly for the FSI to send the data. One possible solution of using the DMA to continuously feed the transmit buffer is shown below:

- Set up two DMA channels to be triggered by the same FSI transmitter and DMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps the after 16 words are copied.

#### Note

Because the frame tag and user data must be written in to in order to initiate the transmission of the frame, use two consecutive DMA channels. This ensures that the DMA channels are always executed in sequence. The DMA channel servicing the data buffer should be the lower numbered channel and the tag/user data channel should be the next. For example, configure DMA channel 3 to service the data buffer, and configure DMA channel 4 to service the tag and user data.

### 32.3.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer from which it pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. This mode of operation is the only way in which the overrun, underrun, and pointer status are meaningful. If data is being sourced by the DMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, it means that the buffer went out of sync. This would not only affect the current transfer, but all future transfers also could not be guaranteed due to the ring buffer. Under such conditions, the underrun would need a soft reset to cleanly recover. Alternately, the software could manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and will guarantee a full reset of the control registers.

Due to the flexibility of the transmit buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields may be ignored without adversely affecting the transmitter capability. Additionally, the CURR\_WORD\_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX\_BUF\_PTR\_LOAD. This will force the transmitter to start picking the data from the indicated location in the buffer.

### 32.3.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX\_OPER\_CTRL\_LO.SW\_CRC appropriately.

If hardware CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial  $0x7 (x^8 + x^2 + x + 1)$ . The transmitter module will automatically compute the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC Submodule, refer to [Section 32.3.7](#).

If software CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 1), the CRC must be computed by software and placed in the TX\_USER\_CRC register. The next frame to be transmitted will use the value placed in the TX\_USER\_CRC register in place of the CRC value generated by the hardware.

As the TX\_USER\_CRC register is software-programmable, the application may use this field as an extra data field for application specific purposes. If TX\_USER\_CRC is used in this manner, the CRC detection on the receiver will not be valid and should be ignored.

### 32.3.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt may or may not require a soft reset in order to resume proper operation. This determination is up to the application software. Refer to [Section 32.3.2.4](#) for more information on the transmit buffer.

### 32.3.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX\_MASTER\_CTRL.CORE\_RST.

A module reset will cause the registers to be reset to their default state.

### 32.3.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after they pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU, CLA, and the DMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- DMA support
- CLA task triggering
- FSI-SPI compatibility mode

Figure 32-5 provides a high-level overview of the internal modules present in the FSI receiver. Figure 32-6 shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

The following sections describe the various aspects of the FSI receiver module.

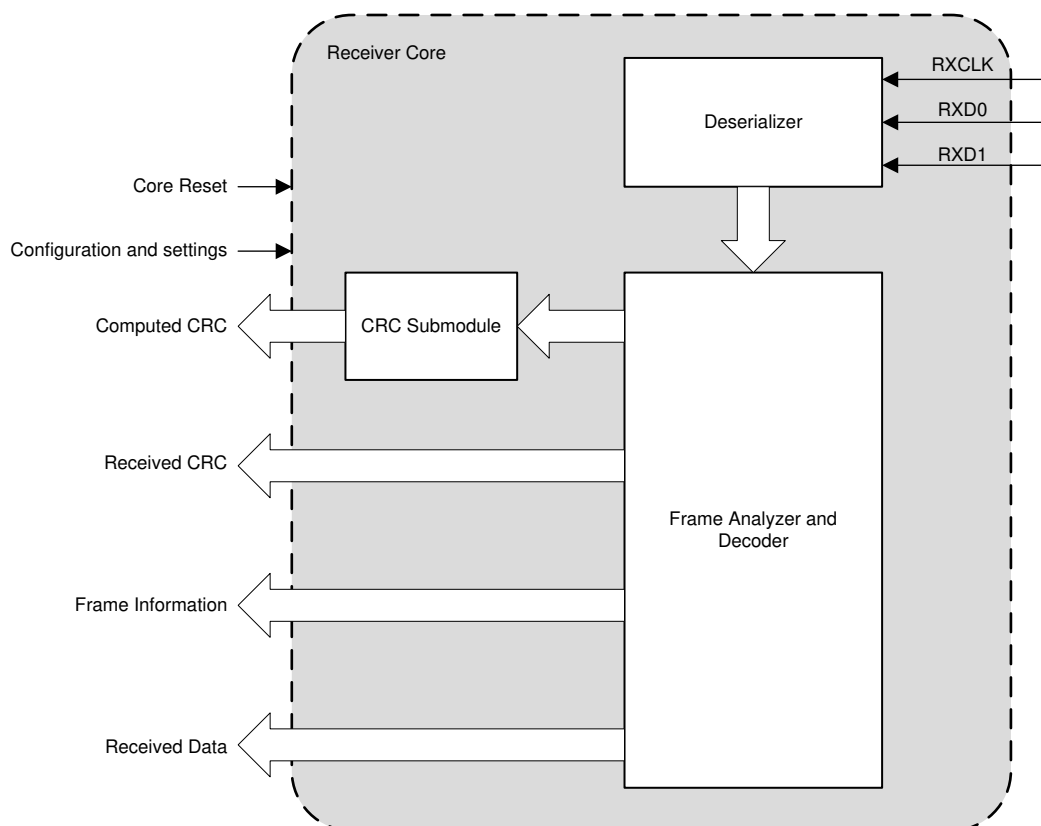

Figure 32-5. FSI Receiver Block Diagram

**Figure 32-6. FSI Receiver Core Block Diagram**

### 32.3.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module should assert and release the receiver core reset bit (RX\_MASTER\_CTRL.CORE\_RST) prior to any other initialization. Once the receiver module is initialized, the following steps may be executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See [Section 32.3.3.4](#) for configuration details.
3. If required, configure the frame watchdog to ensure that each frame is received within a predetermined window. See [Section 32.3.3.5](#) for configuration details.
4. Initialize the receive buffer pointer by writing to the RX\_BUF\_PTR\_LOAD register. Received data will be placed into the buffer starting with the address loaded in this register.
5. Ensure all errors and flags have been cleared from the RX\_EVT\_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX\_EVT\_STS register for various conditions. For example, when the RX\_EVT\_STS.FRAME\_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application should configure the various features such as the ping and frame watchdogs, DMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in [Section 32.4.1](#).

### 32.3.3.2 FSI\_RX Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

#### CAUTION

RXCLK should never be faster than SYSCLK.

### 32.3.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. It is important to note that there is no equivalent to a chip select signal to gate incoming data. Every valid clock edge will latch data into the receiver.

The header information of the received frame will be placed in their respective register fields.

- RX\_FRAME\_INFO.FRAME\_TYPE will contain the received frame type.
- RX\_FRAME\_TAG\_UDATA.FRAME\_TAG will contain the received frame tag.
- RX\_FRAME\_TAG\_UDATA.USER\_DATA will contain the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag will be set in the RX\_EVT\_STS register.

#### Note

If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The following errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

#### 32.3.3.3.1 Receiving Frames with DMA

The FSI receiver can continuously receive data and move it from the receiver buffer with the DMA. A DMA trigger will be generated every time a data frame has been received. This is concurrent with the FRAME\_DONE signal that sets the RX\_EVT\_STS.FRAME\_DONE flag. In order to receive continuous data with the DMA, some configurations need to be made on the receiver.

First, set RX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This will allow the DMA trigger to propagate to the DMA module. The receiver is now able to trigger a DMA event upon the reception of a data frame.

The DMA must also be configured properly for the FSI to receive the data. One possible solution for using the receiver to continuously feed the DMA is show below:

- Set up two DMA channels to be triggered by the FSI Receiver DMA Trigger.
- Configure one DMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next DMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the DMA channel which is handling the data buffer, execute before the DMA channel handling the received tag and user data.

#### 32.3.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event will be triggered which can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter which is reset and restarted upon the successful reception of a ping frame. The watchdog counter will be incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting `RX_PING_WD_CTRL.PING_WD_RST` to 1 and then subsequently clearing it to 0.
2. Set `RX_OPER_CTRL.PING_WD_RST_MODE` to the desired watchdog reset event, either 0 for ping frames only, or 1 for any frame.
3. Set `RX_PING_WD_REF` to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting `RX_PING_WD_CTRL.PING_EN` to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the `RX_PING_WD_CNT` value reaches the value programmed in `RX_PING_WD_REF`, the `RX_EVT_STS.PING_WD_TO` flag will be set. If configured, an interrupt can be generated on this event.

#### 32.3.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration that it takes for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog will be triggered which can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting `RX_FRAME_WD_CTRL.FRAME_WD_CNT_RST` to 1 and then subsequently clearing it to 0.
2. Set `RX_FRAME_WD_REF.FRAME_WD_REF` to the maximum number of SYSCLK cycles expected to be in the longest frame that may be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting `RX_FRAME_WD_CTRL.FRAME_WD_CNT_EN` to 1.

The frame watchdog is now enabled and can detect a failed frame.

If the `RX_FRAME_WD_CNT` reaches the value programmed in `RX_FRAME_WD_REF`, the `RX_EVT_STS.FRAME_WD_TO` flag will be set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

### 32.3.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX\_DLY\_LINE\_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values should only be adjusted while the FSIRX is held in soft reset, ensuring that there are no active transmissions during this process. Figure 32-7 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits will behave similarly.

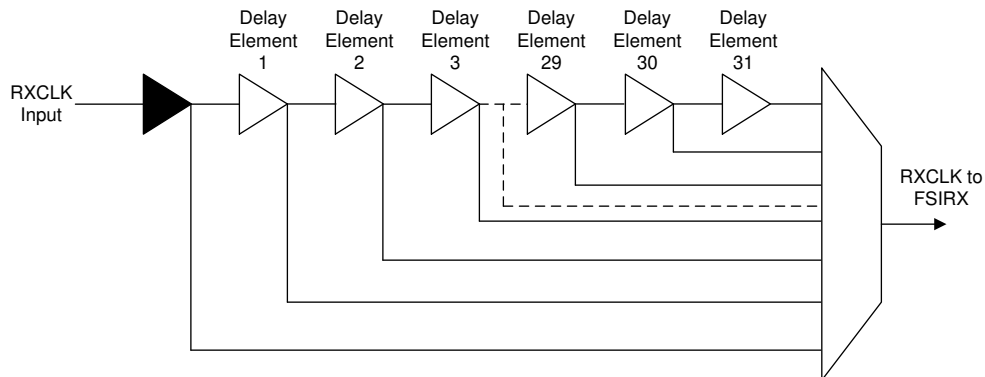

Figure 32-7. Delay Line Control Circuit

For more information on skew compensation, refer to the [Fast Serial Interface \(FSI\) Skew Compensation Application Report](#).

### 32.3.3.7 Buffer Management

The FSI receiver has a 16-word buffer into which the data is copied to when it has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no guaranteed receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer guarantee which values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields may be ignored without adversely affecting the receiver capability. Additionally, the CURR\_WORD\_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX\_BUF\_PTR\_LOAD. This will force the receiver to start storing the received data starting at the indicated location in the buffer.

### 32.3.3.8 CRC Submodule

The receive module will automatically calculate the CRC on the incoming data. The received CRC value is placed into `RX_CRC_INFO.RX_CRC`. The CRC value calculated by hardware on the received data is placed into `RX_CRC_INFO.CALC_CRC`. These values are compared by hardware and will set `RX_EVT_STS.CRC_ERROR` if there is a mismatch. The receiver can generate an interrupt based on `RX_EVT_STS.CRC_ERROR` if enabled.

Since the CRC is only used in data frames, the values found in `RX_CRC_INFO.RX_CRC` and `RX_CRC_INFO.CALC_CRC` are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to [Section 32.3.7](#).

If the transmitting module is sending a software-defined CRC value (`FSITX.TX_OPER_CTRL_LO.SW_CRC = 1`) the receiver module will trigger a CRC Error event if the received value does not match the hardware-calculated value. As this is an application level decision, the FSIRX can safely disregard the CRC error event. Application software will need to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field may have also been used as an application-specific value, not a CRC, the application can use the `RX_CRC_INFO.RX_CRC` as required. All CRC errors and flags can be ignored in this situation.

### 32.3.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (`RX_FRAME_TAG_UDATA`) register and receiver ping tag (`RX_PING_TAG`) register) have the Least Significant Bit is set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions which can be called depending on the tag value. A function pointer needs a 32-bit storage space and hence each successive pointer will be offset by 2. If the first pointer is at address  $x$ , then the second pointer will be at address  $x+2$ , the third at address  $x+4$  and so on. By keeping the LSB 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

### 32.3.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver will receive data on every clock edge. While there are specific patterns which determine the a start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset in order to ensure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver may be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (`RX_VIS_1.RX_CORE_STS`) can be monitored to determine if it has entered into an error state requiring a soft reset in order to resume communication. Incorrect frame type and end of frame errors will always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout will always require a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. `RX_CORE_STS` can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also will not cause `RX_CORE_STS` to be set. Similar to the frame watchdog, a corrupt receiver may not be the reason for the ping frame to have timed out. The transmitter may have gone offline and never sent a ping frame. Alternately, during idle time, a noise event may have occurred, thereby putting the receiver into a corrupt state. As the receiver will be able to detect this during the ping frame watchdog timeout interrupt handler, this type of event will not be lost and the application can act appropriately.

As the receiver is clocked by `RXCLK`, not `SYSCLK`, a noisy clock or data line may cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Ensure that the clock and data

lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the data manual for this device. Failure to do so may cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application should check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun may warrant a soft reset in order to resynchronize with the local application software. Refer to [Section 32.3.3.8](#) for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device should stop transmitting and begin a new synchronization phase.

### 32.3.3.11 FSI\_RX Reset

The receiver module and its registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX\_MASTER\_CTRL.CORE\_RST.

A module reset will cause the registers to be reset to their default state. After a module reset, the receiver module must be re-initialized, and the data link re-established.

### 32.3.4 Frame Format

The FSI module transmits and receives information in frames. Each frame will contain multiple phases where different information can be found. The number of phases as well as the total length of the frame will vary depending on the frame type being transmitted. Frames may be as short as 16 bits long for a ping or error frame or 288 bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown below. Each phase of the frame (such as start-of-frame, frame type, and so on) will be transmitted with the most significant bit first. [Table 32-4](#) describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

**Table 32-4. Basic Frame Structure**

Idle State	Preamble	Start of Frame	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	End of Frame	Postamble	Idle State
	1111	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	1111	

The FSI also supports a FSI-SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to [Section 32.3.11](#) for more information on how to configure and use the FSI-SPI compatibility mode.

---

#### Note

One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI.

---

### 32.3.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail.

- **Idle State:** During the idle state, the clock and data lines will be driven high, the inactive state.
- **Preamble:** The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare it for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame:** The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type:** The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in [Section 32.3.4.2](#). The transmitter must set the TX\_FRAME\_CTRL.FRAME\_TYPE field before transmitting a frame. The received frame type is stored in the RX\_FRAME\_INFO.FRAME\_TYPE.
- **User Data:** The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX\_FRAME\_TAG\_UDATA.USER\_DATA. The received user data is stored in RX\_FRAME\_TAG\_UDATA.USER\_DATA.
- **Data:** The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and will be placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames is found in [Section 32.3.4.2.3](#).
- **CRC Byte:** The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX\_OPER\_CTRL\_LO.SW\_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag:** The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX\_FRAME\_TAG\_UDATA.FRAME\_TAG bits for data frames. Ping frames use the tag defined in TX\_PING\_TAG.TAG. The receiver can access the received frame tag in RX\_FRAME\_TAG\_UDATA.FRAME\_TAG.
- **End of Frame:** The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble:** The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines will be driven high, their inactive state. This phase is not present in FSI-SPI compatibility mode.

### 32.3.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

[Table 32-5](#) provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

**Table 32-5. Frame Types and Their 4-bit Codes**

Frame Type	4-bit Frame Code	Description
PING	0000	This is the ping frame that can be sent either by software or automatically by hardware.
ERROR	1111	This should be used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software is at liberty to use this for any purpose.
DATA_1_WORD	0100	1 word data packet (16 bits of data)
DATA_2_WORD	0101	2 word data packet (32 bits of data)
DATA_4_WORD	0110	4 word data packet (64 bits of data)
DATA_6_WORD	0111	6 word data packet (96 bits of data)
DATA_N_WORD	0011	N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules should have the same value programmed.
Reserved	0001, 0010, and 1000-1110	Reserved

#### 32.3.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. [Table 32-6](#) shows the structure of the ping frames.

**Table 32-6. Ping Frame**

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0000	xxxx	0110	1111	

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to ensure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See [Section 32.3.2.3.3](#) for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between it and the transmitter has been broken. See [Section 32.3.3.4](#) for information on how the receiver handles ping frames.

### 32.3.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. [Table 32-7](#) shows the structure of an error frame.

**Table 32-7. Error Frame**

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	1111	xxxx	0110	1111	

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX\_FRAME\_TAG\_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX\_FRAME\_TAG\_UDATA register and act on up to 16 different conditions.

### 32.3.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. [Table 32-8](#) shows the general structure of data frames.

**Table 32-8. Data Frame**

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0xxx	xxxx xxxx	1-16 words	xxxx xxxx	xxxx	0110	1111	

The frame type field will reflect the 4-bit code of the frame type. A list of frame types can be seen in [Table 32-5](#). The number of the data words transmitted will be determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N\_WORDS field of the transmitter’s TX\_FRAME\_CTRL register and receiver’s RX\_OPER\_CTRL register.

### 32.3.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits will be split between the data lines while the start of frame, frame type, frame tag, and end of frame fields will be identical and complete on each line. The user data, data, and CRC fields will be split between the data lines. Starting with the most significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the following example, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12...d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

**Table 32-9. Multi-Lane Frame Format**

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
TXD0	1111	1001	0011	u <sup>7</sup> u <sup>5</sup> u <sup>3</sup> u <sup>1</sup>	d <sup>15</sup> d <sup>13</sup> ...d <sup>1</sup>	c <sup>7</sup> c <sup>5</sup> c <sup>3</sup> c <sup>1</sup>	xxxx	0110	1111	
TXD1	1111	1001	0011	u <sup>6</sup> u <sup>4</sup> u <sup>2</sup> u <sup>0</sup>	d <sup>14</sup> d <sup>12</sup> ...d <sup>0</sup>	c <sup>6</sup> c <sup>4</sup> c <sup>2</sup> c <sup>0</sup>	xxxx	0110	1111	

### 32.3.5 Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before it can receive and decode frames. The receiver core has an asynchronous reset mechanism which will allow the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset will be released synchronous to the receive clock (RXCLK). Thus, the receiver will require five full clock pulses to be able to come out of reset. Sending the flush pattern will ensure that these clock edges are received and any subsequent frames sent to the receiver will be correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI will have the same effect as a flush sequence.

Figure 32-8 shows a sample plot of the flush sequence.

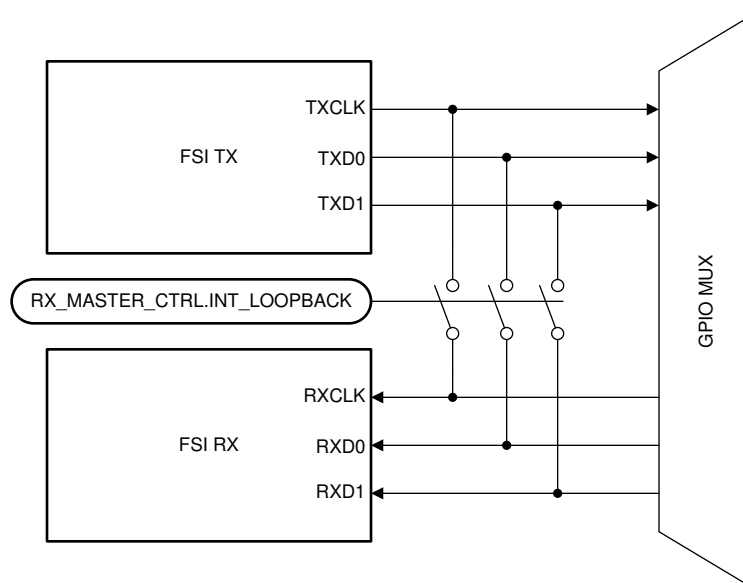

**Figure 32-8. Flush Sequence Signals**

### 32.3.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting `RX_MASTER_CTRL.INT_LOOPBACK` to 1. Internal loopback routes the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter.

Figure 32-9 shows the signal connections with internal loopback.

In this device, there are two FSI transmitter cores (A and B), and eight receiver cores (A, B, C, D, E, F, G, H). When using loopback mode, FSITXA can be used in the loopback mode with FSIRXA, FSIRXB, FSIRXC and FSIRXD. At the same time, FSITXB can be used in loopback mode with FSIRXE, FSIRXF, FSIRXG, and FSIRXH.

**Figure 32-9. FSI with Internal Loopback**

### 32.3.7 CRC Generation

The FSI uses CRC-8 with the polynomial `0x07` for the internal hardware CRC generation. This polynomial is also represented as  $x^8+x^2+x+1$ .

For example, for a 2-word data packet the following calculation would occur:

Data-1 = `0x4433`

Data-0 = `0x2211`

User Data = `0xAA`

The CRC would be computed with the bytes being taken in the following order (first to last):

`0xAA` – Byte 0, User Data

`0x11` – Byte 1, Data-0, Least-significant byte

`0x22` – Byte 2, Data-0, Most-significant byte

`0x33` – Byte 3, Data-1, Least-significant byte

`0x44` – Byte 4, Data-1, Most-significant byte

### 32.3.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX\_OPER\_CTRL\_HI.ECC\_SEL to 1.
2. Write the data to the TX\_ECC\_DATA register as well as the transmit buffer.
3. Read TX\_ECC\_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX\_ECC\_VAL to TX\_FRAME\_TAG\_UDATA.USER\_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX\_ECC\_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX\_FRAME\_TAG\_UDATA.USER\_DATA to the RX\_ECC\_VAL register.
3. Read the RX\_ECC\_LOG register. This contains the result of the ECC computation using the RX\_ECC\_DATA and RX\_ECC\_VAL registers.
  - a. If no ECC errors were detected, RX\_ECC\_LOG will be 0. The correct data will be available in RX\_ECC\_SEC\_DATA.
  - b. If a single bit error was detected, RX\_ECC\_LOG.SBE will be 1. The autocorrected data will be available in RX\_ECC\_SEC\_DATA.
  - c. If multiple bit errors occurred, RX\_ECC\_LOG.MBE will be set to 1. The data in RX\_ECC\_SEC\_DATA is invalid and should not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame and allocate one of the data words to be the ECC value.

### 32.3.9 Tag Matching

The FSI receiver core has the capability of generating an interrupt when the received data or ping frame's tag matches the reference tag in RX\_FRAME\_TAG\_CMP or RX\_PING\_TAG\_CMP, respectively.

Each tag compare register allows the user to not only select a reference tag (TAG\_REF) but also set up a mask (TAG\_MASK) to ignore specified bits in the reference tag. In order for tag matching to be enabled, the CMP\_EN bit must be set. When the tag compare is enabled and a successful match occurs, the PING\_TAG\_MATCH, the DATA\_TAG\_MATCH or the ERROR\_TAG\_MATCH in RX\_EVT\_ERR\_STATUS will be set. The corresponding match register status can be cleared by writing to RX\_EVT\_ERR\_CLEAR. Also, if it is required to set the match register status in software, the user must do so by writing to the RX\_EVT\_ERR\_SET register.

The tag matching scheme is NOT a filtering scheme. Tag matching is only a notification scheme to alert the user when a specific tag is detected in a data or ping frame. Both RX\_INTR\_EVT\_CTRL\_1 and RX\_INTR\_EVT\_CTRL\_2 interrupts can be set up to generate an interrupt when a tag match event occurs.

Another feature used when tag matching is enabled, is the broadcast feature. The broadcast feature can be enabled by setting the BRDCST\_EN in RX\_FRAME\_TAG\_CMP or RX\_PING\_TAG\_CMP. When broadcast mode is enabled, the third bit of the tag will be treated as a broadcast bit. If the received tag has its third bit set, then it will be treated as a match regardless of the other tag bit comparisons. It is important to note that, a match caused by TAG\_REF and TAG\_MASK will also be considered a match.

It is important to reiterate that the tag matching scheme is not a filtering scheme. For example, if tag matching is enabled and a frame is received with a non matching tag, the frame is still saved in the buffer and the corresponding event status bits (FRAME\_DONE, DATA\_FRAME\_RCVD) will be set.

Tag matching should be used in TDM configuration described in [Section 32.3.10](#). However it can be used in single slave configurations as needed.

### 32.3.10 TDM Configurations

The FSI module in this device supports multi-node TDM configurations, whereas a single main device can control multiple remote node devices.

In order to use the FSI module in the multi-node TDM configuration described, the remote node device must utilize tag matching, and the CLB module.

This multi-node TDM configuration is supported in the FSI module through time-division multiplexing. When TDM is enabled, each remote node device must also have tag matching enabled. [Figure 32-10](#) shows a scheme where a single main device is communicating with multiple remote node devices. All FSI receive modules in the remote node devices are directly connected to the main device transmit module. The transmit modules of the remote node devices are chained serially such that each transmit module is connected to the next remote node device and the last remote node device output connects to the main device receive module. Each remote node device will decide, based on the received frame's tag, whether to transmit their own data, or to enter bypass mode where they directly connect the previous remote node device transmit module to the next remote node device. This is done by using the FSI transmit module TDM\_IN.

Figure 32-10. FSI multi-node TDM Configuration

When an FSI transmitter module is used in TDM mode, TXCLK\_TDM\_IN, TXD0\_TDM\_IN and TXD1\_TDM\_IN pins are used if the transmitter is required to enter bypass mode. Figure 32-11 shows how the FSI module operates when in multi-node TDM mode.

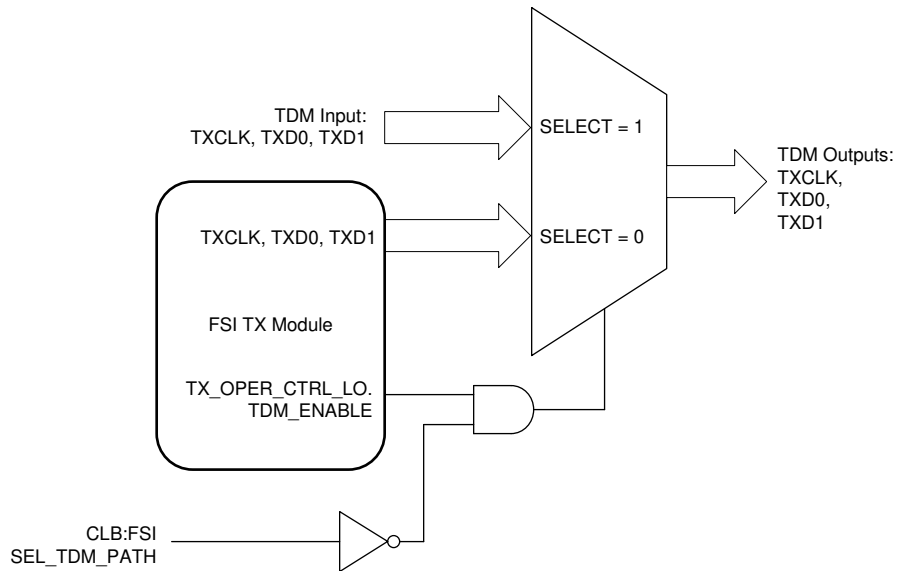

Figure 32-11. FSI Transmitter Multi-node TDM Multiplexing

The SEL\_TDM\_PATH signal is sourced from the CLB module. The CLB module will also generate the transmit trigger for the FSI transmitter. The CLB module must be configured to decide when to generate the FSI transmit trigger based on the status of the data, ping, and frame tag match generated by the FSI receiver module. The FSITX module must be configured to transmit on an external trigger and the corresponding CLB trigger input must be selected. In a broadcast scenario (FSI tag match will notify all remote node devices that a match has occurred), the CLB module inside each remote node device will generate a trigger and SEL\_TDM\_PATH signal. The main key here is that the trigger and the SEL\_TDM\_PATH signal must be generated at a different time interval in a non-overlapping manner. Figure 32-12 shows an example of FSI transmit triggers and the multi-node TDM SEL\_TDM\_PATH signals generated by the RX\_TRIGx signal or the CLB module of the remote node devices in a broadcast scenario.

**Figure 32-12. Generated Signals for FSI Multi-node TDM Configuration**

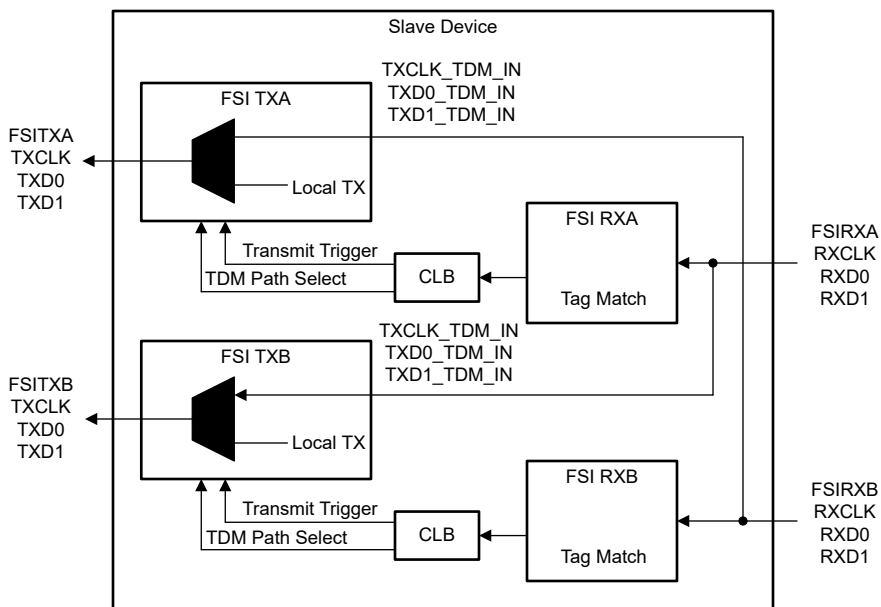

The TXCLK\_TDM\_IN, TXD0\_TDM\_IN, and TXD1\_TDM\_IN for the FSI transmit modules available in this device are shown in Table 32-10.

**Table 32-10. FSI TDM Inputs**

FSI Transmit Module	TXCLK_TDM_IN	TXD0_TDM_IN	TXD1_TDM_IN
FSITXA	FSIRXB RXCLK	FSIRXB RXD0	FSIRXB RXD1
FSITXB	FSIRXA RXCLK	FSIRXA RXD0	FSIRXA RXD1

The FSI transmit modules will be configured to use the external triggers generated by the CLB to initiate the transmission. Through appropriate configurations, the logic is designed to work assuming that only one TDM trigger will be generated until the transmission is completed. In the case where there is another trigger before the current transmission is completed, an error will be flagged in the TX\_EVT\_ERR\_STATUS register. Figure 32-13 shows the connections between CLB, FSITX, and FSIRX modules.

**Figure 32-13. FSI and CLB Multi-node TDM Connections**

In [Figure 32-10](#), the main device is connected to three remote node devices. The main device uses FSITXA to transmit frames to the three remote node devices. Each remote node device will receive every frame, using their FSIRXA. The remote node devices are chained together using their FSITXA output and FSIRXB inputs (configured as FSITXA TDM input). When a remote node device receives a frame using its FSIRXA, it will check the tag of the frame to see if the tag matches the specified reference value in its tag compare register. When a match does occur, the CLB module will configure the FSITXA of the remote node device to select the local FSITXA outputs as the source for the output pins. However, if a match does not occur, the FSITXA of the remote node device will be configured to enter bypass mode. There, it will select the FSITXA TDM inputs (which is FSIRXB) to be passed on to the output pins.

In this case when a frame is transmitted by the main device, and the frame tag is matched only in one of the remote node devices, all other devices with non-matching tags will enter bypass mode to allow the main device to receive frames from the chosen remote node device.

### 32.3.11 FSI-SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode follow:

- Data will transmit on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 will be driven like an active-low, chip-select signal. The signal will be low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks will be transmitted. All signals return to the IDLE state after the frame phase is finished.
- It is not possible to transmit in the SPI slave configuration because the FSI TXCLK cannot take an external clock source.

[Table 32-11](#) lists the frame structure of the FSI-SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI slave, the standard SPI must encode the transmission to be sent.

**Table 32-11. FSI-SPI Compatibility Frame Structure**

Idle State	Start of Frame	Frame Type	User Data	Data Words	CRC byte <sup>(1)</sup>	Frame Tag	End of Frame	Idle State
	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	

(1) The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data would be arranged in the following manner. The example provided in [Table 32-12](#) assumes a DATA\_2\_WORD frame has been sent.

**Table 32-12. Contents of Data Received by a Standard SPI**

SPI Data	Data Contents
SPI word 0	1001, 0100, 8-bit User Data
SPI word 1	Data word 1
SPI word 2	Data word 2
SPI word 3	8-bit CRC, 4-bit Frame Tag, 0110

### 32.3.11.1 Available SPI Modes

There are a few wiring schemes available for the FSI to use when communicating with an SPI module.

#### 32.3.11.1.1 FSITX as SPI Master, Transmit Only

The FSITX can operate as an independent SPI Master module. In this condition, TXCLK will be connected to SPICLK, TXD0 will be connected to SPISIMO, and TXD1 will be connected to  $\overline{\text{SPISTE}}$ , the chip select.

**Figure 32-14. FSITX as SPI Master, Transmit Only**

When the FSI is a SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver will require some software to act upon this information.

**Table 32-13. FSI as Master Transmitter, SPI as Slave Receiver**

Capability	Availability	Comment
Framing checks on the data frames	Yes	Can be implemented in software on the SPI receiver.
Ability to detect line breaks	Yes	Can be implemented in software on the SPI receiver but will require additional software overhead such as a timer, or watchdog.
CRC check	Yes	Can be implemented in software on the SPI receiver. For devices that have VCRC , this will be more efficient.
ECC on data	Yes	Can be implemented in software in the SPI receiver
Detection of abruptly terminated frames	No	
Double edge data rate	No	
Recovery from glitches on signal lines between frames	No	
Skew adjustment on signal lines	No	

#### 32.3.11.1.1.1 Initialization

To configure the FSITX module to be a SPI master for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX\_OPER\_CTRL\_LO.SPI\_MODE to 1. This will enable the SPI clocking scheme and signaling structure.

#### 32.3.11.1.1.2 Operation

The operation of the FSITX module in FSI-SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to [Section 32.3.2](#) for more information on each of these features.

### 32.3.11.1.2 FSIRX as SPI Slave, Receive Only

The FSIRX can operate as an independent SPI slave module. In the usage, RXCLK will be connected to SPICLK, and RXD0 will be connected to SPISIMO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence will be required to resynchronize the FSIRX module with the Master.

**Figure 32-15. FSIRX as SPI Slave, Receive Only**

When the FSI is a SPI receiver communicating with a SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

**Table 32-14. SPI as Master Transmitter, FSI as Slave Receiver**

Capability	Availability	Comment
Framing checks on the data frames	Yes	Standard on FSI
Ability to detect line breaks	Yes	Can be implemented in software in the SPI transmitter. But will have to use some timer or watchdog in the transmitting SPI device
CRC check	Yes	Can be implemented in software in the SPI transmitter.
ECC on data	Yes	Can be implemented in software in the SPI transmitter.
Detection of abruptly terminated frames	Yes	This is accomplished with the FSI setting up the frame watchdog counter.
Double edge data rate	No	
Recovery from glitches on signal lines between frames	Yes	Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame will discard the effects of these glitches and will cause the receiver to resynchronize when the real "start-of-frame" pattern is seen. So, the ability to reject glitches in between frames is hence very high.
Skew adjustment on signal lines	Yes	The FSI receiver has the ability to add delays to the incoming signal lines.

#### 32.3.11.1.2.1 Initialization

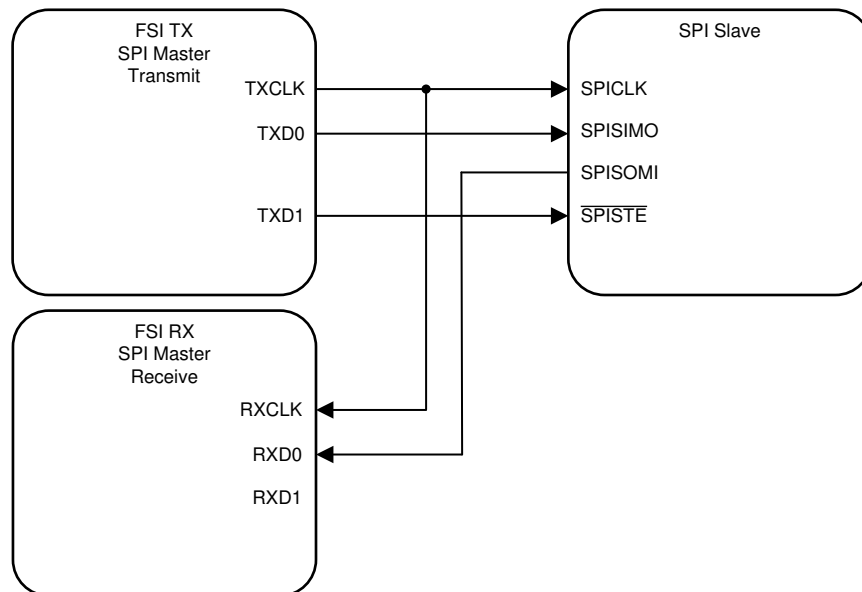

To configure the FSIRX module to be a SPI slave for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set `RX_OPER_CTRL.SPI_MODE` to 1. This will enable the SPI clocking scheme and signaling structure.

#### 32.3.11.1.2.2 Operation

The operation of the FSIRX module in FSI-SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to [Section 32.3.3](#) for more information on each of these features.

### 32.3.11.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Master

In this configuration, the FSITX is the clock master. The FSITX module will drive TXCLK (SPICLK), TXD0 (SPISIMO), and TXD1 (SPISTE/chip select), to the SPI slave. The SPISOMI signal will be connected back to the RXD0 signal. RXCLK can be fed either internally using the internal SPI pairing feature or wired externally, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX could also be thought of as an additional SPI slave. Some software logic will be required in order for the FSI to emulate a SPI master fully.

**Figure 32-16. FSITX and FSIRX as SPI Master, Full Duplex**

#### 32.3.11.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI master operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set their respective SPI\_MODE bits. This will enable the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX\_MASTER\_CTRL.SPI\_PAIRING to 1. This will internally connect TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK may be reallocated to other application requirements.

If the application requires an external clock loopback, ensure that TXCLK is connected to RXCLK. This may be required if the SPI Slave is across an isolation barrier and there is latency between TXCLK being launched and SPISOMI data being received on RXD0.

#### 32.3.11.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI master module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

## 32.4 FSI Programming Guide

This section describes various operational sequences and features for the FSI.

### 32.4.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules may exchange data. Since the receiver will accept data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example provides a suggested approach for establishing a clean communication link on two separate devices that may power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to ensure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 32-17 shows the connection of the devices in this example. While there is no true concept of a master or a slave node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

**Figure 32-17. Point to Point Connection**

Device 1 is the master node; it will be the driver of the initialization sequence. Device 2 is the slave node; it will respond to the master's commands. In this example, as well as in a real world use-case, neither the master nor the slave may know precisely when the other is ready to receive communication.

Sample sequences for both the master device and slave device are provided in the following subsections.

### 32.4.1.1 Establishing the Communication Link from the Master

The following sequence is an example of how the master node can establish the communication link with the slave without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
  - Send the flush sequence.
  - Send a ping frame with the frame tag 0000.
  - Wait for some time. (determined by application)
  - If the FSIRX has received a valid ping frame, continue; else iterate the loop again.
  - If the received ping frame tag was 0001, continue; else iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point both the master transmit and receive channels have successfully received a frame from their slave counterparts. The link has been established and standard application communication may begin.

### 32.4.1.2 Establishing the Communication Link from the Slave

The following sequence is an example of how the slave node can establish the communication link with the master without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else return to step 4.
6. If the received frame tag was 0000, continue; else discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else return to step 4.
11. If the received ping frame tag was 0001, continue; else if the received frame tag was 0000, return to step 9.  
This can happen if a second ping frame was already in transit before receiving the slave's response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from their master counterparts. The link has been established and regular communication may now proceed. The application may configure periodic ping frames from the transmitter, initialize the receiver's ping and frame watchdogs and begin the communication required by the application.

### 32.4.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a master register lock. These protections ensure that no spurious writes or unintentional modifications to these registers are accepted. For the list of registers with write protections available and the register and bit descriptions, refer to [Section 32.6](#).

#### EALLOW Protection

EALLOW is a device-level register protection. For those registers with EALLOW protection, the EALLOW bit should be set before modifying the register. The application should then clear the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

#### Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. In order to write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX\_MASTER\_CTRL.CORE\_RST must be set. To do this, write 0xA501 to TX\_MASTER\_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE\_RESET bit. Refer to the register descriptions for more information on which registers have write keys added.

#### Control Register Lock Protection

There also exists a master lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the register descriptions section. The control register lock will prevent any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX\_LOCK\_CTRL and TX\_LOCK\_CTRL for the receiver and transmitter respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV\_CFG\_REGS.SOFTPRESx) for the FSI module. Refer to [Section 32.3.2.7](#) for more information on SYSRSn.

### 32.4.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores will always be in free running mode. CPU halts will not have any effect on the operation of the FSI. However, reads of registers and data buffers by the debugger will not affect any flags, or status of the data buffers.

If you want to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

## 32.5 Software

### 32.5.1 FSI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/fsi

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 32.5.1.1 FSI Loopback:CPU Control

FILE: fsi\_ex1\_loopback\_cpucontrol.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Automatic (Hardware triggered) Ping frame transmission is also setup along with data.

User can edit some of configuration parameters as per use case. These are as below. Default values can be referred in code where these globals are defined

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

For any errors during transfers, that is, *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time (detected through software counters - txTimeOutCntr and rxTimeOutCntr)

#### External Connections

For FSI internal loopback (EXTERNAL\_FSI\_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL\_FSI\_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:

GPIO\_27 -> FSITXA\_CLK

- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

#### Watch Variables

- *dataFrameCntr* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.2 FSI Multi-Rx Tag-Match - C28X\_DUAL

FILE: fsi\_ex1\_multiRx\_tagmatch\_cpu1.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Multiple receivers receive data as per the received frame tag.

This is a dual core example where FSITxA and FSIRxA instances are owned by CPU1 while FSIRxB, FSIRxC, and FSIRxD are owned by CPU2. Internal loopback mode is enabled for FSIRxA, FSIRxB, FSIRxC, and FSIRxD which connects data and clock lines of these receivers to FSITxA internally.

FSITxA infinitely sends data frames with alternating tag values. Receivers are configured to receive data frame with different tag values with tag-match feature enabled. Tx does not send next frame of data until it all receivers receive the data. Synchronization among all the receivers is maintained through IPC flags.

User can edit some of configuration parameters as per use case. These are as below. Default values can be referred in code where these globals are defined:-

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers

For any errors during transfers, that is, *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time (detected through software counters - txTimeOutCntr and rxTimeOutCntr)

#### *External Connections*

For FSI internal loopback, no external connections needed

#### *Watch Variables*

- *dataFrameCntrA* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

### **32.5.1.3 FSI Multi-Rx Tag-Match - C28X\_DUAL**

FILE: fsi\_ex1\_multiRx\_tagmatch\_cpu2.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Multiple receivers receive data as per the received frame tag.

This is a dual core example where FSITxA & FSIRxA instances are owned by CPU1 while FSIRxB, FSIRxC & FSIRxD are owned by CPU2. Internal loopback mode is enabled for FSIRxA, FSIRxB, FSIRxC & FSIRxD which connects data & clock lines of these receivers to FSITxA internally.

FSITxA infinitely sends data frames with alternating tag values. Receivers are configured to receive data frame with different tag values with tag-match feature enabled. Tx doesn't send next frame of data until it all receivers receive the data. Synchronization among all the receivers is maintained through IPC flags.

User can edit some of configuration parameters as per usecase. These are as below. Default values can be referred in code where these globals are defined:-

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers

For any errors during transfers i.e. *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time(detected through software counters - txTimeOutCntr and rxTimeOutCntr)

#### *External Connections*

For FSI internal loopback, no external connections needed

### Watch Variables

- *dataFrameCntrB* Number of Data frame received by FSIRxB
- *dataFrameCntrC* Number of Data frame received by FSIRxC
- *dataFrameCntrD* Number of Data frame received by FSIRxD
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.4 FSI Loopback CLA control

FILE: fsi\_ex2\_loopback\_clacontrol.c

Example sets up infinite data frame transfers where trigger happens through *CLA*. Automatic (Hardware triggered) Ping frame transmission is also setup along with data. This example is similar to fsi\_ex1\_loopback\_cpucontrol and only different in the sense that data frame transfer are triggered from a *CLA* task. Using *CLA* will release some of load from CPU and help it in providing time for other tasks.

User can edit some of configuration parameters as per use case. These are as below. Default values can be referred in code where these globals are defined

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

For any errors during transfers, that is, *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time (detected through software counters - txTimeOutCntr and rxTimeOutCntr)

### External Connections

For FSI internal loopback (`EXTERNAL_FSI_ENABLE == 0`), no external connections needed

For FSI external loopback (`EXTERNAL_FSI_ENABLE == 1`), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:

GPIO\_27 -> FSITXA\_CLK

- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

### Watch Variables

- *dataFrameCntr* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.5 FSI DMA frame transfers:DMA Control

FILE: fsi\_ex3\_loopback\_dmacontrol.c

Example sets up infinite data frame transfers where DMA trigger happens once through CPU and then DMA takes control to transfer data iteratively. This example demonstrates the FSI feature about triggering DMA events which in turn can copy data and trigger next transfer.

Two DMA channels are setup for FSI Tx operation and two for Rx. Four areas in GSx memories are also setup as source and sink for data and tag values of frame under transmission.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### *External Connections*

For FSI internal loopback (`EXTERNAL_FSI_ENABLE == 0`), no external connections needed

For FSI external loopback (`EXTERNAL_FSI_ENABLE == 1`), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:

GPIO\_27 -> FSITXA\_CLK

- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

#### *Watch Variables*

- *countDMAtransfers* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

### **32.5.1.6 FSI data transfer by external trigger**

FILE: `fsi_ex4_loopback_epwmtrigger.c`

FSI frame transfer can be triggered by external sources. It can connect up to 32 trigger sources but as of now, only 16 ePWMx-SOCy(x-1:8, y-A:B) are supported. FSI supports external trigger for both PING and DATA frame transfers and in this example we demonstrate how to setup infinite DATA transfers using selectable ePWM-SOC as a trigger source. The TB counter for ePWM operation is in up/down count mode for this example.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### *External Connections*

For FSI internal loopback (`EXTERNAL_FSI_ENABLE == 0`), no external connections needed

For FSI external loopback (`EXTERNAL_FSI_ENABLE == 1`), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:

GPIO\_27 -> FSITXA\_CLK

- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

#### Watch Variables

- *dataFrameCnt* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.7 FSI data transfers upon CPU Timer event

FILE: fsi\_ex5\_periodic\_frame.c

Example sets up infinite data frame transfers where trigger comes from ISR handling the periodic CPU Timer event. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

CPU Timer0 is chosen for setting up periodic timer events. User can choose any other Timer-1/Timer-2 as well.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI internal loopback (EXTERNAL\_FSI\_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL\_FSI\_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:
- GPIO\_27 -> FSITXA\_CLK
- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

#### Watch Variables

- *dataFrameCnt* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.8 FSI and SPI communication(fsi\_ex6\_spi\_master\_tx)

FILE: fsi\_ex6\_spi\_master\_tx.c

FSI supports SPI compatibility mode to talk to the devices not having FSI but SPI module. Example sets up infinite data frame transfers where FSI acts like master Tx and SPI as slave Rx. API to decode FSI frame received at SPI end is implemented and checks are made to ensure received details(frame tag/type, userdata, data) match with transfered frame.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI <-> SPI communication, make below connections in GPIO settings

- GPIO\_2 -> GPIO\_18 :: To connect FSITX\_CLK with SPICLKA
- GPIO\_0 -> GPIO\_16 :: To connect FSITX\_TX0 with SPISIMOA

- GPIO\_1 -> GPIO\_19 :: To connect FSITX\_TX1 with SPISTEPA

#### Watch Variables

- *dataFrameCnt* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.9 FSI and SPI communication(*fsi\_ex7\_spi\_slave\_rx*)

FILE: *fsi\_ex7\_spi\_slave\_rx.c*

FSI supports SPI compatibility mode to talk to the devices not having FSI but SPI module. Example sets up infinite data frame transfers where FSI acts like slave Rx and SPI as master Rx. API to build the FSI frame at SPI end before transfer is implemented in SW and checks are made to ensure received details(frame tag/type, userdata, data) on FSI Rx match with transferred data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

For FSI(Rx) <-> SPI(Tx) communication, make connections in GPIO settings

There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge.

- GPIO\_13 -> GPIO\_18 :: To connect FSIRXCLKA with SPICLKA
- GPIO\_12 -> GPIO\_16 :: To connect FSIRXD0A with SPISIMOA

#### Watch Variables

- *dataFrameCnt* Number of Data frame transferred
- *error* Non zero for transmit/receive data mismatch

#### 32.5.1.10 FSI P2Point Connection:Rx Side

FILE: *fsi\_ex8\_ext\_p2pconnection\_rx.c*

Example sets up FSI receiving device in a point to point connection to the FSI transmitting device. Example code to set up FSI transmit device is implemented in a separate file.

In a real scenario two separate devices may power up in arbitrary order and there is a need to establish a clean communication link which ensures that receiver side is flushed to properly interpret the start of a new valid frame.

There is no true concept of a master or a slave node in the FSI protocol, but to simplify the data flow and connection we can consider transmitting device as master and receiving side as slave. Transmitting side will be driver of initialization sequence.

Handshake mechanism which must take place before actual data transmission can be use case specific; points described below can be taken as an example on how to implement the handshake from receiving side -

- Setup the receiver interrupts to detect PING type frame reception
- Begin the first PING loop
  - Wait for receiver interrupt
  - If the FSI Rx has received a PING frame with *FSI\_FRAME\_TAG0*, come out of loop. Otherwise iterate the loop again.
- Begin the second PING loop
  - Send the Flush sequence
  - Send the PING frame with tag `\bFSI_FRAME_TAG1`
  - Wait for receiver interrupt
  - If the FSI Rx has received a PING frame with *FSI\_FRAME\_TAG1*, come out of loop. Otherwise iterate the loop again.

Now, the receiver side has received the acknowledged PING frame (tag1), so it is ready for normal operation further.

After above synchronization steps, FSI Rx can be configured as per use case, that is, *nWords*, lane width, enabling events etc and start the infinite transfers. More details on establishing the communication link can be found in device TRM.

User can edit some of configuration parameters as per use case, similar to other examples.

*nWords* - Number of words per transfer may be from 1 -16 *nLanes* - Choice to select single or double lane for frame transfers *fsiClock* - FSI Clock used for transfers *txUserData* - User data to be sent with Data frame *txDataFrameTag* - Frame tag used for Data transfers *txPingFrameTag* - Frame tag used for Ping transfers *txPingTimeRefCntr* - Tx Ping timer reference counter *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

### External Connections

For FSI external P2P connection, external connections are required to be made between two devices. Device 1 FSI TX and RX pins need to be connected to device 2 FSI RX and TX pins, respectively. See below for external connections to make and GPIOs used:

External connections required between independent RX and TX devices:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:
- GPIO\_27 -> FSITXA\_CLK
- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

### Watch Variables

- *dataFrameCntr* Number of Data frame received
- *error* Non zero for transmit/receive data mismatch

### 32.5.1.11 FSI P2Point Connection:Tx Side

FILE: fsi\_ex8\_ext\_p2pconnection\_tx.c

Example sets up FSI transmitting device in a point to point connection to the FSI receiving device. Example code to set up FSI receiving device is implemented in a separate file.

In a real scenario two separate devices may power up in arbitrary order and there is a need to establish a clean communication link which ensures that receiver side is flushed to properly interpret the start of a new valid frame.

There is no true concept of a master or a slave node in the FSI protocol, but to simplify the data flow and connection we can consider transmitting device as master and receiving side as slave. Transmitting side will be driver of initialization sequence.

Handshake mechanism which must take place before actual data transmission can be use case specific; points described below can be taken as an example on how to implement the handshake from transmitting side -

- Setup the receiver interrupts to detect PING type frame reception
- Begin the PING loop
  - Send the Flush sequence
  - Send a PING frame with the frame tag *FSI\_FRAME\_TAG0*
  - Wait for some time (determined by application)
  - If the FSI Rx has received a PING frame with *FSI\_FRAME\_TAG1*, come out of loop. Otherwise iterate the loop again

Send a PING frame with the frame tag *FSI\_FRAME\_TAG1*

After above synchronization steps, FSI Tx can be configured as per use case, that is, *nWords*, lane width, enabling events etc and start the infinite transfers. More details on establishing the communication link can be found in device TRM.

User can edit some of configuration parameters as per use case, similar to other examples.

*nWords* - Number of words per transfer may be from 1 -16 *nLanes* - Choice to select single or double lane for frame transfers *fsiClock* - FSI Clock used for transfers *txUserData* - User data to be sent with Data frame *txDataFrameTag* - Frame tag used for Data transfers *txPingFrameTag* - Frame tag used for Ping transfers *txPingTimeRefCntr* - Tx Ping timer reference counter *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

### External Connections

For FSI external P2P connection, external connections are required to be made between two devices. Device 1 FSI TX and RX pins need to be connected to device 2 FSI RX and TX pins, respectively. See below for external connections to make and GPIOs used:

External connections required between independent RX and TX devices:

- FSIRX\_CLK to FSITX\_CLK
- FSIRX\_RX0 to FSITX\_TX0
- FSIRX\_RX1 to FSITX\_TX1
- ControlCard FSI Header GPIOs:

GPIO\_27 -> FSITXA\_CLK

- GPIO\_26 -> FSITXA\_TX0
- GPIO\_25 -> FSITXA\_TX1
- GPIO\_9 -> FSIRXA\_CLK
- GPIO\_8 -> FSIRXA\_RX0
- GPIO\_10 -> FSIRXA\_RX1

### Watch Variables

- *dataFrameCntr* Number of Data frame transmitted
- *error* Non zero for transmit/receive data mismatch

## 32.6 FSI Registers

This section describes the Fast Serial Interface Registers. The FSI module contains two distinct sets of registers. One for the FSI receiver and one for the FSI transmitter.

### 32.6.1 FSI Base Address Table (C28)

**Table 32-15. FSI Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
FsiTxaRegs	FSI_TX_REGS	FSITXA_BASE	0x0000_6600	YES	YES	YES	YES	YES
FsiRxaRegs	FSI_RX_REGS	FSIRXA_BASE	0x0000_6680	YES	YES	YES	YES	YES
FsiTxbRegs	FSI_TX_REGS	FSITXB_BASE	0x0000_6700	YES	YES	YES	YES	YES
FsiRxbRegs	FSI_RX_REGS	FSIRXB_BASE	0x0000_6780	YES	YES	YES	YES	YES
FsiRxcRegs	FSI_RX_REGS	FSIRXC_BASE	0x0000_6880	YES	YES	YES	YES	YES
FsiRxdRegs	FSI_RX_REGS	FSIRXD_BASE	0x0000_6980	YES	YES	YES	YES	YES
FsiRxeRegs	FSI_RX_REGS	FSIRXE_BASE	0x0000_6A80	YES	YES	YES	YES	YES
FsiRxfRegs	FSI_RX_REGS	FSIRXF_BASE	0x0000_6B80	YES	YES	YES	YES	YES
FsiRxcRegs	FSI_RX_REGS	FSIRXC_BASE	0x0000_6C80	YES	YES	YES	YES	YES
FsiRxdRegs	FSI_RX_REGS	FSIRXD_BASE	0x0000_6D80	YES	YES	YES	YES	YES

### 32.6.2 FSI\_TX\_REGS Registers

Table 32-16 lists the memory-mapped registers for the FSI\_TX\_REGS registers. All register offset addresses not listed in Table 32-16 should be considered as reserved locations and the register contents should not be modified.

**Table 32-16. FSI\_TX\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	TX_MASTER_CTRL	Transmit master control register	EALLOW	<a href="#">Go</a>
2h	TX_CLK_CTRL	Transmit clock control register	EALLOW and LOCK	<a href="#">Go</a>
4h	TX_OPER_CTRL_LO	Transmit operation control register low	EALLOW and LOCK	<a href="#">Go</a>
5h	TX_OPER_CTRL_HI	Transmit operation control register high	EALLOW and LOCK	<a href="#">Go</a>
6h	TX_FRAME_CTRL	Transmit frame control register		<a href="#">Go</a>
7h	TX_FRAME_TAG_UDATA	Transmit frame tag and user data register		<a href="#">Go</a>
8h	TX_BUF_PTR_LOAD	Transmit buffer pointer control load register	EALLOW	<a href="#">Go</a>
9h	TX_BUF_PTR_STS	Transmit buffer pointer control status register		<a href="#">Go</a>
Ah	TX_PING_CTRL	Transmit ping control register	EALLOW and LOCK	<a href="#">Go</a>
Bh	TX_PING_TAG	Transmit ping tag register		<a href="#">Go</a>
Ch	TX_PING_TO_REF	Transmit ping timeout counter reference	EALLOW and LOCK	<a href="#">Go</a>
Eh	TX_PING_TO_CNT	Transmit ping timeout current count		<a href="#">Go</a>
10h	TX_INT_CTRL	Transmit interrupt event control register	EALLOW and LOCK	<a href="#">Go</a>
11h	TX_DMA_CTRL	Transmit DMA event control register	EALLOW and LOCK	<a href="#">Go</a>
12h	TX_LOCK_CTRL	Transmit lock control register	EALLOW and LOCK	<a href="#">Go</a>
14h	TX_EVT_STS	Transmit event and error status flag register		<a href="#">Go</a>
16h	TX_EVT_CLR	Transmit event and error clear register	EALLOW	<a href="#">Go</a>
17h	TX_EVT_FRC	Transmit event and error flag force register	EALLOW	<a href="#">Go</a>
18h	TX_USER_CRC	Transmit user-defined CRC register		<a href="#">Go</a>
20h	TX_ECC_DATA	Transmit ECC data register		<a href="#">Go</a>
22h	TX_ECC_VAL	Transmit ECC value register		<a href="#">Go</a>
40h + formula	TX_BUF_BASE_y	Base address for transmit buffer		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 32-17 shows the codes that are used for access types in this section.

**Table 32-17. FSI\_TX\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 32-17. FSI\_TX\_REGS Access Type Codes  
(continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 32.6.2.1 TX\_MASTER\_CTRL Register (Offset = 0h) [Reset = 0h]

TX\_MASTER\_CTRL is shown in [Figure 32-18](#) and described in [Table 32-18](#).

Return to the [Summary Table](#).

Transmit master control register

**Figure 32-18. TX\_MASTER\_CTRL Register**

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED						FLUSH	CORE_RST
R-0h						R/W-0h	R/W-0h

**Table 32-18. TX\_MASTER\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key In order to write to any bit in this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-2	RESERVED	R	0h	Reserved
1	FLUSH	R/W	0h	Flush Operation Start bit This bit will cause the transmitter to initiate a flush pattern of a single toggle on the TXD0 and TXD1 followed by five full cycles of TXCLK. This bit should be written only when the CORE_RST bit is 0 and the clock to the Transmitter core is turned on. 0h (R/W) = Clear this bit. 1h (R/W) = Setting this bit will initiate flush sequence. To properly execute a flush sequence, Set FLUSH to 1, wait for five TXCLK cycles then clear FLUSH to 0. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. The software must keep this bit set to 1 for at least five TXCLK cycles before setting it back to 0. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Transmitter Main Core Reset bit This bit controls the transmitter main core reset. In order to send any frame, this bit must be cleared. 0h (R/W) = Transmitter core is not in reset and can transmit frames. 1h (R/W) = Transmitter core is held in reset. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

### 32.6.2.2 TX\_CLK\_CTRL Register (Offset = 2h) [Reset = 0h]

TX\_CLK\_CTRL is shown in [Figure 32-19](#) and described in [Table 32-19](#).

Return to the [Summary Table](#).

Transmit clock control register

**Figure 32-19. TX\_CLK\_CTRL Register**

15	14	13	12	11	10	9	8

PING_TO_MODE	SW_CRC	START_MODE			SPI_MODE	DATA_WIDTH	
R/W-0h	R/W-0h	R/W-0h			R/W-0h	R/W-0h	

**Table 32-20. TX\_OPER\_CTRL\_LO Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9	TDM_ENABLE	R/W	0h	Transmit TDM Mode Enable bit. This bit enables the TDM Mode for multi-remote TDM operation. 0h (R/W) Transmit TDM Mode is not enabled. 1h (R/W) Transmit TDM Mode is enabled. Reset type: SYSRSn
8	SEL_PLLCLK	R/W	0h	Input Clock Select bit This bit selects the input clock source for the transmitter core. 0h (R/W) = SYSCLK is the source of the transmitter clock into the clock prescaler. 1h (R/W) = PLLRAWCLK is the source of the transmitter core clock into the clock prescaler. Reset type: SYSRSn
7	PING_TO_MODE	R/W	0h	Ping Counter Reset Mode Select bit This bit selects when the ping counter will reset. 0h (R/W) = The ping counter will reset and restart only on hardware initiated ping frames, when ping counter has timed out. 1h (R/W) = The ping counter will reset and restart on any software initiated frame as well as a ping counter timeout Reset type: SYSRSn
6	SW_CRC	R/W	0h	CRC Source Select bit This bit selects the source of the CRC value that is transmitted. 0h (R/W) = The transmitted CRC value is computed by hardware. 1h (R/W) = The transmitted CRC value is sourced from the value programmed in the TX_USER_CRC register. Reset type: SYSRSn
5-3	START_MODE	R/W	0h	Transmission Start Mode Select bit These bits select the method by which a new frame transmission is started. 0h (R/W) = Only a software write to TX_FRAME_CTRL.START initiate a new transmission. 1h (R/W) = The configured external trigger will initiate a new transmission. 2h (R/W) = Either writing to TX_FRAME_CTRL.START or the TX_FRAME_TAG_UDATA register will initiate a new transmission. All other combinations of bits are illegal and reserved for future use. Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Select bit This bit enables and disables SPI compatibility mode. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn

**Table 32-20. TX\_OPER\_CTRL\_LO Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	DATA_WIDTH	R/W	0h	Transmit Data Width Select bits These bits define the number of data lines used by the transmitter. 0h (R/W) = Data will be transmitted on one data line (TXD0) 1h (R/W) = Data will be transmitted on two data lines (TXD0 and TXD1). The format of the data is described in the preceding chapter. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

### 32.6.2.4 TX\_OPER\_CTRL\_HI Register (Offset = 5h) [Reset = 0h]

TX\_OPER\_CTRL\_HI is shown in [Figure 32-21](#) and described in [Table 32-21](#).

Return to the [Summary Table](#).

Transmit operation control register high

**Figure 32-21. TX\_OPER\_CTRL\_HI Register**

15	14	13	12	11	10	9	8
RESERVED			EXT_TRIG_SEL				
R-0h			R/W-0h

Bit	Field	Type	Reset	Description
15-13	RESERVED	R	0h	Reserved
12-7	EXT_TRIG_SEL	R/W	0h	External Trigger Select bit These bits define which of the 64 external inputs will be used as the source for the external input trigger. 00h (R/W) = Trigger 1 is the source. 01h (R/W) = Trigger 2 is the source. 02h (R/W) = Trigger 3 is the source. ... 3Fh (R/W) = Trigger 64 is the source. Reset type: SYSRSn
6	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between 16-bit and 32-bit ECC computation. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
5	FORCE_ERR	R/W	0h	Error Frame Force bit This bit will force the the CRC value of the transmitted data frame to 0 whenever there is a buffer overrun or underrun condition. This can be used to force a corrupted CRC as the data is not guaranteed to be reliable. The receiver will treat the data as invalid and can handle this as needed. Note: DO NOT use FORCE_ERR if using the SW CRC mode (FSI Transmit). 0h (R/W) = The CRC will not be forced to 0. 1h (R/W) = The CRC will be forced to 0 in a buffer overrun or underrun condition. Reset type: SYSRSn
4-0	RESERVED	R	0h	Reserved

### 32.6.2.5 TX\_FRAME\_CTRL Register (Offset = 6h) [Reset = 0h]

TX\_FRAME\_CTRL is shown in [Figure 32-22](#) and described in [Table 32-22](#).

Return to the [Summary Table](#).

Transmit frame control register

**Figure 32-22. TX\_FRAME\_CTRL Register**

15	14	13	12	11	10	9	8
START	RESERVED

7	6	5	4	3	2	1	0
N_WORDS				FRAME_TYPE			
R/W-0h				R/W-0h			

**Table 32-22. TX\_FRAME\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	START	R/W	0h	Start Transmission bit This bit will cause the FSI to start transmitting the next frame. 0h (R/W) = Writing a 0 to this bit will have no effect. 1h (R/W) = Start the next transmission. This bit will be cleared by hardware. Reset type: SYSRSn
14-8	RESERVED	R	0h	Reserved
7-4	N_WORDS	R/W	0h	Number of Words to be Transmitted This field defines the number of words which will be transmitted in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the receiver. Set this bitfield to be one less than the number of words to be transmitted. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
3-0	FRAME_TYPE	R/W	0h	Transmit Frame Type This field determines the type of frame that will be transmitted next. 0000b (R/W) = Ping Frame. This frame can be sent either by software or automatically by hardware. 0100b (R/W) = DATA_1_WORD Frame. One word data frame (16-bit data). 0101b (R/W) = DATA_2_WORD Frame. Two word data frame (32-bit data). 0110b (R/W) = DATA_4_WORD Frame. Four word data frame (64-bit data). 0111b (R/W) = DATA_6_WORD Frame. Six word data frame (96-bit data). 0011b (R/W) = DATA_N_WORD Frame. The N_WORDS field will determine the number of words (1 to 16) to be sent. Both the transmitter and receiver must have the same value programmed. 1111b (R/W) = Error Frame. This frame can be used during error conditions or any condition where the transmitter wants to notify the receiver of a high priority status. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

### 32.6.2.6 TX\_FRAME\_TAG\_UDATA Register (Offset = 7h) [Reset = 0h]

TX\_FRAME\_TAG\_UDATA is shown in [Figure 32-23](#) and described in [Table 32-23](#).

Return to the [Summary Table](#).

**Table 32-25. TX\_BUF\_PTR\_STS Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-13	RESERVED	R	0h	Reserved
12-8	CURR_WORD_CNT	R	0h	Words Remaining in the transmit buffer This value indicates the number of words present in the data buffer which have not yet been transmitted. This value is only valid when there is no active transmission. Note: This value will not be valid if there is a buffer overrun or underrun condition. Reset type: SYSRSn
7-4	RESERVED	R	0h	Reserved
3-0	CURR_BUF_PTR	R	0h	Current Buffer Pointer Index This bitfield will show the current index of the buffer pointer. This value is only valid when there is no active transmission. Reset type: SYSRSn

### 32.6.2.9 TX\_PING\_CTRL Register (Offset = Ah) [Reset = 0h]

TX\_PING\_CTRL is shown in [Figure 32-26](#) and described in [Table 32-26](#).

Return to the [Summary Table](#).

Transmit ping control register

**Figure 32-26. TX\_PING\_CTRL Register**

15	14	13	12	11	10	9	8
RESERVED							EXT_TRIG_SEL
R-0h							R/W-0h
7	6	5	4	3	2	1	0
EXT_TRIG_SEL				EXT_TRIG_EN	TIMER_EN	CNT_RST	
R/W-0h				R/W-0h	R/W-0h	R/W-0h	

**Table 32-26. TX\_PING\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8-3	EXT_TRIG_SEL	R/W	0h	External Trigger Select bits This bitfield will select one of the 64 external trigger inputs to be the source to generate a ping frame. A ping frame will only be generated if the EXT_TRIG_EN bit is set. 0h (R/W) = Trigger 1 will be used to generate a ping frame. 1h (R/W) = Trigger 2 will be used to generate a ping frame. .. 3Fh (R/W) = Trigger 64 will be used to generate a ping frame. Reset type: SYSRSn
2	EXT_TRIG_EN	R/W	0h	External Trigger Enable bit This bit will allow the external trigger logic to generate a ping frame. 0h (R/W) = External triggers will not be used to generate ping frames. 1h (R/W) = The selected external trigger (selected by EXT_TRIG_SEL bits) will be able to generate a ping frame. The ping timer will be ignored if this bit is set. Reset type: SYSRSn
1	TIMER_EN	R/W	0h	Ping Timer Enable bit This bit will enable the ping timer for generating periodic ping frames. 0h (R/W) = The ping timer is disabled and will not generate ping frames. 1h (R/W) = The ping timer is enabled and can be used to generate ping frames. Once the timer count reaches the value set by the TX_PING_TO_REF register, it will initiate a ping frame transmission. Note: If the ping timer is used, EXT_TRIG_EN should not be set as it will override this function. Reset type: SYSRSn
0	CNT_RST	R/W	0h	Ping Counter Reset bit Writing a 1 to this bit will reset the ping counter to 0. The counter will stay in reset as long as this bit is set to 1. This bit needs to be cleared to 0 to use the counter. 0h (R/W) = Clear the CNT_RST. 1h (R/W) = The ping counter will be reset to 0. Reset type: SYSRSn

### 32.6.2.10 TX\_PING\_TAG Register (Offset = Bh) [Reset = 0h]

TX\_PING\_TAG is shown in [Figure 32-27](#) and described in [Table 32-27](#).

Return to the [Summary Table](#).

Transmit ping tag register

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3-0	TAG	R/W	0h	<p>Ping Frame Tag</p> <p>This field contains a 4-bit tag which will be sent in any ping frame that is initiated by an external trigger or the ping timer. This field is user-defined and can be set based on the application requirement. If a ping frame is generated manually, the transmitted tag will be from TX_FRAME_TAG_UDATA.FRAME_TAG, not this value.</p> <p>Reset type: SYSRSn</p>

### 32.6.2.11 TX\_PING\_TO\_REF Register (Offset = Ch) [Reset = 0h]

TX\_PING\_TO\_REF is shown in [Figure 32-28](#) and described in [Table 32-28](#).

Return to the [Summary Table](#).

Transmit ping timeout counter reference

**Figure 32-28. TX\_PING\_TO\_REF Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TO_REF																															
R/W-0h																															

**Table 32-28. TX\_PING\_TO\_REF Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TO_REF	R/W	0h	Ping Timer Reference Value. This is the 32-bit reference value for the ping timer. The timer will increment the counter starting from 0. When the reference value is reached, it will generate a timeout event, triggering a ping frame transmission. The counter will then reset to 0 and continue counting. Reset type: SYSRSn

### 32.6.2.12 TX\_PING\_TO\_CNT Register (Offset = Eh) [Reset = 0h]

TX\_PING\_TO\_CNT is shown in [Figure 32-29](#) and described in [Table 32-29](#).

Return to the [Summary Table](#).

Transmit ping timeout current count

**Figure 32-29. TX\_PING\_TO\_CNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TO_CNT																															
R-0h																															

**Table 32-29. TX\_PING\_TO\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TO_CNT	R	0h	Ping Timer Counter Value This register contains the current value of the ping timer counter. After reset, this counter will increment until it reaches the reference value (TX_PING_TO_REF), at which point it generates a ping frame transmission. After this point, the counter will reset to 0 and continue counting. This is a free-running counter Reset type: SYSRSn

### 32.6.2.13 TX\_INT\_CTRL Register (Offset = 10h) [Reset = 0h]

TX\_INT\_CTRL is shown in [Figure 32-30](#) and described in [Table 32-30](#).

Return to the [Summary Table](#).

Transmit interrupt event control register

15-0	BASE_ADDRESS	R/W	0h	Transmit Data Buffer Base Address This is the base address of the 16-word data buffer used by the transmitter. Reset type: SYSRSn

### 32.6.3 FSI\_RX\_REGS Registers

Table 32-40 lists the memory-mapped registers for the FSI\_RX\_REGS registers. All register offset addresses not listed in Table 32-40 should be considered as reserved locations and the register contents should not be modified.

**Table 32-40. FSI\_RX\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	RX_MASTER_CTRL	Receive main control register	EALLOW	<a href="#">Go</a>
4h	RX_OPER_CTRL	Receive operation control register	EALLOW and LOCK	<a href="#">Go</a>
6h	RX_FRAME_INFO	Receive frame control register		<a href="#">Go</a>
7h	RX_FRAME_TAG_UDATA	Receive frame tag and user data register		<a href="#">Go</a>
8h	RX_DMA_CTRL	Receive DMA event control register	EALLOW and LOCK	<a href="#">Go</a>
Ah	RX_EVT_STS	Receive event and error status flag register		<a href="#">Go</a>
Bh	RX_CRC_INFO	Receive CRC info of received and computed CRC		<a href="#">Go</a>
Ch	RX_EVT_CLR	Receive event and error clear register	EALLOW	<a href="#">Go</a>
Dh	RX_EVT_FRC	Receive event and error flag force register	EALLOW	<a href="#">Go</a>
Eh	RX_BUF_PTR_LOAD	Receive buffer pointer load register	EALLOW	<a href="#">Go</a>
Fh	RX_BUF_PTR_STS	Receive buffer pointer status register		<a href="#">Go</a>
10h	RX_FRAME_WD_CTRL	Receive frame watchdog control register	EALLOW and LOCK	<a href="#">Go</a>
12h	RX_FRAME_WD_REF	Receive frame watchdog counter reference	EALLOW and LOCK	<a href="#">Go</a>
14h	RX_FRAME_WD_CNT	Receive frame watchdog current count		<a href="#">Go</a>
16h	RX_PING_WD_CTRL	Receive ping watchdog control register	EALLOW and LOCK	<a href="#">Go</a>
17h	RX_PING_TAG	Receive ping tag register		<a href="#">Go</a>
18h	RX_PING_WD_REF	Receive ping watchdog counter reference	EALLOW and LOCK	<a href="#">Go</a>
1Ah	RX_PING_WD_CNT	Receive pingwatchdog current count		<a href="#">Go</a>
1Ch	RX_INT1_CTRL	Receive interrupt control register for RX_INT1	EALLOW and LOCK	<a href="#">Go</a>
1Dh	RX_INT2_CTRL	Receive interrupt control register for RX_INT2	EALLOW and LOCK	<a href="#">Go</a>
1Eh	RX_LOCK_CTRL	Receive lock control register		<a href="#">Go</a>
20h	RX_ECC_DATA	Receive ECC data register		<a href="#">Go</a>
22h	RX_ECC_VAL	Receive ECC value register		<a href="#">Go</a>
24h	RX_ECC_SEC_DATA	Receive ECC corrected data register		<a href="#">Go</a>
26h	RX_ECC_LOG	Receive ECC log and status register		<a href="#">Go</a>
28h	RX_FRAME_TAG_CMP	Receive frame tag compare register	EALLOW and LOCK	<a href="#">Go</a>
29h	RX_PING_TAG_CMP	Receive ping tag compare register	EALLOW and LOCK	<a href="#">Go</a>
30h	RX_DLYLINE_CTRL	Receive delay line control register	EALLOW and LOCK	<a href="#">Go</a>
38h	RX_VIS_1	Receive debug visibility register 1		<a href="#">Go</a>
40h + formula	RX_BUF_BASE_y	Base address for receive data buffer	EALLOW and LOCK	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 32-41](#) shows the codes that are used for access types in this section.

**Table 32-41. FSI\_RX\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 32.6.3.1 RX\_MASTER\_CTRL Register (Offset = 0h) [Reset = 0h]

RX\_MASTER\_CTRL is shown in [Figure 32-40](#) and described in [Table 32-42](#).

Return to the [Summary Table](#).

Receive main control register

**Figure 32-40. RX\_MASTER\_CTRL Register**

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED					SPI_PAIRING	INT_LOOPBACK	CORE_RST
R-0h					R/W-0h	R/W-0h	R/W-0h

**Table 32-42. RX\_MASTER\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-3	RESERVED	R	0h	Reserved
2	SPI_PAIRING	R/W	0h	Clock Pairing for SPI-like Behavior Enable bit This bit enables the internal clock pairing with the FSI TX module. This feature internally connects the TXCLK to RXCLK allowing the FSI TX module, acting as a SPI controller, to clock data into the receiver and out of the transmitter like a standard SPI module. This configuration is valid when the Module is in SPI mode only (RX_OPER_CTRL.SPI_MODE = 1) 0h (R/W) = SPI clock pairing is not enabled. 1h (R/W) = SPI clock pairing is enabled. The RXCLK will be internally connected to the TXCLK of the corresponding FSI module. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn
1	INT_LOOPBACK	R/W	0h	Internal Loopback Enable bit This bit enables the internal loopback functionality of the FSI receiver. By enabling this bit, a mux will select the signals coming directly from the corresponding FSI transmitter module rather than from the pins. 0h (R/W) = Internal loopback is disabled. The FSI RX module will receive signals coming from the pins. 1h (R/W) = Internal loopback is enabled. The FSI RX module will receive signals from the directly from FSI TX module rather than the pins. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Receiver Main Core Reset bit This bit controls the receiver main core reset. In order to receive any frame, this bit must be cleared. 0h (R/W) = Receiver core is not in reset and can receive frames. 1h (R/W) = Receiver core is held in reset. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

### 32.6.3.2 RX\_OPER\_CTRL Register (Offset = 4h) [Reset = 0h]

RX\_OPER\_CTRL is shown in [Figure 32-41](#) and described in [Table 32-43](#).

Return to the [Summary Table](#).

Receive operation control register

**Figure 32-41. RX\_OPER\_CTRL Register**

15	14	13	12	11	10	9	8
RESERVED							PING_WD_RST_MODE
R-0h							R/W-0h
7	6	5	4	3	2	1	0
ECC_SEL	N_WORDS				SPI_MODE	DATA_WIDTH	
R/W-0h	R/W-0h				R/W-0h	R/W-0h	

**Table 32-43. RX\_OPER\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	PING_WD_RST_MODE	R/W	0h	Ping Watchdog Timeout Mode Select bit This bit selects the mode by which the ping watchdog counter is reset. The watchdog counter can be reset and restarted only by ping frames or by any received frame. 0h (R/W) = The ping watchdog counter will reset and restart only by ping frames. 1h (R/W) = The ping watchdog counter will reset and restart by any received frame. Reset type: SYSRSn
7	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between whether the ECC computation is done on 16-bit or 32-bit words. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
6-3	N_WORDS	R/W	0h	Number of Words to Receive This field defines the number of words which will be received in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the transmitter. Set this bitfield to be one less than the number of words to be received. This value is only applicable when the frame type received is DATA_N_WORD. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Enable bit This bit enables and disables the SPI compatibility mode of the FSI RX. The received data must be formatted as an FSI frame in order for the data to properly be received. SPI compatibility mode will allow FSI RX to receive data that is sent using SPI signal format. Refer to the applicable section in the FSI TRM chapter for more information. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn
1-0	DATA_WIDTH	R/W	0h	Receive Data Width Select bit These bits decide the number of data lines used for receiving data. 0h (R/W) = Data will be received on one data line, RXD0. 1h (R/W) = Data will be received on two data lines, RXD0 and RXD1. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

### 32.6.3.3 RX\_FRAME\_INFO Register (Offset = 6h) [Reset = 0h]

RX\_FRAME\_INFO is shown in [Figure 32-42](#) and described in [Table 32-44](#).

Return to the [Summary Table](#).

Receive frame control register

15-4	RESERVED	R	0h	Reserved
3-0	FRAME_TYPE	R	0h	<p>Received Frame Type This field indicates the type of non-ping frame that was successfully received last.</p> <p>Note: Ping frame reception does not update this field, we want to retain the last successful non-ping frame FRAME_TYPE and PING_FRAME_RCVD flag already conveys PING info to the user.</p> <p>0100b (R/W) = A DATA_1_WORD frame was received (16-bit data).            0101b (R/W) = A DATA_2_WORD frame was received (32-bit data).            0110b (R/W) = A DATA_4_WORD frame was received (64-bit data).            0111b (R/W) = A DATA_6_WORD frame was received (96-bit data).            0011b (R/W) = A DATA_N_WORD frame was received. The N_WORD field will determine the number of words (1 to 16) to be sent. The number of words received must equal the value programmed in RX_OPER_CTRL.N_WORDS.            1111b (R/W) = An error frame was received. This frame can be used during error conditions or any condition where the transmitter wants to signal the receiver for attention. However, the user software is at liberty to use this for any purpose.            0001b, 0010b, and 1000b through 1110b are Reserved and should not be used.</p> <p>Reset type: SYSRSn</p>

### 32.6.3.4 RX\_FRAME\_TAG\_UDATA Register (Offset = 7h) [Reset = 0h]

RX\_FRAME\_TAG\_UDATA is shown in [Figure 32-43](#) and described in [Table 32-45](#).

Return to the [Summary Table](#).

Receive frame tag and user data register

RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED				BUF_PTR_LOAD			
R-0h				R/W-0h			

**Table 32-51. RX\_BUF\_PTR\_LOAD Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3-0	BUF_PTR_LOAD	R/W	0h	Buffer Pointer Load. This is the value to be loaded into the receive word pointer when written. This is to allow software to force the receiver to start storing the received data starting at a specific location in the buffer. NOTE: The value of the CURR_BUF_PTR in the RX_BUF_PTR_STS will not get reflected immediately. This will take effect only when there is a valid receive operation with incoming clocks after (3 RXCLK + 3 SYCLK) cycles. Reset type: SYSRSn

### 32.6.3.11 RX\_BUF\_PTR\_STS Register (Offset = Fh) [Reset = 0h]

RX\_BUF\_PTR\_STS is shown in [Figure 32-50](#) and described in [Table 32-52](#).

Return to the [Summary Table](#).

Receive buffer pointer status register

### 32.6.3.21 RX\_LOCK\_CTRL Register (Offset = 1Eh) [Reset = 0h]

RX\_LOCK\_CTRL is shown in [Figure 32-60](#) and described in [Table 32-62](#).

Return to the [Summary Table](#).

Receive lock control register

**Figure 32-60. RX\_LOCK\_CTRL Register**

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED							LOCK
R-0h							R/W-0h

**Table 32-62. RX\_LOCK\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-1	RESERVED	R	0h	Reserved
0	LOCK	R/W	0h	Control Register Lock Enable bit This bit locks the contents of all the receive control registers that support a lock protection. Once locked, further writes will not take effect until SYSRS unlocks the register. Once set, further writes even to this bit will be ignored. 0h (R/W) = Receive control registers can be modified and are not locked. 1h (R/W) = Receive control registers are locked and cannot be modified until this bit is cleared by SYSRS. Any further writes to this bit are ignored. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

### 32.6.3.22 RX\_ECC\_DATA Register (Offset = 20h) [Reset = 0h]

RX\_ECC\_DATA is shown in [Figure 32-61](#) and described in [Table 32-63](#).

Return to the [Summary Table](#).

Receive ECC data register

**Figure 32-61. RX\_ECC\_DATA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA_HIGH																DATA_LOW															
R/W-0h																R/W-0h															

**Table 32-63. RX\_ECC\_DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DATA_HIGH	R/W	0h	Upper 16 bits of ECC Data Writing to this bitfield will cause the ECC logic to compute the ECC(SEC-DED) the entire 32-bit register and update TX_ECC_VAL register with the results. Software should write to these 16 bits of the register in a 32-bit write when needing to compute ECC for 32-bits for the full TX_ECC_DATA register. Reset type: SYSRSn
15-0	DATA_LOW	R/W	0h	Lower 16 bits of ECC Data Writing to this bitfield will cause the ECC logic to compute the ECC(SEC-DED) for these 16 bits and update the TX_ECC_VAL register with the results. Software should write to these register bits as a 16-bit write when needing to compute ECC for 16-bits. Reset type: SYSRSn

### 32.6.3.23 RX\_ECC\_VAL Register (Offset = 22h) [Reset = 0h]

RX\_ECC\_VAL is shown in [Figure 32-62](#) and described in [Table 32-64](#).

Return to the [Summary Table](#).

Receive ECC value register

**Figure 32-62. RX\_ECC\_VAL Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED		ECC_VAL					
R-0h		R/W-0h					

**Table 32-64. RX\_ECC\_VAL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	ECC_VAL	R/W	0h	ECC Value for SEC-DED check This field contains the ECC value to be used for SEC-DED either for 16-bit or 32-bit data in the RX_ECC_DATA register. Reset type: SYSRSn

### 32.6.3.24 RX\_ECC\_SEC\_DATA Register (Offset = 24h) [Reset = 0h]

RX\_ECC\_SEC\_DATA is shown in [Figure 32-63](#) and described in [Table 32-65](#).

Return to the [Summary Table](#).

Receive ECC corrected data register

**Figure 32-63. RX\_ECC\_SEC\_DATA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEC_DATA																															
R-0h																															

**Table 32-65. RX\_ECC\_SEC\_DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	SEC_DATA	R	0h	ECC Single Error Corrected Data The ECC corrected data will be available in this register. This value is valid only when there are no bit errors, or a single bit error was detected. Otherwise, the contents of this register are invalid and should not be used. Reset type: SYSRSn

### 32.6.3.25 RX\_ECC\_LOG Register (Offset = 26h) [Reset = 3h]

RX\_ECC\_LOG is shown in [Figure 32-64](#) and described in [Table 32-66](#).

Return to the [Summary Table](#).

Receive ECC log and status register

**Figure 32-64. RX\_ECC\_LOG Register**

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3	RX_CORE_STS	R	0h	Receiver Core Status bit This bit indicates the status of the receiver core. If this bit is set, the receiver should undergo a reset and subsequent resynchronization with the transmitter. This bit will be always be set when the receiver has detected and end of frame error or a frame type error. This bit can also be set if the receiver becomes corrupted due to noise on the signal lines. If the receiver has experienced a ping watchdog or frame watchdog timeout, this bit should be read to determine if the cause was due to a corrupt transaction, thus putting the receiver core into an unrecoverable state. Only a soft reset will reset the receiver core and thus reset this bit. 0h (R) The receiver core is operating normally. 1h (R) The receiver core has entered into an error state and should be reset. Reset type: SYSRSn
2-0	RESERVED	R	0h	Reserved

### 32.6.3.30 RX\_BUF\_BASE\_y Register (Offset = 40h + formula) [Reset = 0h]

RX\_BUF\_BASE\_y is shown in [Figure 32-69](#) and described in [Table 32-71](#).

Return to the [Summary Table](#).

Base address for receive data buffer

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

---

### Note

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this document. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMDR.

## 33.1 Introduction

The I2C module supports any slave or master I2C-compatible device. [Figure 33-1](#) shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

**Figure 33-1. Multiple I2C Modules Connected**

### 33.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers
  - Support for multiple slave-transmitters and master-receivers
  - Combined master transmit/receive and receive/transmit mode
  - Data transfer rate from 10 kbps up to 400 kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as slave
  - I2Cx\_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable and disable capability
- Free data format mode

### 33.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

### 33.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the master or the slave when performing data transfers. A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave. The I2C module supports the multi-master mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in [Figure 33-2](#). These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins both are bidirectional. They each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See the I2CCNT register in [Section 33.7](#) for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in [Section 33.7](#) for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

[Figure 33-2](#) shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

Figure 33-2. I2C Module Conceptual Block Diagram

### 33.1.5 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C master clock on the SCL pin. Figure 33-3 shows the clock generation diagram for I2C module.

Figure 33-3. Clocking Diagram for the I2C Module

#### Note

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7-12 MHz.

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$I2C \text{ Module Clock (Fmod)} = \frac{SYSCLK}{(I2CPSC + 1)} \tag{25}$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 33-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 33.1.6 for the master clock frequency equation.

### 33.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 33.1.5, when the I2C module is a master, the I2C module clock is divided down further to use as the master clock on the SCL pin. As shown in Figure 33-4, the shape of the master clock depends on two divide-down values:

- ICCL in I2CCLKL. For each master clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCLKH. For each master clock cycle, ICCH determines the amount of time the signal is high.

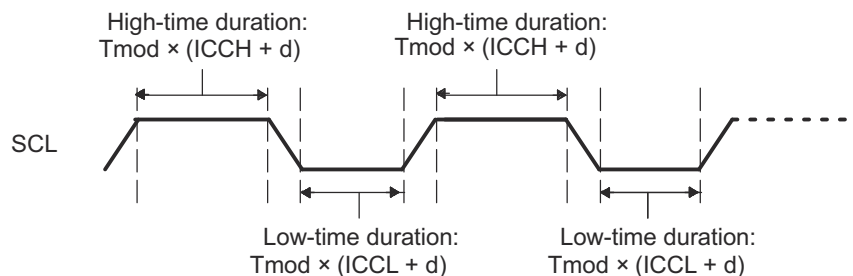

Figure 33-4. Roles of the Clock Divide-Down Values (ICCL and ICCH)

#### 33.1.6.1 Formula for the Master Clock Period

The master clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Master Clock period (Tmst)} = \frac{[(ICCH + d) + (ICCL + d)]}{I2C \text{ Module Clock (Fmod)}} \tag{26}$$

where d depends on the divide-down value IPSC, as shown in Table 33-1. IPSC is described in the I2CPSC register.

Table 33-1. Dependency of Delay d on the Divide-Down Value IPSC

IPSC	d
0	7
1	6
Greater than 1	5

### 33.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

#### Note

The GPIO configuration register GPyODR must be set to normal mode when the I2C is used. The open-drain operation for I2C is managed by the I2C module

### 33.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

#### 33.3.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of  $V_{DD}$ . For details, see your device-specific data sheet.

#### 33.3.2 Data Validity

The data on SDA must be stable during the high period of the clock (see [Figure 33-5](#)). The high or low state of the data line, SDA, should change only when the clock signal on SCL is low.

Figure 33-5. Bit Transfer on the I2C bus

#### 33.3.3 Operating Modes

The I2C module has four basic operating modes to support data transfers as a master and as a slave. See [Table 33-2](#) for the names and descriptions of the modes.

If the I2C module is a master, it begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. To receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, it begins as a slave-receiver and typically sends acknowledgment when it recognizes its slave address from a master. If the master will be sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

**Table 33-2. Operating Modes of the I2C Module**

Operating Mode	Description
Slave-receiver mode	<p>The I2C module is a slave and receives data from a master.</p> <p>All slaves begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See <a href="#">Section 33.3.7</a> for more details.</p>
Slave-transmitter mode	<p>The I2C module is a slave and transmits data to a master.</p> <p>This mode can be entered only from the slave-receiver mode; the I2C module must first receive a command from the master. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its slave-transmitter mode if the slave address byte is the same as its own address (in I2COAR) and the master has transmitted R/ <math>\bar{W}</math> = 1. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See <a href="#">Section 33.3.7</a> for more details.</p>
Master-receiver mode	<p>The I2C module is a master and receives data from a slave.</p> <p>This mode can be entered only from the master-transmitter mode; the I2C module must first transmit a command to the slave. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its master-receiver mode after transmitting the slave address byte and R/ <math>\bar{W}</math> = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.</p>
Master-transmitter mode	<p>The I2C module is a master and transmits control information and data to a slave.</p> <p>All masters begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.</p>

To summarize, SCL will be held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Slave-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Slave-transmitter mode.

I2C slave nodes have to accept and provide data when the I2C master node requests it.

- To release SCL in slave-receiver mode, read data from I2CDRR.
- To release SCL in slave-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

**Table 33-3. Master-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR**

RM	STT	STP	Bus Activity <sup>(1)</sup>	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D.	START condition, slave address, n data bytes (n = value in I2CCNT)
0	1	1	S-A-D..(n)..D-P	START condition, slave address, n data bytes, STOP condition (n = value in I2CCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D.	Repeat mode transfer: START condition, slave address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

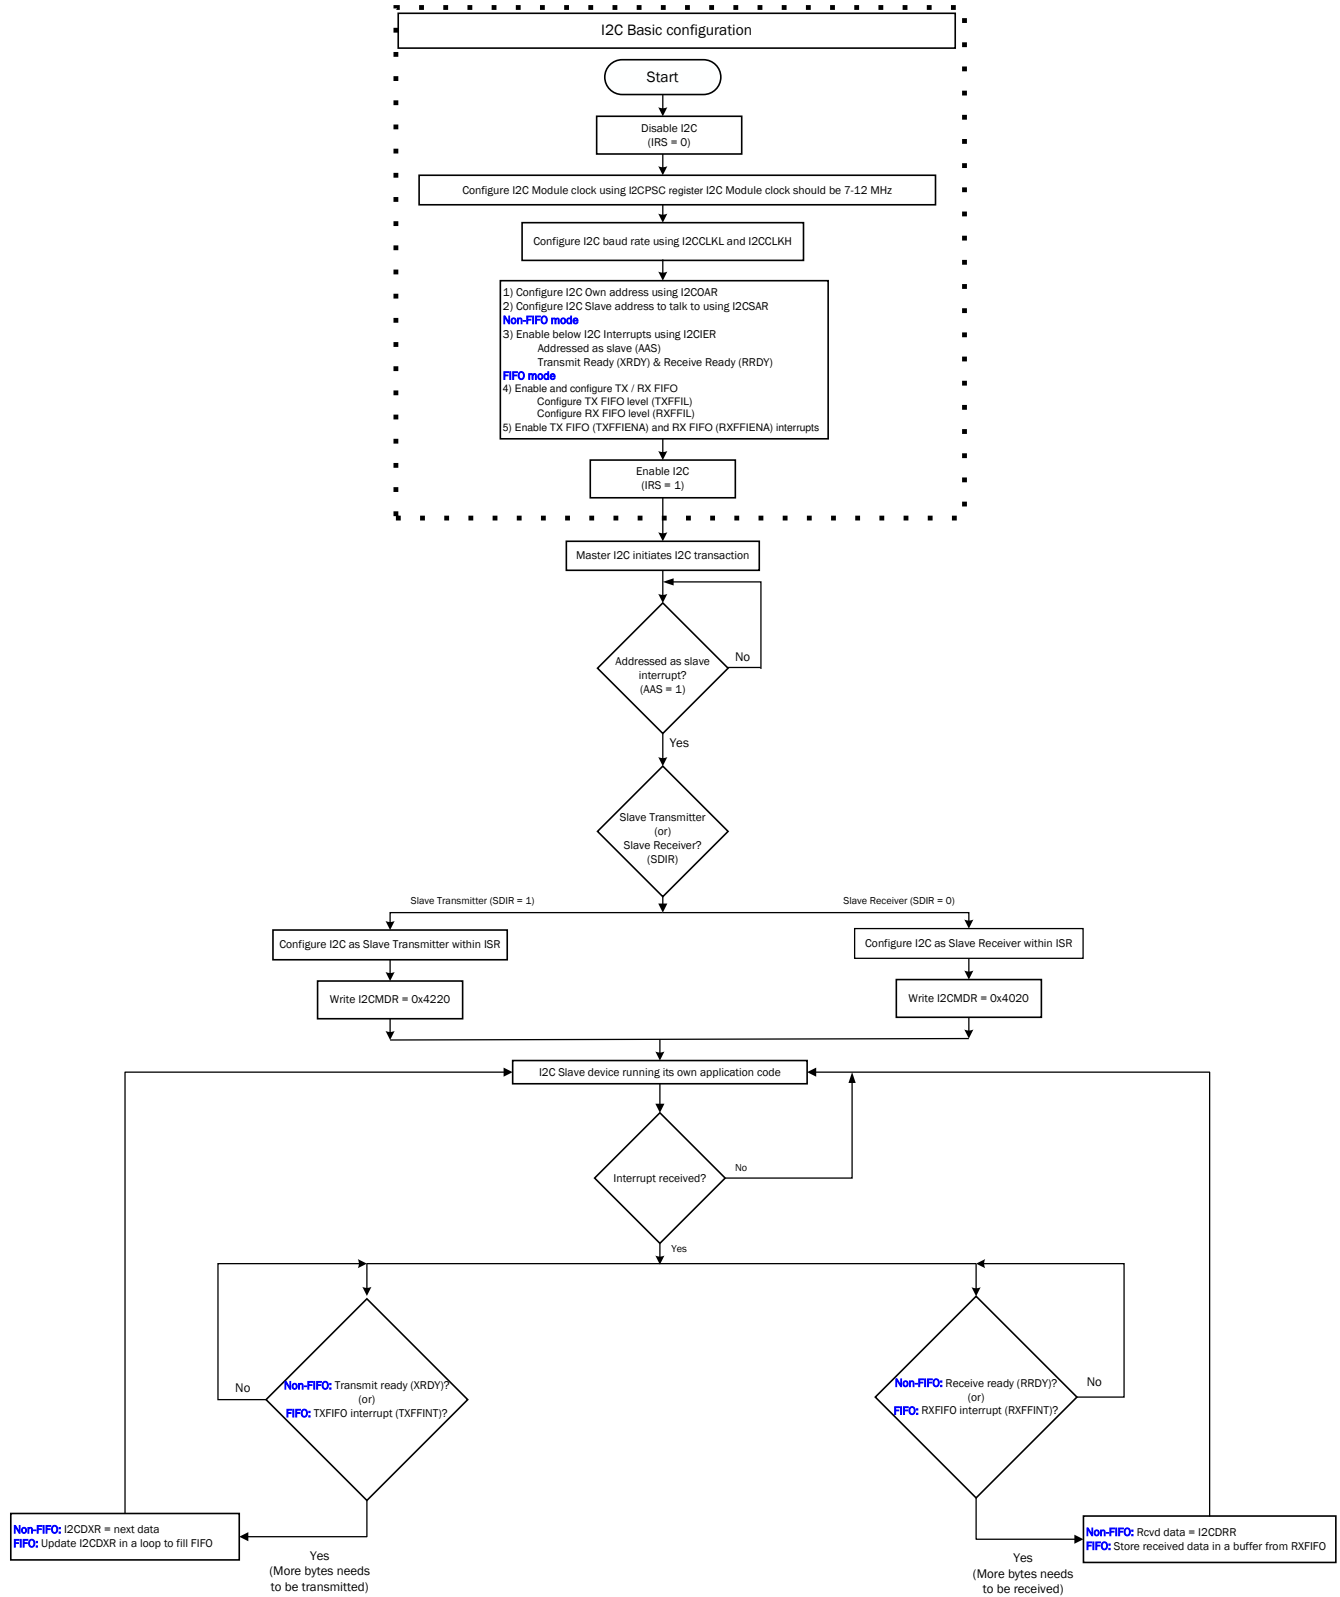

Figure 33-6. I2C Slave TX / RX Flowchart

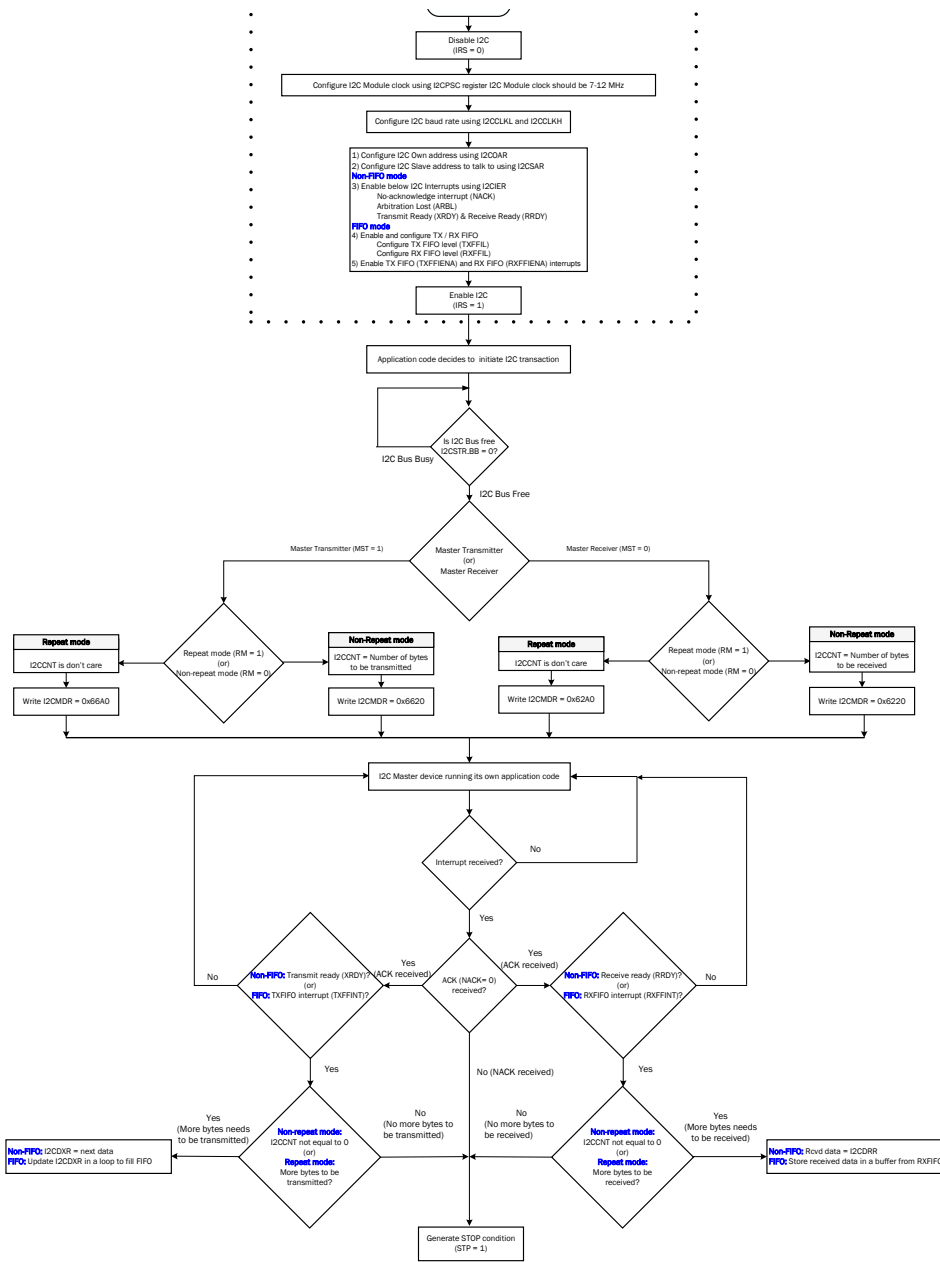

Figure 33-7. I2C Master TX / RX Flowchart

### 33.3.4 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a master on the I2C bus. As shown in [Figure 33-8](#):

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

**Figure 33-8. I2C Module START and STOP Conditions**

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and its bits (including MST, STT, and STP), see [Section 33.7](#).

The I2C peripheral cannot detect a START or STOP condition while it is in reset (IRS = 0). The BB bit will remain in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1) the BB bit will not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, users can ensure that at least one START or STOP condition will have occurred on the I2C bus and been captured by the BB bit. After this period, the BB bit will correctly reflect the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers ensures that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

### 33.3.5 Non-repeat Mode versus Repeat Mode

#### Non-repeat mode:

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted (or) received.
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit doesn't get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

---

#### Note

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C state machine expects to transmit (or) receive 65536 bytes and not 0 bytes.

---

#### Repeat mode:

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents don't determine the number of bytes to be transmitted (or) received.
- Number of bytes to be transmitted (or) received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte.

---

#### Note

Once you start I2C transaction in non-repeat mode (or) repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

---

### 33.3.6 Serial Data Formats

Figure 33-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 33-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 33-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 33-10 through Figure 33-12 and described in the paragraphs that follow the figures.

**Note**

In Figure 33-9 through Figure 33-12, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

**Figure 33-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)**

#### 33.3.6.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 33-10), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/  $\bar{W}$  bit. R/  $\bar{W}$  determines the direction of the data:

- R/  $\bar{W}$  = 0: The I2C master writes (transmits) data to the addressed slave. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/  $\bar{W}$  = 1: The I2C master reads (receives) data from the slave. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

**Figure 33-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)**

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/  $\bar{W}$  bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

### 33.3.6.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 33-11) is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and R/ $\bar{W}$ . The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

**Figure 33-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)**

### 33.3.6.3 Free Data Format

The free data format can be enabled by setting I2CMDR.FDF = 1.

In this format (see Figure 33-12), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

**Figure 33-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)**

#### Note

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

**Table 33-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR**

MST	FDF	I2C Module State	Function of TRX
0	0	In slave mode but not free data format mode	TRX is a don't care. Depending on the command from the master, the I2C module responds as a receiver or a transmitter.
0	1	In slave mode and free data format mode	The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module:  TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	0	In master mode but not free data format mode	TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	1	In master mode and free data format mode	TRX = 0: The I2C module is a receiver. TRX = 1: The I2C module is a transmitter.

### 33.3.6.4 Using a Repeated START Condition

I2C master can communicate with multiple slave addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, and free data formats. Figure 33-13 shows a repeated START condition in the 7-bit addressing format.

**Figure 33-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)**

#### Note

In Figure 33-13, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMR.

### 33.3.7 Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. Figure 33-14 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL is held low by the device with the longest low period. The other devices that finish their low periods must wait for SCL to be released, before starting their high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

**Figure 33-14. Synchronization of Two I2C Clock Generators During Arbitration**

### 33.3.8 Arbitration

If two or more master-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 33-15 illustrates the arbitration procedure between two devices. The first master-transmitter that releases the SDA line high is overruled by another master-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, it switches to the slave-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

**Figure 33-15. Arbitration Procedure Between Two Master-Transmitters**

### 33.3.9 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

$$n = 8 * (\text{SYSCLK}) / (\text{I2C module clock (Fmod)})$$

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 33-16 shows the signal routing in digital loopback mode.

**Figure 33-16. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit**

#### Note

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

### 33.3.10 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. [Table 33-5](#) summarizes the various ways you can allow the I2C module to send a NACK bit.

**Table 33-5. Ways to Generate a NACK Bit**

I2C Module Condition	NACK Bit Generation Options
Slave-receiver modes	Allow an overrun condition (RSFULL = 1 in I2CSTR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Master-receiver mode AND Repeat mode (RM = 1 in I2CMDR)	Generate a STOP condition (STP = 1 in I2CMDR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Master-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR)	If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition If STP = 0, make STP = 1 to generate a STOP condition Reset the module (IRS = 0 in I2CMDR). = 1 to generate a STOP condition Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive

### 33.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in [Section 33.4.1](#).
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in [Section 33.4.2](#)

#### 33.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in [Table 33-6](#). As shown in [Figure 33-17](#), all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, its flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if it is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A\_ISR). The I2CINT1A\_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A\_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to it.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

**Table 33-6. Descriptions of the Basic I2C Interrupt Requests**

I2C Interrupt Request	Interrupt Source
XRDYINT	Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.
RRDYINT	Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.
ARDYINT	Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR. As an alternative to using ARDYINT, the CPU can poll the ARDY bit.
NACKINT	No-acknowledgment condition: The I2C module is configured as a master-transmitter and did not received acknowledgment from the slave-receiver. As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.
ARBLINT	Arbitration-lost condition: The I2C module has lost an arbitration contest with another master-transmitter. As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.
SCDINT	Stop condition detected: A STOP condition was detected on the I2C bus. As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.
AASINT	Addressed as slave condition: The I2C has been addressed as a slave device by another master on the I2C bus. As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.

**Figure 33-17. Enable Paths of the I2C Interrupt Requests**

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AASINT

The normal transmit interrupt timing makes it possible for stale data to remain in the transmit buffer if a transaction is aborted in the middle of a byte. To avoid this, set the FCM bit in the I2CEMDR register. When this bit is set, the transmit data ready interrupt is generated only when data is required for a bus transaction. In master mode, the interrupt is first generated when the ACK of the address byte is received. In slave mode, the interrupt is first generated when the address is matched. Further interrupts are generated when the data is ACKed. In this mode XRDY is asserted at the same time as the transmit ready interrupt.

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in [Figure 33-18](#) demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a slave-transmitter.

Slave Transmitter

Figure 33-18. Backwards Compatibility Mode and Forward Compatibility Bit, Slave Transmitter

### 33.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 33-19 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

Figure 33-19. I2C\_FIFO\_interrupt

### 33.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMODR). All status bits (in I2CSTR) are forced to their default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the  $\overline{\text{XRS}}$  pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the  $\overline{\text{XRS}}$  pin is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

## 33.6 Software

### 33.6.1 I2C Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/i2c

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 33.6.1.1 I2C Digital Loopback with FIFO Interrupts

FILE: i2c\_ex1\_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

This pattern is repeated forever.

#### *External Connections*

- None

#### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 33.6.1.2 I2C Loopback with Slave Receive Interrupt - CM

FILE: i2c\_ex1\_slave\_receive\_int.c

This program shows how to configure a receive interrupt on the slave module. This includes setting up the I2C0 module for loopback mode as well as configuring the master and slave modules. Loopback mode internally connects the master and slave data and clock lines together. The address of the slave module is set to a value so it can receive data from the master.

This is a 7-bit slave module address sent in the following format: [A6:A5:A4:A3:A2:A1:A0:RS]

A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

#### *External Connections*

- None

#### *Watch Variables*

- *ui32DataTx* - Data to send
- *ui32DataRx* - Received data
- *result* - Status of the I2C communication

#### 33.6.1.3 I2C EEPROM

FILE: i2c\_ex2\_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, *i2cMsgOut*. The data read back will be contained in the message structure *i2cMsgIn*.

### External Connections

- Connect external I2C EEPROM at address 0x50
- Connect DEVICE\_GPIO\_PIN\_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE\_GPIO\_PIN\_SCL on to external EEPROM SCL (serial clock) pin

### Watch Variables

- *i2cMsgOut* - Message containing data to write to EEPROM
- *i2cMsgIn* - Message containing data read from EEPROM

#### 33.6.1.4 I2C Digital External Loopback with FIFO Interrupts

FILE: i2c\_ex3\_external\_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

This pattern is repeated forever.

### External Connections

- Connect SCLA(DEVICE\_GPIO\_PIN\_SCL) to SCLB (DEVICE\_GPIO\_PIN\_SCLB)
- and SDAA(DEVICE\_GPIO\_PIN\_SDAA) to SDAB (DEVICE\_GPIO\_PIN\_SDAB)
- Connect DEVICE\_GPIO\_PIN\_LED1 to an LED used to depict data transfers.

### Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 33.6.1.5 I2C EEPROM

FILE: i2c\_ex4\_eeprom\_polling.c

This program will show how to perform different EEPROM write and read commands using I2C polling method. EEPROM used for this example is AT24C256.

### External Connections

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM  
SCL | DEVICE\_GPIO\_PIN\_SCL | SCL SDA | DEVICE\_GPIO\_PIN\_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

#### 33.6.1.6 I2C master slave communication using FIFO interrupts

FILE: i2c\_ex5\_master\_slave\_interrupt.c

This program shows how to use I2CA and I2CB modules in both master and slave configuration. This example uses I2C FIFO interrupts and doesn't use polling.

Example1: I2CA as Master Transmitter and I2CB working Slave Receiver  
Example2: I2CA as Master Receiver and I2CB working Slave Transmitter  
Example3: I2CB as Master Transmitter and I2CA working Slave Receiver  
Example4: I2CB as Master Receiver and I2CA working Slave Transmitter

\b External \b Connections on launchpad should be made as shown below \n Signal | I2CA | I2CB

SCL | DEVICE\_GPIO\_PIN\_SCLA | DEVICE\_GPIO\_PIN\_SCLB

SDA | DEVICE\_GPIO\_PIN\_SDAA | DEVICE\_GPIO\_PIN\_SDAB

*Watch Variables* in memory window

- *I2CA\_TXdata*
- *I2CA\_RXdata*
- *I2CB\_TXdata*
- *I2CB\_RXdata* stream for error checking

### 33.6.1.7 I2C EEPROM

FILE: i2c\_ex6\_eeprom\_interrupt.c

This program will shows how to perform different EEPROM write and read commands using I2C interrupts  
EEPROM used for this example is AT24C256

*External Connections*

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE\_GPIO\_PIN\_SCLA | SCL SDA | DEVICE\_GPIO\_PIN\_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

//Example 1: EEPROM Byte Write //Example 2: EEPROM Byte Read //Example 3: EEPROM word (16-bit)  
write //Example 4: EEPROM word (16-bit) read //Example 5: EEPROM Page write //Example 6: EEPROM word  
Paged read

*Watch Variables*

- *TX\_MsgBuffer* - Message buffer which stores the data to be transmitted
- *RX\_MsgBuffer* - Message buffer which stores the data to be received

## 33.7 I2C Registers

This section describes the C28x I2C Module Registers.

### 33.7.1 I2C Base Address Table (C28)

**Table 33-7. I2C Base Address Table (C28)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
I2caRegs	I2C_REGS	I2CA_BASE	0x0000_7300	YES	YES	-	-	YES
I2cbRegs	I2C_REGS	I2CB_BASE	0x0000_7340	YES	YES	-	-	YES

### 33.7.2 I2C\_REGS Registers

Table 33-8 lists the memory-mapped registers for the I2C\_REGS registers. All register offset addresses not listed in Table 33-8 should be considered as reserved locations and the register contents should not be modified.

**Table 33-8. I2C\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	I2COAR	I2C Own address		<a href="#">Go</a>
1h	I2CIER	I2C Interrupt Enable		<a href="#">Go</a>
2h	I2CSTR	I2C Status		<a href="#">Go</a>
3h	I2CCLKL	I2C Clock low-time divider		<a href="#">Go</a>
4h	I2CCLKH	I2C Clock high-time divider		<a href="#">Go</a>
5h	I2CCNT	I2C Data count		<a href="#">Go</a>
6h	I2CDRR	I2C Data receive		<a href="#">Go</a>
7h	I2CSAR	I2C Slave address		<a href="#">Go</a>
8h	I2CDXR	I2C Data Transmit		<a href="#">Go</a>
9h	I2CMDR	I2C Mode		<a href="#">Go</a>
Ah	I2CISRC	I2C Interrupt Source		<a href="#">Go</a>
Bh	I2CEMDR	I2C Extended Mode		<a href="#">Go</a>
Ch	I2CPSC	I2C Prescaler		<a href="#">Go</a>
20h	I2CFFTX	I2C FIFO Transmit		<a href="#">Go</a>
21h	I2CFFRX	I2C FIFO Receive		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 33-9 shows the codes that are used for access types in this section.

**Table 33-9. I2C\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

**Table 33-9. I2C\_REGS Access Type Codes  
(continued)**

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 33.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0h]

I2COAR is shown in [Figure 33-20](#) and described in [Table 33-10](#).

Return to the [Summary Table](#).

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used write 0s to bits 9-7.

**Figure 33-20. I2COAR Register**

15	14	13	12	11	10	9	8
RESERVED						OAR	
R-0h						R/W-0h	
7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	SDIR	R/W1C	0h	Slave direction bit Reset type: SYSRSn 0h (R/W) = I2C is not addressed as a slave transmitter. SDIR is cleared by one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - Digital loopback mode is enabled. - A START or STOP condition occurs on the I2C bus. 1h (R/W) = I2C is addressed as a slave transmitter.
13	NACKSNT	R/W1C	0h	NACK sent bit. This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Reset type: SYSRSn 0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset). 1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.
12	BB	R	0h	Bus busy bit. BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information Reset type: SYSRSn 0h (R/W) = Bus free. BB is cleared by any one of the following events: - The I2C module receives or transmits a STOP bit (bus free). - The I2C module is reset. 1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus.

**Table 33-12. I2CSTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	RSFULL	R	0h	<p>Receive shift register full bit.</p> <p>RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = Overrun detected</p>
10	XSMT	R	1h	<p>Transmit shift register empty bit.</p> <p>XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Underflow detected (empty)</p> <p>1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events:</p> <ul style="list-style-type: none"> <li>- Data is written to I2CDXR.</li> <li>- The I2C module is reset</li> </ul>
9	AAS	R	0h	<p>Addressed-as-slave bit</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the 7-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or by a slave address different from the I2C peripheral's own slave address.</p> <p>1h (R/W) = The I2C module has recognized its own slave address or an address of all zeros (general call).</p>
8	AD0	R	0h	<p>Address 0 bits</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = AD0 has been cleared by a START or STOP condition.</p> <p>1h (R/W) = An address of all zeros (general call) is detected.</p>

In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- It is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = The I2C module has completed the transmission of a byte.</p>

**Table 33-12. I2CSTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	SCD	R/W1C	0h	<p>Stop condition detected bit.</p> <p>SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit.</li> <li>- SCD is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = A STOP condition has been detected on the I2C bus.</p>
4	XRDY	R	1h	<p>Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data.</p> <p>FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSr). The CPU can poll XRDY or use the XRDY interrupt request. When in FIFO mode, use TXFFINT instead.</p> <p>FCM=1: XRDY is asserted only when next data is required it gets deasserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR.</p> <p>1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSr.</p> <p>XRDY is also forced to 1 when the I2C module is reset.</p>
3	RRDY	R/W1C	0h	<p>Receive-data-ready interrupt flag bit.</p> <p>When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request. When in FIFO mode, use RXFFINT instead.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.</li> <li>- RRDY is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.</p>
2	ARDY	R/W1C	0h	<p>Register-access-ready interrupt flag bit (only Applicable when the I2C module is in the master mode).</p> <p>ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- The I2C module starts using the current register contents.</li> <li>- ARDY is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = The registers are ready to be accessed.</p> <p>In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0).</p> <p>In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.</p>

**Table 33-12. I2CSTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	NACK	R/W1C	0h	<p>No-acknowledgment interrupt flag bit.</p> <p>NACK applies when the I2C module is a master transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK) from the slave receiver. The CPU can poll NACK or use the NACK interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- An acknowledge bit (ACK) has been sent by the slave receiver.</li> <li>- NACK is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received.</p> <p>Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment.</p>
0	ARBL	R/W1C	0h	<p>Arbitration-lost interrupt flag bit (only applicable when the I2C module is a master-transmitter).</p> <p>ARBL primarily indicates when the I2C module has lost an arbitration contest with another master/transmitter. The CPU can poll ARBL or use the ARBL interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- AL is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an</li> </ul> <p>AL interrupt. Emulator reads of the I2CISRC do not affect this bit.</p> <ul style="list-style-type: none"> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = Arbitration lost. AL is set by any one of the following events:</p> <ul style="list-style-type: none"> <li>- The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously.</li> <li>- The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1.</li> </ul> <p>When AL becomes 1, the MST and STP bits of I2CMDBR are cleared, and the I2C module becomes a slave-receiver.</p>

### 33.7.2.4 I2CCLKL Register (Offset = 3h) [Reset = 0h]

To produce the high time duration of the master clock, the period of the module clock is multiplied by (ICCL + d). d is an adjustment factor based on the prescaler. See the Clock Divider Registers section of the Introduction for details. Note: These bits must be set to a non-zero value for proper I2C clock generation. Reset type: SYSRSn

### 33.7.2.6 I2CCNT Register (Offset = 5h) [Reset = 0h]

I2CCNT is shown in [Figure 33-25](#) and described in [Table 33-15](#).

Return to the [Summary Table](#).

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a master receiver. In the repeat mode (RM = 1), I2CCNT is not used.

The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the master mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

I2CCNT indicates the number of data bytes to transfer or receive.</p> <p>If a STOP condition is specified (STP=1) then I2CCNT will decrease after each byte is sent until it reaches zero, which in turn will generate a STOP condition.</p> <p>The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1.</p> <p>The start value loaded to the internal data counter is 65536.</p> <p>The start value loaded to internal data counter is 1-65535.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = data count value is 65536</p> <p>1h (R/W) = data count value is 1</p> <p>2h (R/W) = data count value is 2</p> <p>FFFFh (R/W) = data count value is 65535</p>

### 33.7.2.7 I2CDRR Register (Offset = 6h) [Reset = 0h]

I2CDRR is shown in [Figure 33-26](#) and described in [Table 33-16](#).

Return to the [Summary Table](#).

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.

If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.

When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

### 33.7.2.8 I2CSAR Register (Offset = 7h) [Reset = 3FFh]

I2CSAR is shown in [Figure 33-27](#) and described in [Table 33-17](#).

Return to the [Summary Table](#).

The I2C slave address register (I2CSAR) is a 16-bit register for storing the next slave address that will be transmitted by the I2C module when it is a master. The SAR field of I2CSAR contains a 7-bit or 10-bit slave address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a slave, or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used write 0s to bits 9-7.

15-10	RESERVED	R	0h	Reserved
9-0	SAR	R/W	3FFh	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit slave address that the I2C module transmits when it is in the master-transmitter mode. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit slave address that the I2C module transmits when it is in the master transmitter mode. Reset type: SYSRSn

### 33.7.2.9 I2CDXR Register (Offset = 8h) [Reset = 0h]

I2CDXR is shown in [Figure 33-28](#) and described in [Table 33-18](#).

Return to the [Summary Table](#).

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.

When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

15	NACKMOD	R/W	0h	<p>NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the slave-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit.</p> <p>In the master-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit</p> <p>1h (R/W) = In either slave-receiver or master-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared.</p> <p>Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.</p>
14	FREE	R/W	0h	<p>This bit controls the action taken by the I2C module when a debugger breakpoint is encountered.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = When I2C module is master: If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops.</p> <p>When I2C module is slave: A breakpoint forces the I2C module to stop when the current transmission/reception is complete.</p> <p>1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.</p>
13	STT	R/W	0h	<p>START condition bit (only applicable when the I2C module is a master). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the master mode, STT is automatically cleared after the START condition has been generated.</p> <p>1h (R/W) = In the master mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus</p>
12	RESERVED	R	0h	Reserved

**Table 33-19. I2CMDR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	<p>STOP condition bit (only applicable when the I2C module is a master).</p> <p>In the master mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions.</p> <p>Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STP is automatically cleared after the STOP condition has been generated</p> <p>1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.</p>
10	MST	R/W	0h	<p>Master mode bit.</p> <p>MST determines whether the I2C module is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I2C master generates a STOP condition</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Slave mode. The I2C module is a slave and receives the serial clock from the master.</p> <p>1h (R/W) = Master mode. The I2C module is a master and generates the serial clock on the SCL pin.</p>
9	TRX	R/W	0h	<p>Transmitter mode bit.</p> <p>When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin.</p> <p>1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.</p>
8	XA	R/W	0h	<p>Expanded address enable bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit slave addresses (from bits 6-0 of I2CSAR), and its own slave address has 7 bits (bits 6-0 of I2COAR).</p> <p>1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit slave addresses (from bits 9-0 of I2CSAR), and its own slave address has 10 bits (bits 9-0 of I2COAR).</p>
7	RM	R/W	0h	<p>Repeat mode bit (only applicable when the I2C module is a master-transmitter).</p> <p>The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module.</p> <p>1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.</p>

**Table 33-19. I2CMDR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	DLB	R/W	0h	Digital loopback mode bit. Reset type: SYSRSn 0h (R/W) = Digital loopback mode is disabled. 1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the MST bit must be 1. In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: $n = ((I2C \text{ input clock frequency} / \text{module clock frequency}) \times 8)$ The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR. Note: The free data format (FDF = 1) is not supported in the digital loopback mode.
5	IRS	R/W	0h	I2C module reset bit. Reset type: SYSRSn 0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values. 1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.
4	STB	R/W	0h	START byte mode bit. This bit is only applicable when the I2C module is a master. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C module is a slave, it ignores a START byte from a master, regardless of the value of the STB bit. Reset type: SYSRSn 0h (R/W) = The I2C module is not in the START byte mode. 1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates: <ol style="list-style-type: none"> <li>1. A START condition</li> <li>2. A START byte (0000 0001b)</li> <li>3. A dummy acknowledge clock pulse</li> <li>4. A repeated START condition</li> </ol> Then, as normal, the I2C module sends the slave address that is in I2CSAR.
3	FDF	R/W	0h	Free data format mode bit. Reset type: SYSRSn 0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit. 1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5. The free data format is not supported in the digital loopback mode (DLB=1).
2-0	BC	R/W	0h	Bit count bits. BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits. Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified Reset type: SYSRSn 0h (R/W) = 8 bits per data byte 1h (R/W) = 1 bit per data byte 2h (R/W) = 2 bits per data byte 3h (R/W) = 3 bits per data byte 4h (R/W) = 4 bits per data byte 5h (R/W) = 5 bits per data byte 6h (R/W) = 6 bits per data byte 7h (R/W) = 7 bits per data byte

### 33.7.2.11 I2CISRC Register (Offset = Ah) [Reset = 0h]

I2CISRC is shown in [Figure 33-30](#) and described in [Table 33-20](#).

Return to the [Summary Table](#).

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

**Figure 33-30. I2CISRC Register**

15	14	13	12	11	10	9	8
RESERVED				WRITE_ZEROS			
R-0h				R/W-0h			
7	6	5	4	3	2	1	0
RESERVED				INTCODE			
R-0h				R-0h			

**Table 33-20. I2CISRC Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11-8	WRITE_ZEROS	R/W	0h	TI internal testing bits These reserved bit locations should always be written as zeros. Reset type: SYSRSn
7-3	RESERVED	R	0h	Reserved
2-0	INTCODE	R	0h	Interrupt code bits. The binary code in INTCODE indicates the event that generated an I2C interrupt. A CPU read will clear this field. If another lower priority interrupt is pending and enabled, the value corresponding to that interrupt will then be loaded. Otherwise, the value will stay cleared. The interrupt events below are listed in descending order of priority. That is INTCODE 1 (Arbitration lost) has the highest priority and INTCODE 7 (Addressed as slave) has the lowest priority. In the case of an arbitration lost, a no-acknowledgment condition detected, or a stop condition detected, a CPU read will also clear the associated interrupt flag bit in the I2CSTR register. Emulator reads will not affect the state of this field or of the status bits in the I2CSTR register. Reset type: SYSRSn 0h (R/W) = None 1h (R/W) = Arbitration lost 2h (R/W) = No-acknowledgment condition detected 3h (R/W) = Registers ready to be accessed 4h (R/W) = Receive data ready 5h (R/W) = Transmit data ready 6h (R/W) = Stop condition detected 7h (R/W) = Addressed as slave

### 33.7.2.12 I2CEMDR Register (Offset = Bh) [Reset = 1h]

I2CEMDR is shown in [Figure 33-31](#) and described in [Table 33-21](#).

Return to the [Summary Table](#).

I2C Extended Mode

**Figure 33-31. I2CEMDR Register**

**Table 33-21. I2CEMDR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	FCM	R/W	0h	Forward Compatibility mode. This bit when programmed brings the functionality of Tx request only when Tx data required regardless of data status in Tx buffer for non-FIFO mode. This register affects the XRDY behavior hence needs to be set after releasing the IRS (I2CMDR[5]). Reset type: SYSRSn 0h (R/W) = Legacy functionality of requesting Tx data upon buffer copy to shift register or upon start condition is active. Stale data is reused after illegal start, ARB Lost, NACK conditions. 1h (R/W) = New functionality of requesting data only upon ACK (address/data) is active.
0	BC	R/W	1h	Backwards compatibility mode. This bit affects the timing of the transmit status bits (XRDY and XSMT) in the I2CSTR register when in slave transmitter mode. Reset type: SYSRSn 0h (R/W) = See the "Backwards Compatibility Mode Bit, Slave Transmitter" Figure for details. 1h (R/W) = See the "Backwards Compatibility Mode Bit, Slave Transmitter" Figure for details.

### 33.7.2.13 I2CPSC Register (Offset = Ch) [Reset = 0h]

I2CPSC is shown in [Figure 33-32](#) and described in [Table 33-22](#).

Return to the [Summary Table](#).

The I2C prescaler register (I2CPSC) is a 16-bit register (see [Figure 14-21](#)) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.

IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

**Figure 33-32. I2CPSC Register**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	IPSC	R/W	0h	I2C prescaler divide-down value. IPSC determines how much the CPU clock is divided to create the module clock of the I2C module: module clock frequency = I2C input clock frequency / (IPSC + 1) Note: IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). Reset type: SYSRSn

### 33.7.2.14 I2CFFTX Register (Offset = 20h) [Reset = 0h]

I2CFFTX is shown in [Figure 33-33](#) and described in [Table 33-23](#).

Return to the [Summary Table](#).

The I2C transmit FIFO register (I2CFFTX) is a 16-bit register that contains the I2C FIFO mode enable bit as well as the control and status bits for the transmit FIFO mode of operation on the I2C peripheral.

**Figure 33-33. I2CFFTX Register**

15	14	13	12	11	10	9	8	
RESERVED	I2CFFEN	TXFFRST	TXFFST					
R-0h	R/W-0h	R/W-0h	R-0h

TXFFINT	TXFFINTCLR	TXFFIENA	TXFFIL					
R-0h	R-0/W1S-0h	R/W-0h	R/W-0h					

**Table 33-23. I2CFFTX Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	I2CFFEN	R/W	0h	I2C FIFO mode enable bit. This bit must be enabled for either the transmit or the receive FIFO to operate correctly. Reset type: SYSRSn 0h (R/W) = Disable the I2C FIFO mode. 1h (R/W) = Enable the I2C FIFO mode.
13	TXFFRST	R/W	0h	Transmit FIFO Reset Reset type: SYSRSn 0h (R/W) = Reset the transmit FIFO pointer to 0000 and hold the transmit FIFO in the reset state. 1h (R/W) = Enable the transmit FIFO operation.
12-8	TXFFST	R	0h	Contains the status of the transmit FIFO: xxxxx Transmit FIFO contains xxxxx bytes. 00000 Transmit FIFO is empty. Note: Since these bits are reset to zero, the transmit FIFO interrupt flag will be set when the transmit FIFO operation is enabled and the I2C is taken out of reset. This will generate a transmit FIFO interrupt if enabled. To avoid any detrimental effects from this, write a one to the TXFFINTCLR once the transmit FIFO operation is enabled and the I2C is taken out of reset. Reset type: SYSRSn
7	TXFFINT	R	0h	Transmit FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the TXFFINTCLR bit. If the TXFFIENA bit is set, this bit will generate an interrupt when it is set. Reset type: SYSRSn 0h (R/W) = Transmit FIFO interrupt condition has not occurred. 1h (R/W) = Transmit FIFO interrupt condition has occurred.
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO Interrupt Flag Clear Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a 0. 1h (R/W) = Writing a 1 to this bit clears the TXFFINT flag.
5	TXFFIENA	R/W	0h	Transmit FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = Disabled. TXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. TXFFINT flag does generate an interrupt when set.

**Table 33-23. I2CFFTX Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	Transmit FIFO interrupt level. These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

### 33.7.2.15 I2CFFRX Register (Offset = 21h) [Reset = 0h]

I2CFFRX is shown in [Figure 33-34](#) and described in [Table 33-24](#).

Return to the [Summary Table](#).

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

**Figure 33-34. I2CFFRX Register**

15	14	13	12	11	10	9	8	
RESERVED		RXFFRST	RXFFST					
R-0h		R/W-0h	R-0h					
7	6	5	4	3	2	1	0	
RXFFINT	RXFFINTCLR	RXFFIENA	RXFFIL					
R-0h	R-0/W1S-0h	R/W-0h	R/W-0h					

**Table 33-24. I2CFFRX Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	RXFFRST	R/W	0h	I2C receive FIFO reset bit Reset type: SYSRSn 0h (R/W) = Reset the receive FIFO pointer to 0000 and hold the receive FIFO in the reset state. 1h (R/W) = Enable the receive FIFO operation.
12-8	RXFFST	R	0h	Contains the status of the receive FIFO: xxxxx Receive FIFO contains xxxxx bytes 00000 Receive FIFO is empty. Reset type: SYSRSn
7	RXFFINT	R	0h	Receive FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the RXFFINTCLR bit. If the RXFFIENA bit is set, this bit will generate an interrupt when it is set Reset type: SYSRSn 0h (R/W) = Receive FIFO interrupt condition has not occurred. 1h (R/W) = Receive FIFO interrupt condition has occurred.
6	RXFFINTCLR	R-0/W1S	0h	Receive FIFO interrupt flag clear bit. Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a zero. 1h (R/W) = Writing a 1 to this bit clears the RXFFINT flag.
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable bit. Reset type: SYSRSn 0h (R/W) = Disabled. RXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. RXFFINT flag does generate an interrupt when set.
4-0	RXFFIL	R/W	0h	Receive FIFO interrupt level. These bits set the status level that will set the receive interrupt flag. When the RXFFST4-0 bits reach a value equal to or greater than these bits, the RXFFINT flag is set. This will generate an interrupt if the RXFFIENA bit is set. Note: Since these bits are reset to zero, the receive FIFO interrupt flag will be set if the receive FIFO operation is enabled and the I2C is taken out of reset. This will generate a receive FIFO interrupt if enabled. To avoid this, modify these bits on the same instruction as or prior to setting the RXFFRST bit. Because the I2C on this device has a 16-level receive FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

## 34.1 Introduction

This device provides up to two high-speed multichannel buffered serial ports (McBSPs) that allow direct interface to codecs and other devices in a system. The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in [Figure 34-1](#).

Data is communicated to devices interfaced with the McBSP via the data transmit (DX) pin for transmission and via the data receive (DR) pin for reception. Control information in the form of clocking and frame synchronization is communicated via the following pins: CLKX (transmit clock), CLKR (receive clock), FSX (transmit frame synchronization), and FSR (receive frame synchronization).

The CPU and the DMA controller communicate with the McBSP through 16-bit wide registers accessible via the internal peripheral bus. The CPU or the DMA controller writes the data to be transmitted to the data transmit registers (DXR1, DXR2). Data written to the DXRs is shifted out to the DX pin via the transmit shift registers (XSR1, XSR2). Similarly, receive data on the DR pin is shifted into the receive shift registers (RSR1, RSR2) and copied into the receive buffer registers (RBR1, RBR2). The contents of the receive buffer registers (RBRs) is then copied to the data receive registers (DRRs), which can be read by the CPU or the DMA controller. This allows simultaneous movement of internal and external data communications.

If the serial word length is 8 bits, 12 bits, or 16 bits, the DRR2, RBR2, RSR2, DXR2, and XSR2 registers are not used (written, read, or shifted) For larger word lengths, these registers are needed to hold the most significant bits.

The frame and clock loop-back is implemented at chip level to enable CLKX and FSX to drive CLKR and FSR. If the loop-back is enabled, the CLKR and FSR get their signals from the CLKX and FSX pads; instead of the CLKR and FSR pins.

### 34.1.1 MCBSP Related Collateral

#### Foundational Materials

- [C2000 Academy - Communications](#)

### 34.1.2 Features of the McBSPs

The McBSPs feature:

- Full-duplex communication
- Double-buffered transmission and triple-buffered reception, allowing a continuous data stream
- Independent clocking and framing for reception and transmission
- The capability to send interrupts to the CPU and to send DMA events to the DMA controller
- 128 channels for transmission and reception
- Multichannel selection modes that enable or disable block transfers in each of the channels
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices
- Support for external generation of clock signals and frame-synchronization signals
- A programmable sample rate generator for internal generation and control of clock signals and frame-synchronization signals
- Programmable polarity for frame-synchronization pulses and clock signals
- Direct interface to:
  - T1/E1 framers
  - IOM-2 compliant devices
  - AC97-compliant devices (the necessary multiphase frame capability is provided)
  - I2S compliant devices
  - SPI devices

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits

---

**Note**

A value of the chosen data size is referred to as a *serial word* or *word* throughout the McBSP chapter. Elsewhere, *word* is used to describe a 16-bit value.

---

- $\mu$ -law and A-law companding
- The option of transmitting/receiving 8-bit data with the LSB first
- Status bits for flagging exception/error conditions
- ABIS mode is not supported

### 34.1.3 McBSP Pins/Signals

Table 34-1 describes the McBSP interface pins and some internal signals.

**Table 34-1. McBSP Interface Pins/Signals**

McBSP-A Pin	McBSP-B Pin	Type	Description
MCLKRA	MCLKRB	I/O	Supplies or reflects the receive clock; supplies the input clock of the sample rate generator
MCLKXA	MCLKXB	I/O	Supplies or reflects the transmit clock; supplies the input clock of the sample rate generator
MDRA	MDRB	I	Serial data receive pin
MDXA	MDXB	O	Serial data transmit pin
MFSRA	MFSRB	I/O	Supplies or reflects the receive frame-sync signal; controls sample rate generator synchronization when GSYNC = 1 (see Section 34.4.3)
MFSXA	MFSXB	I/O	Supplies or reflects the transmit frame-sync signal
<b>CPU Interrupt Signals</b>			
MRINT			Receive interrupt to CPU
MXINT			Transmit interrupt to CPU
<b>DMA Events</b>			
REVT			Receive synchronization event to DMA
XEVT			Transmit synchronization event to DMA

#### 34.1.3.1 McBSP Generic Block Diagram

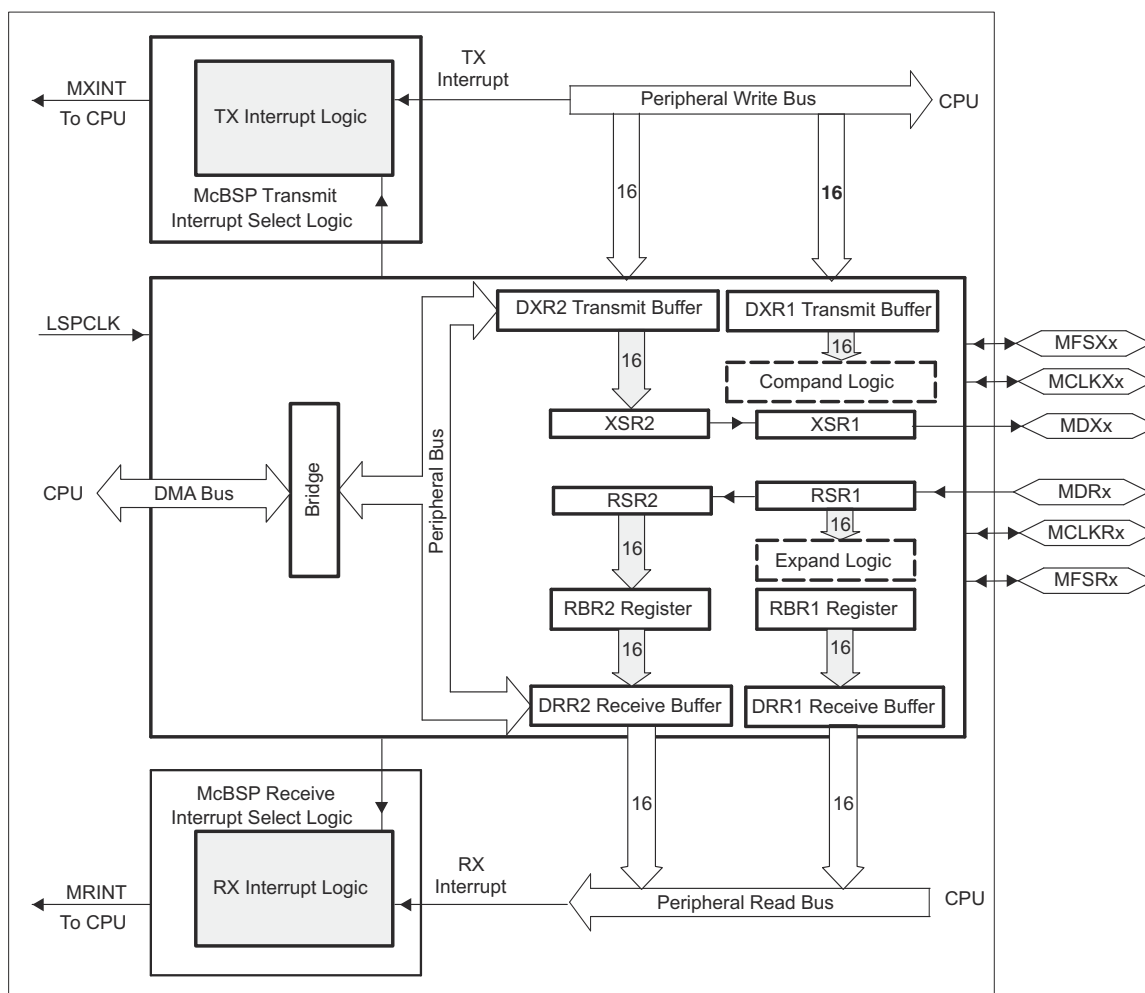

The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 34-1. The figure and the text in this section use generic pin names.

### 34.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

A. Not available in all devices. See the device-specific data sheet

**Figure 34-1. Conceptual Block Diagram of the McBSP**

### 34.3 McBSP Operation

This section addresses the following topics:

- Data transfer process
- Companding (compressing and expanding) data
- Clocking and framing data
- Frame phases
- McBSP reception
- McBSP transmission
- Interrupts and DMA events generated by McBSPs

#### 34.3.1 Data Transfer Process of McBSPs

Figure 34-2 shows a diagram of the McBSP data transfer paths. The McBSP receive operation is triple-buffered, and transmit operation is double-buffered. The use of registers varies, depending on whether the defined length of each serial word is 16 bits.

**Figure 34-2. McBSP Data Transfer Paths**

### 34.3.1.1 Data Transfer Process for Word Length of 8, 12, or 16 Bits

If the word length is 16 bits or smaller, only one 16-bit register is needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are not used (written, read, or shifted).

Receive data arrives on the DR pin and is shifted into receive shift register 1 (RSR1). Once a full word is received, the content of RSR1 is copied to the receive buffer register 1 (RBR1), that is, if RBR1 is not full with previous data. RBR1 is then copied to the data receive register 1 (DRR1), unless the previous content of DRR1 has not been read by the CPU or the DMA controller. If the companding feature of the McBSP is implemented, the required word length is 8 bits and receive data is expanded into the appropriate format before being passed from RBR1 to DRR1. For more details about reception, see [Section 34.3.5](#).

Transmit data is written by the CPU or the DMA controller to the data transmit register 1 (DXR1). If there is no previous data in the transmit shift register (XSR1), the value in DXR1 is copied to XSR1; otherwise, DXR1 is copied to XSR1 when the last bit of the previous data is shifted out on the DX pin. If selected, the companding module compresses 16-bit data into the appropriate 8-bit format before passing it to XSR1. After transmit frame synchronization, the transmitter begins shifting bits from XSR1 to the DX pin. For more details about transmission, see [Section 34.3.6](#).

### 34.3.1.2 Data Transfer Process for Word Length of 20, 24, or 32 Bits

If the word length is larger than 16 bits, two 16-bit registers are needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are needed to hold the most significant bits.

Receive data arrives on the DR pin and is shifted first into RSR2 and then into RSR1. Once the full word is received, the contents of RSR2 and RSR1 are copied to RBR2 and RBR1, respectively, if RBR1 is not full. Then the contents of RBR2 and RBR1 are copied to DRR2 and DRR1, respectively, unless the previous content of DRR1 has not been read by the CPU or the DMA controller. The CPU or the DMA controller must read data from DRR2 first and then from DRR1. When DRR1 is read, the next RBR-to-DRR copy occurs. For more details about reception, see [Section 34.3.5](#).

For transmission, the CPU or the DMA controller must write data to DXR2 first and then to DXR1. When new data arrives in DXR1, if there is no previous data in XSR1, the contents of DXR2 and DXR1 are copied to XSR2 and XSR1, respectively; otherwise, the contents of the DXRs are copied to the XSRs when the last bit of the previous data is shifted out on the DX pin. After transmit frame synchronization, the transmitter begins shifting bits from the XSRs to the DX pin. For more details about transmission, see [Section 34.3.6](#).

## 34.3.2 Companding (Compressing and Expanding) Data

Companding (COMpressing and exPANDING) hardware allows compression and expansion of data in either  $\mu$ -law or A-law format. The companding standard employed in the United States and Japan is  $\mu$ -law. The European companding standard is referred to as A-law. The specifications for  $\mu$ -law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and  $\mu$ -law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The  $\mu$ -law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 34-3 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or  $\mu$ -law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to two's complement format.

**Figure 34-3. Companding Processes**

### 34.3.2.1 Companding Formats

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The receive sign-extension and justification mode specified in RJUST is ignored when companding is used.

For transmission using  $\mu$ -law compression, the 14 data bits must be left-justified in DXR1 with the remaining two low-order bits filled with 0s as shown in Figure 34-4.

**Figure 34-4.  $\mu$ -Law Transmit Data Companding Format**

For transmission using A-law compression, the 13 data bits must be left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 34-5.

**Figure 34-5. A-Law Transmit Data Companding Format**

### 34.3.2.2 Capability to Compand Internal Data

If the McBSP is unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. This can be used to:

- Convert linear to the appropriate  $\mu$ -law or A-law format
- Convert  $\mu$ -law or A-law to the linear format
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 34-6 shows two methods by which the McBSP can compand internal data. Data paths for these two methods are used to indicate:

- When both the transmit and receive sections of the serial port are reset, DRR1 and DXR1 are connected internally through the companding logic. Values from DXR1 are compressed, as selected by XCOMPAND, and then expanded, as selected by RCOMPAND. RRDY and XRDY bits are not set. However, data is available in DRR1 within four CPU clocks after being written to DXR1.

The advantage of this method is its speed. The disadvantage is that there is no synchronization available to the CPU and DMA to control the flow. DRR1 and DXR1 are internally connected if the (X/R)COMPAND bits are set to 10b or 11b (compand using  $\mu$ -law or A-law).

- The McBSP is enabled in digital loopback mode with companding appropriately enabled by RCOMPAND and XCOMPAND. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or

synchronization events (REVT and XEVT) allow synchronization of the CPU or DMA to these conversions, respectively. Here, the time for this companding depends on the serial bit rate selected.

Figure 34-6. Two Methods by Which the McBSP Can Compand Internal Data

### 34.3.2.3 Reversing Bit Order: Option to Transfer LSB First

Generally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits, and LSB-first ordering is done.

### 34.3.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

#### 34.3.3.1 Clocking

Data is shifted one bit at a time from the DR pin to the RSR(s) or from the XSR(s) to the DX pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR) controls bit transfers from the DR pin to the RSR(s). The transmit clock signal (CLKX) controls bit transfers from the XSR(s) to the DX pin. CLKR or CLKX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP. The polarities of CLKR and CLKX are programmable.

Figure 34-7 shows how the clock signal controls the timing of each bit transfer on the pin.

Figure 34-7. Example - Clock Signal Control of Bit Transfer Timing

#### Note

The McBSP cannot operate at a frequency faster than  $\frac{1}{2}$  the LSPCLK frequency. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX and/or CLKR, choose an appropriate input clock frequency and divide down value (CLKDV) (that is, be certain that  $\text{CLKX or CLKR} \leq \text{LSPCLK}/2$ ).

#### 34.3.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (DR or DX) are transferred in a group called a serial word. You can define how many bits are in a word.

Bits coming in on the DR pin are held in RSR until RSR holds a full serial word. Only then is the word passed to RBR (and ultimately to the DRR).

During transmission, XSR does not accept new data from DXR until a full serial word has been passed from XSR to the DX pin.

In the example in [Figure 34-7](#), an 8-bit word size was defined (see bits 7 through 0 of word B being transferred).

### 34.3.3.3 Frames and Frame Synchronization

One or more words are transferred in a group called a frame. You can define how many words are in a frame.

All of the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR) signal initiate frame transfers on the DR data pin. Pulses on the transmit frame-sync (FSX) signal initiate frame transfers on DX. FSR or FSX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP.

In [Figure 34-7](#), a one-word frame is transferred when a frame-synchronization pulse occurs.

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

### 34.3.3.4 Generating Transmit and Receive Interrupts

The McBSP can send receive and transmit interrupts to the CPU to indicate specific events in the McBSP. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses. Set the appropriate interrupt mode bits to 10b (for reception, RINTM = 10b; for transmission, XINTM = 10b).

#### 34.3.3.4.1 Detecting Frame-Synchronization Pulses, Even in Reset State

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating RINT when the receiver is in reset). In this case, FSRM/FSXM and FSRP/FSXP still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the CPU clock and then sent to the CPU in the form of RINT and XINT at the point at which they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and after this occurs the CPU can take the serial port out of reset safely.

### 34.3.3.5 Ignoring Frame-Synchronization Pulses

The McBSP can be configured to ignore transmit and/or receive frame-synchronization pulses. To have the receiver or transmitter recognize frame-synchronization pulses, clear the appropriate frame-synchronization ignore bit (RFIG = 0 for the receiver, XFIG = 0 for the transmitter). To have the receiver or transmitter ignore frame-synchronization pulses until the desired frame length or number of words is reached, set the appropriate frame-synchronization ignore bit (RFIG = 1 for the receiver, XFIG = 1 for the transmitter). For more details on unexpected frame-synchronization pulses, see one of the following topics:

- *Unexpected Receive Frame-Synchronization Pulse* (see [Section 34.5.3](#))
- *Unexpected Transmit Frame-Synchronization Pulse* (see [Section 34.5.6](#))

You can also use the frame-synchronization ignore function for data packing (for more details, see [Section 34.11.2](#)).

### 34.3.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined by the following equation.

**Equation: McBSP Frame Frequency**

$$\text{Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Clock Cycles Between Frame- Sync Pulses}}$$

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

### 34.3.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined by the following equation.

**Equation: McBSP Maximum Frame Frequency**

$$\text{Maximum Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Bits Per Frame}}$$

Figure 34-8 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

**Figure 34-8. McBSP Operating at Maximum Packet Frequency**

If there is a 1-bit data delay as shown in this figure, the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, making frame-synchronization pulses redundant. Theoretically, only an initial frame-synchronization pulse is required to initiate a multipacket transfer.

The McBSP supports operation of the serial port in this fashion by ignoring the successive frame-synchronization pulses. Data is clocked into the receiver or clocked out of the transmitter during every clock cycle.

**Note**

For XDATDLY = 0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX). For more details, see [Section 34.9.13](#).

### 34.3.4 Frame Phases

The McBSP allows you to configure each frame to contain one or two phases. The number of words and the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, you might define a frame as consisting of one phase containing two words of 16 bits each, followed by a second phase consisting of 10 words of 8 bits each. This configuration permits you to compose frames for custom applications or, in general, to maximize the efficiency of data transfers.

#### 34.3.4.1 Number of Phases, Words, and Bits Per Frame

Table 34-2 shows which bit-fields in the receive control registers (RCR1 and RCR2) and in the transmit control registers (XCR1 and XCR2) determine the number of phases per frame, the number of words per frame, and

number of bits per word for each phase, for the receiver and transmitter. The maximum number of words per frame is 128 for a single-phase frame and 256 for a dual-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

**Table 34-2. Register Bits That Determine the Number of Phases, Words, and Bits**

Operation	Number of Phases	Words per Frame Set With	Bits per Word Set With
Reception	1 (RPHASE = 0)	RFLEN1	RWDLEN1
Reception	2 (RPHASE = 1)	RFLEN1 and RFLEN2	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE = 0)	XFLEN1	XWDLEN1
Transmission	2 (XPHASE = 1)	XFLEN1 and XFLEN2	XWDLEN1 for phase 1 XWDLEN2 for phase 2

#### 34.3.4.2 Single-Phase Frame Example

Figure 34-9 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the DX and DR pins are available one clock cycle after FS(R/X) goes active. The figure makes the following assumptions:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FLEN1 = 0b: 1 word per frame
- (R/X)WDLEN1 = 000b: 8-bit word length
- (R/X)FLEN2 and (R/X)WDLEN2 are ignored
- CLK(X/R)P = 0: Receive data clocked on falling edge; transmit data clocked on rising edge
- FS(R/X)P = 0: Active-high frame-synchronization signals
- (R/X)DATDLY = 01b: 1-bit data delay

**Figure 34-9. Single-Phase Frame for a McBSP Data Transfer**

#### 34.3.4.3 Dual-Phase Frame Example

Figure 34-10 shows an example of a frame where the first phase consists of two words of 12 bits each, followed by a second phase of three words of 8 bits each. The entire bit stream in the frame is contiguous. There are no gaps either between words or between phases.

A. XRDY gets asserted once per phase. So, if there are 2 phases, XRDY gets asserted twice (once per phase).

**Figure 34-10. Dual-Phase Frame for a McBSP Data Transfer**

#### 34.3.4.4 Implementing the AC97 Standard With a Dual-Phase Frame

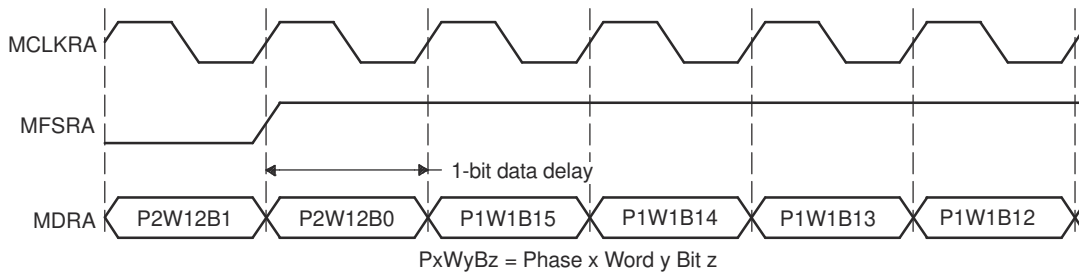

Figure 34-11 shows an example of the Audio Codec '97 (AC97) standard, which uses the dual-phase frame feature. Notice that words, not individual bits, are shown on the D(R/X) signal. The first phase (P1) consists of a single 16-bit word. The second phase (P2) consists of twelve 20-bit words. The phase configurations are listed after the figure.

**Figure 34-11. Implementing the AC97 Standard With a Dual-Phase Frame**

- (R/X)PHASE = 1: Dual-phase frame
- (R/X)FRLN1 = 0000000b: 1 word in phase 1
- (R/X)WDLEN1 = 010b: 16 bits per word in phase 1
- (R/X)FRLN2 = 0001011b: 12 words in phase 2
- (R/X)WDLEN2 = 011b: 20 bits per word in phase 2
- CLKRP/CLKXP= 0: Receive data sampled on falling edge of internal CLKR / transmit data clocked on rising edge of internal CLKX
- FSRP/FSXP = 0: Active-high frame-sync signal
- (R/X)DATDLY = 01b: Data delay of 1 clock cycle (1-bit data delay)

Figure 34-12 shows the timing of an AC97-standard data transfer near frame synchronization. In this figure, individual bits are shown on D(R/X). Specifically, it shows the last two bits of phase 2 of one frame and the first four bits of phase 1 of the next frame. Regardless of the data delay, data transfers can occur without gaps. The first bit of the second frame (P1W1B15) immediately follows the last bit of the first frame (P2W12B0). Because a 1-bit data delay has been chosen, the transition on the frame-sync signal can occur when P2W12B0 is transferred.

**Figure 34-12. Timing of an AC97-Standard Data Transfer Near Frame Synchronization**

### 34.3.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP. For details about how to program the McBSP receiver, see [Section 34.8](#).

Figure 34-13 and Figure 34-14 show how reception occurs in the McBSP. Figure 34-13 shows the physical path for the data. Figure 34-14 is a timing diagram showing signal activity for one possible reception scenario. A description of the process follows the figures.

- A. RSR[1,2]: Receive shift registers 1 and 2
- B. RBR[1,2]: Receive buffer registers 1 and 2
