

UCD3138064A Migration Guide

HPCS / HVPS

ABSTRACT

This application note describes differences between Texas Instruments' UCD3138064 and UCD3138064A Digital power controllers to assist customers in migrating application. While the main focus of this document is migration from UCD3138064 to UCD3138064A, this document is also useful if you are considering migrating in the reverse direction. Functions that are identical in both devices are not included in this document. All efforts have been made to provide a comprehensive list of the differences between the two devices in the UCD3138 family.

UART	UART enhancements	UCD3138064: no auto baud rate adjustment UCD3138064A: UART auto calibration to correct BAUD Rate

2.1.1 Body diode conduction time sensing

Benefits:

- Maximize system efficiency by minimizing MOSFET body diode conduction time
- Robust fast negative current protection.
- Simple interface
 - Minimum component count
 - No external sense element
 - Easy layout
- Superior to R_{DSon} sensing techniques
 - Better accuracy across entire load range
 - No minimum on time requirement
 - No parasitic L & R concerns

UCD3138064A has an advanced dead time control interface where it can accept UCD7138 output signals and optimize SR gate driver signals accordingly. The UCD7138 low-side MOSFET driver is a high performance driver for secondary-side synchronous rectification (SR) with body diode conduction sensing. The device is suitable for high power high efficiency isolated converter applications where dead-time optimization is desired.

The UCD7138 gate driver is a companion device to UCD3138064A highly integrated digital controller for isolated power. DTC0 and DTC1 are received body diode conduction inputs from UCD7138. SR0_DPWM and SR1_DPWM are the DPWM waveforms for the SRs. The yellow and green edges are moving edges controlled by both the filter output and the DTC interface. In each cycle, right after the falling edge of the SR DPWM waveform, a body diode conduction time detection window is generated. The detection window is defined by both DETECT_BLANK and DETECT_LEN registers. During this detection window, a 4-ns timer capture counts how long the body diode conducts. Then the SR DPWM turn off edge of the next cycle is adjusted accordingly.

* Note: DETECT_BLANK and DETECT_LEN starts 1MCLK (32ns) before the falling edge of SR0_DPWM or SR1_DPWM

2.1.2 UART Auto Baud Enhancement

Benefits: The UCD3138064A has many UART enhancements. One of them is that it has an in built hardware dedicated just to capture the receiving pulses on the Rx pin of the UART. This along with some minimal firmware can be used to calculate the exact BAUD rate of the other device.

Some of the other UART enhancements are:

- 1) It has a finer resolution. The BAUD rate granularity is about 64 nS. Hence a new register is introduced "UARTSBAUD".

- 2) It has an auto sync on start bit . The free running counter of the UART gets reset when it detects a start bit. This makes the sampling time well aligned with the center of the pulses.
- 3) It allows independent Rx and Tx BAUD rate capability. The UART Rx has some new registers: UARTRX MBAUD, UARTRXLBAUD and UARTRXSBAUD. They have the same meaning as the general UART registers: UART MBAUD, UARTLBAUD and UARTSBAUD.

DAC	Enhanced DAC Dither on each sample	UCD3138064 : dithers once per period UCD3138064A : adds option of dither once on each EADC sample

DPWM	LLC Fixed rate sampling enabled, update window size increases. Improved transient response and regulation over line and load variations for LLC converter.	UCD3138064 : DPWM has pulse extension if fixed rate sampling is used. Filter sample rate must follow LLC frequency. UCD3138064A : Fixed rate sampling is safe, update window increased from 72ns to 132 ns
DPWM	DPWM–Fault Turn Off & Burst mode	UCD3138064 : When Edgegen module is used, fault may not be able to turn off all DPWMs. UCD3138064A : In Edgegen applications, all faults will result in DPWMs going low
ROM	Add 0xEA check of PFLASH #2	The EA Check means we check the first byte of the flash for a 0xEA, a jump. This shows that it is programmed, probably with a reset vector. If there's no EA, we don't even check for a checksum, just go to ROM mode. UCD3138064 : Default this check was not enabled. Effect was that we jumped to program mode if the flash was programmed to all zeroes, since the checksum of zero at the end would be correct. UCD3138064A : Default this check is enabled thus avoiding above scenario.
ROM	Disallow flash execution if trim data is invalid.	UCD3138064 : we set a bit to flag that the trim data is incorrect, but went to execution anyway without doing trim. UCD3138064A : this prevents code execution from program flash & goes back to ROM mode if trim is incorrect thus providing additional robustness
Front End	PCMC–Duty cycle read	Ability to read duty cycle during PCMC or CBC.
Reset Disable	Disabling the RESET Pin	Added capability to disable the RESET pin. This may be useful in very noisy systems. Here is the code to disable the reset: MiscAnalogRegs.CLKTRIM.bit.RESET_DISABLE = 1. Note that the Reset Pin should no longer be tied to 3.3 Volts directly. A 220 ohm resistor should now be used.
Filter	Yn Consistent Read	UCD3138064 : although YN value is always correct, YN_READ register may read back wrong values occasionally. UCD3138064A : YN_READ register always have consistent read value.
Chip Level	Current consumption	Please refer to electrical specification of UCD3138064A datasheet. [SLUSCA5]
Event	Resonant mode dead times are determined only by Event 1	UCD3138064 : Dead time is programmed by all 4 Event registers. DPWM A Rising Edge = Event 1 DPWM A Falling Edge = Filter Duty – Event 1 + DTC Adjustment Adaptive Sample Trigger A = Event 1 + Filter Duty + Adaptive Sample Register or Adaptive Sample Trigger B = Event 1 + Filter Duty/2 + Adaptive Sample Register DPWM B Rising Edge = Filter Duty + Event 1 DPWM B Falling Edge = Filter Period – Event 1 + DTC Adjustment Phase Trigger = Phase Trigger Register value or Filter Duty
	SyncFET behavior	UCD3138064: SYNCFET soft on starts with the rising edge in its final position, and the falling edge moves out in time until it reaches its calculated position; Soft off moves the falling edge towards the rising edge UCD3138064A: SYNCFET soft on starts with the falling edge in its calculated position, and the rising edge moves forward in time until it reaches its final position. Soft off moves the rising edge back towards the falling edge.

Table 5. Chip Revision ID field updated

Module	Features/ Changes	Detail Description
Chip Level	Device ID/Revision Update	UCD3138064: Device ID is 0x447F & Rev: 0x____ & Firmware: "UCD3138064V1" UCD3138064A: Device ID is 0x947F & Rev: 0x447F & Firmware: "UCD3138064A"

3 Application Migration care about

3.1 Change to Device ID

The TI GUIs designed for use with the UCD parts use a PMBus command called `DEVICE_ID` to determine which device is being used. On the UCD3138064A, the initial part of the `DEVICE_ID` string should change to "UCD3138064A".

The string for the UCD3138064 is "UCD310064V1"

3.2 Possible Changes to Layout and Power Supply Filtering

The UCD3138064A has different sensitivity to EMI and power supply noise than the UCD3138064. Designs that are marginal with the non-A may require changes to board layout and filtering to work with the A version. See the datasheet and the UCD3138 - Practical Design Guideline Application Note for more information.

The added features of the UCD3138A will require a bit more power consumption for the chip, see the datasheet for details.

3.3 LLC Topology

1) Remove the following code:

```
MiscAnalogRegs.CLKTRIM.bit.HFO_LN_FILTER_EN = 0;
```

2) The event update window is increased to 132 ns. Make sure that the moving edges are outside of the event update window.

UCD3138064A has DTC interface that works in conjunction with UCD7138, helps improve reliability and efficiency and reduce development cycle. This peripheral is disabled by default. Please refer to Application note [xxx] for more details on how to program DTC.

3.4 PS- LLC Topology

Remove the following code:

```
MiscAnalogRegs.CLKTRIM.bit.HFO_LN_FILTER_EN = 0;
```

2) The event update window is increased to 132 ns. Make sure that the moving edges are outside of the event update window.

UCD3138064A has DTC interface that works in conjunction with UCD7138, helps improve reliability and efficiency and reduce development cycle. This peripheral is disabled by default. Please refer to Application note [SPRxxx] for more details on how to program DTC.

3.5 HSFB Topology

For voltage mode control, only events update window are necessary to be adjusted. At normal mode, change DpwmRegs.DPWMEV1.all = 480 or greater. At multiple mode, EVT3 should be greater than 480ns.

For peak current mode control, the EVTs update windows follow the same criteria as voltage mode control. Besides those changes, PCM blanking time should be programmed by PCM_BLANK_EN bit. For example, to select DPWM0 blanking time and DPWM1 blanking time, the below code should be used.

```
Dpwm0Regs.DPWMCTRL2.bit.BLANK_PCM_EN = 1;
```

```
Dpwm1Regs.DPWMCTRL2.bit.BLANK_PCM_EN = 1;
```

Delete the code MiscAnalogRegs.CLKTRIM.bit.HFO_LN_FILTER_EN = 0 to improve high frequency clock accuracy.

UCD3138064A has DTC interface that works in conjunction with UCD7138, helps improve reliability and efficiency and reduce development cycle. This peripheral is disabled by default. Please refer to Application note [xxx] for more details on how to program DTC.

The dead time initialization may need to be changed because the algorithm for dead time calculation has changed. See Table 2 - Enhancements in UCD3138064A

3.6 PSFB Topology

The required changes of events update window in the PSFB topology are the same as the HSFB topology. In addition, few other changes are highlighted.

First, EDGESEN modules are used in PSFB topology, at burst mode or fault condition, one of DPWMs aren't turned off in UCD3138064 while all DPWMs are turned off in UCD3138064A. This can affect power stage design. With UCD3138064A, gate transformers can be used for driving primary side MOSFETs.

Second, the blanking time windows are programmed by the below codes for each half period.

```
Dpwm2Regs.DPWMCTRL2.bit.BLANK_PCM_EN = 1;
```

```
Dpwm3Regs.DPWMCTRL2.bit.BLANK_PCM_EN = 1;
```

Third, at Peak Current mode control, the offset applied on EAP pin (EAP2 for PWR027) is significantly reduced to less than 30mV. The offset voltage can be removed if a small voltage step is acceptable.

Fourth, delete the code `MiscAnalogRegs.CLKTRIM.bit.HFO_LN_FILTER_EN = 0`, which is needed any more;

The dead time initialization may need to be changed because the algorithm for dead time calculation has changed. See Table 2 - Enhancements in UCD3138064A

Some other enhancements are listed in the Table 2, such as DAC dithering, reading duty cycle when CBC happens or PCM control, and so on.

3.7 PFC Topology

Please note following modifications are required to support UCD3138064A

- Delete this code:

```
MiscAnalogRegs.CLKTRIM.bit.HFO_LN_FILTER_EN = 0;
```

- The event update window is increased to 132 ns, so set:

```
DpwmxRegs.DPWMEV1.all = 480; //normal mode
```

And also set EVENT3 if in multi mode:

```
DpwmxRegs.DPWMEV3.all = 480; //multi mode
```

In addition to above changes please make sure if any of changes listed in Table 1 and/or Table 2 are applicable to you.

4.11.7 PMBus Control Register 2 (PMBCTRL2) Address FFF7F618

Bit Number	22:21	20	19	18:16
Bit Name	RX_BYTE_ACK_CNT	MAN_CMD	TX_PEC	TX_COUNT
Access	R/W	R/W	R/W	R/W

Default	11	0	0	000
---------	----	---	---	-----

Bit Number	15	14:8	7	6:0
Bit Name	PEC_ENA	SLAVE_MASK	MAN_SLAVE_ACK	SLAVE_ADDR
Access	R/W	R/W	R/W	R/W
Default	0	111_1111	0	111_1100

Bit 22-21: RX_BYTE_ACK_CNT – Configures number of data bytes to automatically acknowledge when receiving data in slave mode.

00 = 1 byte received by slave. Firmware is required to manually acknowledge every received byte.

01 = 2 bytes received by slave. Hardware automatically acknowledges the first received byte. Firmware is required to manually acknowledge after the second received byte.

10 = 3 bytes received by slave. Hardware automatically acknowledges the first 2 received bytes. Firmware is required to manually acknowledge after the third received byte.

11 = 4 bytes received by slave. Hardware automatically acknowledges the first 3 received bytes. Firmware is required to manually acknowledge after the fourth received byte (Default)

Bit 20: MAN_CMD – Manual Command Acknowledgement Mode

0 = Slave automatically acknowledges received command code (Default)

1 = Data Request flag generated after receipt of command code, firmware required to issue ACK to continue message

Bit 19: TX_PEC – Asserted when the slave needs to send a PEC byte at end of message. PMBus Interface will transmit the calculated PEC byte after transmitting the number of data bytes indicated by TX Byte Cnt(Bits 19:17).

0 = No PEC byte transmitted (Default)

1 = PEC byte transmitted at end of current message

Bit 18-16: TX_COUNT– Number of valid bytes in Transmit Data Register

Bit 15: PEC_ENA – PEC Processing Enable

0 = PEC processing disabled (Default)

1 = PEC processing enabled

Bit 14-8: SLAVE_MASK – Used in address detection, the slave mask enables acknowledgement of multiple device addresses by the slave. Writing a ‘0’ to a bit

within the slave mask enables the corresponding bit in the slave address to be either '1' or '0' and still allow for a match. Writing a '0' to all bits in the mask enables the PMBus Interface to acknowledge any device address. Upon power-up, the slave mask defaults to 7Fh, indicating the slave will only acknowledge the address programmed into the Slave Address (Bits 6-0).

Bit 7: MAN_SLAVE_ACK– Manual Slave Address Acknowledgement Mode

0 = Slave automatically acknowledges device address specified in SLAVE_ADDR, Bits 6-0 (Default)

1 = Enables the Manual Slave Address Acknowledgement Mode.

Firmware is required to read received address and acknowledge on every message

Bits 6-0: SLAVE_ADDR – Configures the current device address of the slave. Used in automatic slave address acknowledge mode (default mode). The PMBus Interface will compare the received device address with the value stored in the Slave Address bits and the mask configured in the Slave Mask bits. If matching, the slave will acknowledge the device address.
